As part of the TechCare project (2020-2024), various new technologies are tested in seven pilot farms (5 countries) to assess their use as potential early warning of animal welfare issues or of risk factors for small ruminant sectors. Among different welfare indicators, we are interested in water intake as one of the pillars of good health and well-being in sheep. Our objective is to study the watering behaviour of sheep in sheds to potentially detect early welfare or health problems. Our device is composed of three main components. (1) Each animal wears an ultra high frequency (UHF) Radio frequency identification (RFID) tag, and a reading antenna is installed above each water trough. The data is collected using a reader connected to the internet. (2) Each water trough is equipped with a connected water meter with automatic data transmission on a web platform. (3) The device is completed by a motion detection camera to validate our data and observations. In France, this device has been set up in: (1) a meat sheep shed to monitor fattening lambs (91) for 4 weeks in 2022; and in (2) a dairy sheep shed to monitor a batch of lactating ewes (40) for 6 weeks in 2022 and 12 weeks in 2023. A welfare assessment protocol has been designed alongside to collect individual observations and measurements on a series of welfare indicators. These attendance data are studied at the individual scale, at the flock scale, and in relation to other data characteristic of the animals' environment (temperature and humidity of the shed, for example), and results on how they tally with the welfare measurements will be presented in this paper. Monitoring water trough attendance could be a relevant indicator to design an early warning system for sheep health or welfare.

TechCare UK pilots – integrated sheep system studies using technologies for welfare monitoring

Small ruminant production systems are found in diverse contexts, including extensive grazing regions, where environmental conditions can be harsh and day to day supervision of animals challenging. In addition, farmers within these systems may lack access to, or not be aware of, technologies that may help to improve performance, efficiency and welfare. As part of the H2020 TechCare project, a series of pilot studies have been set up in 5 partner countries to explore the application of technologies to address different welfare priorities, as identified by industry stakeholder groups in each country. In the UK, these priorities included nutritional issues (under/malnutrition), poor maternal relationships and health problems (particularly lameness, mastitis and endoparasites). Two pilot studies have been set-up one at SRUC's Hill & Mountain Research Farm in the West Highlands and the other at MRI's Firth Mains Farm in Midlothian. The technologies investigated on these units include the use of low frequency electronic identification (EID) enabled equipment (e.g. weigh crates and stick readers), proximity and ID loggers (Bluetooth beacons and ultra-high frequency (UHF) tags and reader systems), accelerometers, GNSS trackers, and electronic weather stations. In addition to live weight and body condition score data collection, and in-field observation work including measures of gut parasitic infections (for MRI pilot), regular welfare assessments of the animals are being carried out using the Animal Welfare Indicator (AWIN) protocols. Through a series of different studies covering in combination most of the sheep production cycle (pregnancy; lambing; summer rearing period; weaning and post weaning of lambs) and which will be detailed in this paper, the suitability of these technologies to improve our understanding of the welfare issues highlighted, and potentially to act as an early warning indicator, are being assessed.

Precision livestock farming (PLF) is developing as a powerful on-farm tool to monitor animal welfare. ClearFarm aims to contribute to this by developing an algorithm that can assess animal welfare continuously, based on the five Welfare Domains. This study summarises the main achievements and barriers experienced in the development of the algorithm. PLF-derived indicators that are relevant to the related Welfare Domains were validated in pig farms, including activity, feeding and play behaviour, body weight, climatic measurements, and respiratory health. Each indicator was classified as: (1) having a solid threshold based on literature; (2) having a range as a threshold based on literature; (3) being unsuitable for a fixed threshold; or (4) having no existing literature to support a threshold. Next, the ClearFarm platform algorithm to aggregate the indicators was meant to be fed with the different indicators extracted from sensor data and the predefined thresholds, providing a score (0-100) for each Welfare Domain. However, several barriers were encountered. First, few indicators from PLF technology have been validated to assess pig welfare. Second, no sensors are currently available to monitor relevant indicators for the mental state domain. Also, other domains (e.g. health) are underrepresented because only one indicator is available (i.e. respiratory health). Third, the pig production chain has different phases (e.g. gestating sows, weaners, fattening pigs) with different durations and welfare threats. Also, the common practice to mix pigs between units and farms makes tracking pigs across these phases difficult. Yet, it is not feasible to propose an algorithm that meaningfully aggregates welfare indicators across domains and production stages in pigs. Rather, ClearFarm proposes how welfare indicators can be achieved from sensors and how they can contribute to assessing pig welfare in different domains.

Is sensor technology ready for use in animal welfare assessments of gestating sows?

I.J.M.M. Boumans and E.A.M. Bokkers

Wageningen University & Research, Animal Production Systems group, P.O. Box 338, 6700 AH Wageningen, the Netherlands; eddie.bokkers@wur.nl

Sensor data is expected to be valuable for continuous and real-time animal welfare assessment. The availability of robust and reliable sensor technologies that are already applied in farms, however, is limited and their value for animal welfare assessment has not been shown in commercial farms. Therefore we aimed to study to what extent commercially available sensors can be used for welfare assessment, with gestating sows as a case study. Two sensor technologies were studied: climate sensors (temperature, relative humidity, CO₂ and NH₃; dol-sensors, Denmark) and electronic sow feeders (ESF, Nedap, The Netherlands). Sensor data was collected on a conventional and an organic farm, for a period of a year. Potential welfare indicators were selected based on scientific literature and calculated and compared between the two different farming systems. Examples of selected welfare indicators are days above a critical temperature indicative of risk on heat stress, days above a critical NH₃ level indicative of risk on respiratory problems and discomfort, average feeder occupation indicative for feed competition and aggression, mean days per sow gestation of low feed intake indicative of reduced appetite and impaired health. Sensor technology can have added value for welfare assessment and lead to new indicators to assess welfare, however, several challenges were identified, including the availability and quality of data, functioning of technology and influence of farm management practices. The availability and quality of results relates strongly on technical functioning of sensors, presence of erroneous data and data cleaning. In particular data cleaning poses challenges as it requires different standards per farm. Outliers in data can corrupt results, but they cannot simply be removed as they might also reflect reality, and as such can contain important information related to welfare. For correct interpretation of results also background information is required about the farming system, e.g. farm management practices, such as use of bedding and (in case of ESF) changing ESF settings. Sensor data can provide valuable additions to welfare assessments, however, the interpretation should be done carefully and further validation is required.

Session 39

Theatre 6

Identification of behavioural pattern associated with mastitis in dairy cowsL. Herve¹, Y. Gómez², K. Chow³, A.H. Stygar⁴, G.V. Berteselli⁵, E. Dalla Costa⁵, E. Canali⁵ and P. Llonch²

¹PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France, ²Universitat Autònoma de Barcelona, Department of Animal and Food Science, 08193 Cerdanyola del Vallès, Spain, ³Universitat Autònoma de Barcelona, Department of Information and Communications Engineering, 08193 Cerdanyola del Vallès, Spain, ⁴Natural Resources Institute Finland (Luke), Latokartanonkaari 9, 00790 Helsinki, Finland, ⁵Università degli Studi di Milano, Dipartimento di Medicina Veterinaria e Scienze Animali, 26900 Lodi, Italy; lucile.herve@inrae.fr

Mastitis is major health issue compromising the welfare of dairy cows. Individual behaviour of dairy cows few days before mastitis is a potential tool for higher detection accuracy. However, little is known about the existence of behavioural patterns usually expressed by cows in healthy conditions that are associated with the subsequent onset of mastitis. This study aimed to determine whether cows that will subsequently be affected by mastitis express distinctive behavioural patterns compared to the ones that stay healthy throughout lactation. Daily hours spent standing, lying down, walking, ruminating and eating were recorded from calving to 15 d prior mastitis using accelerometer collars in two commercial farms in Italy. The mastitis group (n=16) was constituted with the cows suffering from one mastitis during lactation. A control group of healthy cows (n=16) balanced for parity and lactation stage has been constituted afterwards. The group effect (mastitis vs no mastitis) on the intercept and the slope of the regression curve of each individual cows for all behaviours was analysed using ANOVA. Cows from the mastitis group spent less time lying (9.25 vs 9.66 h/d) and more time walking (2.69 vs 2.40 h/d) and ruminating (8.56 vs 8.14 h/d) than control cows 100 days before the onset of mastitis ($P<0.001$). Behavioural changes over time before mastitis also differed as shown by the lower slope coefficient for lying, walking and ruminating in mastitis than in control cows ($P<0.001$). This study may suggest that cows suffering from mastitis exhibited different lying, walking and ruminating durations, months before the onset of the disease. Further investigations are needed to confirm if differences in behavioural patterns can be considered as promoters of disease.

Use of PLF sensors to monitoring rumination as an alternative for early clinical mastitis detection

G.V. Berteselli¹, E. Dalla Costa¹, Y. Gómez Herrera², M.G. Riva¹, S. Barbieri¹, R. Zanchetta¹, P. Llonch², X. Manteca² and E. Canali¹

²Universitat Autònoma de Barcelona, Department of Animal and Food Science, Campus UAB, 08193 Cerdanyola del Vallès, Barcelona, Spain; greta.berteselli@unimi.it

Mastitis is a costly disease and remains a major welfare concern in the dairy industry. Rumination is a vital behaviour for dairy cattle, decreased rumination time has been linked with acute stress, anxiety, or disease. The aim of this study was to clarify whether a decreased rumination time, monitored with accelerometry collars, can predict the onset of mastitis in lactating dairy cows. Two groups of dairy cows balanced for stage of lactation and parity order, were recruited: mastitis group (n=14) and control group (n=14). Mastitis was diagnosed through somatic cell count in milk and clinical examination. For each cow, daily hours spent ruminating was monitored for a total of 21 days using accelerometry collars: 10 days prior, the day of diagnosis and 10 days after the diagnosis. The same time-frame was considered for the control group. A repeated-measures ANOVA determined that mean Rumination time and the interaction between Days and Group differed significantly across the days ($F=4.200$ and $P=0.030$, $F=5.518$ and $P=0.014$ respectively). A post hoc pairwise comparison using the Bonferroni correction showed differences between the mastitis and control group at D-9, D-3, D-2, D1 and D10. The results show that a decrease in rumination time can be used as an early indicator of clinical mastitis few days before the onset. PLF technology allows an early detection of decrease in rumination time, helping the farmer to early identify clinical cases, thus improving the welfare of dairy cows and reducing the negative effects of mastitis (e.g. costs, antibiotic treatment).

Session 39

Theatre 8

Monitoring the stress of light goat kids transported over short journeys

M. Sort, A. Elhadi, R. Costa, A. Recio, A.A.K. Salama and G. Caja

Universitat Autònoma de Barcelona, Group of Ruminant Research (G2R), Animal and Food Sciences, Av. dels Turons, 08193 Bellaterra, Spain; gerardo.caja@uab.es

Despite the large number of suckling goat kids harvested in the EU, the EC 1/2005 regulation for animal transport does not mention kid requirements. With this aim, 25 suckling goat kids (9.5 ± 0.4 kg LW) of Murciano-Granadina breed (male, n=10; female, n=15) were used to evaluate the effects of 2 space densities for road transport over a short journey (2 h), using a trailer ($1.8 \times 1.0 \times 1.3$ m; 2 floors and 4 compartments of 0.9 m²), equipped with sensors (temperature, humidity, sound and acceleration). A second accelerometer was placed in the driver's cabin. Kid densities were: (1) low (0.018 m²/kg; n=10); and (2) high (0.013 m²/kg; n=15). Trip was done on national roads, at moderate speed and under mild weather conditions. Kids were weighed, temperature measured, and blood sampled at h 0 (uploading), 2 (downloading) and 24 (resting) from departure. Acceleration peaks in the z-axis during transport were much higher ($P<0.001$) in the trailer ($11.8 \times g$) than in the cabin ($1.5 \times g$). Similarly, high noise peaks were detected in the trailer (volume >800 dB and frequency $>1,400$ Hz) which should be considered as stressful. All kids decreased weight during transport (-3.5% LW; $P>0.05$), but recovered after 24 h. Moreover, no differences were detected by sex or density. Despite the mild ambient conditions during the journey (27°C and 44% RH; THI=74), goat kids lost rectal temperature (-0.2°C ; $P<0.001$), which recovered at h 24, without effect of density. All metabolic indicators increased after transport, except urea, which indicated a situation of metabolic stress aggravated by the cold (12% of the kids showed shivering at arrival). High density during transport only increased serum creatine kinase (71%; $P=0.031$) and tended to increase lactate dehydrogenase (15%; $P=0.13$), which recommended using the low density. In conclusion, a density of 0.018 m²/kg LW may be adequate for suckling kids, although deficiencies in temperature, noise and acceleration were detected. The use of closed trailers with conditioned ambient and efficient shock absorbers, is recommended. Acknowledgements: Funded by the EU H2020 program (Contract #862050, TechCare Project).

Monitoring the stress of light suckling lambs transported over short journeys

A. Elhadi, J.C. Jesús, R. Costa, A. Recio, A.A.K. Salama and G. Caja

Universitat Autònoma de Barcelona, Group of Ruminant Research (G2R), Animal and Food Sciences, Av. dels Turons, 08193 Bellaterra, Spain; abdelali.elhadi@uab.cat

Space allowance for lambs <20 kg LW in the EC 1/2005 regulation for animal transport must be under 0.2 m²/lamb (density, 0.010 m²/kg), but it is unknown if this is adequate for suckling lambs. To assess this, 20 lambs (13.9±0.4 kg LW) of 2 breeds (Manchega, MN; n=10; Lacaune, LC; n=10) were submitted to a transport experiment over a short journey (2 h) with 2 densities: 0.016 m²/kg (n=8) and 0.011 m²/kg (n=12). A trailer (1.8×1.0×1.3 m; 2 floors and 4 compartments of 0.9 m²), equipped with sensors (temperature, humidity, sound and acceleration) and a second accelerometer placed in the driver's cabin, were used. The trip was on national roads, at moderate speed and under mild weather conditions. Lambs were weighed, temperature measured, and blood sampled at h 0 (uploading), 2 (downloading) and 24 (resting). Only MN lambs were slaughtered after arrival and their carcasses evaluated. Acceleration peaks (z-axis, 11.9×g) and noise recorded (volume, 491±98 dB; frequency, 395±98 Hz) in the trailer were much greater ($P<0.001$) than in the cabin and considered as stressful. Transport produced a non-significant weight loss (-3.2%; $P>0.05$), which was recovered in the LC lambs after resting, without differences by breed, sex or transport density. Despite the mild ambient conditions (15.6 °C and 69% RH; THI=74), rectal temperature decreased during transport, which was greater in LC than MN lambs (-0.68 vs -0.26 °C; $P=0.031$) agreeing their fleece traits, but without effect of density. All serum indicators increased during transport ($P<0.001$), indicating metabolic stress, but only lactate dehydrogenase increased in the high density lambs (+14%; $P=0.032$). Carcasses of MN differed in colour, which was darker ($P<0.05$) in low density lambs. In conclusion, >0.010 m²/kg LW seems to be adequate for suckling lambs transport over short journeys, although stressing effects of cold, noise and acceleration were detected. The use of closed trailers, with conditioned ambient and efficient shock absorbers avoiding noise and jumps, is recommended in light lambs. Acknowledgements: Funded by the EU H2020 program (Contract #862050, TechCare Project).

Session 39

Theatre 10

Exploration of indicators measured by PLF sensors to monitor pig welfare during transportationH.-L. Ko¹, P. Fuentes Pardo², F. Jiménez Caparros³, X. Manteca¹ and P. Llonch¹*¹Universitat Autònoma de Barcelona, Department of Animal and Food Science, Campus UAB, 08193 Cerdanyola del Vallès, Spain, ²CEFU, S.A., Department of I+D+i, Paraje de la Costera, s/n, 30840 Alhama de Murcia, Spain, ³ElPozo Alimentación, S.A., Department of I+D+i, Avenida Antonio Fuertes, no. 1, 30840 Alhama de Murcia, Spain; henglun.ko@uab.cat*

Most pigs experience transportation at least once in their lives. However, the welfare of the pigs during transportation is often overlooked. The aim of the current study was to investigate potential welfare indicators measured by PLF technologies during truck transportation to the slaughterhouse. Two trucks were used in the study. One GPS tracker and two climate sensors, DOL 114 and DOL 19, were installed on each truck. The GPS tracker recorded the journey distance (km), journey duration (minute), and number of stops during the journey. DOL 114 measured temperature (°C) and humidity (%), and DOL 19 measured CO₂ concentration (ppm), both every 15 minutes. A modified Welfare Quality® assessment was conducted during unloading, with the following parameters recorded: number of dead pigs on arrival, fasting duration, and number of sick/lamed/falling/reluctant-to-move/turning-back pigs. A total of 25 journeys were followed with the averages of 173 pigs on the truck, 51 km and 53.6 minutes per journey, and a fasting duration of 16.2 hours. Data were analysed with correlation tests and general liner models. Preliminary results showed that journey distance and duration were correlated with number of reluctant-to-move pigs during unloading ($r=0.62$ and $r=0.63$ respectively, $P<0.05$). Journey distance was also correlated with humidity ($r=0.62$, $P<0.05$) and temperature ($r=0.71$, $P=0.07$). Additionally, number of falling pigs during unloading was associated with fasting duration ($P=0.06$) and CO₂ concentration ($P<0.05$). Our preliminary results suggest that longer journey increases temperature, humidity, and CO₂ concentration. Together with long fasting duration, the aversive micro-climate could affect animals' status on arrival and therefore lead to difficult handling during unloading.

Quantifying the value of early warning system (EWS) based on 'smart water trough' in a sheep farmA. Bar-Shamai^{1,2}, I. Shimshoni¹, A. Godo², J. Lepar² and I. Halachmi^{2,3}

¹Haifa University, Dept. of Information systems, 65 Hanamal St., Haifa, Israel, ²Agricultural Research Organization (A.R.O.) – Volcani Institute, Precision Livestock Farming (PLF) Lab., 68 Hamaccabim Road, P.O. Box 15159, Rishon Lezion 7505101, Israel, ³Ben Gurion University of the Negev, Dept. of Industrial Engineering and Management, P.O. Box 653, Be'er Sheva 8410501, Israel; halachmi@volcani.agri.gov.il

This work describes the calculated economic value of an early warning system (EWS) for meat sheep production. An EWS was developed including a multi-sensor monitored drinking station. Weight, drinking behaviour and water consumption data was collected from 53 Assaf-breed sheep, two to five months old, over a period of three months. The financial benefit model comprised of calculating alternative costs for cases of ineffective growth, and optimal selection for marketing. The EWS uncovered significant potential profit increase of up to 50% by employing a decision support system on farms. In addition, a reduction in labour and feed costs and identification of welfare changes is evident. Acknowledgements: Funded by the EU H2020 program (Contract #862050, TechCare Project).

Session 39

Theatre 12

Economic feasibility of using sensing technologies for welfare monitoring in the pig value chainA.H. Stygar¹, M. Pastell¹, P. Llonch², E.A.M. Bokkers³, J.D. Bus³, I.J.M.M. Boumans³, L.J. Pedersen⁴ and J.K. Niemi¹

¹Natural Resources Institute Finland (Luke), Latokartanonkaari 9, 00790 Helsinki, Finland, ²Universitat Autònoma de Barcelona, Campus UAB, Barcelona, 08193 Cerdanyola del Vallès, Spain, ³Wageningen University and Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ⁴Aarhus University, Blichers Allé 20, 8830 Tjele, Denmark; anna.stygar@luke.fi

The use of sensors provides an opportunity for continuous monitoring of animal welfare status that can potentially benefit the entire pig value chain. However, the economic rationale for using sensor technology to provide welfare information is rarely explored. The aim of this study was to assess the economic benefits of different sensor technologies used to monitor pig welfare and discuss economic implications of comprehensive welfare monitoring throughout the pig value chain. Bio-economic models, based on dynamic programming, were used to determine the effect of sensor application to monitored welfare (good feeding, good housing, good health and appropriate behaviour) at various production stages (sows, piglets, growing pigs). Studied examples concerned application of sensor technologies to monitor tail biting, pen fouling, respiratory diseases in growing pigs, body weight in sows and growing pigs, thermal comfort in sows and playing behaviour in piglets. Model parameters were set to represent average costs and benefits in the Netherlands, Spain and Denmark. The simulated results indicated that the economic benefits of using sensors may not outweigh the costs, particularly on farms where good husbandry practices are already in place. However, our analyses indicated that the use of technologies could bring additional benefits in terms of reducing the environmental impact of pig production (e.g. reduced sow replacement rate). Therefore, it is necessary to integrate all sustainability indicators (social, economic and environmental) in order to provide an overview of the benefits that can be obtained from the application of sensors. Business models based on the sharing of sustainability data should be developed. This study was conducted within the ClearFarm project which received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No. 862919.

ORIOLE: a web application for cleaning data from the walk-over-weighing device in livestock systems*I. Sanchez, E. González-García, B. Fontez and B. Cloez**INRAE, 2 place pierre viala, 34060, France; eliel.gonzalez@inrae.fr*

The use of the walk-over-weighing (WoW), which automatically records animal live weight (LW) in an automated, non-invasive manner, involves filtering the primary datasets produced by this technology. Removing outliers allows the correct data to be retained for a more consistent interpretation of individual daily physical activity progression. However, the standard methods used so far to perform this cleaning were impractical, time-consuming and required minimal mastery of the methods used. This limits the adoption of WoW by farmers and other end users. Our team previously developed a Kalman filter with impulse noised outliers algorithm for the automatic detection of outliers generated by the WoW (kfino; <https://arxiv.org/abs/2208.00961>). Once the kfino algorithm was tuned, the ORIOLE web-application was developed and deployed by our team (for OutlieRs detectIOn waLk wEighing; <https://oriole.sk8.inrae.fr/>). The Shiny library of the R software which enables to easily create user-friendly interactive web apps straight from R was used (<https://shiny.rstudio.com/>). Our web application allows users to import raw data measured from the WoW and through simple settings to perform outlier detection and weight prediction during the experiment. Descriptive statistics are then available such as number of daily weighing, evolution of weight per animal, evolution of the flock weight, 24 h kinetics of individuals. The web app is a dashboard composed of a menu of several subsets offering a user-friendly experience: (1) a 'Welcome' section; (2) the 'Genesis' of the technology and the web-app project; (3) the heart of the app with a section for the import and analysis of 'WoW data' and producing useful reports; (4) a 'How to' section documenting how to use the app. Users can analyse their data using full advantage of descriptive and statistics plots and download reports for communication and decision making.

Monitoring liveweight in Sarda dairy sheep using a walk-over-weighing system*M. Decandia¹, M. Acciaro¹, V. Giovanetti¹, G. Molle¹, F. Chessa¹, I. Llach² and E. González-García²**¹AGRI Sardegna, Loc. Bonassai S.S. 291 Sassari-Fertilia, 07100 Sassari, Italy, ²SELMET, INRAE, Montpellier SupAgro, CIRAD, Université Montpellier, 34060 Montpellier, France; mdecandia@agrisricerca.it*

Live weight (LW) monitoring is important in livestock management to check nutritional, reproduction and welfare status of animals. In dairy sheep system LW measurement is less frequent because it is time and labour consuming. The use of automated weighing system could facilitate this practice. Within the H2020 Techcare project, aiming to use innovative technologies to improve welfare management for small ruminant systems, a short-test was run to evaluate the precision and accuracy of LW measures carried out using an automated walk-over-weighing (WoW) scale in comparison with a static scale. Thirty-six dry Sarda dairy ewes (LW, mean $\pm$ SE 55.49 $\pm$ 0.92) were used in a 3-day session. Ewes were daily weighed 3 times following the same circuit, which included a first static LW measurement; once a static position was achieved and LW recorded, the animals continued and traversed the WoW scale for the WoW LW recording. The ewes were previously accustomed to the circuit during a pre-experimental week. Raw static and automatic LW data were first filtered for removing misbehaviours and outlier with Kalman filter algorithm. The concordance correlation coefficient (CCC) has been then calculated (Model Evaluation System) to simultaneously account for precision and accuracy. The two component of CCC ($\approx$ 0.98), correlation coefficient estimate (r , that measure precision) and the bias correction factor (C_b , that indicates the accuracy) were respectively 0.98 and 0.99 indicating high agreement between measures. The WoW system evaluated here is an alternative to the static scales conventionally used on dairy sheep farms. If sound filtration of raw data is applied, WoW could contribute to the close (daily) monitoring of individual LW without operator intervention (i.e. voluntary weighing), taking animal welfare into account (i.e. no stress related to the weighing session on static scales), and potentially detecting nutrition issues highlighted by LW changes.

Stakeholders' attitudes to early warning systems to promote animal welfare in small ruminants

TechCare project aims to demonstrate innovative approaches to monitor and improve welfare management in small ruminants' farming systems. An integral part of this approach is the early warning systems (EMS) for the timely alert on welfare issues on an individualized base. An integrated multi-actor approach is applied to constantly collect feedbacks from stakeholders and co-design the EWS through a series of national workshops. The 3rd series of TechCare national workshops engaged all relevant stakeholders and collected their feedback on the critical aspects of developing the EWS. Despite the different background, the stakeholders from all countries recognized specific features of the EWS as highly favourable. These features include: the ability to track and trend history and past trendlines of critical data; the integration of novel EWS with existing tools and data management applications; the option to manually add data recordings and other information (i.e. mortality data, diets' information); the ability to group animals; that the EWS should be customizable to the specific needs of each farming system; that the EWS should be easily expandable to include new precision livestock farming (PLF) tools or welfare indicators; and that the interface should be simple and concise.

Session 39

Poster 16

Comparison between automatic milking and milking parlour system on dairy cows' welfare

G.V. Berteselli, S. Cannas, E. Dalla Costa, R. Zanchetta, G. Pesenti Rossi and E. Canali

University of Milan, Department of Veterinary Medicine and Animal Science, via dell'Università 6, 26900 Lodi, Italy; greta.berteselli@unimi.it

The use of robot milking in dairy farming has led to numerous advantages (e.g. increasing hygiene, health; reducing labour) but the impact on animal behaviour and welfare is not fully explored. The aim was to compare behaviours' time-budget, animal-based measures related to welfare, and productivity in two different milking systems: automatic milking and milking parlour. Two groups of healthy lactating cows of two intensive farms (located in a region of Northern Italy) were recruited. Automatic milking group (AM) milking parlour group (MP): 44 and 50 cows respectively. A welfare assessment was performed including the evaluation of animal cleanliness (udder, legs, flank); presence of lesions/swelling and presence of hairless patches; nasal, ocular, vulvar discharge; diarrhoea; locomotion score, BCS, human-animal relationship (avoidance distance test). Furthermore, for each cow, daily hours spent lying, ruminating, walking and eating were recorded using accelerometry collars. A time window of 15 day was considered (7 days prior the assessment, the day of assessment, 7 days after assessment) as well as the milk production. A significant difference was found in the time budgets between AM and MP groups as well as the milk production (Mann Whitney U-test; $P < 0.05$): AM group spent more time lying (10.88 ± 1.58 h), walking (2.97 ± 0.84 h), whereas MP group spent more time ruminating (8 ± 0.84 h), and eating (5.01 ± 1.31 h); the milk production was higher in MP-group. A significant difference between groups was also found for udder cleanliness and the presence of lesion/swelling (Chi-square test; $P < 0.05$). In particular, MP-group showed a higher % of animals with dirty udder, whereas most of the injured animals belonged to AM group. The AM group showed a better human-animal relationship, with only a 23% of animals showing avoidance behaviours towards unfamiliar person (Chi-square test; $P = 0.066$). The results show that the milking system can have an impact on different aspects of dairy cows' life in particular on time-budget and welfare. The human-animal relationship could be positively affected by the automatic milking, but this requires further studies.

Prioritization of welfare issues and precision technologies for welfare monitoring in dairy sheepA. Elhadi¹, R. González-González² and G. Caja¹¹Universitat Autònoma de Barcelona, Group of Ruminant Research (G2R), Animal and Food Sciences, Av. dels Turons, 08193 Bellaterra, Spain, ²Gestión Empresarial de Ovino (GEO), Av. Americas 7, 49600 Benavente, Spain; abdelaali.elhadi@uab.cat

According to the planned activities of WP1 in the TechCare project, 2 National Workshops (NW) were held in 9 countries to discuss and to prioritize (top 3) the welfare issues and sensor technologies for welfare monitoring in sheep (meat and dairy) and goats (dairy), according to species and systems. In Spain, NW were: NW1 (47 participants from 10 Autonomous Communities: 22 scientists, 10 veterinarians, 10 technicians and 5 farmers), which prioritized the welfare issues from an exhaustive list (n=437) based on bibliographic references (WP2), and NW2 (46 part. from 12 A.C.: 16 sci., 8 vet., 15 tech. and 7 farm.), which prioritized a list (n=116) of PLF sensors based on bibliographic references and available market products (WP3). Suckling and fattening lambs and goat kids were also included. Because the COVID-19 pandemic, both Consortium and Spanish meetings were telematic (by Zoom). Additionally, to validate the NW1 and NW2 prioritizations, a presential and *in situ* workshop (Medina del Campo, Valladolid), with focus on dairy farmers, was held late in 2022: NW3 (40 part.: 4 vet., 10 tech. and 26 farm.) before the tools implementation in large-scale trials on commercial farms. The NW3 prioritizations, according to percentage of votes, were: Welfare issues (1st, mastitis and milking management 70%; 2nd, abortion and perinatal mortality 55%; 3rd, housing conditions 43%), and Sensors (1st, weather stations 60%; 2nd, automatic milk meters 53%; 3rd, behaviour accelerometers 43%). The results of NW3 remarkably agreed with those obtained in the NW1 of the TechCare consortium-9 (256 part.) and in the specific case of NW1 for dairy sheep in Spain. The coincidence was greater in the sensor prioritization, which was similar to the NW2 of the TechCare consortium-9 (150 part.) and in the Spanish NW2. In conclusion, Spanish farmers showed interest in welfare monitoring for dairy sheep and prioritized the use of weather stations (with external and internal sensors) to record the environmental conditions of intensive dairy farms. Acknowledgements: Funded by the EU H2020 program (Contract #862050, TechCare Project).

Session 40

Theatre 1

Update of nutritional requirements of goats for growth and pregnancy in hot environmentsI.A.M.A. Teixeira¹, C.J. Härter², J.A.C. Vargas³, A.P. Souza⁴ and M.H.M.R. Fernandes⁵¹University of Idaho, 315 Falls Avenue Evergreen Buiding, 83303-1827 Twin Falls, ID, USA, ²Universidade Federal de Pelotas, Rua Gomes carneiro, 01, 96160-000 Pelotas, RS, Brazil, ³Universidade Federal Rural da Amazônia, PA-275 s/n, 68515-000 Paraupabas, PA, Brazil, ⁴Universidade Federal do Sul e Sudeste do Para, R. Alberto Santos Dumont, 68557-335 Xinguara, PA, Brazil, ⁵UNESP-Universidade Estadual Paulista, Via de Acesso Paulo Donato Castellane, 14884-900 Jaboticabal, SP, Brazil; izabelle@uidaho.edu

Goats are an important source of income in the agricultural business, such as milk and meat. They are also the preferred livestock for rural households due to their inherent resiliency and adaptability to many environments and suitability in sustainable production systems. In the last decades, the nutrition of goats, particularly their nutritional requirements, has received special attention. Different research groups around the world have dedicated efforts to updating feeding systems for goats. In this invited talk, our objective is to present the recent findings on the energy and nutrient requirements of growing and pregnant goats in hot environments. The literature and studies considered herein comprise growing goats of different sexes (females, intact and castrated males) and genotypes (dairy, meat, and indigenous). In short, the energy and protein requirements (maintenance and growth) of growing goats are influenced by sex and genotype only when mature weight is not considered in the models. The maintenance and growth requirements of major minerals are not affected by sex and genotype. Sex and genotype affect the efficiency of energy use for growth but did not affect the efficiency of protein use. The literature findings also suggest that losses in urine and methane in goats are lower than the ones reported for bovine and sheep. Regarding requirements for pregnancy, there was no effect of days of pregnancy on the energy or protein requirements. The efficiency of metabolizable energy utilization for pregnancy increased with the progress of pregnancy. Mineral accretion for pregnancy differs between single and twin pregnancies and irrespective of pregnancy the mineral requirements increased as pregnancy progressed. New approaches and limitations to goat requirements are also presented.

Intramammary administration of lipopolysaccharides at parturition affects colostrum quality

M. González-Cabrera¹, A. Torres², M. Salomone-Caballero¹, N. Castro¹, A. Argüello¹ and L.E. Hernández-Castellano¹
¹Universidad de Las Palmas de Gran Canaria, Institute of Animal Health and Food Safety, Trasmontaña s/n, 35413 Arucas, Spain, ²Canary Islands Institute for Agricultural Research, Animal Production, Pasture, and Forage in Arid and Subtropical Areas, Finca El Pico, s/n, 38260 La Laguna, Spain; marta.gonzalezcabrera@ulpgc.es

In this study, 20 Majorera dairy goats were used. The TRT group (n=10) received an intramammary administration (IA) of saline (2 ml) containing 50 µg of lipopolysaccharides (LPS) from *Escherichia coli* (O55:B5) in each quarter at parturition. The CON group (n=10) received an IA of saline (2 ml) without LPS. Rectal temperature (RT) was recorded, and a blood sample collected at parturition (before the IA). In addition, RT was recorded, and blood and colostrum/milk samples were collected at 3 and 12 hours, and on days 1, 2, 4, 7, 15 and 30 relatives to IA. Plasma immunoglobulin (Ig) G and M and serum β-hydroxybutyrate, glucose, calcium, free fatty acids, lactate dehydrogenase and total proteins concentrations were determined. Colostrum/milk yield as well as chemical composition, somatic cell count (SCC) and IgG and IgM concentrations were measured. The MIXED procedure (SAS 9.4) was used, and the model included the IA, time, and the interaction between both fixed effects. Statistical significance was set as $P \leq 0.05$. Goats from the TRT group increased RT after the IA, while the CON decreased RT ($P_{IA \times T} = 0.007$). Serum biochemical parameters, and plasma IgG and IgM concentrations were not affected by IA. Colostrum and milk yield as well as chemical composition were not affected by IA, except for milk lactose that was lower in the TRT group compared to the CON group ($P_{IA} = 0.026$). Colostrum SCC was higher in the TRT group than in the CON group (3.5 ± 0.09 and 3.1 ± 0.09 cells $\times 10^6$ /ml, respectively; $P_{IA} = 0.009$). Similar results were observed for milk SCC ($P_{IA} = 0.004$). The TRT group showed higher IgG ($P_{IA} = 0.044$) and IgM ($P_{IA} = 0.037$) concentrations on colostrum than the CON group (31.9 ± 4.8 and 19.0 ± 4.5 mg/ml, 0.7 ± 0.08 and 0.4 ± 0.08 mg/ml, respectively). No differences on milk IgG and IgM concentrations between groups were observed. In conclusion, the IA of LPS at parturition increases RT, SCC and IgG and IgM concentrations in colostrum without affecting either yield or chemical composition.

Session 40

Theatre 3

Goat kids are not affected by the intramammary administration of lipopolysaccharides at parturition

M. González-Cabrera¹, M. Salomone-Caballero¹, S. Álvarez², A. Argüello¹, N. Castro¹ and L.E. Hernández-Castellano¹
¹Universidad de Las Palmas de Gran Canaria, Institute of Animal Health and Food Safety, Trasmontaña s/n, 35413 Arucas, Spain, ²Canary Agronomic Research Institute, Animal Production, Pasture, and Forage in Arid and Subtropical Areas, Finca El Pico, s/n, 38260 La Laguna, Spain; marta.gonzalezcabrera@ulpgc.es

This study evaluated the effect of an intramammary administration (IA) of lipopolysaccharides (LPS) from *Escherichia coli* (O55:B5) to dairy goats at parturition, on performance, biochemical parameters (calcium, LDH, glucose and total proteins) and immune status (IgG and IgM) of goat kids. Twenty dairy goats were used. The treatment (TRT) group (n=10) received an IA of saline solution (2 ml) containing 50 µg LPS per gland at parturition. Similarly, the control (CON) group (n=10) received an IA of saline solution (2 ml) without LPS. At birth, goat kids (n=45) were weighted (day 0) and immediately allocated into either the TRT group (n=19) or the CON group (n=26) based on the experimental group of the dam. They were bottle-fed dam colostrum equivalent to 10% of the birth body weight (BW) divided in two meals (3 and 12 h after birth), and then fed twice daily with milk replacer. Individual milk intake (MI) and BW were recorded on days 7, 15, 21 and 30 of life. Blood samples were taken on days 0, 1, 2, 4, 7, 15, 21 and 30 after birth. Data was analysed using the MIXED procedure of SAS (9.4). The model included IA, time (T) and the interaction ($IA \times T$). Both groups showed similar MI, except for day 7 as the TRT group showed higher MI than the CON group (911 ± 73.9 ml/day and 652 ± 64.6 ml/day, respectively; ($P_{IA \times T} = 0.001$)), although no differences were observed on BW during the experiment ($P_{IA} = 0.367$). The TRT group showed higher calcium ($P_{IA} = 0.001$) and total protein ($P_{IA} < 0.001$) concentrations than the CON group (12.8 [12.5 - 13.1] and 12.2 [12.0 - 12.5] mg/dl, respectively). The CON group showed higher LDH activity than the TRT group (626 ± 20.51 U/l and 561 ± 20.51 , respectively; $P_{AI} = 0.016$). Glucose and plasma IgG and IgM concentrations were not affected by IA ($P_{IA} = 0.217$, $P_{IA} = 0.151$ and $P_{IA} = 0.157$, respectively). In conclusion, the IA of LPS to dairy goats at parturition does not affect performance or immune status of goat kids but affects calcium, total protein and LDH activity on serum.

Near-infrared spectroscopy prediction models preliminary results in ewes' colostrumS. González-Luna^{1,2}, E. Albanell², G. Caja² and C. L. Manuelian²¹Facultad de Estudios Superiores Cuautitlán, Universidad Nacional Autónoma de México (UNAM), Departamento de Ciencias Pecuarias, Ctra. Cuautitlán-Teoloyucan km 2.5, 54714 Cuautitlán Izcalli, Mexico, ²Universitat Autònoma de Barcelona (UAB), Group of Ruminant Research (G2R), Department of Animal and Food Sciences, Campus Universitari de la UAB, 08193 Bellaterra, Spain; carmen.manuelian@uab.cat

Colostrum is key for nutrients provision and passive immunity transfer in newborns. Thus, rapid methods to determine its quality at farm level is crucial. The aim was to investigate near-infrared spectroscopy feasibility to prediction colostrum gross composition, IgG, and insulin. A total of 45 colostrum samples collected <6 h post-partum from Lacaune (n=21) and Manchega (n=24) ewes were scanned in duplicate by using NIR System 5000 equipment (FOSS Electric A/S, Hillerød, Denmark) from 1,100 to 2,500 nm wavelength every 2 nm. Absorbance was recorded as log(1/ Transflectance). Reference data were matched with the sample spectra, and modified partial least squares regressions prediction models were developed applying a 5-fold cross-validation. Outlier were discarded before building the final model. Average mean $\pm$ SD for fat, protein, true protein, casein, total solids, IgG, and insulin of the retained samples were 7.35 $\pm$ 3.45%, 15.84 $\pm$ 4.89%, 15.22 $\pm$ 4.73%, 5.81 $\pm$ 1.84%, 26.17 $\pm$ 7.16%, 25.10 $\pm$ 10.96 mg/ml, and 13.32 $\pm$ 6.12 μ g/l, respectively. Calibration models were considered excellent for total solids, total protein, and true protein with a coefficient of determination in cross-validation (R²_c) of 0.99, and a RPD (SD/SE_c) that ranged from 9.40 (true protein) to 15.84 (total solids). Very good calibration model applicable for quality control was achieved for total fat (R²_c, 0.96; RPD, 3.58), and poor calibration applicable for a rough screening was obtained for casein (R²_c, 0.80; RPD, 2.29). However, very poor calibration models resulted for IgG (R²_c, 0.88; R²_c, 0.39; RPD, 1.27) and insulin (R²_c, 0.68; R²_c, 0.26; RPD, 1.14). In conclusion, these preliminary results suggested the potential use of near-infrared spectroscopy to estimate sheep colostrum quality, and confirm the need for further investigation for IgG.

Session 40

Theatre 5

No kid, no milk? Trials about induction of goat lactation without gestation

L. Fito, C. Constancis and M. Bouy

FiBL France, Research Institute of Organic Agriculture, 150 avenue de Judée, 26400 Eurre, France; caroline.constancis@fibl.org

In dairy production, female small ruminants usually give birth every year to produce milk and be profitable. However, repeated gestation leads to exhaustion of the animals and early culling. Furthermore, consumer demand for goat kid meat is very low, impeding farmers to retrieve satisfying economic and social value from these repeated births. In response to these issues, the practice of 'long or extended lactation' appears like an interesting solution, but raises concerns about animal and farmer welfare. Alternative methods consist of inducing lactation in non-gestating females by subjecting them to intense hormonal treatments which simulate the prepartum period, but these also come with animal welfare and environmental drawbacks. Some farmers do this on one or two non-gestating goats each year but very little research has been done on this practice. The goal of the study was to assess if natural induction of lactation in non-gestating goats was possible, and to evaluate the impact on milk production and on endocrinology. trials on 6 farms has been conducted to investigate the induction of lactation in non-gestating goats by manual stimulation of the teats and by keeping them in presence of gestating ones. twenty-eight non-gestating goats were manually stimulated by farmer in the milking parlour, for one month. Prolactin, progesterone and oestradiol levels, involved in the lactation process, were measured before and after parturition. Kruskal-Wallis tests were used using R software version 3.5.3. Lactation was induced in 61% of the stimulated non-gestating goats. Milk production level of these non-gestating goats gradually increased during the first month, but they reached the same production level and the same milk composition as the others at the end of the lactation. Overall production was 30% lower in non-gestating goat. We evidenced that the propensity for non-gestating goats to induce lactation was correlated to a higher prolactin level prior to the onset of stimulation (P -value<0.001). In conclusion, induction of lactation therefore seems to be promising, and would allow valuable improvements of animal welfare and farm sustainability, but the underlying hormonal mechanisms still need better understanding.

Perinatal rumen microbiota in relation to feed utilization and biochemical parameters in sheep

J.X. Chen

Hebei Agricultural University, college of animal science and technology, No.2596, Lekainan Street, Lianchi District, 071000 Baoding, China, P.R.; chenjiixin1226@163.com

This study aimed to investigate the relationship between rumen microflora and nutrient digestion, rumen fermentation and biochemical parameters in sheep. Blood, rumen fluid and faeces samples (n=10) were collected on days -21, -14, -7, 3, 7 and 14 (Q21, Q14, Q7, H3, H7 and H14) relative to expected parturition. Dynamic changes of average daily feed intake (ADFI), nutrient digestibility, rumen fluid and serum parameters were detected. The 16S rRNA sequencing was performed for rumen microflora and the Random Forest method was used to predict Perinatal time-related changes. All data were evaluated by one-way ANOVA. The results showed that the digestibility of dry matter (DMD), crude protein (CPD) and neutral detergent fibre (NDFD) in Q7 d was higher than that in H3 d ($P<0.05$); Compared with Q21 d, ADFI and total volatile fatty acids (T-VFA) increased after lambing, while acetate to propionate ratio (A/P) decreased ($P<0.05$); Serum concentrations of glucose, β -hydroxybutyric acid (BHBA), 25-hydroxy vitamin D3 (25HVD3) and neuropeptide Y (NPY) were increased in H14 d compared to Q21 d; Total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), glucagon and leptin were the highest at Q21 d and decreased after lambing ($P<0.05$). The 16S rRNA gene sequencing revealed that rumen microflora composition also differed in rumens before and after lambing ($P<0.05$). Nineteen perinatal time-related bacterial genera were predicted, in which the relative abundance of *Anaeroplasma* and *Lachnospiraceae_ND3007_group* was the highest at Q21 d, and was positively correlated with rumen pH, acetate and TC, negatively correlated with propionate ($P<0.05$), *Endomicrobium*, *Suttonella*, *M2PT2-76_termite_group* decreased after parturition and were positively correlated with HDL-C and TC, negatively correlated with T-VFA, 25HVD3 and NPY ($P<0.05$); *Ruminococcus* and *UCG-005* is increasing in H3 d, and *Ruminococcus* is positively correlated with T-VFA, 25HVD3 and NPY ($P<0.05$), while *UCG-005* is negatively correlated with NDFD, CaD, PD, CPD and DMD ($P<0.05$). These results suggest that rumen bacterial community in the perinatal period of ewes affect feed utilization and rumen fermentation patterns, and play an important role in shaping biochemical parameters.

Session 40

Theatre 7

Alpine goats divergent for functional longevity differ in metabolic profile during transition periodJ. Pires¹, T. Fossier², M. Tourret¹, C. Huau³, N. Friggens⁴ and R. Rupp³

¹INRAE, UCA, VetAgro Sup, UMRH, Theix, 63122, France, ²Domaine de Bourges, INRAE, Osmoy, 31326, France,

³GenPhySE, Université de Toulouse, INRAE, Castanet Tolosan, 31320, France, ⁴UMR 0791 MoSar, INRAE, AgroParisTech, Université Paris-Saclay, Paris, 75005, France; jose.pires@inrae.fr

The objective was to study associations among functional longevity and plasma indicators of metabolic adaption in Alpine goats during periparturient period. Two Alpine goat strains divergent for longevity (LGV+ and LGV-) were produced by AI selecting for extreme functional longevity but nondifferent milk yield. A total of 174 primiparous goats were studied in 2018, 2019, 2020 and 2021. Jugular plasma collected on wk -4, -3, -2, -1 relative to expected parturition, and wk 1, 2, 4, 13, 24, 33 of lactation was analysed for NEFA, BHB, glucose, urea and bilirubin. Data were analysed using SAS mixed models with repeated measures, including strain, litter size (LS), wk, and interactions as fixed effects, and year and goat (year) as random effects. Significant wk effects were observed for all metabolites. LGV- goats had greater plasma NEFA on wk-3 (181 vs 123 μ M; strain $\times$ wk prepartum: $P=0.05$), and greater BHB prepartum (0.45 vs 0.41 mM; strain effect: $P=0.04$) than LGV+, which denotes greater fat mobilization and partial oxidation in late gestation LGV- goats. 35% of goats carried multiple foetus (LS2+) and LS not differ with LGV. Prepartum plasma NEFA, BHB and bilirubin were greater for LS2+ compared to single (LS1; $P<0.001$; 260 vs 174 μ M; 0.51 vs 0.39 mM; 0.069 vs 0.056 mg/dl, respectively), whereas glucose was lower for LS2+ ($P<0.001$; 49.8 vs 54.7 mg/dl). Conversely, plasma NEFA was greater for LS1 during wk 1 and wk 2 postpartum ($P<0.05$; 558 vs 442 on wk 1, and 421 vs 330 μ M on wk 2, respectively), reflecting greater availability of body reserves to support lactation in LS1. Prepartum incidence of BHB>0.80 mM was significantly greater for LS2+ than LS1 (30 vs 3.7%), and for LGV- carrying LS2+ than LGV+ carrying LS2+ (42 vs 28%). Marked LS effects were observed in plasma metabolite profiles in primiparous goats. LGV strains differ in their metabolic adaptations peripartum. This study has received funding from the EU H2020 research and innovation program under grant agreement No 772787 (SMARTER) and from APISGENE (ACTIVEGOAT).

Effects of sodium butyrate supplementation at late gestation of ewes

Y.J. Zhang, X.Y. Zhang, X.H. Duan, R.C. Yang and S.W. Zhang

Hebei Agricultural University, College of Animal Science and Technology, Lekai Street, Baoding, 071000, China, P.R.; zhangyingjie66@126.com

The purpose of this experiment was to study the effects of different levels of sodium butyrate on growth performance, nutrient apparent digestibility and body immunity during late gestation of ewes. Sixty female Hu sheep with similar age, body weight and parity were randomly divided into 4 groups ($n=15$), and the basal diet was supplemented with 0 g/d (control group), 2.5 g/d (group A), 5 g/d (group B) and 7.5 g/d (group C) sodium butyrate for each sheep, respectively. The trial lasted from day 90 to day 15 before lamb birth. Feed intake and body weight (BW) were recorded and blood samples from jugular vein were collected at day 90 and day 15 before lamb birth. Three ewes in each group were randomly selected for digestion and metabolism test. The results showed that the dry matter intake (DMI) in group B was significantly higher than that of control group and group A ($P<0.05$), but there was no significant difference between group B and group C ($P>0.05$). The BW of ewes in group B was significantly higher than that of control group and group A ($P<0.05$), but there was no significant difference between group B and group C ($P>0.05$). The apparent digestibility of dry matter, crude protein, gross energy and crude fibre in groups B was significantly higher than that in control group ($P<0.05$). At 60 days before lamb birth, the serum level of immunoglobulin G (IgG), interleukin-2 (IL-2), interleukin-4 (IL-4) and interleukin-6 (IL-6) in experimental groups had no differences compared to the control group. At day 15 before lamb birth, IgG in group B was significantly higher than that in control group and group C ($P<0.05$), but there was no significant difference between group A and group B ($P>0.05$). The serum level of IL-2 and IL-6 in groups B and C were significantly lower than those in control group and group A ($P<0.05$). In conclusion, dietary sodium butyrate supplementation at late gestation of ewes can increase feed intake, nutrient apparent digestibility and improve the body immunity. The optimal supplemental level of sodium butyrate was 5 g/d per sheep.

Session 40

Theatre 9

New artificial teats to improve goat milking device laboratory tests

M. Despinasse, C. Bonin, G. Coquereau and J.L. Poulet

Institut de l'Élevage, 149 rue de Bercy, 75595 Paris Cedex, France; jean-louis.poulet@idele.fr

In general, milking devices are evaluated first in laboratories by applying standardized 'wet tests' (ISO 3918:2007 and ISO 6690:2007), with a single design of goat artificial teats (AT). However, studies previously conducted (CASDAR RT Mamovicap, 2017) have stigmatized the shapes and dynamic characteristics (deformation, milk flow) diversities of these teats. CapriMam3D (CASDAR RT, 2020-2023) aims to investigate teat-liner interactions, using new technologies to develop and evaluate new artificial teats. For this project, goat teats of our 2 partner experimental farms (Experimental Farm of Le Pradel and INRAE Experimental Station of Bourges). 3 shapes of teats have been selected: 'M' (Medium, $L=60$ mm and $\varnothing=38$ mm), with dimensions very close to those of standard AT (ISO 6690:2007), 'S' (Small and short, $L=40$ mm and $\varnothing=30$ mm), close to ewe's teat, and 'C' (large and Conical, $L=90$ mm and $\varnothing=55$ mm), finally quite present on farms. For these 3 shapes, different constitutions of AT were evaluated: RAT (Reference Artificial Teat), made with hard plastic and standardized size, SAT (Soft Artificial Teat), obtained by casting silicone in moulds made by 3D printing, and SAAT (Soft Anatomic Artificial Teat), produced in an identical way to the previous ones but with a cavity simulating the teat cistern, obtained using a counter-mould. Milking Liners (ML), among the most widely used in France (analysis of an extraction from Logimat 3, Milking Machine Control input and monitoring software of the French Interprofessional Committee for Milk Production Techniques) were tested with this new AT panel. It emerges from an initial analysis of the results that the characterization of the operation of the AT/ML interface (vacuum fluctuations) can differ greatly depending on the AT used (and possibly the underlying methods). The use of RAT sometimes leads to laboratory test results that are quite different from farm findings (experimental and commercial), while the use of SAAT leads to characterizations of the AT/ML interface closer to these, despite sometimes more complex implementations. The work is currently continuing, by deepening the comparisons between characterization in laboratory and in experimental farms of 2 ML, common but opposed in terms of design.

Olive cake feeding alters the expression of lipogenic genes in mammary and adipose tissue in goats

M.C. Neofytou¹, A.L. Hager-Theodorides², E. Sfakianaki², S. Symeou¹, D. Sparaggis³, O. Tzamaloukas¹ and D. Miltiadou¹

¹Cyprus University of Technology, Department of Agricultural Sciences, Biotechnology and Food Science, P.O. Box 50329, Limassol, Cyprus, ²Agricultural University of Athens, Department of Animal Science, Iera Odos, 11855 Athens, Greece, ³Agricultural Research Institute, P.O. Box 22016, Nicosia, Cyprus; despoina.miltiadou@cut.ac.cy

This study assessed the effect of dietary inclusion of ensiled olive cake (OC) on milk yield, composition, fatty acid (FA) profile and the expression of selected genes involved in lipid metabolism in the udder and adipose tissue of goats. Three iso-nitrogenous and iso-energetic diets containing 0% (OC0), 10% (OC10), and 20% (OC20) of EOC (DM) were formulated and offered to mid-lactating Damascus goats (3 pens of 8 animals each) for 42 days. At the end of the trial, mammary and perirenal adipose tissue samples were collected from 6 animals per treatment from OC0 and OC20 groups for gene expression analysis by quantitative RT-PCR. The expression of 10 genes, involved in FA synthesis (ACACA, FASN, G6PDH), FA uptake and/or translocation (VLDLR, LPL, SLC2A1, CD36, FABP3), FA desaturation (SCD1) and transcriptional regulation (PPAR γ), was evaluated. The results showed that, among milk traits, milk fat percentage was risen with increasing OC inclusion rates in the diets, while milk protein percentages were elevated in both OC groups. Although, the content of medium-chain FA was reduced in the milk of OC groups, the mammary expression levels of ACACA, FASN, and SCD1 was unaffected. In contrast, the significant increase of the long-chain FA content observed in the milk of OC20 group, coincided with elevated expression of SLC2A1 ($P<0.05$), VLDLR ($P<0.01$), FABP3 ($P<0.01$) in the mammary gland of OC goats. In the adipose tissue, significant increments of C18:1 trans isomers found in the milk of OC group may have affected the mRNA abundance of FASN ($P<0.01$) which was increased in the perirenal fat of OC cows. Similarly, the OC20 diet upregulated the SLC2A1 in the adipose tissue of goats that could likely increase LCFA and glucose uptake in caprine adipose tissue. Overall, OC can be used up to 20% (DM) in goats' diets, without adversely affecting milk traits or the expression of genes involved in lipid metabolism.

Session 40

Poster 11

Chemical composition and physicochemical characteristics of mountainous goat milk during lactation

E. Kasapidou¹, I.V. Iliadis², G. Papatzimos¹, M.A. Karatzia³, Z. Basdagianni⁴ and P. Mitlianga²

¹University of Western Macedonia, Department of Agriculture, Florina, 53100, Greece, ²University of Western Macedonia, Department of Chemical Engineering, Koila, 50100 Kozani, Greece, ³Research Institute of Animal Science, HAO-Demeter, Paralimni, 58100 Giannitsa, Greece, ⁴Aristotle University of Thessaloniki, School of Agriculture, Department of Animal Production, Thessaloniki, 54124, Greece; ekasapidou@uowm.gr

Milk composition affects its capability to produce superior quality dairy products. Additionally, the favourable composition of milk from upland origin has been reported in several studies. The study aimed to record changes in mountainous goat milk's composition and physicochemical characteristics during lactation. Bulk tank milk samples (n=134) were collected every fortnight between March and October 2022 from 10 dairy goat farms following the semi-intensive production system located in an area with an average altitude of 772 m. Daily milk yield and the population of lactating goats were recorded. Milk composition and physicochemical characteristics were determined. One factor variance analysis examined differences at monthly level. The average number of lactating goats per farm was 151 whereas mean daily milk yield (171 l) differed significantly ($P<0.001$) during lactation. The average fat, protein, lactose and solids non-fat content were 4.39, 3.63, 9.14 and 4.49 g/100 ml respectively. Highly significant differences ($P<0.001$) were observed in gross composition during lactation. Higher protein and fat contents were found at the end of the lactation period whereas lactose content was variable throughout lactation. Mean values for physicochemical characteristics were 1.3481, 5.30 mS/cm and 6.75 for refractive index, electrical conductivity and pH respectively. Electrical conductivity and pH were significantly affected ($P<0.001$) during lactation whereas there was no effect ($P>0.05$) on refractive index. Lower pH and higher electrical conductivity values were recorded in late spring and summer months. Results confirm that lactation stage affects milk composition. Information about milk composition during lactation could be beneficial for producers of mountain dairy products enabling standardization of product composition and quality. Support: AGROTOUR Project (MIS 5047196), NSRF 2014-2020.

Energy balance and body reserve dynamics in early lactation dairy ewes

F. Corbiere¹, C. Machefert², J.M. Astruc³, M. El Jabri³, B. Fanca³, P. Hassoun⁴, C. Marie-Etancelin², A. Meynadier² and G. Lagriffoul³

The objective of this study conducted on two experimental dairy sheep flocks and eight commercial farms was to evaluate the use of two blood metabolites, beta-hydroxy-butyrate (BHB) and non-esterified fatty acids (NEFA), to assess energy balance and body reserve mobilization in dairy sheep. On 9 farms, body condition scoring (BCS) was performed on 3 occasions (one month before lambing, 3 weeks after lambing and after weaning at the time of the first official milk recording) for a total of 2,125 ewes. In parallel, blood BHB and NEFA concentrations were measured on a subset of 466 2nd lactation ewes in these flocks. On two farms, the diurnal kinetics of blood BHB and NEFA during the day was also studied. Comparisons between BHB and NEFA values measured at different time points or between different groups were performed by Wilcoxon rank tests (for paired data if necessary) and by multivariable linear mixed regression models, with a Holm correction applied for multiple comparisons. Results confirm that the composition of the ration and the postprandial delay are major factors of diurnal variation in BHB and NEFA values. While plasma NEFA values measured 3 weeks after lambing were found to be positively correlated with the extent of BCS loss since late gestation, no significant relationship could be demonstrated for blood BHB. When measured at the first official milk recording (52±9.9 days after lambing), neither BHB and NEFA were correlated to body reserve mobilization. Further, the overall milk yield throughout lactation was strongly correlated with BCS dynamics between late gestation and early lactation. These results support the importance of exploring the early lactation period in dairy ewes, during which lambs are kept under their dams.

Effects of *Sulla flexuosa* hay as alternative feed resource on goat's milk production and quality

S. Boukrouh^{1,2}, A. Noutfia¹, N. Moula², C. Avril³, J.-L. Hornick², M. Chentouf⁴ and J.-F. Cabaraux²

¹National Institute of Agricultural Research, Regional Center of Agricultural Research of Tangier, 10090 Rabat, Morocco,

²ULiège, Department of veterinary management of animal resources, FARA, Faculty of Veterinary Medicine, Quartier Vallée 2, Avenue de Cureghem, 6, Bât. B43, 4000 Liège, Belgium, ³HEPH Condorcet, Agronomy category, Rue de la Sucrerie, 10, 7800 Ath, Belgium; jfcabaraux@uliege.be

Sulla flexuosa (*Hedysarum flexuosum* L.) is an endemic legume growing in some Mediterranean areas in rainfed and cold mountainous conditions. It could be used in goat diets as an alternative protein source instead of alfalfa to supplement forest rangeland. This study aimed to test the effects of incorporating *Sulla flexuosa* (SF) hay in the diet of Beni Arouss goats on their milk production and quality. The hay was introduced at two levels, i.e. 35 or 70% (SF70), on a DM basis; it partially or totally replaced the alfalfa hay of the control diet. The Data were analysed using the PROC MIXED function, including the random effect of goats, the fixed effects of the diet, the sampling week and their interaction. Post hoc analyses were performed using the Tukey test when the results for a parameter were significantly different according to the diets. SF incorporation did not affect milk production or physicochemical composition. However, milk FA content varied in proportion to the percentage of SF incorporation. The SF70 diet was associated with increased milk levels in C18:1n-9, C18:2n-6, C18:3n-3, and C22:6n-3 and total monounsaturated, polyunsaturated, and n-3 fatty acids. As a consequence, atherogenic and thrombogenic indices were improved. Tannins present in SF hay probably had a protective effect on fatty acid biohydrogenation in the rumen and an impact on fatty acid desaturating enzymes in the mammary gland. Additionally, better antioxidant capacity in milk was observed in SF70. The data of this study suggest that SF hay should be incorporated with no less than half of dry matter intake to show noticeable effects. Therefore, SF should be suggested as an alternative forage and protein resource in the lactating goat diet.

High DCAD and ascorbic acid modify acid base, oxidative stress and kidney function in dairy goatsS. Thammacharoen¹, S. Semsirboon¹, D.K. Do Nguyen¹, S. Poonyachoti¹, T.A. Lutz² and N. Chaiyabutr¹¹Faculty of Veterinary Science, Chulalongkorn University, Department of Physiology, Pathumwan, Bangkok, 10330, Thailand, ²Vetsuisse Faculty, University of Zurich, Veterinary Physiology, Zurich, 8057, Switzerland; sprueksagorn@hotmail.com

Acid-base imbalance and systemic oxidative stress are the consequences of the high ambient temperature (HTa) in dairy animals. This is the important condition that down regulate the mammary gland function. We have shown in dairy goats that the negative effect of HTa can be alleviated by enhancing heat dissipation with high dietary cation and anion difference (DCAD) regimen. In addition, high-dose ascorbic acid (AA) could improve oxidative status. The present study aimed to evaluate the effect of both supplements on acid-base balance, oxidative stress and the kidney function in dairy goats. Data containing 2 factors were analysed with general linear model using repeated two-way analysis of variance. When compared with control diet (n=6), high DCAD (n=6) had no effect on urine flow rate (V_U) and endogenous creatinine clearance (C_{cr}) throughout the experiment. High DCAD significantly decreased net acid excretion (NAE) and increased fractional excretion of potassium (FE_K). The results suggested that high DCAD regimen influenced tubular functions without changing urine synthesis. During the period of high DCAD regimen, supplementation with high dose AA significantly increased V_U , however, could not change endogenous C_{cr} . This effect of AA on V_U apparently came from the AA effect that could increase in NAE. high dose of AA decreased in FE_K . Moreover, both high DCAD and AA influenced urine pH. High-dose AA decreased plasma glutathione peroxidase activity and malonaldehyde. The effect was enhanced by a high DCAD. Taken together, it can be concluded that high DCAD regimen and high dose of AA influence kidney function mainly by changing the tubular function. The tubular handling of bicarbonate and acid molecules is activated and partially explains the effect of both treatments on systemic acid-base balance. Finally, it seems likely that body water is maintained at least from the insignificant effect of the present high DCAD regimen on urine synthesis rate.

Link between chest circumference at late gestation and milk somatic cell count in Sarda ewe-lambs

D. Sioutas, A. Ledda, A. Mazza, A. Marzano, M. Sini and A. Cannas

University of Sassari, Agricultural Sciences, viale Italia 39/a, Sassari, 07100, Italy; dsioutas@uniss.it

The objective of this study was to evaluate in Sarda ewe-lambs the association between chest circumference (CC) at 120 d of gestation and udder health, as indicated by somatic cell count (SCC) during the successive lactation. In previous studies conducted on ewes of the Sarda breed, CC has been proven an interesting and accurate alternative method for the assessment of body condition score (BCS) of the animals at the farm level, eliminating the subjectivity factor related to the evaluation of body reserves by trained operators. A total of 26 pregnant Sarda ewe-lambs were selected. The animals presented an average BCS of 2.97 ± 0.12 , and CC of 91.15 ± 4.66 cm at 120 d in gestation, while the average age at first partum was 413 ± 26 d. For the determination of the SCC, milk samples were recorded individually during the morning and afternoon milking, once a week, from day 1 to day 105 of lactation. Taking into consideration that milk SCC does not follow the normal distribution, the milk SSC of each animal was log transformed. Average values for SCC during lactation were 1.125×10^6 cells/ml, which corresponds to log SCC equal to 2.37. The effect of CC at late gestation on average log SCC during lactation was analysed using the General Linear Model (GLM) procedure of R software. The results of our study showed that CC at late gestation had a significant effect on average lactation values of log SCC ($P < 0.01$). Moreover, CC presented a high and significant correlation with log SCC ($r = 0.59$; $P < 0.01$), as well as a moderate but significant correlation with BCS ($r = 0.43$; $P < 0.05$). Interestingly, average values for log SCC during lactation increased proportionally to the values of CC at late gestation, i.e. a positive linear relationship was found between CC and log SCC ($R^2 = 0.35$). These findings imply that animals with relatively higher levels of body reserves close to parturition have a higher probability of presenting an impaired overall udder health status during successive lactation, probably because extensive mobilization of body reserves leads to ketone-body synthesis, which induce a state of sub-ketosis and thus of immunosuppression. However, further studies are needed to confirm this hypothesis.

Incorporating high-dimensional omics phenotypes into models for predicting breeding values*O.F. Christensen**Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Alle 3, 8000 Aarhus C, Denmark; olef.christensen@qgg.au.dk*

Incorporating high-dimensional omics phenotypes into models for predicting breeding values Ole F. Christensen, Center for Quantitative Genetics and Genomics, Aarhus University High dimensional phenotypes like metabolomics and transcriptomics are becoming available in larger quantities and at decreasing costs. Since they are both heritable and associated to phenotypes of interest, they may be relevant to incorporate into a genetic evaluation system. In this presentation I will provide an overview on models and methods for incorporating such high-dimensional omics into genetic evaluation. The primary modelling framework will consist of two parts, where the first part is a model for how the phenotype of interest depends on omics phenotypes and genetic effects that are not mediated by the omics phenotypes, and the second part is a model for how omics phenotypes depend on genetic effects. Definition of true breeding value, prediction of breeding values, and to how evaluate predictive performance of predicted breeding values will be discussed. An analysis of metabolomic data and mating quality traits in barley will be presented.

Biologically informed genomic predictions with the NextGP.jl statistical analysis package*E. Karaman, V. Milkevych and L. Janss**Aarhus University, Center for Quantitative Genetics and Genomics, C. F Møllers allé 3, 8000 Aarhus C, Denmark; emre@qgg.au.dk*

Genomic prediction and genome-wide association studies have now become the backbone of quantitative genetics. Bayesian multiple-regression methods are predominant in genomic research with complete genomic data, i.e. when all phenotyped individuals are also genotyped. As many other genomic data analysis software, the NextGP.jl Julia package implements a collection of widely used 'Bayesian alphabet' methods, such as BayesB and BayesR. One of its key contributions to the field is that it also implements sophisticated Bayesian multiple-regression methods to incorporate prior biological information in genomic predictions. Such prior information can be in the form of functional annotations, which can be either categorical or continuous covariates. Most functional information is coded as 0/1 to indicate membership of a marker in one or more annotation categories. To incorporate such information, it implements recently developed methods, i.e. BayesRC+ and BayesRC π . Marker-association results such as inclusion probabilities, P -values, or t -statistics can be used when partially overlapping and nested functional categories exist. NextGP.jl implements a log-linear functional genomic prediction model, BayesLV, to handle such continuous covariates. Although the package was primarily developed for multiple-regression methods, traditional mixed linear models based on relationship matrices (genomic or non-genomic) can also be fitted. This work describes the capabilities of NextGP.jl in genomic prediction of complex traits, with a focus on biologically informed genomic predictions. It uses Bayesian approach in parameter estimations, in most cases, a Gibbs sampling procedure is run. The NextGP.jl package is written purely in an open source language, Julia, and the source code is available at <https://github.com/datasciencetoolkit/NextGP.jl>.

Fine mapping QTL associated with fertility in dairy cattle using gene expression

I. Van Den Berg¹, A.J. Chamberlain^{1,2}, I.M. MacLeod¹, T.V. Nguyen¹, M.E. Goddard^{1,3}, R. Xiang^{1,3}, B. Mason¹, S. Meier⁴, C.V.C. Phyn⁴, C.R. Burke⁴ and J.E. Pryce^{1,2}

¹Agriculture Victoria, 5 Ring Road, 3082 Bundoora, Australia, ²School of Applied Systems Biology, La Trobe University, 3082 Bundoora, Australia, ³Faculty of Veterinary and Agricultural Science, University of Melbourne, 3010 Parkville, Australia, ⁴DairyNZ Limited, 605 Ruakura Rd, 3240 Hamilton, New Zealand; irene.vandenberg@agriculture.vic.gov.au

While the inclusion of fertility in dairy cattle breeding objectives has helped to improve female reproductive performance, further improvements are desirable. Detecting genomic regions associated with fertility may help to increase our understanding of the biology underpinning fertility traits, and may lead to the identification of markers to increase the accuracy of genomic prediction of fertility. However, the relatively low heritability and highly polygenic nature of conventional female fertility traits in dairy cattle reduces the power to detect such regions. Recently, gene expression data has been used to facilitate fine mapping of quantitative trait loci (QTL) associated with various quantitative traits. An alternative approach is to select cows for high and low genetic merit for fertility and subsequently investigate phenotypic and genomic differences between these divergent groups, as has been done in a selection experiment in New Zealand. Our aim was to combine gene expression data, fertility phenotypes and allele frequencies in high and low fertility cows to fine map QTL associated with fertility in New Zealand and Australia. We performed a genome wide association study on calving interval using an Australian dataset containing imputed whole genome sequences from 60,395 dairy cattle. Using a New Zealand dataset that had 197 high and 168 low fertility cows, we detected gene expression QTL (eQTL) and QTL for fertility phenotypes. Variants that were significantly associated with calving interval were highly enriched for eQTL. Many of the overlapping QTL were in regions with a high number of copy number variants. We detected 671 genes that were significantly differentially expressed between high and low fertility cows. In conclusion, our results demonstrate how multiple data sources, including expression data, can be used to detect candidate genes for fertility.

How heritable are metabolomic features? An omic based approach in pigs

S. Bovo¹, G. Schiavo¹, F. Fanelli², A. Ribani¹, F. Bertolini¹, V. Taurisano¹, M. Gallo³, G. Galimberti⁴, S. Dall'olio¹, P.L. Martelli⁵, R. Casadio⁵, U. Pagotto² and L. Fontanesi¹

¹University of Bologna, Department of Agricultural and Food Sciences, Viale Giuseppe Fanin 46, 40127 Bologna, Italy, ²University of Bologna, Department of Surgical and Medical Sciences, Via Massarenti 9, 40138 Bologna, Italy, ³Associazione Nazionale Allevatori Suini, Via Nizza 53, 00198 Roma, Italy, ⁴University of Bologna, Department of Statistical Sciences 'Paolo Fortunati', Via Belle Arti 41, 40126 Bologna, Italy, ⁵University of Bologna, Department of Pharmacy and Biotechnology, Via San Giacomo 9/2, 40126 Bologna, Italy; giuseppina.schiavo2@unibo.it

Dissecting the complexity of production traits in their biological basic components may contribute to define novel phenotypes that can be useful to design new selection strategies in livestock. Metabolites are simple phenotypes that are the products of many different biological processes that underline more complex phenotypes. Metabolites cover a broad range of transient and stable levels over different environmental conditions and physiological stages. Therefore, before metabolites can be used as phenotypes in animal breeding, it is compulsory to estimate their heritability. In this study, we evaluated the heritability of about 200 plasma metabolites analysed in ~900 Italian Large White and ~400 Italian Duroc pigs using a targeted metabolomic platform. All pigs were also genotyped with a high-density single nucleotide polymorphism panel. Pedigree-based and genomic heritabilities were estimated in both pig breeds. The two estimates were highly correlated across different metabolite families. Correlation between breeds was however lower. Heritability was also evaluated in relation to the number of carbons and the degree of unsaturation of different metabolite classes, showing some relation derived by the biochemical features of different biomolecules. According to the obtained results, many metabolites can be considered as proxy phenotypes to substitute more complex phenotypic parameters in estimating breeding values in pigs, opening new avenues to improve complex traits.

Combined transcriptomics and metabolomics in the whole blood to depict feed efficiency in pigsC. Juigné^{1,2}, E. Becker¹ and F. Gondret²¹Univ Rennes, Inria, CNRS, IRISA – UMR 6074, Campus de Beaulieu, 35000 Rennes, France, ²PEGASE, INRAE, Institut Agro, 16, le clos, 35590 Saint Gilles, France; camille.juigne@irisa.fr

Feed efficiency is a research priority to support a sustainable meat production, but it is also recognized as a complex trait that integrates multiple biological pathways orchestrated in and by various tissues. This study aims to determine the relationships between biological entities underlying the inter-individual variation of feed efficiency in growing pigs. The feed conversion ratio (FCR) was calculated from a total of 47 Large White pigs from a divergent selection for residual feed intake and fed high starch or high-fat high fibre diets during 58 days. We considered transcriptomics (60 k porcine microarray) and metabolomics (1H-NMR analysis and target gas chromatography) datasets obtained in the whole blood of pigs at the end of the trial. We studied whether connecting these two levels of biological organization will help for a better understanding of the key biological processes driving the phenotypic difference in feed efficiency. We identified 33 weighted gene co-expression networks (WGCNA) in the whole blood (13 to 2,491 unique genes). The eigengenes of six modules were correlated to FCR ($P < 0.05$). Most of these modules were enriched in genes participating in immune and defence-related processes. Profiles in circulating metabolites and fatty acids were summarized by weighed linear combinations from principal component analyses, and correlated to the eigengenes of the co-expressed genes modules. A significant association was found between a module of co-expressed genes participating to T cell receptor signalling and cell development process and related to FCR, and the circulating concentrations of omega-3 fatty acids. Finally, we provided a new method to integrate those experimental data and the public knowledge from metabolic pathway networks databases, to show where and how these molecules at different levels of biological organization participate and interact with each other. Databases of biological pathways in BioPAX format, represented by graphs, were queried to identify participants of interest in interactions. Altogether, these different approaches will help to depict biological systems and understand complex traits such as feed efficiency.

Session 41

Imputation of sequence variants in more than 250,000 German HolsteinsA.M. Krizanac¹, C. Falker-Gieske¹, C. Reimer², J. Heise³, Z. Liu³, J. Pryce^{4,5}, J. Bennewitz⁶, G. Thaller⁷ and J. Tetens¹¹University of Göttingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany, ²Friedrich-Loeffler-Institut, Institute of Farm Animal Genetics, Höltystraße 10, 31535 Neustadt, Germany, ³Vereinigte Informationssysteme Tierhaltung w.V. (VIT), Heinrich-Schröder-Weg 1, Verden 27283, Germany, ⁴School of Applied Systems Biology, La Trobe University, 5 Ring Road, Bundoora, Victoria 3083, Australia, ⁵Agriculture Victoria Research, AgriBio, Centre for AgriBioscience, 5 Ring Road, Bundoora, Victoria 3083, Australia, ⁶University of Hohenheim, Institute of Animal Science, Garbenstraße 17, 70599 Stuttgart, Germany, ⁷Christian-Albrechts-University, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany; ana-marija.krizanac@uni-goettingen.de

Imputation allows us to obtain sequence-dense genomic marker information in a cheap and efficient way. The usage of whole-genome sequence (WGS) data helps to improve the power of genome-wide association studies (GWAS) and consequently facilitates the detection of causal variants. A large number of individuals is usually needed to obtain reliable GWAS results. The combination of WGS data and large samples enables the identification of highly significant lead variants that may point to pleiotropic loci in a large, multi-trait GWAS and are probably the underlying quantitative trait nucleotides. In this study, we aimed to identify significant trait-specific and trait-shared variants between 57 milk, health, and conformation traits in German Holstein. For that purpose, a large dataset of 252,285 SNP-chip genotyped cows was imputed to the WGS level using a two-step imputation approach. After quality control and applying different GWAS approaches to infer the best method for correction of genomic inflation, both single-trait and multi-trait GWAS were carried out using the deregressed proofs as phenotypes. Single-trait and multi-trait GWAS led to the discovery of numerous known but also novel quantitative trait loci. Our results will aid in the development of novel breeding strategies for the improvement of animal welfare.

Longitudinal study on the rabbit's gut microbiota variation through age*I. Biada¹, M.A. Santacreu¹, A. Blasco¹, R.N. Pena² and N. Ibáñez-Escriche¹*¹*Universitat Politècnica de València, Instituto de Ciencia y Tecnología Animal, Camí de Vera, s/n, 46022 València, Spain,*²*Escuela Técnica Superior de Ingeniería Agraria, Av Rovira Roure, 191, 25198 Lleida, Spain; ibiada@posgrado.upv.es*

Unlike the animals' genome, which is static, the microbiome's profile is inherently dynamic, and the host's age is one of the main factors influencing it. Furthermore, it is well known that the microbiome can influence the host's health and possibly longevity, by modulating different physiological functions, like the host's immune system. The aim of this study is to conduct a longitudinal study to investigate the evolution of gut microbiota of two rabbit lines with different longevity (LP, a line founded with longevity criteria, and A, a standard commercial line). To do so, the gut microbiome's profile was analysed using the 16S rRNA gene. A total of 368 soft faeces samples collected from 195 does (78 of line A and 117 of line LP) were sequenced using Illumina MiSeq. After quality control, the sequences were analysed with DADA2 in R. Taxonomic annotation, alpha, and beta diversity were computed within QIIME2. Alpha diversity indices (Shannon and Pielou evenness) were used to compute the ranking Spearman correlation with age, and also as response variables in a repeatability linear model with the parity order (OP) grouped into four categories (OP1, OP 2, OP 3-8, OP>9) and the rabbit line with two levels (LP and A) as fixed effects, age as a covariate, and the animal effect as random. Principal Coordinate Analysis (PCoA) based on beta diversity distance matrices (Bray-Curtis, Jaccard, and UniFrac) were computed. The results evidenced changes in microbial diversity while age increases. Shannon and Pielou's evenness alpha showed a negative Spearman correlation (-0.7 and -0.4, respectively) with age. Moreover, the group OP>9 showed smaller diversity than the rest of the OP groups, with a probability of at least 97%. Finally, PCoA graphs showed clear gradual separations between samples with increasing age. Preliminary alpha and beta diversity results showed clear changes in the rabbits' microbiota with increasing age. Further studies will carry out to investigate how microbial abundance changes over time between the two lines A and LP and its possible implication in longevity.

Session 41

Theatre 8

Studying cattle structural variation and pangenome using whole genome sequencing*G.E. Liu**USDA ARS, AGIL, Building 306 Room 111, Beltsville, MD, 20705, USA; george.liu@usda.gov*

A cattle pangenome representation was created based on the genome sequences of 898 cattle representing 57 breeds. The pangenome identified 83 Mb of sequence not found in the cattle reference genome, representing 3.1% novel sequence compared with the 2.71-Gb reference. A catalogue of structural variants developed from this cattle population identified 3.3 million deletions, 0.12 million inversions, and 0.18 million duplications. Estimates of breed ancestry and hybridization between cattle breeds using insertion/deletions as markers were similar to those produced by single nucleotide polymorphism-based analysis. Hundreds of deletions were observed to have stratification based on subspecies and breed. For example, an insertion of a Bov-tA1 repeat element was identified in the first intron of the APPL2 gene and correlated with cattle breed geographic distribution. This insertion falls within a segment overlapping predicted enhancer and promoter regions of the gene, and could affect important traits such as immune response, olfactory functions, cell proliferation, and glucose metabolism in muscle. The results indicate that pangenomes are a valuable resource for studying diversity and evolutionary history, and help to delineate how domestication, trait-based breeding, and adaptive introgression have shaped the cattle genome.

Host genetics affect the composition of the lower gut microbiota in dairy cows

L. Brulin^{1,2}, S. Ducrocq^{2,3}, J. Estelle¹, G. Even^{2,3}, S. Martel^{2,3}, S. Merlin^{2,3}, C. Audebert^{2,3}, P. Croiseau¹ and M.P. Sanchez¹

²GD Biotech – Gènes Diffusion, 1 Rue du Professeur Calmette, 59019 Lille, France, ³PEGASE-Biosciences, Institut Pasteur de Lille, 1 Rue du Professeur Calmette, 59019 Lille, France; louse.brulin@inrae.fr

Symbiotic microorganisms are organized into specific ecosystems along the gastrointestinal tract of animals. In ruminants, studies showed a complex crosstalk between the ruminal microbiota and the host: beyond its role in the digestive process, the microbiota modulates the host phenotype but is also under the influence of the host genome. Concerning the intestinal microbiota, its role on numerous traits, in particular health maintenance, is increasingly described and could make it a key component of a sustainable breeding. However, its genetic control remains elusive. In this context, the present work will aim to perform a comprehensive genetic study of the lower gut microbiota. Faecal samples were collected between 2020 and 2022 from a population of 1930 Holstein cows, reared on 140 French commercial farms. Microbiota 16S rRNA analyses were performed on the samples and the data were processed to obtain amplicon sequence variant (ASV) tables. Genetic parameters were estimated using animal models for (1) the samples' diversity expressed as the Shannon index, and (2) the abundance of the most frequently observed ASVs and genera (with a prevalence threshold of 60%). The 152 ASVs and 87 genera analysed showed low to moderate heritability estimates. Indeed, 32% of ASVs had a heritability between 0.05 and 0.23 (s.e. from 0.04 to 0.10), with an ASV of the *Negativibacillus* genus being the most heritable taxon. Almost half of the genera had heritabilities ranging from 0.05 to 0.21 while the Shannon diversity index appeared to be poorly heritable ($h^2=0.04$, s.e.=0.05). Overall, our results demonstrate that the host genetics shapes the composition of the cow faecal microbiota. These first encouraging results will be complemented to assess the genetic correlations between the microbiota composition and production traits, and to identify genomic regions involved in the genetic determinism of the bovine gut microbiota through GWAS analyses.

Session 41

Theatre 10

A model including host genotype, gut microbiome, and fat deposition measures in swine

F. Tiezzi¹ and C. Maltecca²

¹University of Florence, DAGRI, Piazzale delle Cascine 18, 50144 Firenze, Italy, ²North Carolina State University, Animal Science, 120 W Broughton dr, 27695 Raleigh, NC, USA; francesco.tiezzi2@unifi.it

We propose a systematic approach to elicit the host genome control over microbial composition and tissue deposition while accounting for these two components' effects on each other. We developed a mediation test in a Structural Equation Model (SEM) and applied it to measured and latent dependent variables describing fat deposition in swine (*Sus scrofa*). Host genotype (G) contribution was determined using a 60k SNP beadchip. Gut microbiome composition was assessed using 16S sequencing of faecal swabs at 18 and 26 weeks of age (M1 or M2, respectively). Back fat accumulation was measured with ultrasound scan at 18 weeks of age (P1). In addition, a latent variable was constructed (P2), compounding ultrasound and mechanical backfat measures at slaughter, together with the weight of the belly cut. We focused our analysis on this measure that we considered the relevant target endogenous variable. We implemented a SEM and a standard model used in Genome-Wide Association Studies (sGWAS). Both included common effects to account for environmental variation and family stratification. The SEM aimed at estimating the sign and magnitude of the following mediated paths: Path1: G->P1->P2; Path2: G->M2->P2; Path3: G->M1->P2; Path4: G->P1->M2->P2; Path5: G->M1->M2->P2; together with the direct path Path0: G->P2. The sGWAS model, without using microbial information, estimated the total effect of G on P2, such as Path00: G->P2. The two models were run for each 42,546 SNP included in the analysis. The significance of the estimates was assessed using bootstrapping, which allowed to obtain an empirical distribution of the estimates by sampling with replacement. Compared to the sGWAS model, the SEM identified additional SNPs with significant mediated effects. Notably, these did not overlap with those identified as having a significant effect with the standard GWAS model. While the loci showing stronger total effects were primarily located on SSC1 and SSC5, the loci with the strongest indirect effects were found on SSC9, SSC6, SSC7, and SSC13. Results suggest that gut microbial information can be successfully included in (more complex) models.

protiPig: microbial analyses of traits related to nitrogen utilization efficiency in pigs

M. Schmid, N. Sarpong, M. Rodehutschord, J. Seifert, A. Camarinha-Silva and J. Bennewitz

Institute of Animal Science, University of Hohenheim, Garbenstr. 17, 70599 Stuttgart, Germany; markus_schmid@uni-hohenheim.de

In pig production, improving protein efficiency is required to reduce emissions and water pollutions caused by the excretion of nitrogenous compounds as well as to ease the competition between protein sources fed to the animals but also edible for humans. Besides an adequate diet, breeding for an improved protein utilization efficiency and its equivalent nitrogen utilization efficiency (NUE) is a promising approach. As such traits are hard to measure, proxy traits are required for routine animal evaluation. Blood urea nitrogen (BUN) has shown to be a heritable indicator for NUE. Studies revealed that the animal genome as well as the gut microbiome, which is also mediated by genetics, impact efficiency traits in pigs. Results directly using the trait NUE are rare and most of the experiments focus one single sampling timepoint. Within the frame of the protiPig project, around 450 Piétrain × Large White crosses were phenotyped for traits related to NUE and faecal microbiota composition was determined in the grower and finisher phase, respectively. Genomic analyses in this dataset showed that the traits were moderately heritable but the contribution of the genetics to the phenotypic variance differed between grower and finisher phase particularly for NUE. We investigated the role of the faecal microbiome with regard to nitrogen intake and retention, NUE and BUN. The microbial variance, microbiabilities and the microbial correlation between traits were quantified and microbiome-wide association studies (MWAS) were conducted. The influence of the microbial composition on the traits varied strongly within each phase and was substantially larger in the finisher phase. The microbiability was significant for all traits except for NUE in the grower phase. For NUE in the grower phase, the microbiability could not be estimated (model not converged) and was $m^2=0.162$ in the finisher phase. Estimated microbiabilities were $m^2=0.103$ ($m^2=0.157$) for BUN in the grower (finisher) phase. MWAS revealed polymicrobial trait architectures with the majority of microbial effects being small. We demonstrated that the microbiome mediates NUE and related traits, which might be utilized in a breeding effort.

Rumen microbiome promote host metabolism and microbial bile acids bio-transformation in sheep

B.Y. Zhang, Y. Yu, X.Z. Jiang, Y.M. Cui, H.L. Luo and B. Wang

China Agricultural University, State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, 2 yuanmingyuan west road, Haidian District, 100193, Beijing, China, P.R.; wangb@cau.edu.cn

Bile acids are not only essential for gut fat metabolism but act as signalling molecules and mediums through the interaction between gut microbiota and host. This study aimed to determine the potential efficient roles of rumen microorganisms in bile acid biotransformation, the exogenous porcine bile acids was added to the rumen in both *in vivo* and *in vitro* sheep model. In the *in vivo* experiment, ten male Tan-lambs (approximately 6-month-old) with similar body weights were selected and randomly divided into two groups: control (CON) and supplementation of 0.04% bile acids in the diet (dry matter basis, HCA). In the *in vitro* experiment, control group (no addition, C) and bile acids group (16 mg per 75 ml incubation, CB) were conducted. Rumen fluid was collected from the *in vivo* experiment after 70 d consecutive feeding and from the *in vitro* experiment after 24 h incubation. Exogenous bile acids significantly affected the ruminal microbial fermentation activity and microbiome. We annotated 907 bile acid metabolism-related genesets in 20 rumen fluid samples and found 77 secondary bile acid metabolism pathways among these genesets. Potential primary and secondary bile acid metabolism genes and some specific microbial bile acid metabolic genes were discovered through metagenome-wide association studies *in vivo* and *in vitro* based on KEGG and eggNOG databases. Mediation analysis established 12,010 mediation linkages: 3,540 for the microbial taxonomy, 1,452 for the genes annotated by KEGG and 7,018 for the genes annotated by eggNOG impact on the serum metabolites through rumen bile acids. Finally, significant correlations were established between the serum hyocholic acid, hyodeoxycholic acid, glycohyocholic acid and host phenotypes including body fat (assessed as GR value in sheep), heart ratio, kidney ratio, tail fat ratio, kidney fat ratio. In conclusion, our study provides insights into the potential new roles of rumen microorganisms in bile acid biotransformation and their impact on host metabolism.

Blending multivariate models to predict feed efficiency and explore multiple omics in meat sheepQ. Le Graverand¹, F. Tortoreau¹, C. Marie-Etancelin¹, A. Meynadier¹, J.L. Weisbecker¹ and K.A. Lê Cao²¹GenPhySE, Université de Toulouse, INRAE, ENVT, Castanet Tolosan, 31326, France, ²School of Mathematics and Statistics, University of Melbourne, VIC 3010, Australia; quentin.le-graverand@inrae.fr

Selecting sheep for feed efficiency would improve the sustainability of sheep farming by decreasing feeding needs. However, due to the costs of recording feed intake, feed efficiency is rarely selected in sheep. Identifying feed efficiency biomarkers could help resolve this issue. A total of 258 Romane male lambs were phenotyped in the growing period for Residual Feed Intake (RFI) – in three different batches. Rumen fluid and blood were sampled as potential sources of biomarkers for feed efficiency. Multivariate analyses were performed with six distinct ‘blocks’ of predictors: fixed effects and covariates (FC), genotypes (SNPs), plasma NMR spectra (NMR), ruminal volatile fatty acids (VFAs), long-chain fatty acids (LFAs), bacteria and archaea abundances (16S amplicon sequencing). We modified a Partial Least Square regression approach (PLS) to account for the three batches while selecting biomarkers of feed efficiency. Cross-validation was repeated to fit one model per block on our training data (60% of the samples). Then, predictions for the validation set (30% of the samples) were obtained by using a weighted aggregation – based on the performance on each validation set. Testing data (10%) were independently used to assess the overall prediction accuracy based on Pearson correlations. When RFI was predicted from separate blocks, the average accuracy was low to moderate: 0.08 (standard deviation: 0.17) from VFAs to 0.44 (0.13) from SNPs. When RFI was predicted with our approach combining different omics, accuracy increased and reached an average of 0.55 (0.11). Based on weights attributed to blocks of predictors, we were able to rank the most predictive blocks to explain RFI: SNPs, FC, NMR, 16S, LFA and VFA. Furthermore, within each block we identified variables that were highly associated with feed efficiency RFI, including β -hydroxyisovaleric acid and a SNP located on the chromosome 3. To conclude, blending models is useful to integrate heterogeneous omics data: from predicting efficiency, to identifying associations between multi-omics predictors.

The effect of dietary *Laminaria digitata* on the muscle proteome and metabolome of weaned pigletsD.M. Ribeiro¹, D.F.P. Carvalho¹, C.C. Leclercq², S. Charton², K. Sergeant², E. Cocco², J. Renaut², J.A.M. Prates^{3,4}, J.P.B. Freire¹ and A.M. Laminaria digitata is a brown seaweed with bioactive micronutrients, such as n-3 PUFA and minerals. Its recalcitrant cell wall polysaccharides can cause antinutritional effects for monogastrics. Carbohydrase supplementation is a putative solution. The objective of this study is to evaluate the impact of dietary *L. digitata* and alginate lyase supplementation on the muscle proteome and metabolome of weaned piglets. Weaned (♂, Large White × Duroc) piglets were randomly assigned to three diets (n=10): control (standard diet), LA (10% *L. digitata* replacing control) and LAL (LA + 0.01% alginate lyase). After two weeks of trial, they were slaughtered, and samples of *longissimus lumborum* taken. The muscle proteome and metabolome were analysed using label free LC-MS and GC-MS platforms, respectively. The diets had no effect on growth performance. A total of 126 proteins were differentially abundant ($P < 0.05$, $0.67 < FC < 1.5$) in the muscle proteome of these piglets. Proteins involved in energy metabolism (e.g. PHKG1, ATP5F1A, GPI) were of lower abundance in LA piglets, possibly reflecting a lower dietary energy availability. Accordingly, the abundance of proteins involved in gluconeogenesis (TRAPPC10, CYB5A, IVD) increased in LA piglets. LA and LAL piglets downregulated oxidative metabolism (NEBL), possibly in relation to reduced lipid oxidation compared to control. These diets caused incipient differences on the metabolome. Our study demonstrates that digestion of *L. digitata* influences the metabolism of piglet muscle.

Search for new mutations in cattle by systematic whole genome resequencing

M. Boussaha¹, C. Eché², C. Escoufflaire³, C. Grohs¹, C. Iampietro², A. Capitan¹, M. Denis^{2,4}, S. Fritz³, C. Donnadieu² and D. Boichard¹

¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, Jouy-en-Josas, 78350, France, ²INRAE, US1426, GeT-PlaGe, Genotoul, France Genomique, Université Fédérale de Toulouse, Castanet-Tolosan, 31326, France, ³Eliance, Paris, 75012, France, ⁴GenPhySE, Université de Toulouse, INRAE, INPT, ENVT, Castanet-Tolosan, 31326, France; mekki.boussaha@inrae.fr

Systematic whole genome sequencing provides a rapid and powerful method to identify recent novel mutations on a cattle population scale. It helps farmers to detect early carriers of new genetic anomalies and more generally to boost genomic selection. Regarding genetic defects, the aim is to identify new candidate mutations that may have deleterious potential before they are widely spread in the population to inform the breeders. A major drawback is the high rate of false positives, ie of variants with a strong annotation but without any effect. Therefore the annotation is the most critical step. We focussed only on still unknown variants (ie de novo or likely very recent mutations) in highly conserved sequences in other species and/or with effects predicted to be similar to those described in OMIM or MGI databases. We applied this strategy on whole genome sequences on 571 artificial insemination bulls from 14 dairy and beef breeds. In large breeds, recently marketed bulls were selected. In smaller breeds, influential ancestors not yet sequenced were chosen. In total, we identified 1,548 novel genomic variants with a potential link to certain quantitative traits of interest or possible genetic abnormalities. These variants were investigated by searching for carrier or homozygous descendants, and by adding these variants on the custom part of the EuroGenomics SNP chip for an easy screening of the population. This information is also returned back to bull's owners, with a specific alert only for the few most critical variants. Although the annotation still lacks accuracy, we believe that whole genome sequencing of all artificial insemination bulls is an early, rapid and always cheaper method for identifying genetic defects before they disseminate in the population. The SeqOccIn project was funded by the Occitanie region, FEDER, and Apis-Gene.

Poster 16

Estimation of non-additive genetic effects for semen production traits in beef and dairy bulls

R. Nagai¹, M. Kinukawa², T. Watanabe², A. Ogino², K. Kurogi³, K. Adachi³, M. Satoh¹ and Y. Uemoto¹

¹Graduate School of Agricultural Science, Tohoku University, Laboratory of Animal Breeding and Genetics, Sendai, Miyagi, 980-8572, Japan, ²Livestock Improvement Association of Japan, Inc., Maebashi Institute of Animal Science, Maebashi, Gunma, 371-0121, Japan, ³Livestock Improvement Association of Japan, Inc., Cattle Breeding Department, Koto-ku, Tokyo, 135-0041, Japan; rintaro.nagai.q7@dc.tohoku.ac.jp

Non-additive genetic effects are considered as a key factor to understand reproductive traits, such as semen production traits, in cattle. In order to evaluate the relevance of non-additive genetic effects for semen production traits in beef and dairy bulls using the Illumina BovineSNP50 BeadChip, we performed genome-wide association studies (GWAS) to detect non-additive quantitative trait loci (QTLs). We also evaluated non-additive polygenic effects by estimating non-additive genetic (i.e. dominance and epistatic) variance components. In total, 65,463 records for 615 genotyped Japanese Blacks (JB) as beef bulls and 50,734 records for 873 genotyped Holstein (HOL) as dairy bulls were used to detect QTLs and to estimate non-additive genetic variance components for five semen production traits: semen volume (VOL), sperm number (NUM), sperm motility (MOT), MOT after freeze-thawing (aMOT) and sperm concentration (CON). Additive QTL was detected on *Bos taurus* autosome (BTA) 24 for MOT in JB and on BTA17 for MOT in HOL. Non-additive QTLs were detected on BTA2 for MOT and on BTA26 for CON in JB and BTA6 for MOT, BTA11 for aMOT and BTA17 for NUM, MOT, aMOT and CON in HOL. In HOL, a non-additive QTL on BTA17 has pleiotropic effects on these traits. Assuming non-additive genetic variance components, the broad-sense heritability (0.17 to 0.43) was more than twice as high as the narrow-sense heritability (0.04 to 0.11) for all traits and breeds. In addition, the difference between the broad-sense heritability and repeatability were very small for VOL, NUM and CON, because a large proportion of permanent environmental variance was explained by epistatic variance. In conclusion, our present study suggest that non-additive QTLs and polygenic effects play important roles in semen production traits in beef and dairy bulls.

Evaluating functional properties of feeding black soldier fly larvae in laying hens by FeedOmics

A. Rezaei Far, E. Zaccaria, I. Fodor, P. Van Wikselaar, S. Naser El Deen, S. Kar and T. Veldkamp

Wageningen Livestock Research / Wageningen University & Research, Animal Nutrition, De Elst 1, 6708 WD, Wageningen, the Netherlands; edoardo.zaccaria@wur.nl

Insect proteins, such as black soldier fly larvae meal (BSFM), are a more sustainable alternative protein source than soybean meal (SBM). We engage multi-omics techniques to characterise the potential functional properties of protein-containing feed ingredients that we often refer to as the FeedOmics approach. In this study, we evaluated the effects of replacing SBM with two inclusion levels of BSFM, i.e. 5 and 10%, on production performance and egg quality in laying hens in an aviary system. Measurements of production performance in laying hens have shown that replacing SBM with 10% BSFM significantly ($P < 0.05$) improves feed efficiency while increasing eggshell thickness. To further explain the response of laying hens to a partial and complete replacement of SBM with BSFM, we employed a comprehensive multi-omics approach on a wide range of data obtained from various biological samples. We have collected ileum and jejunum digesta to perform bacterial compositional and diversity analysis, jejunum, ileum, liver and uterus for genome-wide transcriptomics, tissues, and blood plasma for global metabolites profiling. The data are being generated from the multi-omics approaches, and results will be presented showing the functional effects of feeding BSFM in laying hens. Such multiomics dataset is the first of its kind to our knowledge that can provide a deep insight into the biological systems of laying hens, revealing new insights into the effects of different inclusion levels of BSFM on laying hen health, production performance and egg quality.

Characterization of two divergent lines through functional inference of ruminal microbiotaJ. Guibert¹, A. Meynadier¹, V. Darbot¹, C. Allain² and C. Marie-Etancelin¹*¹INRAE- UMR GENPHYSE, GA, chemin de Borde Rouge, 31326 Castanet Tolosan Cedex, France, ²INRAE – UE La Fage, Domaine Expérimentale de La Fage, 12250 Roquefort sur soulzon, France; christel.marie-etancelin@inrae.fr*

The ruminal microbiota plays an important role in the nutrition of its host, having a direct impact on milk production and animal health. However, as the links between bacteria abundances and host's traits are often difficult to interpret, we proposed to infer the abundances of bacteria functions to characterize divergent lines on somatic cell score (SCS) or on milk persistency (PERS). From 2015 to 2019, we sampled the rumen juice of 700 adults dairy Lacaune ewes belonging to either SCS line (94 SCS+/204 SCS-) or PERS line (200 PERS+/202 PERS-). DNA was extracted from ruminal juice and sequenced for the 16s rRNA gene. We analysed microbiota sequences with FROGS pipeline to obtain relative abundances of bacteria and then to infer functions. The inference consisted of using PICRUSt2 bioinformatic approach to predict the functional composition of a metagenome using marker gene sequences. For the 700 ewes, abundances of 2,059 ASVs were computed. After filtering to ensure a good quality of inference (Nearest Sequenced Taxon Index < 0.4 and identity/coverage percentage > 90%), abundances of 1,146 ASVs were kept enabling us to quantify abundances of 330 bacterial functions. A mixed model was computed on the function's abundances (after GBM imputation and CLR transformation to consider their compositional nature) within SCS and PERS lines respectively, with fixed effects such as the line, run of sequencing, number of sequences, date of sampling, lactation stage and, for SCS line only, litter size. This analysis revealed functions significantly different for either the SCS (n=14) or PERS (n=60) lines (P -value < 0.05), responsible for branched amino acids (SCS) or glycan/lipopolysaccharide (PERS) biosynthesis. Finally, a sparse PLS discriminant analysis (with MixOmics R package) was performed on residual of functional abundances obtained from the previous model (without line effect), considering the divergent line as discriminant factor. While balanced error rates (BER) were poor for both SCS (0.52±0.08) and PERS (0.49±0.04) lines, interesting discriminant functions, needed for vitamin (SCS) or glycan (PERS) biosynthesis, were found.

Blood transcriptomic comparison under different THI in HolsteinJ.-E. Park¹, H. Kim², J.-H. Cho³, H.-G. Lee³, W. Park⁴ and D. Shin²¹Jeju National University, 102, Jejudaehak-ro, Jeju-si, Jeju-do, 63243, Korea, South, ²Jeonbuk National University, 567, Baekje-daero, Deokjin-gu, Jeonju-si, Jeollabuk-do, 54896, Korea, South, ³Konkuk University, 120, Neungdong-ro, Gwangjin-gu, Seoul, 05029, Korea, South, ⁴National Institute of Animal Science, 1500, Kongjwipatjiwi-ro, Iseo-myeon, Wanju-gun, Jeollabuk-do, 55365, Korea, South; jepark@jejunu.ac.kr

Recently, the average temperature of the atmosphere has been rising due to rapid climate change, which causes environmental stress such as high temperatures in livestock. Environmental changes due to temperature and humidity in cows are accompanied by decreased milk production, decreased immunity, and changes in body metabolism, which lead to economic losses for farmers due to decreased productivity and death. This study attempted to understand the biological mechanisms of the gene level by comparing the gene expression patterns of cows according to the temperature and humidity index (THI). The specification experiment was carried out for total 14 days which are 3 days of initial adaptation, 4 days of normal level (THI=70-71, temperature 22 °C, humidity 50-60%), 7 days of critical level (THI=72-73, 25-26 °C, 35-50). Differential expression and functional analysis were performed on RNA-seq data with a total of six blood samples collected on the 7th and 14th days of the experiment. 795 differentially expressed (FDR<0.05, FC>1.0) genes (DEGs) were discovered between the two experimental groups. Among them, 441 were expressed upward and 354 were expressed downward. These DEGs were found to have 40 biological processes, 17 Molecular Functions, and 13 Cellular Component functions of Gene Ontology (GO) term. A total 15 of KEGG pathway were identified, including Rap1 and PPAR signalling pathways activated in response to thermal stress. The results suggested that these DEGs and functions are related with climate stress and give the clue for their reaction mechanisms for climate change in dairy cows.

Metabolome profile of the pectoralis major muscle of red-winged tinamou: a pilot studyJ.M. Malheiros¹, C.S.M.M. Vilar¹, P.F. Silva², L.A. Colnago³, J.A.I.I.V. Silva⁴ and M.E.Z. Mercadante¹¹Animal Science Institute, Sertãozinho, SP, Brazil, ²University of São Paulo, São Carlos, SP, Brazil, ³Embrapa Instrumentation, São Carlos, SP, Brazil, ⁴São Paulo State University, Botucatu, SP, Brazil; jehmalheiros@gmail.com

This study was conducted to reveal the differences in the metabolome profile of *pectoralis major* muscle of red-winged tinamou (*Rhynchotus rufescens*) selected for growth trait. Phenotypic selection index composed of growth traits (live weight and chest and thigh circumference) and male reproductive traits (semen volume and sperm concentration) were used to classify two experimental groups: selection group with a higher index (TinamouS) and commercial group with a lower index (TinamouC). Couples were housed separately for reproduction. Subsequently, eggs were collected, artificially incubated and 20 males of second generation (n=10/group) slaughtered with 350 days of life. Next, *pectoralis major* muscle sample were collected for metabolomics assays by Proton Nuclear Magnetic Resonance Spectroscopy (¹H NMR). Sixty-five polar metabolites were identified and quantified; however, 29 metabolites showed significant difference ($P<0.05$) between the experimental groups. TinamouS group exhibited higher concentrations ($P<0.05$) of asnerine, arginine, aspartate, betaine, carnosine, creatine, creatine phosphate, creatinine, glutamate, leucine, proline, threonine, 3-methylhistidine, ADP, AMP, ATP, adenosine, IMP, inosine, NAD⁺, acetate, 1,3-dihydroxyacetone, glucose, pyruvate and taurine. However, the concentrations of lactose, cysteine, beta-alanine, and choline were lower ($P<0.05$) in TinamouS group. Correlations between metabolites showed 197 significant positive (≥ 0.5 ; $P<0.05$) and 79 significant negative (≥ -0.5 ; $P<0.05$). Eight significant pathways were detected ($P<0.05$; impact value>0.35): phenylalanine, tyrosine and tryptophan biosynthesis; alanine, aspartate and glutamate metabolism; D-glutamine and D-glutamate metabolism; β -alanine metabolism; glycine, serine and threonine metabolism; taurine and hypotaurine metabolism; histidine metabolism; phenylalanine metabolism. In conclusion, these findings provide convincing evidence that selection index for muscle growth in the second generation led to differences metabolome in red-winged tinamou.

Post-mortem muscle proteome of crossbred bulls and steers: carcass and meat quality

O.R.M. Neto, W.A. Baldassini, L.A.L. Chardulo, R.A. Curi, G.L. Pereira, B.M. Santiago and R.V. Ribeiro
 São Paulo State University, School of Veterinary Medicine and Animal Science, 3780 Universitária Ave, 18610160, Botucatu, São Paulo, Brazil; otavio.machado@unesp.br

Beef cattle producers routinely use castration to simplify the rearing of stock, which helps reducing unwanted breeding and to modify the quality of the carcasses. However, the biochemical and molecular mechanisms that control and regulate these traits are not fully understood. Few studies used young animals and feedlot finishing of 180 days, which support the need for more studies using such a biological model. This study investigated the muscle proteome of crossbred bulls and steers with the aim of explaining the differences in carcass and meat quality traits. Therefore, 640 post-weaning Angus-Nellore calves were fed a high-energy diet for 180 days. In the feedlot trial, comparisons of steers (n=320) and bulls (n=320) showed lower ($P<0.01$) performance (1.38 vs 1.60 ± 0.05 kg/d), slaughter weight (547.4 vs 585.1 ± 9.3 kg), which resulted in lower hot carcass weight (298.4 vs 333.7 ± 7.7 kg) and ribeye area (68.6 vs 81.0 ± 2.56 cm²). Steers had higher ($P<0.01$) carcass fatness, meat colour parameters and lower meat pH. Lower ($P<0.01$) Warner-Bratzler shear force (WBSF) were observed in steers compared to bulls (WBSF= 3.68 vs 4.97 ± 0.08 kg; and 3.19 vs 4.08 ± 0.08 kg). The proteomic approach using two-dimensional electrophoresis, mass spectrometry and bioinformatics procedures revealed several differentially expressed proteins between steers and bulls ($P<0.05$). Interconnected pathways and substantial changes were revealed in biological processes, molecular functions, and cellular components between the *post-mortem* muscle proteomes of animals. Steers had increased ($P<0.05$) abundance of proteins related to energy metabolism (CKM, ALDOA, and GAPDH), and bulls had greater abundance of proteins associated with catabolic processes (PGM1); oxidative stress (HSP60, HSPA8 and GSTP1); and muscle structure and contraction (TNNI2 and TNNT3). The better carcass and meat quality traits of steers were associated with higher abundance of key proteins of energy metabolism and lower abundance of enzymes related to catabolic processes, oxidative stress, and proteins of muscle contraction. São Paulo Research Foundation (FAPESP) – Grant number – 2019/11028-0.

ITGA6 homozygous splice-site mutation causes junctional epidermolysis bullosa in Charolais cattle

C. Grohs¹, M. Boussaha¹, A. Boulling¹, V. Wolgast², L. Bourgeois-Brunel¹, P. Michot^{1,3,4}, N. Gaiani¹, M. Vilotte¹, J. Riviere¹ and A. Capitan^{1,4}

¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, 4 rue Jean Jaurès, 78350 Jouy-en-Josas, France, ²Unité de Pathologie du Bétail, ENVA, 7 av. du Général-de-Gaulle, 94700 Maisons-Alfort, France, ³Herd Book Charolais, Agropole du Marault, 58470 Magny-Cours, France, ⁴Eliance, 149 rue de Bercy, 75012 Paris, France; cecile.grohs@inrae.fr

Junctional epidermolysis bullosa (JEB), characterized by mechanically induced blisters of the skin and mucous membranes, is one of the most painful and life threatening recessive genetic disorders described in humans and other animal species. Congenital skin fragility resembling JEB was recently reported in three Charolais calves born in two distinct herds from unaffected parents. Phenotypic and genetic analyses were carried out to describe this condition and its molecular etiology. Genealogical, clinical and histological examinations confirmed the diagnosis of recessive JEB, even if affected calves showed milder symptoms than those of another form of JEB, previously reported in the same breed, and due to a homozygous deletion of ITGB4. Homozygosity mapping followed by analysis of the whole genome sequences of 2 cases and 5,031 control individuals enabled us to prioritize a splice donor site of ITGA6 (c.2160+1G>T; Chr2 g.24112740C>A) as the most compelling candidate variant. This substitution showed a perfect genotype-phenotype correlation in the two affected pedigrees and was found to segregate only in Charolais, and at a very low frequency ($f=1.6\times10^{-4}$) after genotyping 186,154 animals from 15 breeds. Finally, RT-PCR analyses revealed increased retention of ITGA6 introns 14 and 15 in a heterozygous mutant cow as compared with a matched control. The mutant mRNA is predicted to cause a frameshift (ITGA6 p.I657Mfs1) affecting the assembly of the Integrin $\alpha6\beta4$ dimer and its correct anchoring to the cell membrane. This dimer is a key component of the hemidesmosome anchoring complex, which ensures the attachment of basal epithelial cells to the basal membrane. In conclusion, we report a rare example of partial phenocopies observed in the same breed and due to mutations affecting two members of the same protein dimer, as well as the first evidence of an ITGA6 mutation causing JEB in livestock species.

A sheep pangenome reveals the spectrum of structural variations and their effects on tail phenotypes

R. Li¹, M. Gong¹, X.M. Zhang¹, F. Wang¹, Z.Y. Liu¹, L. Zhang¹, S.Q. Gan² and Y. Jiang¹

¹Northwest A&F University, Xinong Road 22, Yangling, Shaanxi, 712100, China, P.R., ²Xinjiang Academy of Agricultural and Reclamation Sciences, Wuyi Road 221, Shihezi, Xinjiang, 832000, China, P.R.; gongmian2767@126.com

Structural variations (SVs) are a major contributor to genetic diversity and phenotypic variations, but their prevalence and functions in domestic animals are largely unexplored. Here we generated high-quality genome assemblies for fifteen individuals from genetically diverse sheep breeds using PacBio HiFi sequencing, discovering 130.3 Mb non-reference sequences, from which 588 genes were annotated. A total of 149,158 biallelic insertions/deletions, 6,531 divergent alleles and 14,707 multiallelic variations with precise breakpoints were discovered. The SV spectrum is characterized by an excess of derived insertions compared to deletions (94,422 vs 33,571), suggesting recent active LINE expansions in sheep. Nearly half of the SVs displayed low to moderate linkage disequilibrium with surrounding SNPs and most SVs cannot be tagged by SNP probes from the widely used ovine 50K SNP chip. We identified 865 population stratified SVs including 122 SVs possibly derived in the domestication process among 690 individuals from sheep breeds worldwide. A novel 168-bp insertion in the 5' UTR of HOXB13 was found at high frequency in long-tailed sheep. Further genome-wide association study (GWAS) and gene expression analyses suggest that this mutation is causative for the long-tail trait. In summary, we developed a panel of high-quality de novo assemblies and presented a catalogue of structural variations in sheep. Our data captures abundant candidate functional variations that were previously unexplored and provides a fundamental resource for understanding trait biology in sheep.

Chinese indicine cattle harbour a much higher genetic diversity compared to other domestic cattle, but their genome architecture remains uninvestigated. Using PacBio HiFi sequencing data from 10 Chinese indicine cattle across southern China, we assembled 20 reference-quality partially phased genomes, and integrated them into a multi-assembly graph containing 148.5 Mb (5.6%) of novel sequence. We identified 156,009 high-confidence non-redundant structural variants (SVs) and 206 SV hotspots spanning ~195 megabases of gene-rich sequence. We detected 34,249 archaic introgressed fragments in Chinese indicine cattle covering 1.93 Gb (73.3%) of the genome. We inferred an average of 3.8%, 3.2%, 1.4%, 0.5%, of introgressed sequence originating respectively from banteng-like, kouprey-like, gayal-like, gaur-like *Bos* species, and 0.6% of unknown origin. We therefore show that the high genetic diversity of Chinese indicine cattle is due to substantial introgression from multiple donors. Altogether, this study highlights the contribution of interspecies introgression to the genomic architecture of an important livestock population, and demonstrates how exotic genomic elements can contribute to the genetic variation available for selection.

Multi-omic analysis reveal epigenetic regulation during muscle growth and development in sheep

Q.J. Zhao, Y.H. Ma and Y. Liu

Institute of Animal Science, Chinese Academy of Agricultural Sciences, NO.2 Yuanmingyuan, Haidian district, Beijing, 100193, China, P.R.; zhaoqianjun@caas.cn

Skeletal muscle is the muscle tissue attached to the bone, accounting for about 40% of the total body weight in mammals. It has important functions such as maintaining the state of the body, generating heat and protecting organs. Skeletal muscle has been developed in the embryonic stage and is accompanied by a series of complex regulatory processes. Although there have been a lot of studies on muscle growth and development, as an important agricultural animal, the three-dimensional genomic structure and epigenetic regulation of sheep skeletal muscle has never been revealed. We generated datasets of profiling expression dynamics (RNA-Seq), chromatin accessibility (ATAC-Seq), 3D genome (Hi-C), and histone modifications (ChIP-Seq) in ovine skeletal muscle at different stages. We found that the number of accessible regions identified at each stage of muscle development varied, mainly reflecting a gradual increase in the number of peaks in the early stages of embryonic development and a gradual decrease in the number of peaks in the later stages. In addition, there were difference in compartment switch, the number and size of TAD and Loop during ovine skeletal muscle growth. The three-dimensional chromatin interaction map showed that there were abundant gene remote regulation relationships in sheep skeletal muscle. The dynamic change of TAD boundary leads to the change of gene expression, which in turn regulate muscle development. A total of 110 genes were found in the altered TAD structure, which were enriched in the pathways related to muscle development, such as Ras signalling pathway, Citrate cycle (TCA cycle), TNF signalling pathway, Glycolysis / Gluconeogenesis. Several long-range enhancers were identified, which modulate muscle development through the loops. Overall, our study provides a global genome-wide resource of chromatin dynamics that define unrecognized regulatory networks and the epigenetic regulation of ovine skeletal muscle growth and muscle. The present study also provide novel insights into the mechanisms underlying myogenesis and muscle development.

The effect of production system on the muscle proteome of dromedary camel (*Camelus dromedarius*)M. Lamraoui¹, D.M. Ribeiro², Y. Khelef³, N. Sahraoui⁴, H. Osório⁵ and A.M. De Almeida²

¹Laboratoire de Biophysique, Bio Mathématiques, Biochimie et Scientométrie, Université de Bejaia, 06000, Béjaia, Algeria, ²LEAF-Linking Landscape, Environment, Agriculture and Food Research Center, Associated Laboratory, Instituto Superior de Agronomia, Tapada da Ajuda, 1349-017, Portugal, ³Laboratory of Biology, Environment and Health, University of El Oued, 39000, El Oued, Algeria, ⁴Laboratoire de Biotechnologies Liées à la Reproduction, Veterinary Institute, Université Saad Dahlab, 09000, Blida, Algeria, ⁵Instituto de Investigação e Inovação em Saúde, University of Porto, 4200-135, Porto, Algeria; messaouda.lamraoui@univ-bejaia.dz

Proteomics has been a common tool used to study domestic animal science over the last decade, being employed in a wide range of topics, namely on meat science. Unlike conventional species, studies concerning dromedary meat proteomics are lacking. This work characterizes the longissimus lumborum muscle proteome of male Sahraoui dromedary camel as affected by the production system (extensive vs intensive) by using a label-free proteomics approach. Samples were taken from six camels of similar body weight and nutritional condition from the two production systems in southern Algeria. In total, 1,405 proteins were identified in the muscle proteome; with 40 showing differential accumulation. Proteome characterization reveals similarities with domestic ruminants, most biological process annotations were comprised between catalytic activity (32.8%) and binding (16.7%). Production systems affected several metabolic pathways. The extensive system group had an increased accumulation of energy metabolism and contractile apparatus proteins such as MYBPC1 and MYL2. This could be explained by the need for dromedaries to move in search of food in the extensive rangeland. On the contrary, the intensive system group showed an increase in proteins related to amino acid and lipid metabolisms (ACAT1 and ACAA2). This is likely a consequence of the higher growth rates and nutritional levels of the animals in the intensive system. These results contribute to differentiate the traditional extensive production system from the intensive production system.

Effect of mitochondrial DNA copy number on productive traits and meat quality in pigs

E. Molinero, R.N. Pena, J. Estany and R. Ros-Freixedes

University of Lleida – Agrotecnio-CERCA Center, Department of Animal Science, Av Alcalde Rovira Roure, 191, 25198, Spain; eduard.molinero@udl.cat

Mitochondria are essential for the regulation of cellular energy metabolism. Mitochondrial DNA copy number (mtDNA_CN) is an indicator of mitochondrial number and size, as well as the cellular capacity to generate energy. Studies in livestock species showed that mtDNA_CN is a heritable trait (0.33-0.65) associated with productive traits such as birth and weaning weight, in cattle, and carcass and breast meat yield and abdominal fat, in chickens. Our aim was to evaluate the effect of mtDNA_CN on productive and meat quality traits in pigs, and to identify which genes underlie this association. We sequenced 280 Duroc pigs from different batches of a commercial line at an average coverage of $7.9\times$ (SD $2.4\times$). The reads were processed using a standard bioinformatic pipeline and aligned to the Sscrofa11.1 reference genome. We calculated mtDNA_CN as the natural logarithm of the ratio between mitochondrial and nuclear DNA coverages. We studied the correlation between mtDNA_CN and different productive traits (growth: weight at 180 and 210 d, and carcass weight; carcass quality: backfat and loin thickness; and meat quality: fat content and composition, pH and colour), accounting for the batch effect. We performed a genome-wide association study for the mtDNA_CN using GEMMA to fit a linear mixed model that accounted for the batch effect and the kinship matrix. Variants with a P -value $< 10^{-5}$ were taken as significant and we explored the genes located ± 50 kb from those. In contrast with what has been observed in other livestock species, no correlation between mtDNA_CN and growth traits was observed in our population, nor did we observe associations with fat content and composition traits. Yet, mtDNA_CN was correlated with meat quality traits such as pH ($+0.15$; $P=0.02$) and colour parameter L^* (-0.29 ; $P=0.04$). The genome-wide association study detected 29 associated variants in 12 regions of chromosomes 3, 4, 5, 7, 10, 12, 13, 14 and 17. These regions contained candidate genes MTHFD2, which contributes to the folate mitochondrial pathway, and the KRTs gene family, which are associated with mitochondrial homeostasis and activity. Such candidate genes could influence mitochondrial function and energy metabolism.

Session 41

Poster 28

Multi-omics analysis revealed the interaction of microbiota and host in rumen of hanwooW.C. Park¹, J.W. Son¹, M.J. Jang¹, N.R. An¹, H.J. Choi¹, S.A. Jung¹, J.A. Lim¹, D.H. Kim¹, J.H. Cha¹, S.Y. Choi¹, Y.J. Lim¹, S.S. Jang², D.J. Lim¹ and H.H. Chai¹

¹National Institute of Animal Science, Animal Genomics and Bioinformatics, Wanju, Jeollabuk-do, 55365, Korea, South,
²National Institute of Animal Science, Hanwoo Research, Daegwallyeong-myeon, Pyeongchang-gun, Gangwon-do, 25340, Korea, South; wcpark1982@korea.kr

Hanwoo is Korean native cattle breed. These cattle have been subjected to intensive artificial selection for last 70 years to improve its meat production traits. However, studies on the mechanism of interaction between the host and the microorganisms in the cattle rumen are insufficient. In this study, we performed multi-omics analysis using rumen tissue (RNA-seq) and microorganism (16S rRNA) at 10, 12, 14, 18, 22, 26 and 30 months to confirm changes between host gene and microbial expression patterns according to growth stages. We used the DIABLO method from the mixOmics package. This is because it uses two datasets (RNA-seq and 16S rRNA) and one variable (Month). As a result, our multi-omics dataset consists of two components, 1 and 121, 1 and 161 were identified in genes and microorganisms in component 1 and component 2, respectively. In addition, we identified that the GP5 (glycoprotein V platelet) and ENSBTAG00000047411 (novel) gene was significantly correlated with 3 and 13 microorganisms respectively according to the growth stage of Hanwoo. Except for the negative correlations of ENSBTAG00000047411 and *Oscillospira* (genus level), all correlations between genes and microorganisms were positive. Moreover, GP5 and ENSBTAG00000047411 gene have a high contribution at 18 months and 26 months, respectively. These results suggest that interaction between host and microorganisms in rumen according to the growth stage of Hanwoo were identified. Therefore, there is a need to understand the genetic approach of microorganisms and host interaction of rumen according to the growth stage of Hanwoo, our findings will help in developing a multi-omics approach to improve growth performance.

Challenge session: animal genetics to address food security and sustainability

A. Granados and J. Sölkner

EFFAB-FABRETP, Rue de Trèves 61, 1040, Belgium; ana.granados@effab.info

Food security exists when populations have physical and financial access to sufficient, safe, and nutritious food that meets their dietary needs and food preferences for a healthy life. We all need to produce and consume food sustainably while reducing food waste, GHG emissions and the use of resources and improving animal health, welfare, and food quality. Current crises due to the aggression of Russia on Ukraine have shown how access to affordable, healthy, and sustainable food could be compromised. The importance of farmed animals is vital not only for diets, manure, or diversification in agricultural systems but also for the livelihoods of millions of people and the vitality of rural areas across the globe. In its many forms, animal production plays an integral role in the food system by turning inedible crops for humans into highly nutritious, protein-rich food too. Available technologies and innovation in animal genetics open the door to more sustainable production systems. Societal and ethical concerns related to animal welfare standards and the use of technology are increasing due to the association of genomic techniques with enhancing animal productivity. Transparency of animal breeding strategies and the responsible use of technologies are needed. Modern animal breeding is the responsible combination of different breeding goals and traits balanced between them, including novel breeding goals and traits. The self-regulative initiative, Code EFABAR(CE), recognises the role of resilience and sustainability in safeguarding food security by showing a commitment to practising responsible use of technologies and balanced breeding. In this FABRE TP challenge session, we will discuss these topics and the application of animal genetics to alleviate the pressure. We want to invite experts worldwide to have constructive debates on the importance of animal genetics, diversity and techniques that could be considered in future breeding programmes. The regulatory framework, ethics, and societal context of food production with all the necessary and relevant stakeholders in this debate are essential. CE, more knowledge gained on animal genomes and traits of vital importance could go towards a progressive regulatory approach to look at the potential of NGTs and other technological advances in the animal breeding and reproductive sector.

Causal structures between gut microbiota and efficiency traits in poultry

V. Haas, M. Rodehutschord, A. Camarinha-Silva and J. Bennewitz

Institute of Animal Science, University of Hohenheim, Garbenstraße 17, 70599 Stuttgart, Germany; valentin.haas@uni-hohenheim.de

Livestock farming struggles with social acceptance, environmental impact, and animal welfare. From these points of view, consideration of feed and phosphorus efficiency is becoming increasingly important in poultry production. Efficiency of nutrients can be divided into digestive and metabolic efficiency. The gastrointestinal tract harbours a large community of microbes. These microbial settlers can influence the digestive efficiency and thus affect the expression of efficiency traits of the animals. It is well known that efficiency traits and gut microbiota composition are partly under the control of the host genome. Thus, the gut microbiota composition can be seen as a mediator trait between the host genome and the efficiency traits. However, causal relationships are not well understood and were to be separated in the present study. A data set of 750 F2 cross Japanese quail was used as a model species for important poultry species. All birds were genotyped for 4k SNPs and trait recorded for phosphorus utilization (PU), phosphorus retention (PR), body weight gain (BWG) and feed per gain ratio. In addition to the genotypic and phenotypic information, the ileum microbiota composition was characterized using targeted amplicon sequencing and the alpha diversity was calculated as the Pielou's evenness index (J'). A Hill-climbing learning algorithm was applied to construct a stable network with the efficiency traits and the alpha diversity index. The network identified direct and indirect links via the traits used and placed the J' as the most upstream trait and BWG as the most downstream trait. Structural equation models quantified the direct and indirect effects between J' , PU, and PR. Three genome-wide significant quantitative trait loci (QTL) with 49 trait-associated SNPs within the QTL regions were identified with QTL linkage mapping. The extension of structural equation model (SEM) to the SEM association analysis separated the total SNP effect for a trait into a direct effect and indirect effects mediated by upstream traits. The method applied allows for the detection of shared genetic architecture of quantitative traits and microbiota diversity.

Exploring crossbreeding to reduce GHG Emissions and feed-food competition in beef production

A. Mertens¹, L. Kokemohr², E. Braun³, L. Legein¹, C. Mosnier³, G. Pirlo⁴, P. Veysses³, S. Hennart¹, M. Mathot¹ and D. Stilman¹

¹Walloon Agricultural Research Centre, Agricultural Systems, rue du serpont, 100, 6800 Libramont, Belgium, ²University of Bonn, Institute for Food and Resource Economics, Nußallee 21, 53115, Bonn, Germany, ³Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, 63122 Saint-Genès-Champanelle, France, ⁴Council for Agricoltural Research and Economics, Via Antonio Lombardo 11, 26900 Lodi, Italy; a.mertens@cra.wallonie.be

In the context of a growing population, beef production is expected to reduce its consumption of human edible food, and its contribution to global warming. We hypothesize that implementing the innovations of fast rotational grazing alone and with redesigning existing production systems using crossbreeding and sexing may reduce these impacts. In this research, recently accepted in *Animals*, the bio-economic model FarmDyn is used to assess the impact of such innovations, taking into account farmer's decisions, on farm profit, workload, global warming potential and feed-food competition. The innovations are tested in (1) a Belgian system composed of a Belgian Blue breeder and a fattener farm, (2) a French-Italian system where calves raised in a French suckler cow farm and fattened in a farm in Italy, (3) a German dairy farm that fattens its male calves. The practice of fast rotational grazing with a herd of dairy-to-beef crossbred males from the (1) system is found to have the best potential of greenhouse gases reduction because of the share of the environmental load with milk production while implementing fast rotational grazing alone induced only marginal GHG emission reduction. The reduction of the use of human edible food is also observed when by-products are available and at low stocking rate. The crossbreeding with early maturing beef breeds shows a good potential to produce grass-based beef with little feed-food competition if the stocking rate is adapted to the grassland yield. The results motivate field trials in order to validate the findings.

Session 43

Theatre 1

Genetic selection for dairy calf disease resistance traits: opportunities and challenges

C. Lynch¹, F.S. Schenkel¹, N. Van Staaveren¹, F. Miglior^{1,2}, D. Kelton³ and C.F. Baes^{1,4}

¹Centre for Genetic Improvement of Livestock, University of Guelph, 553 Gordon St, N1G 1Y2, Guelph, Ontario, Canada, ²Lactanet Canada, 660 Speedvale Ave W, N1K 1E5, Guelph, Ontario, Canada, ³Department of Population Medicine, University of Guelph, 50 Stone Road East, N1G 2W1, Guelph, Ontario, Canada, ⁴Institute of Genetics, University of Bern, Bremgartenstr.109a, Postfach, 3001, Bern, Switzerland; clynch@uoguelph.ca

The dairy industry needs to ensure animal health standards are continuously being reviewed and improved. One tool to achieve this is genetic selection, however, limited research has been conducted on the genetics of calf-hood diseases. Therefore, this study aimed to understand the current impact of calf diseases on Canadian farms by investigating incidence rates, estimating genetic parameters, and providing industry recommendations. Producer recorded calf disease data comprised of 69,695 Holstein calf disease records for respiratory problems (RESP) and diarrhoea (DIAR) from 62,361 calves collected on 1,617 Canadian dairy herds from 2006 to 2021. Two combined morbidity traits were also analysed, a binary trait and a categorical trait. Single and multiple trait analyses using a linear animal model for all traits were evaluated. Furthermore, each trait was analysed using two scenarios with respect to minimum herd-year disease incidence threshold criterion (1 and 5%), to highlight the impact of different filtering thresholds on selection potential. Heritability estimates for RESP, DIAR and the two morbidity traits ranged from 0.02 to 0.08 across analyses, while estimated genetic correlations between RESP and DIAR ranged from 0.50 to 0.62. Genetic correlations between both disease traits and production traits were low ranging from 0.03 to 0.08. Furthermore, sires were compared based on their estimated breeding value and their daughter diseased incidence rates. On average, calves born to the bottom 10% of sires were 2.2 times more likely to develop DIAR, 1.8 times to develop RESP, and 1.6 times more likely to exhibit morbidity compared to daughters born to the top 10% of sires. Results from the current study are promising, however, industry outreach on the value of recording and the standardization of collection practices is required for effective genetic evaluation.

Genetic research on colostrum quality traits and passive transfer of immunity in Greek dairy herds

A. Soufleri¹, G. Banos^{1,2}, N. Panousis¹, G. Arsenos¹, A. Kougoumtzis¹, V. Tsiamadis¹ and G.E. Valergakis¹

¹Faculty of Veterinary Medicine, School of Health Sciences, Aristotle University of Thessaloniki, Box 393, 54124 Thessaloniki, Greece, ²Scotland's Rural College, Roslin Institute Building, EH25 9RG Midlothian, United Kingdom; asoufler@vet.auth.gr

The genetic component of colostrum quality traits and passive transfer of immunity was investigated in 10 Greek dairy herds. Colostrum fat (F), protein (P), lactose (L) and total solids (TS) content records on 1,074 Holstein cows were available. Trait heritability estimates were 0.21, 0.19, 0.15 and 0.27, respectively ($P < 0.05$). The genetic correlation of TS measured on-farm with a Brix refractometer with colostrum P and F was unity and zero, respectively. Data on serum total protein content, a proxy for passive transfer of immunity, on 1,013 calves were analysed and a heritability estimate of 0.21 ($P < 0.05$) was derived. A strong positive genetic correlation of 0.99 ($P < 0.05$) was detected between calf serum total protein content and colostrum P. Estimated breeding values (EBVs) for colostrum traits of 67 Holstein sires were derived using data from 699 cows. Number of daughters (purebred Holsteins with full pedigree) per sire ranged from 5 to 49. The EBVs difference for colostrum TS between the 10th and 90th percentile was 3.20% (-1.50 to +1.70, respectively). The EBVs difference for colostrum F between the 10th and 90th percentile was 2.23% (-1.56 to +0.67, respectively). The EBVs difference for colostrum P between the 10th and 90th percentile was 2.32% (-0.92 to +1.40, respectively). The EBVs difference for colostrum L between the 10th and 90th percentile was 0.33% (-0.21 to +0.12, respectively). Three bulls had positive EBVs, and five negative EBVs for all four colostrum traits studied. When considering TS, F and P only, 13 bulls had positive EBVs and 19 had negative EBVs for all three traits. The EBVs difference between the 13 'positive' bulls and 19 'negative' bulls for TS, F and P were 2.15, 1.10 and 1.28%, respectively. Colostrum traits are amenable to improvement with genetic selection. Correlations of colostrum and calf traits with other productive and functional traits should be investigated.

Session 43

Theatre 3

Phenotypic and genetic analysis of beef-on-dairy crossbred calves

R.H. Ahmed, C. Schmidtman, J. Mugambe and G. Thaller

University of Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Str. 6, 24118 Kiel, Germany; rahmed@tierzucht.uni-kiel.de

Beef semen has been increasingly used in dairy herds since a few years. This trend is driven by volatile milk markets, higher revenues for crossbred calves compared to purebred dairy calves but also due to innovative reproductive technology and management in dairy herds, which allows to inseminate surplus cows with beef semen. However, the production strategy Beef-on-Dairy might increase the risk for calving difficulty and stillbirth compromising animal welfare and resulting in economic losses. In this study, a dataset consisting of 3,500 records for traits such as birthweight, chest circumference, gestation length and calving ease from crossbred calvings was analysed to identify differences among beef breeds used for insemination in dairy herds. Data was analysed using mixed linear regression models for weight of calves and binary logit regression models for calving difficulty. The results showed that calves sired by Angus breed had highest rate of calving difficulty, which might be due to the fact that these crossbred calves had significantly higher chest circumference compared to calves sired by other breeds in the dataset (Belgian Blue & Limousin). Moreover, the results revealed differences in gestation length for the dams inseminated with beef semen (280 d for Angus, 282 d for Belgian Blue and 287 d for Limousin). Additionally, genotypic information for all crossbred and most of the sires were available. This data was utilized for principal component analysis to investigate the genetic structure among crossbred calves within the same breed of sire. The results revealed closest genetic relatedness among calves sired by Belgian Blue. On the other hand, Angus crossbred calves showed highest genetic variability.

Assessing passive immune transfer in newborn calves: salivary and serum IgG association

F.G. Silva^{1,2}, E. Lamy¹, S. Pedro¹, I. Azevedo¹, P. Caetano³, J. Ramalho³, L. Martins³, A.M.F. Pereira¹, J.O.L. Cerqueira^{2,4}, S.R. Silva² and C. Conceição¹

¹Mediterranean Institute for Agriculture Environment and Development & Change, University of Évora, Department of Zootechnic, Largo dos Colegiais 2, 7004-516 Évora, Portugal, ²Veterinary and Animal Research Centre & AI4Animals, University of Trás-os-Montes e Alto Douro, Department of Animal Science, Quinta de Prados, 5000-801 Vila Real, Portugal, ³Mediterranean Institute for Agriculture Environment and Development & Change, University of Évora, Department of Veterinary Medicine, Polo da Mitra, Apartado 94, 7004-516 Évora, Portugal, ⁴Polytechnic Institute of Viana do Castelo (IPVC) – Agrarian School of Ponte de Lima, Rua D. Mendo Afonso, 147 Refóios do Lima, 4990-706 Ponte de Lima, Portugal; fsilva@uevora.pt

The calf is born with very low levels of antibodies, which makes colostrum, abundant in antibodies, crucial for passive immunization. The efficiency of passive immune transfer is assessed by the IgG concentration in the calf's blood 24 h after birth. However, this method undergoes blood collection, which needs specialized training and a good animal constraint and can be a source of physical injury and stress. Thus, measuring IgG in the saliva is a more accessible, simpler, and non-invasive alternative method. This study evaluated the association between total protein and IgG in the serum and saliva of calves before and after passive immunization. Total protein and IgG concentration was measured in eighty saliva and blood samples from twenty calves collected at 4-time points: at birth (approximately 30 min before colostrum consumption), 24 h, 48 h and at day 7 after birth. Total protein was measured by the Bradford method, and IgG was quantified using the ELISA technique. The correlation between IgG between blood and saliva was assessed and will be presented during the EAAP 2023 Annual Meeting.

Biochemical predictors of successful transition from milk to solid feed in Holstein calves

P. Kazana, N. Siachos, N. Panousis, G. Arsenos and G.E. Valergakis

Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Laboratory of Animal Production, Aristotle University Campus Box 393, 54124 Thessaloniki, Greece; geval@vet.auth.gr

The objective of the study (9 commercial dairy farms, 249 healthy Holstein calves) was to establish tests predicting: (1) which calves are ready to be weaned; and (2) which calves successfully adapted to the solid feed diet. At three time-points relative to the day of weaning (-7, 0 and 7 d), for each calf we performed the following: (1) a clinical examination; (2) blood sampling for determination of serum concentration of β -hydroxybutyrate acid (BHB) and non-esterified fatty acids (NEFA); (3) sampling of rumen fluid to determine the concentration of total volatile fatty acids (VFA, gas chromatography); and (4) measurement of ruminal fluid pH. At each time-point, critical thresholds of total VFA concentrations were identified, below or over which there is increased probability of low or high pH values (multiple ROC curves), using total VFA concentrations as quantitative variables and pH as test variable. Thresholds of total VFA <80-85 mmol/l and >116-134 mmol/l for 'low' and 'high' pH values, respectively, yielded the best predictive values, based on the area under the curve (AUC). Using these thresholds, we divided calves into 3 categories, indicative of 'low', 'adequate' and 'high' solid feed consumption, respectively. Subsequently, multinomial logistic regression (MLR) models were fit within each time-point with BHB and NEFA concentrations as predictors of calves' classification, accounting for the effects of farm and age at weaning. When statistically significant effects of either BHB and/or NEFA were detected, ROC curves were used to determine thresholds dichotomizing calves into 'adequate/high' vs 'low' categories. As BHB and NEFA concentrations on -7 d increased, the odds of a calf being classified as having 'adequate/high' solid feed consumption pre-weaning increased. A BHB concentration of >260 μ mol/l and a NEFA concentration of >175 μ mol/l predicted the categorization of calves into the 'adequate/high' solid feed consumption with sensitivities of 94.1 and 83.5%, respectively. On 7 d, a NEFA concentration of <245 μ mol/l predicted the categorization of calves into the 'low' solid feed consumption with a specificity of 79.2%.

The impact of dairy farm management on long-term robustness of veal calvesF. Marcato^{1,2}, H. Van Den Brand², L. Webb³, M. Wolthuis-Fillerup¹, F. Hoorweg¹ and K. Van Reenen¹¹Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ²Wageningen University & Research, Adaptation Physiology Group, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ³Wageningen University & Research, Animal Production Systems Group, P.O. Box 338, 6700 AH Wageningen, the Netherlands; francesca.marcato@wur.nl

Dam parity and dam-rearing are known to have an impact on calf health and welfare, but little is known about the effects on long-term measures of robustness in veal calves. The aim of this study was to investigate the impact of dam parity and dam-rearing on veal calf robustness. Calves (n=683) were transported from 13 dairy farms to 8 veal farms at 2 or 4 weeks of age. Within the large study on 13 dairy farms, the study on dam-rearing was conducted on one of these farms where half of the calves were directly separated from their dam at birth (n=39 of 76), and half of the calves (n= 37 of 76) were reared with their dam during their entire stay at the dairy farm and abruptly separated on the day of transport (2 or 4 weeks). At all farms, dam characteristics were recorded, body weight (BW) of calves was recorded at birth, weekly at the dairy farm, upon arrival at the veal farm and at slaughter. A blood sample was collected from the dam a week before calving and in calves a week after birth, a day before transport and in week 2 and 10 post-transport. These samples, together with colostrum samples were analysed for IgG. Health of calves was scored weekly at the dairy farm and in weeks 2, 6, 18 and 24 at the veal farm. Calves born from first parity cows had the lowest BW until slaughter (day before transport: $\Delta = -4.7$ kg, $P=0.01$; at slaughter: $\Delta = -6.1$ kg, $P=0.07$). First parity cows produced lower quality colostrum and their calves' serum-IgG was lower up to week 2 post-transport ($P<0.01$). Dam-reared calves had a higher BW and more signs of disease (58 vs 27%, $P=0.05$) at the dairy farm, and higher BW upon arrival at the veal farm (70 vs 63 kg, $P=0.01$) than calves raised without their dam, but no differences in serum IgG or carcass weights were present. This study suggests that calves from first parity dams may require extra attention, while more research is necessary to understand whether or not dam-rearing affects veal calf robustness at a transport age of 2 or 4 weeks.

Session 43

Theatre 7

The assessment of transfer of passive immunity in dairy calves affected by neonatal diarrhoeaG. Sala¹, V. Bronzo², A. Boccardo², A.L. Gazzonis², P. Moretti², V. Ferrulli², A.G. Belloli², L. Filippone Pavesi², G. Pesenti Rossi² and D. Pravettoni²¹University of Pisa, Department of Veterinary Sciences, Via Livornese s.n.c, 56122, San Piero a Grado, Italy, ²University of Milan, Department of Veterinary Medicine and Animal Science, Via dell'Università 6, 26900, Lodi, Italy; gaia.pesenti@unimi.it

The assessment of immune status has practical implications in calves' management and health. However, the presence of hemodynamic alterations like dehydration caused by neonatal calf diarrhoea (NCD), makes the diagnosis of failure of transfer of passive immunity (FTPI) challenging. This study aimed to evaluate the diagnostic performances of serum total protein refractometry (STP) and gamma-glutamyl-transferase activity (GGT) for assessing FTPI in dairy calves affected by NCD. 91 Friesian calves aged 1 to 10 days were enrolled for this study. Among them, 72 were admitted to the Veterinary Teaching Hospital of the University of Milan as affected by NCD, while 19 were healthy. Each calf underwent a complete clinical examination and dehydration assessment. Blood sampling was performed and serum was tested for STP concentration, GGT activity and IgG concentration. The effect of dehydration status and age on the correlation between the two methods under study and the gold standard (IgG) was investigated with Spearman's correlation index R for ranks. Receiver operating characteristic (ROC) curve analysis was performed to identify the optimal cut-off point to distinguish between diarrheic calves with or without FTPI (IgG<10 g/l). Significant differences in IgG concentration ($P= 0.009$), STP concentration ($P= 0.040$), and age ($P= 0.042$) were found between healthy and NCD calves, while no statistical difference was found in GGT activity ($P=0.081$). GGT was affected by age ($P= 0.003$), while STP was influenced by dehydration ($P= 0.013$). The cut-offs for identifying FTPI were 52 g/l of STP in normohydrated calves, 58 g/l of STP in dehydrated calves, and 126 U/l of GGT in calves with more than 3 days of age. In normohydrated diarrheic calves STP refractometry showed better diagnostic accuracy, whereas in dehydrated calves its accuracy dropped, and it resulted advisable to use GGT activity. This study confirms the hypothesized better performance of GGT activity in diagnosing FTPI in dehydrated calves.

Automatic monitoring of calves' behaviour for a precision weaning approach

R. Colleluori, D. Cavallini, A. Formigoni and L. Mammi

University of Bologna, Department of Veterinary Medical Sciences, Via Tolara di Sopra, 50, 40064, Ozzano dell'Emilia (BO), Italy; riccardo.colleluori2@unibo.it

Aim of this study was to evaluate the potential of an accelerometer ear tag monitoring system (AMS) (SenseHub Dairy, MSD Animal Health) for a precision management of pre-weaned dairy calves. This AMS records times of suckling, activity, rumination and intake of calves and, based on these patterns, develop a health index (HI; 0-100 scale) that generates a health alarm (HA) when lower than 86. Twenty-eight Holstein female calves were monitored for the first 90 days of life. After colostrum feeding, animals were fed bulk milk twice daily, pelleted calf starter and long hay with *ad libitum* access to water. For the first 2 months, calves were housed in individual pens, and individual milk, feed, and hay intake was recorded. At d 66.5±13.3 calves were moved to multiple pens. In both housing system, calves were weighed fortnightly and clinically assessed 3 times a week. Moreover, health checks (HC) were carried out at day 0, 1, 2 and 3 from the HA sent by the AMS. Body weight (BW) of calves was 36.68±5.44 kg at birth and 89.65±12.14 kg at the weaning age (74.56±8.08 d). The average daily gains (ADG) recorded at 60 and 90 days were respectively 0.65±0.13 and 0.76±0.14 kg/d. Total number of HA received for each calf varied from 0 to 7, and for the 63.2% of HA mild (25.0%) or severe symptoms (38.2%), were detected at the HC. Animals were retrospectively divided into 3 clusters (C1, C2, C3) based on number of the HA received in the first 90 days (0-1 HA for C1, 2-3 HA for C2, >3 HA for C3), and intakes and growth rate were compared between clusters. Milk and hay intakes showed no differences between the 3 clusters, while starter intake resulted lower ($P<0.001$) for C3 (198.1±39.8 g/d) and C2 (293.5±35.4 g/d) compared to C1 (388.3±33.1 g/d). BW recorded at 60 and 90 days was lower ($P<0.001$) for C3 compared to C1 (-16.78 and -22.53 kg, respectively), as well as ADG (0.68±0.04 and 0.52±0.05 kg/d, respectively at 60 d, and 0.82±0.05 vs 0.64±0.05 kg/d at 90 d). According to this data, the automatic monitoring of calves' behaviour reveals the potential to promptly detect weaker calves even though the complete potential of these systems is far from being explored.

Session 43

Theatre 9

Can dairy herds be in a positive colostrum stock balance?A. Soufleri¹, G. Banos^{1,2}, N. Panousis¹, G. Arsenos¹, A. Kougioumtzis¹, V. Tsiamadis¹ and G.E. Valergakis¹¹Faculty of Veterinary Medicine, School of Health Sciences, Aristotle University of Thessaloniki, Box 393, 54124 Thessaloniki, Greece, ²Scotland's Rural College, Roslin Institute Building, EH25 9RG Midlothian, United Kingdom; asoufler@vet.auth.gr

The importance of colostrum for passive transfer of immunity to newborn calves is indisputable. Keeping a stock of frozen high-quality colostrum, is a well-established practice to cater the needs when cows have low quality/quantity. In this simulation study we investigated whether it is practically feasible for all farms to have adequate stock of high-quality colostrum and the factors associated with it. Data from 9 dairy herds in Greece including 1,067 Holstein cows were used. In each farm, sampling covered on average a period of 8-9 months. Only first milking colostrum was considered. Colostrum yield (CY) was recorded, and quality was determined using a digital Brix refractometer. Cow parity and calving calendar season (CS) were also recorded. The simulation included the following steps: (1) 4 l of good quality colostrum (Brix≥22%) were 'fed' to each calf born (twins included) and any excess quantity was stored; (2) if colostrum quality was poor (Brix<22%), it was 'rejected' and 4 l from the colostrum stock were used; and (3) if quality was good but quantity was <4 l per calf, it was supplemented from stock. These steps created a 'colostrum stock balance' after every calving that was either positive or negative (continuous variable). Effect of CS, parity, CY and quality and the interactions between them on 'colostrum stock balance' was analysed with a univariate general linear model. Four farms were continuously in positive stock balance, four others were in negative stock balance for one or two periods during the study and one farm was continuously in negative stock balance. CS (spring and summer were favourable), CY and the interaction of colostrum CY × quality and of CS × quality, had a statistically significant ($P<0.05$) effect on colostrum stock balance. The simulation was repeated with a hypothetical supply of 6 l per calf and a quality threshold set at Brix ≥26%, but in both cases, none of the farms were ever in a positive stock balance. Colostrum replacers should be used in case of negative 'colostrum stock balance' for parts or the whole year.

Dairy-beef calves: current practices and views of calf producers and rearers*D.J. Bell, M.J. Haskell, C.S. Mason and C.-A. Duthie**SRUC, Peter Wilson Building, West Mains Road, Edinburgh. EH9 3JG, United Kingdom; david.bell@sruc.ac.uk*

In the United Kingdom, there has been a year-on-year increase in the number of dairy-beef cross calves being born as a result of the increasing use of sexed dairy semen in dairy herds. These dairy-beef cross calves tend to be sold pre-weaned for further rearing on another unit and enter the beef production cycle. As part of the study, a small selection of semi-structured qualitative interviews was carried out with dairy farmers (calf producers; $n=5$) and calf rearers ($n=7$). The aim of these interviews was to explore the current practices carried out by each group in terms of calf sales, calf purchasing decisions, transfer of information and the information they would be willing to share/receive. The analysis of the interviews highlighted that the calf rearers tended to select calves for purchase by visual assessment based on the appearance of the calves for their age. Apart from the statutory requirements, no additional information, such as immunity status, prior health events and treatments, was formally transferred between parties. Any information that was transferred between calf producers and calf rearers was usually gathered via informal dialogue. All the calf rearers conveyed a desire to obtain as much information as possible about the calves they were purchasing. There was an expression of interest from the calf producers in receiving feedback about the subsequent performance of their calves whilst on the rearing unit but none of them actively pursued this type of information. Calf producers also highlighted the need to establish a good personal reputation as a producer of calves that met the market requirements. Some calf rearers said that they were now selecting calves with genetics that suited their production system. Calf producers all believed that such calves were a valuable additional source of financial income to their business and questioned such calves being referred to as 'surplus'. The calf rearers interviewed stated that they preferred to group calves by source farm when they received them at their rearing unit with health being quoted as the main reason for this practice. Overall, the interviews illustrated the themes of appropriate terminology, selection of the correct genetics, good communication, developing relationships and reputation.

Session 43

Theatre 11

Sodium percarbonate as a preservative in waste milk fed to dairy calves*D.J. Wilson¹, G.M. Goodell², R. Dumm³, T. Kelly² and M. Bethard²*

¹Utah State University, Veterinary Clinical and Life Sciences, 955 E 700 N, Logan, UT 84322, USA, ²The Dairy Authority, 8215 W. 20th St., Unit A, Greeley, CO 80634, USA, ³Dairy Tech, Inc., 10027 County Road 70, Windsor, CO 80550, USA; david.wilson@usu.edu

The objective was evaluation of sodium percarbonate (SP), a preservative used in milk and drinking water, as an inhibitor of bacterial growth in pasteurized waste milk to be fed to dairy calves. Bacteria standard plate counts (SPC) in cfu/ml were performed using standard methods for the examination of dairy products procedures. After pasteurization at 63 °C for 30 min, dairy farm waste milk was incubated at 32 °C (100 °F) in a 0.4 m³ (14.3 ft³) incubator. SPC were calculated for 296 aliquots from 7.6 l (2 gal) batches of pasteurized milk at times 0 (as soon as milk was cooled to 49 °C for safe handling) and at 1, 2, 3, 4, 5, 6, 7, 8 and 24 hr after pasteurization. Concentrations of SP added to milk were 0 (untreated control), 200 and 400 mg/l. Statistical significance between SPC for the SP concentrations within each time point was tested using ANOVA. SPC means at the times following pasteurization for the 3 concentrations of SP were as follows: Untreated: 4,499; 4,634*; 5,485*; 3,344*; 85,282*; 58,424*; 88,663*; 245,050; 476,679*; 193,743,750**. 200 mg/l: 3,702; 2,814; 428; 857; 21,706; 5,036; 2,465; 4,188; 4,127; 444,000**. 400 mg/l: 4,062; 1,720; 845; 1,714; 4,008; 5,085; 7,533; 3,722; 2,738; 15,324**. * = untreated milk SPC higher than for either SP treatment, $P<0.05$, ANOVA. ** = SPC were different among all 3 treatments, $P<0.0001$, ANOVA. SP added to pasteurized milk at 200 or 400 mg/l was associated with SPC remaining significantly lower according to ANOVA, usually <8,000 cfu/ml, with all counts <22,000 cfu/ml, compared to those in untreated milk in milk at 32 °C. In contrast, SPC increased markedly beginning 4 h after pasteurization in untreated milk, reaching nearly 500,000 cfu/ml after 8 hr. SP has potential as a preservative for milk fed to calves; further studies are being conducted.

Pre-transport diet affects the physiological status of calves during transport by road and ferry

S. Siegmann^{1,2}, L.L. Van Dijk^{2,3}, N.L. Field², G.P. Sayers³, K. Sugrue², C.G. Van Reenen¹, E.A.M. Bokkers¹ and M. Conneely²

¹Wageningen University & Research, Animal Production Systems, Wageningen, the Netherlands, ²Teagasc, Animal & Grassland Research Centre, Fermoy, Ireland, ³Munster Technological University, Dept. of Biological and Pharmaceutical Sciences, Tralee, Ireland; susanne.siegmann@wur.ie

Extended feeding intervals during long-distance transport require strategies to be developed that reduce the potential for dehydration, negative energy balance and stress. We studied the effects of providing different amounts of feed pre-transport on the physiology of unweaned dairy calves undergoing long-distance transport by road and ferry from Ireland to the Netherlands. At the Irish assembly centre, calves (n=116) were either fed 2 l of milk replacer the morning of transport (STD) or 3 l of milk replacer the evening before and the morning of transport (ALT). Calves were divided equally over two commercial trips and blood samples were taken before transport at the assembly centre (t=0 h), after roll-on-roll-off ferry transport at a French lairage, after road transport upon arrival at a Dutch veal farm (t=56 h) and one week later. Blood was analysed for parameters indicating energy balance (glucose, NEFA, BHB), dehydration (urea, haematocrit) and stress (cortisol, creatine kinase). Preliminary results show that ALT calves had higher levels of plasma glucose after ferry transport than STD calves (3.7 vs 3.2 mmol/l, $P=0.02$), but not on arrival at the veal farm. ALT calves had lower BHB (0.06 vs 0.13 mmol/l, $P=0.001$) and NEFA (0.09 vs 0.24 mmol/l, $P=0.0007$) levels at the assembly centre than STD calves. BHB was lower for ALT calves than for STD calves after ferry transport (0.28 vs 0.37 mmol/l, $P<0.0001$), whereas NEFA was higher for ALT calves on arrival at the veal farm (0.83 vs 0.66 mmol/l, $P=0.008$). ALT calves had lower urea concentrations after ferry transport than STD calves (2.7 vs 3.7 mmol/l, $P=0.0001$). Haematocrit and stress parameters showed no differences between treatments. There were no effects of treatment or transport one week after arrival. Overall, feeding larger volumes of milk replacer before long-distance transport has positive effects on calf energy balance and hydration status that are not sustained for the entire duration of the journey.

Theatre 13

Clonal dissemination of MDR *Pasteurella multocida* ST79 in a Swiss veal calves

J. Becker, J. Fernandez, A. Rossano, M. Meylan and V. Perreten

Vetsuisse Faculty, Bremgartenstrasse 109a, 3012 Bern, Switzerland; jens.becker@unibe.ch

In the framework of a large field study where prevalence of and antimicrobial resistance in *P. multocida* in calves was investigated in 38 Swiss farms, we observed that 20 isolates exhibited an MDR profile. Minimum inhibitory concentrations were determined using Thermo Scientific™ Sensititre™ EUST2 plates for tetracycline, streptomycin, sulfamethoxazole and trimethoprim, and BOPO6F plates for other tested antimicrobial agents, following CLSI recommendations. The complete genome of the *P. multocida* isolates was obtained from Nextera DNA Flex libraries sequenced on Illumina MiSeq (2×150 bp paired-end). Several parenteral treatments with tulathromycin, tylosin and oxytetracycline, and oral administration of amoxicillin were recorded during the study year and the previous year. Clonal dissemination of *P. multocida* sequence type (ST) 79 was observed throughout a period that was distinctly longer than the lifespan of a calf, indicating that *P. multocida* ST79 was maintained within the herd by circulating among calves that were present on the farm at the same time. The frequent use of macrolides, tetracyclines and β -lactams and the presence of *P. multocida* ST79 exhibiting resistance to these antimicrobial agents in different calves over several months indicate that antimicrobial selective pressure was responsible to select and maintain the bacterium over time. Antimicrobial resistance in animal pathogens and the use of antimicrobial agents, particularly of the most critically important ones, need to be strictly monitored to identify farms acting as reservoirs to limit the further spread of such MDR bacteria in livestock.

Effects of feeding milk with antibiotic residues on calf performance during the pre-weaning periodA. Flynn^{1,2}, C. Mc Aloon¹, M. Mc Fadden², J.P. Murphy², S. Mc Pherson², C. Mc Aloon¹ and E. Kennedy²¹University College Dublin, School of Veterinary Medicine, Belfield, Dublin, Ireland, ²Teagasc, Grassland Department, Grassland Dept., Teagasc, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy, Cork, Ireland; anna.flynn@teagasc.ie

The practice of feeding waste milk, containing antibiotic residues, to pre-weaned calves is not recommended as it is associated with increased risk of diseases such as diarrhoea, and can result in poorer growth rates. However, there is evidence that many farmers feed this non-saleable milk to calves. As such, more knowledge on the effects of duration of exposure to milk with antibiotic residues is needed. This study aimed to investigate the effects of feeding milk replacer (MP) containing antibiotic residues on calf health, and growth across the pre-weaning period (PWP). The study was a randomised block design, dairy heifer calves (n=87) were balanced by birth weight, breed, and birth date. Treatments included: (1) long-term; calves that were fed antibiotic spiked MP for the entire duration of the PWP until weaning (LTA); (2) short-term; calves that were fed the antibiotic spiked MP for a duration of two weeks from the age three to five weeks of age (STA); (3) the negative controls fed MP free from antibiotics (CONT). Calves were fed MP containing neomycin (2.28 mg/l) and amoxicillin (1.68 mg/l), based on previous literature and reflected milk collected from cows during the withdrawal period, following intramammary treatment for mastitis. Measurements included health scores, treatment incidence, and weekly weights (kgs). All calves were gradually weaned by 12 weeks old. Weights data were analysed in linear mixed models, fixed effects included treatment and breed. Health data were analysed by logistic regression, reported as odds ratios (OD). Weights were similar in all treatment groups ($P=0.301$) across the PWP. Results showed faecal scores of LTA (OD 1.356) and STA (OD 1.561) calves were more likely to be higher than CONT during the PWP, STA calves were also more likely to have nasal discharge than CONT (OD 1.349). A similar number of calves required intervention with antibiotics in all treatments. The findings of this study will help to better inform farmers as to the risks associated with feeding waste milk.

Session 43

Theatre 15

Effects of extending lactation for dairy cows on health, development and production of their calvesY. Wang¹, R. Goselink², E. Burgers^{1,2}, A. Kok¹, B. Kemp¹ and A.T.M. Van Kneegsel¹¹Wageningen University & Research, Animal Science group, Adaptation Physiology group, De Elst 1, 6708 WD Wageningen, the Netherlands, ²Wageningen University & research, Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, the Netherlands; yapin.wang@wur.nl

Extending the voluntary waiting period for insemination (VWP) in dairy cows is of interest to reduce the frequency of calving events and inseminate at a moment with less fertility problems. Little is known about the impact of extension of the dams' VWP on the calf. The aim of this study was to evaluate the effect of extending VWP of dams on growth, metabolites, and production performance of their offspring. Holstein Friesian dairy cows (n=154) were blocked according to parity, milk yield, somatic cell count and randomly assigned to a VWP of 50, 125, or 200 days. For the current study, Holstein-Friesian heifer calves (n=61) from cows with different VWP were monitored from birth until 100 days in milk (DIM) after their first calving. Birth weight did not differ among heifer calves of the 3 VWP groups. During the rearing phase, body weight (BW) of heifers was not different among VWP groups. During the first 100 DIM, heifers in VWP50 had a greater BW (557 kg, $P<0.01$) and a greater fat and protein corrected milk yield (FPCM, 29.01 kg/d, $P<0.01$), compared with heifers in VWP125 (BW: 533 kg; FPCM: 27.04 kg/d). And both VWP50 and VWP 125 did not differ from VWP200 in terms of BW (549 kg) and FPCM (28.78 kg/d). When heifers were regrouped according to their mothers' real calving interval (CInt; CInt_1: <409 days; CInt_2: 409-468 days; CInt_3: >468 days), heifers born to mothers with CInt_3 had a greater BW after calving compared with heifers in CInt_2 (559 vs 537 kg, $P=0.01$). Heifers in CInt_1 had higher FPCM than heifers in CInt_2 (29.13 vs 27.23 kg/d, $P<0.01$). No difference in CInt_1 for BW (544 kg) and CInt_3 for FPCM (28.21 kg/d) compared with other two groups was found. In conclusion, extending VWP of dams did not affect growth of heifer calves during the rearing phase, but affected body condition and milk performance of heifers during the start of their first lactation.

Dam-calf contact rearing in Switzerland: Aspects of management and milking*J. Rell¹, C. Nanchen², P. Savary², C. Buchli¹ and C. Rufener²**¹Centre for Dam-Calf Contact Rearing, Postfach 363, 8903 Birmensdorf ZH, Switzerland, ²Agroscope, Animal Production Systems and Animal Health, Tänikon, 8356 Ettenhausen, Switzerland; julia@mu-ka.ch*

The interest in dam-calf contact rearing systems, where dairy calves remain on their farm of birth and are nursed by their dam, is increasing among consumers and farmers. By means of telephone interviews (n=16), we investigated the current status quo of a large proportion of the existing dam-calf contact farms in Switzerland descriptively. We identified views on practical chances and challenges of the system, individual farming approaches including husbandry, separation and weaning management, milking and health. Furthermore, a controlled on-farm study was conducted to evaluate milkability of nursing cows. Interview data revealed that seven (44%) farmers provide whole-day contact (W), while two (12%) operate with half-day contact (H) and seven (44%) provide short-time contact before (SB) or after (SA) milking. Weaning occurred between two and 12 months of age. Mostly, male calves were weaned abruptly at slaughter while female calves were weaned gradually. None of the farms reported regular calf diarrhoea but most farms had calves with diarrhoea recovering without intervention occasionally. Cow health was reported to be unproblematic on 12 (75%) of the farms. Perception of milkability problems differed widely among farms, ranging between <10 and 80% of cows affected. Eleven (69%) of the farms had taken measures to address poor milkability. Avoiding early separation and better calf health were the main decision criteria to change to a dam-calf contact system. Twenty of the 701 examined milkings (on 10 dam-calf contact farms and 5 control farms with artificial rearing) met the criteria for clear ejection disorder, with 85% of them occurring on W farms and 0% on control farms. Stripping milk fat contents were lower in nursing cows ($P<0.01$). Milk yield and average milk flow during the main milking phase were higher on SA farms than on W and SB farms ($P<0.01$). In summary, dam-calf contact systems are divers and may offer an alternative to artificial calf rearing with a high welfare standard and good calf health. Nursing after milking had the least negative influence on milkability and milk production of all contact types.

Session 43

Poster 17

A survey of colostrum management practices in dairy farms of Piedmont region (Italy): a pilot study*G.V. Berteselli, G. Pesenti Rossi, G. Vezzaro, E. Dalla Costa, S. Barbieri and E. Canali**University of Milan, Department of Veterinary Medicine and Animal Science, Via dell'Università 6, 26900 Lodi, Italy; gaia.pesenti@unimi.it*

Inadequate transfer of immunoglobulins from dam to calf via colostrum remains a challenge in dairy farming. Failure of transfer of passive immunity has been related to increased morbidity and mortality in calves, lower productivity, and increased risk of culling. The aim of this pilot study was to investigate colostrum administration and calves' management in dairy farms of Piedmont region (Northern Italy). The questionnaire included 28 multiple choice questions and it was administered by a single interviewer to 15 farmers. The 28 items regarded calving management and care of the new-born, calf-dam separation, colostrum management, calf feeding, weaning, and calf housing. Descriptive analysis was performed. In 40% of farms surveyed, the disinfection of the calf's navel was not done. The separation from dam occurred immediately after birth in most of farms (67%). All farms used single pens, where calves were housed up to 60 days of age in most of the farms (80%). Colostrum was administered within 3 hours of life in all farms included. In 80% of farms 2 meals of colostrum were provided. Colostrum bank was present in 80% of farms. The quality of colostrum was assessed in almost half of the farms (47%) but only one farmer checked serum IgG. Weaning occurred at 60 days of age in most of the farms (67%). These findings provide preliminary insight into calves' management and colostrum administration in dairy farms of an Italian region, highlighting critical issues for calf welfare. Despite a prompt administration of adequate quantity of colostrum is carried out by the farmers interviewed, the evaluation of the quality is still partially performed. Moreover, the evaluation of passive immunity in calves remains lacking. Correct management and feeding of high-quality colostrum can reduce calf mortality, strengthen immunity, and increase animal life span.

Serum profiles of dairy calves fed a milk replacer or whole milk at two levels of supply

T. Chapelain, J.B. Daniel, J.N. Wilms, J. Martín-Tereso and L.N. Leal

Trouw Nutrition R&D, P.O. Box 299, 3800 AG, Amersfoort, the Netherlands; tchapela@uoguelph.ca

The objective of this study was to compare the effect of feeding fresh whole milk and a milk replacer at two different levels of supply on calf metabolism. Forty-eight newborn Holstein calves (45.0 ± 4.37 kg body weight; 2 ± 1.0 d of age) were enrolled and blocked by age and arrival date and randomly assigned to one of four treatments at: 9.0 l/d of milk replacer (MR-H) or whole milk (WM-H), and 4.5 l/d of MR (MR-L) or WM (WM-L). Dry matter (DM), protein, fat and lactose content (% of DM) in MR and WM were: 16.2 vs 13.9, 23.7 vs 25.8, 17.5 vs 32.7, and 48.8 vs 32.9, respectively. Starter feed and straw were introduced at week 6. Calves were gradually weaned from week 6 to 10 and studied up to week 13. Blood samples were taken weekly, and data was analysed using PROC MIXED (SAS 9.4). Calves fed MR had higher blood glucose concentrations preweaning ($P=0.01$), but lower during weaning ($P=0.02$), compared to WM-fed calves. Preweaning blood concentrations of β -hydroxybutyrate (BHB), non-esterified fatty-acids (NEFA), triglycerides (TG) and cholesterol ($P \leq 0.06$) were greater for WM-fed calves. However, during weaning and postweaning, only TG remained greater ($P \leq 0.04$). Concentrations of total protein, urea, albumin, and globulin were higher for WM-fed calves during preweaning ($P < 0.01$). Total protein and albumin remained higher during weaning ($P \leq 0.01$). Calves fed high milk allowance had greater glucose ($P=0.02$) and lowered cholesterol ($P < 0.01$) concentrations in the blood during preweaning. During weaning, blood concentrations of glucose, NEFA, total protein, albumin ($P < 0.01$) and TG ($P=0.04$) were higher for calves on high milk supply, whereas BHB ($P < 0.01$) and urea ($P=0.06$) were lower. Postweaning, calves fed high milk allowances had greater NEFA ($P=0.04$), total protein and albumin ($P < 0.01$) concentrations and lower TG concentrations ($P < 0.01$). The differences observed in blood metabolites during preweaning and weaning confirm the significant influence of feeding WM or MR and their supply on calf metabolism. However, most metabolites did not differ with the liquid diet source provided during postweaning.

Session 43

Poster 19

Prevalence of foot lesions in French slaughter dairy and beef young bulls housed in indoor feedlotS. Ishak^{1,2}, R. Guatteo², A. Lehébel², N. Brisseau², M. Gall¹, A. Wache¹ and A. Relun²¹French Livestock Institute, Beaucouzé, 49071, France, ²Oniris, INRAE, BIOEPAR, Nantes, 44300, France; sarah.ishak@idele.fr

Almost half of beef calves and 14% of dairy calves are fattened indoor as feedlot cattle in France. Lameness is increasingly reported in French feedlot cattle, particularly at the end of the fattening period. Previous studies suggest that most cases are due to feet lesions. However, the lack of basic knowledge limits the establishment of cost-effective control measures. The aim of this study is to estimate the prevalence of foot lesions at the end of the finishing period in French dairy and beef young bulls. A cross-sectional study will be conducted in the 3 regions with the highest proportion of feedlot cattle slaughtered in spring 2023. The 4 feet of nearly 1,500 animals will be trimmed and examined *post-mortem* by two trained persons, and the type, severity and location of foot lesions will be recorded according to the ICAR Claw Health Atlas and national scoring methods. Descriptive analysis will be conducted to estimate foot, animal and within-batch level prevalence, to describe the severity and location of foot lesions and to estimate the distribution (e.g. breed, geographical area, etc.) of foot lesions. This study will provide an accurate estimate on the prevalence of foot lesions in a large sample of finishing young bulls. It will provide original data for indoor feedlot cattle, including the frequency of lesions on the front feet, association between foot lesions and associations between foot lesions and several dairy and beef breeds.

Effect of direct-fed microbial supplementation on performance and health of pre-weaning dairy calves

¹Sao Paulo State University, School of Veterinary Medicine and Animal Science, Department of Animal Production, Fazenda Lageado, 18618-150 Botucatu, SP, Brazil, ²Chr. Hansen A/S, Bøgle Allé, 10-12, 2970, Denmark, ³Fazenda Santa Luzia, Fazenda Santa Luzia, 37902-377 Passos, MG, Brazil; brbrie@chr-hansen.com

The health of pre-weaning dairy calves dictates long-term performance and profitability of the operation and technologies that support pre-weaning health and performance are warranted. We hypothesized that direct-fed microbial (DFM) supplementation would improve health and performance of pre-weaning dairy calves. Our objective was to evaluate the effects of two DFM combinations on performance and health of pre-weaning dairy calves. At birth, 90 female crossbred Gyr × Holstein calves were assigned to: (1) Control: no DFM (CON; n=30); (2) 1 g/head per day of a *Bacillus*-based DFM (BOVACILLUSTM; Chr. Hansen A/S; BAC; n=30); or (3) BAC plus 1 g/head per day of a lactic acid bacteria-based DFM (LACTIFERM®; Chr. Hansen A/S; MIX; n=30). The BAC and MIX treatments were mixed daily in whole milk throughout the 77-day experimental period. All animals were daily observed for signs of adverse health events. On day 77 of the study, weaning body weight (BW) was recorded for average daily gain (ADG) and feed efficiency (FE) calculation. Contrast analysis were performed: (1) DFM effect: CON vs DFM (BAC + MIX); and (2) DFM type: BAC vs MIX. At weaning, DFM-supplemented calves, regardless of type ($P=0.68$), were heavier than CON calves ($P=0.04$; 81.7, 88.0, and 86.7 kg for CON, BAC, and MIX, respectively). Moreover, ADG and FE tended to be greater ($P=0.06$) for DFM vs CON, but no differences were observed between BAC or MIX ($P>0.88$). Pneumonia occurrence was greater ($P=0.05$; 47.0, 23.0, and 29.0% for CON, BAC, and MIX, respectively), whereas diarrhoea tended to be greater for CON ($P=0.08$; 50.0, 29.0, and 32.0% for CON, BAC, and MIX, respectively). Moreover, no differences were observed on number of days sick and costs of pharmacological intervention per calf ($P>0.21$), but total cost of the interventions was numerically greater for CON calves. In summary, DFM supplementation, regardless of the type, supported health and overall performance of pre-weaning Holstein calves.

Poster 21

The effect of astaxanthin on health and calves performance

E. Sosin¹, I. Furgal-Dierzuk¹, B. Śliwiński¹ and A. Burmańczuk²

¹National Research Institute of Animal Production, Department of Animal Nutrition and Feed Science, Krakowska St. 1, 32-083 Balice, Poland, ²University of Life Sciences in Lublin, Department of Pharmacology, Faculty of Veterinary Medicine, Akademicka 12, 20-033 Lublin, Poland; ewa.sosin@iz.edu.pl

The aim of the study was to determine the effect of astaxanthin on health indicators and calves performance. The experiment was carried out with 16 Polish Holstein-Friesian bull calves aged between 4±1 and 90 days were assigned based on the analogue principle to 2 equal groups. Calves were given colostrum and whole milk before the experiment, and milk replacer from the beginning of the experiment to 56 days of age. Grains in the mixtures were given in rolled form. The control group (C) was fed with the mixture contained corn grain (56%), oats (18%), soybean pressed cake (22%) and minerals (4%) and in the experimental group (AXT) there were the addition of astaxanthin (0.020 g/kg feed). During the experiment the body weight, feed intake, daily gain, haematological and biochemical and immunological parameters were determined. The daily gain of calves from the AXT group was higher than from the control group before the weaning (766 vs 633 g) and after (1,428.3 vs 1,341.5 g) ($P\geq 0.05$). There were no significant differences between the group in haematological and biochemical parameters except the total cholesterol and LDL fraction which were lower for AXT group. The iron content in the blood were also higher for AXT group. There were no statistical differences between IgA and IgM and IgG at the end of the experiment but IgG (13.39 vs 11.46 mg/g) and IgA (1.29 vs 0.97 mg/g) was higher for AXT group before the weaning. There was found positive influence of astaxanthin on calves health and immunity up to 56 d of age.

Strategic grouping of dairy beef calves on arrival at a rearing unit

D.J. Bell, C.S. Mason, K.C. Henderson, M.J. Haskell and C.-A. Duthie

SRUC, Peter Wilson Building, West Mains Road, Edinburgh. EH9 3JG, United Kingdom; david.bell@sruc.ac.uk

There is an increasing trend in the number of dairy beef cross calves being born on dairy farms in the United Kingdom. The majority of these calves are sold off farms pre-weaned for further rearing on dedicated calf rearing units where they enter the dairy-beef production cycle. On these rearing units, such calves are exposed to new environmental and disease challenges as well as often being mixed with other calves from multiple farms. The aim of this preliminary study was to strategically group calves when they arrived on a rearing unit and assess their health and performance after a period of time on the rearing unit. One hundred and forty calves were sourced from seventeen dairy farms within a seventy-mile radius of the rearing unit. The calves ranged from 10 to 67 days of age (mean 26 days). On arrival, the calves were lung ultrasound scanned (LUS) and scored on a scale from 0 (normal aeriated lungs) to 5 (consolidation observed in three or more lung lobes). The calves were also Wisconsin health scored (WS) and weighed. Using this information, calves were then assigned to one of five groups: (1) 'High health' (HH) (LUS 0/1 & WS ≤ 2); (2) 'Low health' (LH) (LUS ≥ 3 & WS ≥ 3); (3) 'Intermediate health' (INT) (LUS 2/3 & WS ≤ 2); (4) 'Mixed health' (MIX) (a proportion of calves (50%) LUS ≤ 2 & WS ≤ 2 along with a proportion of calves (50%) with LUS 4/5 & WS ≥ 2); and (5) 'Normal farm practice' (NFP). The NFP for grouping calves was to keep calves from the same source farm together in the same pen. All calves were weighed, LUS and WS again after 22 days of being on the rearing unit to coincide with the farms routine for handling calves, thus allowing a daily liveweight gain (DLWG; kg/d) to be calculated. A relatively large proportion of the calves (62%) were observed with signs of lung consolidation (LUS ≥ 3) on arrival at the rearing unit. Younger calves had lower LUS on arrival at the rearing unit. Calves grouped as LH had a higher DLWG compared to calves grouped as HH but lower than NFP. The results of this preliminary study highlight some areas of interest that require further investigation.

Session 43

Poster 23

Calves sexing and crossbreeding to optimize the destination of the young from French dairy farms

S. Dominique

Institut de l'Élevage, 23 rue Jean Baldassini, 69364 Lyon cedex 07, France; sandra.dominique@idele.fr

Destination of calves from dairy farms is subject of societal polemics. Indeed, for some dairy breeds, economic value of young male calves is minimal while the export in live of these calves to European countries is contested. In 2022, 370.000 French dairy male calves were exported in Europe to be fattened as young bulls. This number keeps increasing every year: number of French dairy calves exported increased by 58% between 2017 and 2022. In parallel, the number of slaughtered calves in veal calves sector decreased by 6,7% from 2021 to 2022 due to the reduced activity of French integrators and the increase of production costs. Using sexed semen can be a lever for farmers who wants to structure differently calves' destination from his dairy farm. Used in addition with meat crossbreed inseminations and genotyping, it becomes an asset to manage the renewal and calves' valorisation: farmers can choose the sex of calves born. We assessed the evolution of the use of sexed semen in France since 2010 by using the data from the French information genetic system. Our results show a quick expansion from 2010 till 2015, followed by a slow decreased till 2019, and finally a new impulse in its deployment. Data from French suckler farms show a less use of animal inseminations. The proportion of sexed semen used in suckling farms represents only 3% of all sexed semen inseminations in France. Initially used as a last attempt for a non-pregnant dairy cow after several inseminations, the number of first crossbreed animal inseminations with a suckler breed sire as doubled from 2014. Contrary to sexed semen, meat crossbreeding inseminations did not know a decrease in activity. Recent data confirm that volume is still growing. Detailed analysis showed a connection between size of the farms and use of sexed semen. This reproductive tool, associated with meat crossbreed inseminations is useful to focus selection effort on targeted cows and valorise other calves by meat production. Prospects for the evolution of these practices are subjects to various factors. It is not easy to pronounce on the situation tomorrow, but this is a useful tool to optimize valorisation of necessary calves born in dairy sector and a lever to limit exported volumes calves.

Inclusion of grass silage in finishing total mixed rations for rosé veal calvesM. Vestergaard¹, M. Bjerring¹, A.L.F. Hellwing¹, M.B. Jensen¹, B. Muhlig¹, L. Mogensen¹ and N.B. Kristensen²¹Aarhus University, Dept Anim & Vet Sci, Foulum, 8830 Tjele, Denmark, ²SEGES P/S, Agro Food Park, 8200 Aarhus N, Denmark; mogens.vestergaard@anivet.au.dk

Finishing rations in rosé veal calf production are often pelleted feed combined with straw or total mixed rations with maize-silage as sole forage source. Cereals are the dominating starch source and canola meal the protein source. These rations can compromise ruminal health, due to sub-acute rumen acidosis, rumen wall damages and establishment of liver abscesses. Regarding climate issues, these rations keep the methane production low, but the Carbon Footprint of the feed production is often higher than for grass-based rations. The present study aimed at comparing a grass silage-based TMR (Gr) with a corn-cob-based TMR (Ye) on performance, eating behaviour, methane production and carcass quality. Ye consisted of corn-cob silage, rolled barley and rapeseed meal whereas Gr consisted of rolled barley, 1 cut grass silage (25-35% of DM) and untoasted milled fava beans. DM%, crude protein, NDF, starch, and NE were similar but differed in fill value and physical structure. Holstein bull calves (155 kg) were housed in pens of 8 with two automated feeders per pen. Within each pen, 4 calves had access to Gr and 4 to Ye. A total of 8 pens was used. Calves performed equally well on both rations ($P>0.10$), with Gr being numerically best. Feed intake was similar, but Ye calves ate more meals than GR and spend more time eating from the straw-bedding. Accelerometers showed higher rumination activity on Gr vs Ye but similar lying time and health index. Methane production was 13% higher for Gr than Ye ($P<0.10$). When slaughtered 1 year old, at approximately 500 kg, LW was numerically 3% higher for Gr than Ye ($P>0.10$) and carcass characteristics were similar including lean-fat colour. In Gr calves, two liver abscesses were detected and 5 in Ye. In conclusion, both grass silage and fava beans can replace corn-cob silage and canola meal in TMR for rosé veal calves with a tendency to alleviate the high prevalence of liver abscesses.

Session 43

Poster 25

Veal calves' housing in France: current situation and investment needs

M. Tourtier and C. Martineau

Institut de l'Elevage, Qualité des carcasses et des viandes, 8 route de Monvoisin, 35650 Le Rheu, France; christophe.martineau@idele.fr

A survey on veal calves' housing was conducted by the French Livestock Institute, commissioned by INTERBEV Veaux. The main objective was to establish an inventory of the age, state of disrepair and consistency of veal calves' housing in France. A second objective was to estimate the cost needed to modernize the veal calves' housing according to different scenarios that meet the needs expressed by the veal sector. In 2019, the survey was deployed to all French veal calves' breeder via a questionnaire accessible on internet. The answers of 405 farms (i.e. 20% of the French farms) were analysed, representing 583 farm buildings for 122,000 fattening places. The average of size of the farms surveyed was 351 places, with notable differences depending on the region. The farms had an average of 1.6 buildings with a capacity of 213 places. The buildings' average age was 20.7 years. The answers obtained in this survey and those collected in the INOSYS network farms make it possible to provide quantified cost for the modernization of the 'France' farm according to 5 scenarios: biosecurity, health/welfare, work/automation, environment and outdoor access for animals. According to the assumptions, the cost of modernizing buildings extrapolated to all 2,391 French farms in 2019 ranges from 35.8 million euros for 'biosecurity' scenario to 237.2 million euros for 'environment' scenario. 'Outdoor access for animal' scenario has not been qualified, as none of the farms surveyed could evolve in this direction without calling into question the very organisation of the existing buildings or without incurring disproportionate investments. This scenario should therefore only be considered in the case of construction of new buildings. In conclusion, it is clear that veal calves' housing must evolve by taking into account societal expectations in terms of environmental protection, animal health and welfare and landscape quality. It seems equally important to consider the way in which the 'French' farm must adapt to preserve or even improve the organisation of work and ensure a fair remuneration for breeders, and thus guarantee the sustainability of the veal sector.

Evolution of the use of antibiotics in the veal calves' sector in France between 2013 and 2020

M. Chanteperdrix¹, A. Chevance², M. Orlianges³, D. Urban², M. Tourtier¹ and P. Briand⁴

¹Institut de l'Elevage, Qualité des Carcasses et des Viandes, 8 route de Monvoisin, 35650 Le Rheu, France, ²Agence Nationale du Médicament Vétérinaire (Anses-ANMV), 14 rue Claude Bourgelat, 35133 Javené, France, ³INTERBEV, 207 rue de Bercy – TSA 21307, 75564 Paris Cedex 12, France, ⁴Chambre Régionale d'Agriculture de Bretagne, Rue Maurice Le Lannou – CS 74 223, 35042 Rennes Cedex, France; manuel.tourtier@idele.fr

The veal sector participates in Ecoantibio2017 plan by implementing an ambitious program to know the practices and identify levers for effective action to reduce the use of antibiotics on farms. ANSES-ANMV and the French Livestock Institute were commissioned by INTERBEV Veaux to set up a permanent observatory to estimate the quantities of antibiotics in veal calf farms. This national system was set up in 2016 and is based on active collaboration of breeders, integrators, producer groups and veterinarians and on the support of engineers of the Chamber of Agriculture in Brittany. The observatory is made up of 30 volunteer breeders located in 6 departments of western France. They represent nearly 15,000 calf places, raised in production systems representative of national feeding and housing practices. Farms work for 9 integrators or producers' groups. In 2020, data from 47 calf batches (16,553 animals) were analysed. ALEA is the main standardized indicator used in France for the annual sales reporting of antibiotics and reached 3.14 in 2020. In the survey carried out by ANSES-Lyon in 2013 on 186 batches of calves, the average ALEA was 5.86. Based on this indicator, the exposure of calves to antibiotics decreased by 45.3% between 2013 and 2020.

Resilience4Dairy: sharing knowledge to improve sustainability and resilience of the dairy sector

V. Brocard¹, M. Klopčič² and J. Boonen³

¹Institut de l'Elevage, 8 route de Monvoisin, 35650 Le Rheu, France, ²University of Ljubljana, Kongresni trg 12, 1000 Ljubljana, Slovenia, ³LTA, Kréiwenkel, 9374 Gilsdorf, Luxembourg; valerie.brocard@idele.fr

R4D – which stands for Resilience for Dairy – is an EU-funded project which aims at improving the European dairy sector's sustainability and resilience. To achieve this goal, the 18 partners of R4D have created a network enabling the exchange of practical and scientific knowledge among European dairy farmers, researchers and other relevant stakeholders. They will focus on 3 Knowledge Areas: economic & social resilience, technical efficiency and environment, animal welfare and society friendly production systems. Those issues are often addressed separately. However, they are interconnected and depend on the livestock farming system, rearing management, people involved in the production process, feeding and material resources, and level of use of innovation. R4D aims to build bridges between them in an innovative cross-fertilization, crowd-innovation and transdisciplinary approach, focusing on Best Practices allowing optimal benefits to be achieved in all three. The overall objective of R4D is to develop and to strengthen a self-sustainable EU Thematic Network on 'resilient and robust dairy farms' designed to stimulate knowledge exchanges and cross-fertilization among a wide range of actors and stakeholders of the dairy industry. The six specific objectives of the project are the following: (1) structuration of the networks by selecting and connecting innovative resilient farms and relevant Operational Groups into National Dairy AKIS; (2) prioritization of farmers' needs to improve resilience and robustness of dairy farms; (3) matching farmers' needs with the inventory of best practices & setting-up of fine-tuned Knowledge Work Plans; (4) implementing collective evaluation and assessment of solutions (including cost-benefit analysis); (5) adaptation and translation of the Best Practices for practitioners; and (6) communication, dissemination and demonstration of the results and best-practices. The aim of R4D is to widely disseminate relevant ready-to-use best practices based on innovations, facilitating knowledge exchange from farmers to farmers.

Indicators and influencing factors of livestock resilience*I.D.E. Van Dixhoorn¹, J. Ten Napel¹, A. Mens¹ and J.M.J. Rebel²**¹Wageningen Livestock Research, P.O. Box 2176, 8203 AD, the Netherlands, ²Wageningen Bioveterinary Research, Houtribweg 39, 8221 RA Lelystad, the Netherlands; ingrid.vandixhoorn@wur.nl*

Current livestock production systems in Europe have been developed on the premise of a need for supplying more food with the greatest efficiency and least risks. Therefore, these systems have been designed to maximize productivity under well-controlled conditions. This has contributed to highly productive and efficient food production systems. However, we now realize that this strategy has led to vulnerabilities, especially concerning animals in livestock production systems. One of the big questions is how we shift focus from maximized production efficiency towards a system that maximizes animal resilience instead of making the animals more dependent on well-controlled conditions. Then impact of diseases can be reduced simultaneously with the use of antibiotics and the need for animal mutilations, aiming for a more sustainable production. Animal farming utilizing animal resilience starts with farming conditions that are acceptable to society and a level of management that the majority of qualified stockmen can provide. In such farming systems, animals can be bred and prepared for common day-to-day disturbances. Animal resilience can only be explored in an environment that is representative of commercial farming systems in terms of health, climate, housing conditions and diet quality. Differences in resilience between animals can be quantified by measuring variation in longitudinally recorded traits, such as daily milk production, body weight gain, activity patterns, heart rate or body temperature. Resilience at animal level is defined as the capacity of an individual to be minimally affected by disturbances or to quickly recover. A shift in strategy towards more resilient production animals therefore requires indicators of animal resilience as well as knowledge of what factors can be used to influence it. We present concepts of resilience that can be applied in research and give examples of indicators of animal resilience as well as influencing factors in dairy cows and other animals.

Session 44

Theatre 3

Reducing stress of dairy cows and farmers to improve resiliency and welfare*M.T.M. King¹ and T.J. De Vries²**¹University of Manitoba, Department of Animal Science, 12 Dafoe Road, R3T 2N2 Winnipeg, Canada, ²University of Guelph, Department of Animal Biosciences, 50 Stone Road East, N1G 2W1 Guelph, Canada; tdevries@uoguelph.ca*

The dairy industry has, in many ways, always had to be resilient and adaptable to be able to survive and thrive in changing circumstances. The fact that the dairy industry has been able to continue to produce and succeed through rapidly emerging challenges is a testament to the resiliency of the cows, farmers and other professionals who make up the sector. In recent years, however, many of those changes and challenges have become more pronounced and may threaten the sustainability of the industry. One of those challenges that continues to face the dairy industry is stress, both on dairy cows as well as those who take care of them. Stressors can have both physiological and psychological effects on dairy cows, which can lead to changes in cow behaviour and health status, negatively impacting cow production, reproduction, and welfare. Interestingly, there is growing evidence that the welfare of dairy cows, including their health, is related to the well-being of dairy farmers. There is evidence that farmers may experience higher levels of stress, anxiety, and depression than the average citizen. In such a high stress occupation, physical and mental stress may wear down an individual's ability to cope with complex problems; this may affect how dairy farmers deal with the animals in their care. Therefore, when considering ways to reduce stress for dairy cattle and improve their welfare, focus should also be on improving the well-being of the farmer. Combined efforts to reduce stress, and improve welfare, both of dairy cows and their caretakers, will contribute to maintaining resiliency in the dairy industry.

Building resilience in the dairy sector of China

S. Li, W. Wang, W. Du, X. Sun, K. Yao and J. Xia

China Agricultural University, Beijing, 100193, China, P.R.; lisheng0677@163.com

The Chinese dairy sector has undergone a fundamental transition in recent decades, with traditional smallholders being largely replaced by industrial and specialized farming systems. By 2022, the proportion of dairy cattle kept on farms with more than 100 head reached 73%. The intensification of the dairy sector has been accompanied by rapid improvements and the application of modern industrial technology, particularly in feeding strategies and farm management. For instance, there has been a significant improvement in the nutritional conditions of roughage, as TMR (Total Mixed Ration) feeding technology and high-quality whole-plant corn silage have become widely used. Additionally, almost all large-scale dairy farms in China have adopted mechanized milking. According to data published by the National Dairy Industry and Technology System, the average annual milk production per cow on large-scale dairy farms in China reached 10.1 tons in 2022. Furthermore, manure management has greatly improved with the implementation of more advanced treatment facilities, such as those that produce biogas. These advancements have contributed to the promotion of overall industry quality and resilience. Despite these achievements, the Chinese dairy sector faces numerous challenges in areas such as industry chain integration, self-sufficiency in milk and feed raw materials, improvement of cow breeding, reducing production costs, carbon mitigation management, animal welfare, and environmental pollution. China's per capita dairy consumption is only 60% of that in developed Asian countries. Given the prediction that there will be mild growth in national milk consumption in China over the coming decade, it is crucial to address these challenges and work towards a more resilient and sustainable Chinese dairy sector.

Session 44

Theatre 5

Building resilience in farming: dairy cattle and workforce managementG.M. Schuenemann¹ and J.M. Piñeiro²¹The Ohio State University, Dept. of Veterinary Preventive Medicine, Columbus, OH, USA, ²Texas A&M University, Dept. of Animal Science, Amarillo, TX, USA; schuenemann.5@osu.edu

To ensure long-term sustainability of dairy farming, it is essential to build a resilient workforce. Dairy farms in US are consolidating at a faster rate today than any other agricultural commodity. In January 2022, the dairy cattle inventory was 9.3 million cows distributed among 30,000 farms, with an average annual productivity per cow of 11,000 kg of milk. About 50% of licensed dairy farms, mostly with less than 500 cows, ceased operation in the past 20 years at a rate of about 2,300 farms per year without changing the national milk cow inventory. Today, about 5% of US dairy farms are milking 60% of cows with an average herd size of about 3,300 cows. The farm workforce shortages have been an issue for the past few decades and 75% are immigrant workers. This is influenced by demanding work schedules and physically demanding jobs, limited access to educational opportunities or simply individual preferences to live near larger urban communities with greater access to developed infrastructure (e.g. internet, health services, entertainment, schools). Some dairy farms have been able to reverse this labour shortage by providing their employees with housing, covering expenses associated with transportation, offering educational opportunities and work-related clothing. The dairy community faces challenges (e.g. extended drought, increased regulations, changing consumer preferences, workforce shortages) as well as opportunities (e.g. growing demand and precision technology). The adoption of advanced technologies such as automation and data analytics can help reduce labour costs and improve the overall productivity and efficiency of farm operations. However, these solutions include investing in education and training programs, enhancing workplace safety and health, and promoting diversity and inclusion in the workforce. Today, leading dairy operations are completely integrated with an established network of suppliers and professionals, actively engaged with their local communities with a logistic that goes from the farm to consumers. Farms have been integrating best animal welfare and sustainability practices with strong emphasis on prevention and continuous improvement.

Working on resilience in the Ukrainian dairy sector*L. Stepura**Scientific and Methodological Center for Higher and Pre-Higher Vocational Education, Smilianska str. 11, 03151 Kyiv, Ukraine; ludmila.stepura@gmail.com*

The resilience of the dairy sector in Ukraine depends firstly on the cooperation with producers of raw milk. This is especially the case under the conditions of the war. The resilience of raw materials production and adaptation to the real conditions are impacted by many factors: transport logistic, (un)interrupted supply of electricity, use of generators (that leads to production cost increase), mobilization of professionals to the Ukrainian army, etc. The large-scale invasion of the Russian occupiers on the Ukraine territory affected both, producers of dairy raw materials and their processors and consumers. The supply chains between farms, processing plants and trade networks have been disrupted. In order to improve the economy of feeds, farmers started to feed cows only twice per day, which reduced milk yield. In the occupied territories, farms were completely or partially destroyed. The number of cows in all categories of farms decreased by 13.1% in 2022; as a result, the industry did not receive 1 million tons of milk (volume was 8.7 million tons in 2021). Dairy farms in the de-occupied and frontline areas are / will not be able to produce fodder for livestock without demining of their fields and will be forced to reduce or completely close dairy production. Nevertheless, some time after the start of the large-scale war, the country's dairy sector managed to adapt to the new conditions. However, in autumn of 2022, the industry also experienced problems caused by the deliberate damage to the energy infrastructure, but Ukrainian producers also later adapted to these challenges. Nowadays, the dairy sector meets the needs of the domestic market despite considerable industry losses. Due to significant migration of citizens to abroad, the domestic market of dairy products consumption reduced. According to the Association of Milk Producers, the production of milk in 2022 compared to 2021 decreased by 12.1 to 7.66 million tons. The figures for the fall in milk production could have been much higher, but thanks to the efficient functioning of dairy farms in safer regions and the relocation of livestock from war-affected areas, losses were minimized. In particular, the central and western regions of Ukraine increased milk production due to business relocation and increased demand for raw materials.

Session 44

Theatre 7

Future scenarios for livestock agriculture in New Zealand*C. Vannier¹, T. Cochrane², L. Bellamy², T. Merritt², H. Quenol³ and B. Hamon²**¹Landcare research, 54 Gerald Street, 7608 Lincoln, New Zealand, ²University of Canterbury, 20 Kirkwood Avenue, 8041 Christchurch, New Zealand, ³CNRS, place du recteur Henri le Moal, 35043 Rennes, France; vannierc@landcareresearch.co.nz*

Agriculture in New Zealand (NZ) faces disruptions from climate change, increasingly stringent environmental regulations, and emerging technologies. Given the importance of agriculture to the NZ economy, government and industry need to develop policies and strategies to respond to the risks and opportunities associated with these disruptors. Livestock production in NZ represents 64% of the agricultural export revenue and 85% of agricultural GHG emissions, mainly from methane and nitrous oxide. There is a research gap in understanding how future disruptions from climate and technology could impact on the environment and productivity. To address this gap, we have developed and applied an assessment tool of NZ livestock farming systems to explore pathways and interventions for increasing agricultural resilience, sustainability, and profitability over the next 5-30 years. A systems dynamic model developed using Stella Architect was designed as a Decision Support Tool (DST) to bring together production, market values, land use, water use, energy, fertiliser consumption, and emissions for each of the main agricultural sectors (dairy, beef, sheep, cereals, horticulture, and forests). The parameters are customisable by the user for scenario building. With stakeholder consultation, scenarios were designed to assess pathways and interventions to underpin strategy initiatives in the arable, dairy, and beef & lamb sectors related to food security and climate change adaptation and alternative protein production. Simulation results suggest potential synergistic opportunities between sectors to enhance productivity and reduce emissions. Achieving food security and cereal self-sufficiency in NZ through a multi-sectoral approach and the development of an alternative protein market (100% NZ branding) could lead to carbon emission reductions and improvement of carbon sequestration. Furthermore, the interactive DST and simulations improved stakeholder engagement, which can facilitate future land planning and policy formulation.

Breeding approaches to improve robustness and resilience in dairy cows*K. May and S. König**Institute of Animal Breeding and Genetics, Justus-Liebig-University Gießen, Ludwigstraße 21B, 35390 Gießen, Germany; katharina.may@agrar.uni-giessen.de*

Dairy cows are exposed to environmental challenges including rising and fluctuating temperatures, or increasing pathogen infection pressure due to resistances against available drugs. Against this background, it is imperative to develop breeding strategies for improved robustness and resilience. Robustness reflects the cow's adaptation ability to environmental challenges, implying improved disease resistance and tolerance to environmental stressors by maintaining high production (e.g. milk). A resilient cow is robust and recovers quickly from disease. Genetically, breeding for robustness suggests the selection of genotypes with stable genetic values in different environments, i.e. animals being robust against the impact of genotype-by-environment interactions. Classical breeding approaches focus on the analysis of simple production traits in dependence of environmental descriptors including herd management or climate characteristics by applying reaction norm and random regression models. Such approaches can be enhanced by considering novel functional traits reflecting health, metabolic stability or resource efficiency, and by a more detailed description of the farm environment including feeding or emission aspects. Hence, the general approach of genotype-by-environment interactions can be extended. Insights into the causal genetic mechanisms of cow health are possible when considering genomic data, i.e. dense marker genotypes, genome sequences or gene expression data. Approaches in this regard are genome-wide association studies with the ongoing annotation of potential candidate genes, up to the study of gene expressions in different environments. In ruminants, a further genetic contribution is due to the genetics of the microbiome, addressing novel studies on genotype-by-genotype interactions. Similar methods are suggested when studying the genetic mechanisms of disease resistance, i.e. simultaneously considering the genotype of the host (cow) and the genotype of a pathogen (e.g. endoparasite). Setting-up genetic relationships or similarity matrices for both species (host and pathogen) allow deeper insights into the functional diversity, being a main driver for selection response in a long-term perspective.

Session 44

Theatre 9

Resilience from the perspective of farm economics*E. Koloszytz and A. Wilczyński**West Pomeranian University of Technology in Szczecin, Department of Management and Marketing, al. Piastów 17, 70-310 Szczecin, Poland; ewa.koloszytz@zut.edu.pl*

In an era of increasingly emerging economic, social, environmental and institutional shocks, the importance of farm capacity for survival and further development is increasing. The capacity of farms for robustness, adaptability and transformability serves to build resilience to various types of shocks in the perspective of short- and long-term changes in the environment. The three abilities mentioned are correlated and mutually reinforcing. This means, for example, that robustness in the short term is essential for transformability in the long term. The economic aspect is one of the three most important dimensions of resilience beyond the social and environmental dimensions. Economic resilience can be defined as the ability of a farm to maintain economic viability in the face of emerging turbulence (e.g. market and production risks and policy changes), including the ability to transition to a new equilibrium state. The main objective of this research is to assess the economic resilience of selected European dairy farms and diagnose the life cycle phase they are in. Two types of economic resilience were used for comparative analysis: short-term resilience and long-term resilience. The subjects of the research are groups of farms specializing in dairy farming located in the observation field of the European FADN (type 45 in the FADN Public Database). The research area consists of producers operating in the fifteen countries of the European Union represented in the Resilience for Dairy (R4D) project. The research was conducted in groups of farms classified by economic size, adopting the ES6 typology. The research covers the years 2011-2020, when farms operated under different legal conditions, i.e. during milk quotas and after the abolition of milk production limits. Preliminary results showed that farms with a larger scale of production have higher short-term economic resilience, but also lower long-term resilience compared to farms with a smaller economic size. Of all the farm groups analysed, most of them were in the survival phase. This means that the farms surveyed had problems covering the costs of unpaid labour.

Labour: a key factor in the resilience of the European dairy farmer

S. Debevere¹, L. Dejonghe¹, I. Louwagie¹, I. Vuylsteke¹, E. Béguin², S. Fourdin², P. Rondia³, L. Boulet³, S. Mathieux³ and G. Elluin⁴

¹Inagro vzw, Ieperseweg 87, 8800 Rumbek-Beitem, Belgium, ²IDELE, 54-56 avenue Roger Salengro, BP 80039, 62051 St Laurent Blangy, France, ³Centre wallon de Recherches Agronomiques, Rue de Liroux 8, 5030 Gembloux, Belgium, ⁴Chambre d'agriculture du Nord Pas de Calais, 54-56 avenue Roger Salengro, BP 80039, 62051 Saint Laurent Blangy, France; sandra.debevere@inagro.be

In the Horizon 2020 project 'Resilience for Dairy', 82% of questioned people in the European Dairy sector indicated that work-life balance is an important factor for farmers to be resilient. Indeed, today, dairy farmers are under increasing pressure due to rapid herd growth and increased competitiveness. Rising labour demands are affecting the quality of life of livestock farmers. The Franco-Belgian Interreg project 'CowForme' aimed to create jobs and increase labour efficiency on dairy farms. The aim was to reduce the workload and increase quality of life. By means of a survey, CowForme investigated what were the biggest challenges for farmers to work with staff. Also the motivation and obstacles of jobseekers to work on a dairy farm were explored. The results of the survey will be presented and discussed. In focus groups, several advisors and dairy farmers shared their experiences and possible solutions how to optimize the workload on the farm. In the presentation, some practical examples will be given that were proposed in the focus groups. During the project, many ways were used to spread information to farmers: study tours, videos, webinars, fact sheets, etc. All this information can be consulted at www.cowforme.eu. By small, but efficient solutions, farmers can save a lot of time and improve their work-life balance and resilience.

Resilience of dairy farming: the farmers' point of view

E. Castellan¹, C. Bausson² and V. Brocard¹

¹Institut de l'Elevage, 149 rue de Bercy, 75012 Paris, France, ²Chambre d'agriculture de Normandie, 6 rue des Roquemonts – CS 45346, 14053 Caen Cedex 4, France; elisabeth.castellan@idele.fr

The concept of 'resilience' is not a familiar and concrete one for breeders. Within the frame of EU H2020 Eurodairy program, the French dairy farmers involved in the project proposed a definition from their point of view; then, they imagined a methodology to evaluate it on their farms. Hence a tool named 2MAINS (tomorrow, or 2 hands) was created to simply evaluate the resilience of the farms considering 5 topics (strategy, technical efficiency, economics, social issues, environment). This tool is mainly a good support to start discussions and thought processes on a farm. This process was first implemented with a group of dairy farmers from Hauts de France, then nationally widened with farmers from Normandy, Rhône-Alps and Brittany, to make sure that the steps proposed could fit with various production backgrounds. The second stage consisted in identifying practices considered as resilient for each of the 5 topics, and to share them thanks to video testimonies. These practices were gathered on French farms but also abroad, thanks to the exchange trips organized during the project. These exchanges of innovative best practices are now going on within Resilience4Dairy EU project. The dissemination process about the notion of resilience has also been realized in agricultural schools towards the dairy farmers of the future.

Local breed as an alternative to Holstein-Friesian cows in a farm with low level of milk production*M. Sobczuk-Szul, Z. Nogalski, M. Momot and P. Pogorzelska-Przybylek**University of Warmia and Mazury in Olsztyn, Department of Animal Nutrition, Feed Science and Cattle Breeding, Oczapowskiego 5, 10-719 Olsztyn, Poland; monika.sobczuk@uwm.edu.pl*

Local breeds becomes an interesting option for livestock breeding especially for small producers and in organic systems. Developing local breeds usually requires added value, which could be for example health – promoting ingredients in milk. Although, it is important to generate new approaches to milk production from these breeds and determine the quality of milk from farms with reduced supplementation with concentrates. This study aimed to evaluate the milk quality of black-and white and Holstein Friesian cows under system with reduced use of concentrate, simulating organic production conditions. The experimental material were milk samples collected from 32 cows – 16 of each breed. Cows were in the same barn and similar age and calving date. Milk samples were collected twice in winter season. Average milk production level from this farm was 6,500 kg. Local breed cows had lower milk yield compared to the Holstein-Friesian cows. There were no differences between the content of basic ingredients in milk and between breeds, which may indicate a good use of fodder by black-and-white cows. However the milk produced by local breed proved to be a more valuable source of compounds such as desirable fatty acids or proteins than that of the Polish Holstein-Friesian breed. The results of this study are pave the way for future research, within the pasture feeding period. Project financially supported by the Minister of Education and Science under the program entitled ‘Regional Initiative of Excellence’ for the years 2019-2023, Project No. 010/RID/2018/19, amount of funding 12.000.000 PLN.

Session 45

Theatre 1

Product quality as a lever to change farming practices to meet society’s expectations*V. Thenard¹, S. Couvreur², L. Fortun-Lamothe³, B. Méda⁴ and T. Petit²**¹INRAE, UMR AGIR, centre INRAE Occitanie Toulouse, 31327 Castanet-Tolosan, France, ²ESA, URC URSE, ESA Angers, 49007 Angers, France, ³INRAE, UMR GenPhySe, centre INRAE Occitanie Toulouse, 31327 Castanet-Tolosan, France,**⁴INRAE, UMR BOA, L’Ofrasière, 37380 Nouzilly, France; vincent.thenard@inrae.fr*

Product quality has long been the focus of taste improvement in livestock products. Today, new approaches induced by stakeholders aim to introduce new practices into specifications that meet society’s expectations. These changes may emerge at different levels of scale and initiative (private operators, groups of players or entire sector). Based on examples, we show how the evolution of specifications or new approaches meet expectations of society and how practices are being modified. The PDO-PGI labels increase the exigence about environmental issues and local feed use by animals. In milk sector, the cheese production now involves improving the sustainability of farming practices. A commercial approach with the BBC brand aims at modifying the animals’ diet to improve the nutritional aspect, mainly by increasing grass for ruminants, or using linseed for other animals. For poultry, the ‘European Chicken Commitment’ aims to improve welfare of conventional chicken production. This initiative focuses on several farming practices to improve animal welfare, and many operators have agreed to evolve them by 2026. In the rabbit sector, cooperatives and the largest French rabbit slaughterhouse has developed a new system for raising rabbits in large pens on the ground (‘Lapin et Bien’ brand). The aim was to take better account of animal welfare, and opposition with cage farming. In the beef sector, a new demand for red, tender and marbled meat is born especially in restaurants and butchers. To date, this type of meat is mainly imported. A wholesale butcher company has developed an integrated local chain with cattle farmers to adapt breeds, and practices to improve sustainability. These approaches are evaluated with criteria to assess sustainable livestock farming for tomorrow (feed-food competition, climate change mitigation, nutritional intake and animal welfare). In addition to the co-construction of the technical system between the stakeholders, the approach is also based on shared governance, and a better price for the farmers.

Transformation in the dairy sector: a global analysis of sustainability certification standardsK. McGarr-O'Brien^{1,2}, J. Herron¹, L. Shalloo¹, I.J.M. De Boer² and E.M. De Olde²¹Teagasc, Animal and Grassland Research and Innovation Centre, Moorepark West, Fermoy, County Cork, P61 P302, Ireland, ²Wageningen University & Research, Animal Production Systems, P.O. Box 338, 6700 AH Wageningen, the Netherlands; keeley.mcgarra@wur.nl

In the transformation of the livestock sector, private certification standards are increasingly used to meet demand for sustainable dairy production. Research into these standards is, however, lacking. In this study we characterized sustainability certification standards currently used in dairy production globally. A literature search for dairy sustainability initiatives yielded 116 results. Based on selection criteria, 19 of these initiatives qualified as 'sustainability certification standards'. We analysed the 19 standards from three perspectives: (1) the general characteristics; (2) the sustainability themes addressed within each standard; and (3) and the credibility, accessibility, and continuous improvement (also referred to as the 'devil's triangle reflecting the trade-offs in standards). Examining general characteristics of the 19 standards revealed variation in governance, verification processes as well as the demands the standards place on farmers. The variation was recognized also in the sustainability focus between standards, and comprehensiveness of sustainability focus. The most frequently and comprehensively addressed sustainability pillar is the environmental; the least frequently and comprehensively addressed is the economic pillar. The accessibility and credibility of standards are most clearly described and declared within most standards' documents. Whereas continuous improvement is an infrequent area of focus for standards. The variability revealed by this study demonstrates the challenge of using certification standards as proof of sustainability. This could negatively impact upon consumer trust in sustainability certification, as well as impairing the potential use of certification standards as proof of sustainable development in the dairy sector.

Session 45

Theatre 3

The analysis of a co-design process to develop an eco-citizen dairy cattle farming system experimentJ.E. Duval¹, M. Taverne¹, M. Bouchon² and D. Pomiès³¹INRAE, Université Clermont Auvergne, AgroParisTech, INRAE, Vetagro Sup, UMR 1273 Territoires, site de Theix, 63122 Saint-Genes-Champanelle, France, ²INRAE, UE 1414 Herbipole, site de Theix, 63122 Saint-Genes-Champanelle, France, ³Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, site de Theix, 63122 Saint-Genes-Champanelle, France; julie.duval@inrae.fr

The implementation of step-by-step design approaches of farming systems experiments could be a promising way to produce knowledge useful for the transition to new systems. Moreover, it is hypothesized that innovation towards sustainable farming can benefit from combining scientific and expert knowledge. However, co-innovation research processes remain often abstract concepts without a shared understanding of how to carry it out. The objectives of this study are to characterize the step-by-step co-design process of a farming system experiment. The interactions during the first 2 years of the co-design process aiming at designing an 'eco-citizen' dairy cattle farming system were analysed. The process involved livestock farmers, actors of the local dairy value chain and scientists of the public sector. By analysing the co-design process, we show that the format of the co-design activities strongly affected participation rates. Different formats allowed different frequencies of interactions. The experiment leaders rapidly focused the co-design process on the design object 'farming system' and on operational practices (e.g. ideas on practices to manage animal health). However, participants did not always limit themselves the design object or the conception levels by the leaders targeted. Participants also targeted, for example 'the way the group works together during the co-design process' or focused the attention again on the clarification of the objectives. In addition, participants carried out more collaborative design activities than asked from them, by participating in cognitive synchronisation activities for example. These results provide certain elements to understand how co-innovation processes can be enacted, and characterize challenges and possible lessons learned for future co-design experiences.

Perceived quality of meat products in short circuits by producers and their customersC. Couzy¹, G. Haj Chahine¹, V. Diot², S. Masselin-Sylvain¹, S. Meurisse¹, M. Klingler¹ and C. Bièche-Terrier¹¹Idèle – Institut de l'Élevage, 149 rue de Bercy, 75012 Paris, France, ²IFIP, La motte au Vicomte, 35651 Le Rheu, France; ghida.haj-chahine@idele.fr

Within the framework of the VICTOR project, 40 cattle and pig farmers working in short circuits, 77 consumer clients and 9 managers of commercial or collective catering services were questioned about the quality of meat and meat products during in-depth interviews in four different regions in France. For the farmers, the organoleptic quality of their products is essential. Moreover, they strongly emphasize the interest of their farming practices and the services they offer to their customers. It is essential for them to make the link between their farm and the product, to distinguish themselves from the industry by showing the artisanal aspect of their products. The 77 consumers indicated that they were happy with the varied offer. The relationship of trust they have with the farmers, with whom they talk directly and whose animals they can see, is a major factor in their positive perception of product quality. Many elements of the farmers' discourse are also found among their costumers' answers. The geographical proximity of the farmer is a determining factor for the consumer and the more functional role of short circuits was partly observed in two of the study territories with low population density and more distant commercial basins. Regarding the chefs in the catering industry, they have difficulty finding farmers who can meet their requirements, particularly in terms of securing supply volumes. They and their customers are satisfied with the quality of their products and globally there is less waste. Around one hundred online surveys, conducted throughout France, broaden the panel of farmers' answers. They show that farmers working in short circuits are most concerned by controlling production and manufacturing hygiene, and by guaranteeing their products' origin. They do not feel completely at ease with the legal constraints of the activity such as regulations, labelling rules, setting products' shelf life, etc. For farmers, the short circuit activity requires a lot of manpower. They often call upon service providers, employees, or volunteers for different tasks such as cutting, processing, packaging, delivering, and selling.

Session 45

Theatre 5

Value-adding attributes for dairy calves within local beef sector – perceptions among stakeholdersL. Schönfeldt^{1,2}, M.G.G. Chagunda¹ and N. Ströbele-Benschop²¹University of Hohenheim, Animal Breeding and Husbandry in the Tropics and Subtropics, Garbenstr. 17, 70599 Stuttgart, Germany, ²University of Hohenheim, Applied Nutritional Psychology, Fruwirthstr. 12, 70593 Stuttgart, Germany; lea.schoenfeldt@uni-hohenheim.de

Value-added inclusion into the local beef sector is a strategy to improve ethical and economic appreciation for surplus dairy calves. This study aimed to investigate the role of animal welfare and sustainability, on improving dairy calf's marketability within a potential dairy beef value chain. For successful inclusion, awareness of the dairy calf issue, relevance, and willingness to pay for value-adding attributes need to be better understood at both ends of the value chain. A survey on perceptions of calf welfare and sustainability within dairy production was carried out in the state of Baden-Wuerttemberg, Germany. Data from 127 dairy farmers and 288 consumers on relevance of selected attributes for calf welfare and sustainability were captured using rating scales (mean $\pm$ standard deviation). Participants rated physical calf health (1.18 ± 0.55) as most important attribute, followed by a fair compensation for farmer's work (1.26 ± 0.63), calf's space requirement (1.29 ± 0.63), regional food production (1.52 ± 0.91) and avoidance of long-distance transport (1.61 ± 0.97). Contrary to consumers, farmers rated attributes of calf welfare (2.43 ± 0.84) as less important compared to sustainability attributes (1.63 ± 0.66). Dietary habits and awareness of the dairy calf issue influenced relevance of certain calf welfare attributes positively. Practicing organic dairy farming was positively correlated with relevance of sustainability and welfare attributes within the farmers' group. Consumers declared highest willingness to pay a premium for milk (0.43€/litre) and beef (2.63€/kg) derived from cattle, raised under increased welfare standards. This study indicated consensus among dairy farmers and consumers regarding existing importance of the calf's wellbeing and aspects of sustainability within dairy production. Dietary habits and individual understanding of welfare and sustainability might shape farmers and consumers perception. Stakeholder analyses, investigating the feasibility of the inclusion into the local beef sector are proposed throughout the whole dairy beef value chain.

Farmpédia: how to improve the global acceptability of livestock systems with communication*A.-L.J. Thadee and G. Brunschwig**VetAgro Sup, UMR Herbivores, 89 avenue de l'Europe, 63370 Lempdes, France; anne-laure.thadee@vetagro-sup.fr*

Farm and animal products and technics have in common to be both used and unknown from the vast majority of citizens. Life in the city, far from the countryside, cuts children off from the rudiments of nature. High school and college teachers often neglect those topics. This situation is all the more marked as the information available to young citizens comes first from television, second from their entourage and third from school. We have therefore chosen to produce resources for teachers (Farmpédia) and short videos (2-5 mn) for young people. Farmpédia is a multimedia encyclopaedia, designed by researcher to tackle this issue. It offers a series of thematic chapters, enriched with data, from science article to press article, videos and real-life testimonials. We start with a French version in 2020 and develop an English version in 2023. To interest a younger audience, and embody the principles of ranching, we have decided to offer a series of experts to answer societal questions, in addition to offering clear definitions of certain points of jargon. At this point, the results are a better understanding of some of the key points of ranching for the people in reach of our media. The work began by defining the questions to be asked of the specialists, which correspond to questions of interest to non-specialist citizens. On the next step we have to record the researchers' answers and illustrate them with images to propose a fun and instructive video. We would like to expand the social diffusion of our work, without falling into cheap advertising like buzz or clickbaits. To enlarge our audience and get these videos to international levels, we add subtitles in English and also produce video in English with French subtitles. The motivation for this action is based on providing information adapted to the citizen, which seems essential to strengthen the link between society and the actors of animal production. We consider that this project requires the participation of researchers and we hope that Farmpédia and our videos will contribute adequately.

Session 45

Theatre 7

How and why involve citizens in a participatory research project aiming to design livestock farming?*P. Coeugnet¹, J. Labatut², G. Vourc'h¹ and J.E. Duval¹**¹INRAE, Site de Theix, 63122, Saint Genès Champanelle, France, ²INRAE, 5 Boulevard Descartes, 77454, Marne-la-Vallée, France; philippine.coeugnet@inrae.fr*

Various studies have highlighted the interest of collaboration between researchers and citizens in the same project in the light of responsible research and innovation. This has led to an increase of participatory research in different sectors. In agriculture, if many cases of collaboration between agricultural professionals and researchers exist, there are few cases of participation of citizens, within participatory research projects. Citizens are defined as actors who are neither researchers nor agricultural professionals. However, the agricultural sector, and in particular the livestock sector, is the object of various criticisms from society. The participation of citizens in a participatory research project on the design of future livestock systems could be a way of recreating a connection between livestock and society, provided that appropriate participatory methods are mobilized. We set up an innovative co-design process aiming to include citizens at the same level as researchers and livestock professionals within a participatory research project aimed at producing knowledge and solutions for future livestock systems in the French mountain area 'Massif Central'. We adapted the method DKCP (Diagnosis, Knowledge, Concept, Proposal) that was initially developed to support a co-design process between experts within the industrial sector to our study context. The 22 participants were invited to work on the topic of 'the future of dairy calves' and were asked to design dairy farming systems that respect the health and welfare of calves, farmers and society. We analysed the video recordings of the exchanges between the participants and conducted semi-structured research interviews with participants. Our results show that the participation of citizens within this co-design process has made it possible to integrate different types of knowledge, to explore innovations, to democratize science and to generate different types of learning. For this, rigorous participatory methods are necessary in order to ensure the effective participation of citizens within a group of actors with heterogeneous expectations and knowledge.

Social sustainability: what concepts to approach farmers' satisfaction at work

B. Dedieu¹, J. Duval¹, P. Girard², N. Hostiou¹, S. Mercandalli² and G. Soullier²

¹INRAE, ACT, Theix, 63122 Saint-Genes-Champagnelle, France, ²Cirad, E&S ART-Dev, 73 rue Jean-Francois Breton, 34000 Montpellier Cedex, France; benoit.dedieu@inrae.fr

The social pillar of sustainability is, compared to the economic and environmental ones, considered less often in the existing models used to study livestock production systems. With a generation of farmers soon to retire (at least in the EU), the farming sector – and notably the livestock one – is facing the challenge to ensure that a new generation of farmers emerges despite working conditions considered as difficult and unattractive. In Sub-Saharan Africa, agricultural activities are often labour-intensive but generate little value. The attractiveness of the agricultural sector is also a challenge to absorb a growing rural population. We deepen here one domain of social sustainability, referring to farmers' satisfaction at work. Several concepts exist to capture what 'satisfaction' means for the farmers: decent work, job satisfaction, working conditions, working rationalities, farmers' well-being, quality of life at work, etc. Building on a comparative review of these concepts and their definitions, this communication aims to explicit them in order to highlight their common and divergent topics of interest, their underlying frameworks, methodologies and their set of indicators either based on individual factors or on factors related to the nature of the job and its environment. We then analyse: (1) the way they are connected to farming practices and farming styles (agroecology, sustainable intensification, etc.); (2) to what definition of 'work' they refer (a set of tasks; an occupation with its professional norms; a job); (3) how they incorporate gender and age-related issues as well as local, cultural dimensions; (4) what is the balance between objective and subjective indicators. We present some of our operational applications of 'satisfaction at work' approaches in both Northern and Southern contexts. We open the debate to the consideration of other types of workers (family members, wage-earners, volunteers). We conclude by a reflexion toward a shared vision of the future of livestock farming combining high economic and environmental performances, fulfilment and attractiveness for the persons.

Session 45

Theatre 9

Implementing agroecological practices: what are the effects on working conditions of dairy farmers?

A.-L. Jacquot¹, M. Gérard^{1,2}, J.E. Duval³ and N. Hostiou³

¹PEGASE, INRAE, Institut Agro, 16 rue le Clos, 35590 Saint Gilles, France, ²Smart-Lereco, INRAE, Institut Agro, 65 rue de Saint-Brieuc, 35000 Rennes, France, ³Université Clermont Auvergne, INRAE, AgroParisTech, VetAgro Sup, UMR Territoires, campus des cézeaux, 63178 Aubière, France; anne-lise.jacquot@agrocampus-ouest.fr

To limit their impacts on the environment, farmers are encouraged to adopt agroecological practices, which can affect their working conditions. This study aims to explore effects of the adoption of such practices on farmers' working conditions. During fall and winter 2019-2020, 17 dairy farmers located in Western France were individually surveyed. The interview guide was designed to explore the relationships between the adopted agroecological practices and the effects on farmers working conditions. Dairy farmers were invited to make a list of their agroecological practices adopted and to describe how they experienced their working conditions. The latter were analysed with a broad framework allowing to depict farmers' workload and work organisation, and to understand farmer's perceptions of their job (physical and mental workload, skills, social relations, sense of coherence, etc.). More than thirty agroecological practices were identified concerning the crop, livestock system or landscape infrastructures. All farmers declared an effect of those practices on their working conditions. They claimed various impacts on workload, work organization and the need for special equipment, depending on the nature of the production system and the applied agroecological practices, mainly through: (1) a crop diversification or an increase in the share of grasslands; (2) change of technical operations on the cropping system. Farmers report a greater seasonality of tasks to perform. More generally, they all expressed a positive effect due to an improvement of the physical workload, their skills and relationship with the society, and their job satisfaction. This survey highlighted different effects of the adoption of agroecological practices on farmer's working conditions that may help to design an appropriate support for farmers engaging in the agroecological transition. This study is part of the LIFT project funded from the European Union's Horizon 2020 research and innovation programme (No 770747).

Promoting and guiding transformation of French veal calf farms in response to societal expectationsC. Martineau¹, D. Bastien¹, M. Chanteperdrix¹, C. Denoyelle¹, V. Lefoul¹ and M. Orlianges²¹Institut de l'Élevage, Qualité des carcasses et des viandes, 8 route de Monvoisin, station expérimentale veau de boucherie, 35650 Le Rheu, France, ²INTERBEV, 207, rue de Bercy, 75587 PARIS Cedex 12, France; virginie.lefoul@idele.fr

Production and consumption of veal calves is a French specificity. France is the largest consumer in the world of veal calves, with 3.2 kgce per capita. In 2022, approximately 1.1 million calves were slaughtered in France, which is the second largest producer in the world behind the Netherlands. More than 60% of male calves from the French dairy farms are used as veal calves, which plays a major part in regulating the milk and bovine-meat markets. The French veal sector is coveted by countries that have implemented policies of eliminating dairy calves at birth due to the lack of solutions that allow a better valorisation. In this context, the French veal sector must adapt to confront new society's challenges such as environmental protection, animal welfare or animal health. How can the veal production systems converge to meet these societal expectations while preserving the working conditions and a fair remuneration of farmers? INTERBEV Veaux and IDELE proposed to answer these questions through a collective project called 'Le Veau Durable' (= Sustainable Calves) and composed of 3 parts: (1) a research programme to evaluate innovative calves' production methods that meet these societal expectations; (2) the construction of a new collective calves' innovation and research centre (CIRVEAU), to produce references on these innovative breeding methods; (3) a demonstration and communication programme to spread and to promote the results to professionals in the sector, students, and the scientific community. This collective project aims to guide the French veal industry in its reorganisation for the next 20 years by accompanying the transformation of its breeding practices. It involves IDELE as a research and development organisation and INTERBEV Veaux as an interprofessional organisation that federates all the links in the French veal sector, from upstream to downstream.

Session 45

Theatre 11

Designing rabbit breeding systems with access to the outdoors with the innovative design methodL. Fortun-Lamothe¹, M.H. Jeuffroy² and L. Le Du²¹GenPhySE, INRAE, 24 Chemin de Borde Rouge, 31326 Castanet-Tolosan, France, ²AgroParisTech-Innovation, INRAE, IDEAS, CS 20040, 91123 Palaiseau, France; laurence.lamothe@inrae.fr

Today, most rabbit farming (>90%) is carried out in confinement in small unenriched cages, which is inconsistent with animal welfare. Allowing animals access to the outdoors meets a pressing societal demand solving this problem, but requires breakthrough innovations. To this end, we implemented an innovative design process, using the KCP® method. Two design workshops brought together 14 people: veterinarians, advisors, livestock professionals including farmers, and researchers. Each of the workshops was organised in 3 phases: a knowledge sharing, an exploration phase and a debriefing. By exploring the concept of the 'rabbit's health paddock', the first workshop showed that: (1) it is necessary to design several systems to take into account the diversity of breeders and consumers; (2) it is possible to design a win-win system for animals and breeders; (3) there is a strong need to design systems that are attractive to young breeders; (4) it is necessary to have adaptive management rules (weather, feed resources, state of the rabbits); (5) professional skills will have to be renewed to deal with new uncertainties; (6) the management of these innovative systems requires the evolution of performance indicators that are currently dominant in the sector. These are new properties for rabbit farms. By exploring the two concepts of 'adaptive, efficient and welfare-friendly rabbit farming' and 'attractive and renewed rabbit farming', the second workshop aimed to generate coherent combinations of practices. This workshop allowed us to outline 5 coherent contrasting rabbit farming systems, based on different drivers: flexible, integrated into the territory, multi-skilled and enhancing natural resources, adapted to a diversity of markets, extensive and natural. They share common features (e.g. more robust genetics, flexible breeding management) but also have specificities (e.g. living environment, feeding). These results confirm that innovative design method fosters collective creativity and open innovation processes. The results will be used to design a serious game that aims to support the agroecological transition of rabbit farms.

Challenges and opportunities for transitioning to 'low anthelmintics use' in livestock systems*M. Sautier¹ and P. Chiron²**¹INRAE, GenPhySE, Chemin de Borderouge, 31320, France, ²Univ. Grenoble Alpes, CNRS, School of Political Studies, Pacte, Grenoble, 38000 Grenoble, France; marion.sautier@inrae.fr*

Today's level of anthelmintic use in pasture-based livestock production is a major threat to the environment and the livestock industry. In this context, the research community is looking for alternative ways to equip farmers with preventive and treatment strategies that could help decrease livestock-industry dependence on anthelmintics and have beneficial impacts on ecosystems. Production practices for a sustainable control of parasites have been advocated for almost forty years, but farmers' uptake of these practices has been too slow to address the issues at stake. In this presentation, we examine the rationales behind the under-adoption of alternative worm control practices in grassland-based livestock systems. This research builds on 34 semi-structured interviews with dairy sheep farmers, veterinarians, and agricultural extension agents in southwestern France. The interview material was analysed via qualitative discourse analysis. We highlight farmers' representations and rationales underpinning adoption or non-adoption of the 'low anthelmintics use' innovation. We identify six profiles for nematode control according to the way each farmer included treatment and coprology in their on-farm practice. We analyse the divergent set of ideals and representations around animal health management found among the farmer population. We identify socio-technical barriers and opportunities for transforming livestock systems towards lower anthelmintic use. We then articulate our results around the conclusion that the 'low anthelmintics use' innovation has low potential for adoption, and discuss ways to facilitate transformations, such as increased communication, training and farm visits involving farmers, extension agents and veterinarians.

Session 45

Theatre 13

The rearing of calves, kids and lambs with adults in dairy systems in the AuRA region, France*C. Constancis¹, A. Igier¹ and F. Debrez²**¹FiBL France, 150 avenue de Judée, 26400 Eurre, France, ²INRAE, GenPhySE, 24 Chemin de Borde Rouge, 31326 Auzeville Tolosane, France; caroline.constancis@fibl.org*

Animal welfare is at the heart of concerns about the future of farming. In particular, mother and offspring separation from birth in dairy systems is increasingly criticised by society for many reasons. However, some innovative alternative practices to this separation are emerging in France but are still not well known. They appear to break with dominant practices. The study aims to describe the rearing calves, kids, lambs under adults (dam or foster adult) practice in the Auvergne-Rhône-Alpes region (France). To do so, 45 farmers who have implemented such rearing systems have been interviewed (15 famers by species). Using a semi-structured interview guide in order to analyse (1) its implementation (discovery, motivations and challenges encountered), (2) its day-to-day management and (3) the benefits and constraints of the practice for the animals, the farmer and finally the farming system. The interviews, lasting 2 hours on average, has been recorded and transcribed. The collected data has been analysed by Excel to establish typical cases of farmers and practices. Principal component analyses has been carried out using the R software. Our first results show that practices are very diverse and adapted to the constraints of each dairy sector and farm. The rearing with a foster adult is more common in cows than in small ruminants. In the Auvergne-Rhône-Alpes region, foster cow rearing seemed to be more similar to the dam rearing in the milking herd (foster cows are both suckled and milked) than the foster cow rearing in the north-western France where foster cows are no milked and separated to the milking herd. In general, farmers were satisfied and consider that these rearing systems improve animal welfare and meet societal expectations. They are more or less profitable and takes more or less time depending on the managements and species. Finally this practice, which is still confidential, deserves to be known and studied according to the farmers because of the benefits it brings, both for the animal health and welfare.

Expectations of French suckler farmers in terms of technical support services

A. Antoni-Gautier¹, J. Chambeaud², T. Falcour³, C. Galvagnon⁴, N. Lemonnier⁵ and J.B. Menassol²

¹L'Institut Agro Dijon, 26 bd Docteur Petitjean, BP 87999, 21079 Dijon Cedex, France, ²L'Institut Agro Montpellier, 2 place Pierre Viala, 34060 Montpellier, France, ³VetAgro Sup, 89 Avenue de l'Europe, 63370 Lempdes, France, ⁴Bordeaux Sciences Agro, 1 cours du Général De Gaulle, 33175 Gradignan Cedex, France, ⁵L'Institut Agro Rennes-Angers, 65 rue de Saint-Brieuc, CS 84215, 35042 Rennes, France; jean-baptiste.menassol@supagro.fr

In France, support and advice for beef farms have long been used to improve both the technical and economic performances of livestock, while at the same time meeting the needs of the livestock stakeholders and consumers. But these services are increasingly questioned, with a percentage of breeder's members of support structures in constant decline for several years. Consequently, two support structures, Races de France and Eliance, commissioned students from 5 agricultural engineering schools to better understand this evolution. A survey was conducted from October 2022 to February 2023 for which 230 suckler farmers were contacted (whatever the breed) and whether or not they are members of these structures. The final sample consisted of 137 farmers (i.e. a positive response rate close to 60%) that were surveyed using semi-structured interviews, resulting in 134 usable interviews. The analyses revealed that the main reasons for not joining the program were lack of interest (59/106 answers), the cost of the services (57/106) or the time required to prepare the animals for the test (51/106). When questioned about their expectations for such services, breeders mostly asked for advice on specific subjects (legislation changes, evolution of practices, future prospects, valorisation of livestock products, etc.) (40/121 answers) and specific interventions on aspects related to herd management (33/121). A reorganization of the service is also expected by the farmers: more visits, better communication, etc. It is concluded that to help beef farmers and the suckling sector to face new challenges such as climate change, societal evolution and a fluctuating economic context, the consulting offer must evolve and go beyond technical and/or scientific frameworks, by enriching itself with new skills and approaches.

'Antibiotic-free' strategies in chicken production in France: success factors, assets and limitation

N. Rousset and J. Hercule

TAVI, 7 rue du faubourg Poissonnière, 75009 PARIS, France; rousset@itavi.asso.fr

In the early 2010s, in France, different claims 'raised without antibiotic treatment' have appeared for chicken meat, in a context of changing regulatory framework, and the steering of a national program to reduce use by the Ministry of Agriculture. These claims are based on different poultry production sectors that have implemented strategies to reduce the use of antibiotics. Interviews with different actors of the poultry sector were conducted, to understand how these private standards were built, in the particular case of standard/certified broiler production, how they work, and to analyse their success factors, their assets and limits. Although limited to a part of the production, these strategies seem to have benefited the whole poultry production. In fact, training, technical and moral support was carried out on the long term, for all farmers, in order to improve their technical skills. The information collected also emphasizes the importance of formalizing objectives and the commitment of all actors of the sector for the success of these strategies. Nevertheless, 'zero antibiotics' can be questioned considering its limitations in terms of animal welfare and its relevance to the fight against antibioresistance. The economic equilibrium of these sectors, which are positioned on products that are affordable for consumers, is also questioned, as the revaluation of additional production costs remains limited. An evolution towards a more systemic approach seems to be an avenue to be explored, going beyond the unique indicators of care, to take into account the overall health of the flock.

Veal calves' production: what societal expectations in terms of animal housing for their welfare?D. Bastien¹, M. Tourtier¹ and A. Warin²¹Institut de l'Elevage, Qualité des carcasses et des viandes, 8, route de Monvoisin, 35650 Le Rheu, France, ²Bureau BANKIVA, 4 impasse de la fin de chêne, 21410 Gergueil, France; didier.bastien@idele.fr

Calf housing is at the heart of societal and regulatory issues. In this context, the 'Renouveau' project, funded by the Ministry of Agriculture, was launched to identify main societal expectations for this production. Three types of audience were questioned: (1) consumers through an online survey; (2) welfarist NGOs through their public statements; and (3) students in agricultural schools through an idea competition. 26 student groups (100 students in 11 schools) responded to the idea competition and described their vision for calf breeding in the future. The top issue was the possibility of opening the buildings, with 22 projects, 14 of which provided outdoor access for calves. Projects also highlighted breeding on litter (21 projects), increasing the space allowance per calf (12 projects), providing natural light (7 projects), environmental enrichment (7 projects) and hay in feed (8 projects). The main claims of French welfarist NGOs (apart from specific problems linked to transport and slaughter) mainly concern the fact that the animals are kept in individual housing for less than 8 weeks, the absence of litter on the floor and unsuitable feed (insufficiently rich in iron to meet the market demand for white meat). Almost 2,600 consumers responded to the online survey. 58% of them admitted that they did not know how veal calves are bred. Those who said they know this production give an average score for its image of 5.5 out of 10 (from the most negative to the most positive). Among the negative's points, the notions of clausturation, animal welfare and intensive breeding were mentioned. For housing, 83% of consumers want calves to graze in summer and 65% want them to have a farm building or shelter in winter, but with outdoor access. 49% of consumers want a production on litter floor. In conclusion, the main expectations for veal calves are therefore more outdoor access. In addition, societal expectations also relate to group housing of calves from their arrival to fattening farms, with more space, as well as the provision of litter for bedding and a more iron-rich diet.

Salmon welfare perceived by various stakeholders: where do we stand?

C.M. Monestier, L.R.B. Reverchon-Billot, M.S. Stomp and A.W. Warin

Bureau Bankiva, Department of Research & Development, 4 impasse de la fin de chêne, 21410 Gergueil, France; aurelia.warin@bankiva.fr

Salmon production has been the subject of heated debate, in which current controversies focus on the need to take animal welfare into account, notably supported by the demonstration of sensory capacities (such as pain or positive emotions) and cognitive abilities (such as learning or personalities). In this light, we drew up an inventory of current scientific findings and requirements on the basis of a literature review covering 317 scientific papers, analysing the expectations of 7 animal welfare NGOs, and screening the standards of 10 labels encompassing salmon welfare, implemented in a wide array of countries worldwide. The resulting critical synthesis aims at assessing the headway made, highlighting the shortcomings on some issues, and charting avenues worth exploring. Most label specifications and animal welfare NGOs thus define clear requirements regarding the handling of fish out of water and the most controversial stunning and killing methods, for which the scientific literature details the negative impacts on salmon. However, even though NGOs and some labels (such as 'Label Rouge', the European Organic Farming label, Demeter, RSPCA and Friend of the sea) limit the duration of fasting before slaughter to a few days depending on water temperature, little research has been carried out on the issue, only drawing partial conclusions. Conversely, although various environmental enrichments have shown positive effects on several species of marine fish, NGOs and labels provide little or no guidelines in this area. Such cross-analyses prove to be crucial to provide optimum and joint guidance to both producers and policy-makers.

A review of sustainable livestock strategies to deal with anti-livestock activists*M. Dehghani and K.H. Park**Kangwon National University, College of Animal Life Sciences, Kangwon National University, Chuncheon, Gangwon, Republic of Korea, 24341, Korea, South; kpark74@kangwon.ac.kr*

The livestock industry plays an important role in culture, societal well-being, livelihoods, and food security. According to the Food and Agriculture Organization (FAO), this industry supports about 1.3 billion livelihoods and food security by accounting for 40% of the global value of agricultural output in developed countries and 20% in developing ones. During the last decades, rising population, income, and urbanization have all been associated with increasing demand for food products derived from livestock, which has led to increased livestock output and population. Since livestock activities have significant impacts on all aspects of the environment, including air and climate change, land and soil, water and biodiversity, this growth in animal products demand has raised concerns of anti-livestock activists who are against activities of livestock industry without considering the vital role of it in humans life. So far, various solutions have been provided to mitigate and control the destructive effects of this industry, which can promote it towards sustainable development goals such as reduction of enteric fermentation in ruminants through dietary manipulation and improving manure management through acidification. Concerning to sustainability strategies, one of the most effective solutions is circular bio-economy, which has been discussed in this study, and from the results obtained, it can be concluded that activity of the livestock industry is not only an inseparable part of human life, but also for the continuation of other industries it is absolutely vital.

Poster 19

AuthenBeef: use of blockchain technology in beef production to secure authenticity and traceability*G. Arsenos¹, S. Vouraki¹, V. Papanikolopoulou¹, A. Argyriadou¹, V. Fotiadou¹, S. Minoudi^{2,3}, D. Karaouglanis^{2,3}, N. Karaïskou^{2,3}, P. Fortomaris¹ and A. Triantafyllidis^{2,3}**¹School of Veterinary Medicine, Aristotle University, University Campus, 54124 Thessaloniki, Greece, ²School of Biology, Aristotle University, University Campus, 54124 Thessaloniki, Greece, ³Epigenomics Translational Research, Center for Interdisciplinary Research and Innovation, Balkan Center, 57001 Thessaloniki, Greece; svouraki@vet.auth.gr*

The traceability and authenticity system of livestock products is becoming increasingly important from a political, consumer and environmental perspective, promoting the concept of ‘farm to fork’. Research has shown that the main attributes consumers value in addition to quality when buying meat are provenance, traceability and quality. The objective of AuthenBeef is to implement a fully traceable beef supply chain using blockchain technology combined with genetic markers both up the chain to market and back down the chain to farm. The key data entry points include the entire production process from feedlots to the final marketing of meat and its products. A designated protocol for the genetic analysis of 17 microsatellite markers, recommended by the International Society for Animal Genetics (ISAG), has been developed. In the farm, blood samples will be collected from recently slaughtered animals and the full set of markers will be genotyped, building a genetic database of the farm. To test the genetic tracing, system meat samples will be collected, at the selling point stage. Individual identification will depend on the obtained genetic profile for each meat sample. To cater the needs of the above protocols, a recording system, applicable to the beef sector, has been developed providing accurate and traceable data of the whole processes. Moreover, to harness blockchain technologies and to allow verification of data a decoding system using QR-coding has been developed to provide real time information to consumers. AuthenBeef offers a marketing strategy making the most of the provenance and traceability of beef and hence ensuring greater financial returns in the value chain. This research has been co-financed by the European Regional Development Fund of the European Union and Greek National Funds through the Operational Program Central Macedonia 2014-2020 (KMP6-0219662; AuthenBeef).

Structural equation modelling applied to multi-performance objectives in French suckler cattle farms*L. Billaudet, I. Veissier, J.J. Minviel and P. Veyssier**INRAE, UMR Herbivores, Route de Theix, 63122 Saint-Genes-Champanelle, France; larissa.billaudet@inrae.fr*

Faced with increasing input prices coupled with consumers' concern about purchasing power, farmers have to produce goods at affordable prices while ensuring the survival of their farm. Society has in addition many other expectations of livestock farming beside mere production: improve animal welfare, preserve biodiversity, reduce greenhouse gases, etc. In the literature, clear references are lacking to guide farmers on how to manage these multi-performance goals simultaneously. The objective of this work is to give insight on the relationship between the three dimensions – animal welfare, economic performance, and environmental performance. To address this question, we sought to analyse which decision strategies – defined as a combination of practices and rearing conditions – lead to synergies or, on the contrary, to antagonisms between relevant indicators for the three dimensions. Structural equation modelling (SEM) was used as an analytical framework. The resulting model relates latent variables – which are concepts that are not directly observable – to measurable variables – which are directly observable. In our case, the latent variables are the three dimensions under investigation. The measurable variables are either indicators of practices used and rearing conditions offered to animals (input variables) or performance indicators (output variables), derived directly or calculated from a multi-year database, which includes more than 300 suckler cattle farms in mainland France. The specification of the theoretical model, i.e. the description of the relationships between the variables (latent and measurable), was derived from knowledge established in the literature between practices/conditions and each dimension separately. The first results suggest that under certain conditions it is possible to obtain good economic, environmental and animal welfare performances at the same time. The results need to be confirmed by refining the assessment of animal welfare e.g. by using measurements of the Welfare Quality protocol.

Systemic enablers and barriers to extending the productive life of Swiss dairy cows*A. Bieber, R. Home, M. Rödiger, R. Eppenstein and M. Walkenhorst**FiBL, Ackerstr. 117, 5070 Frick, Switzerland; anna.bieber@fibl.org*

The economically and environmentally optimum length of productive life of European dairy cows, which is commonly described in terms of the number of completed lactations or productive life days (milking days) before a cow is replaced, is between six and seven lactations. However, the current average length in Switzerland, and many other countries, is approximately half that figure, which is both inefficient and ethically questionable. The aim of this study is to investigate systemic barriers to, and enablers for, the extension of the length of productive life of dairy cows in Switzerland. Data were collected by means of 29 qualitative expert interviews. Interviewed experts were selected by purposive sampling to cover a broad range of different stakeholder groups within the Swiss dairy farming system. The analysis of the interviews was done by classifying statements to inductive codes based on their content. The results show that breeder associations encourage extended service life by advertising that longer life increases milk yield per day of life. Information on the benefits of extended service life is readily available, but is not a focus of farmer education so farmers are not motivated to use the available calculation tools. Milk prices are low, so farmers try to maximise production while minimising costs so make breeding decisions based on production rather than robustness. Swiss vets are highly educated and familiar with herd management so could potentially motivate a change in the mindset of dairy farmers. However, vets are expensive so few farmers seek advice from veterinarians on herd management. In conclusion, the existing system is so deeply entrenched that no actors feel they can bring about comprehensive change on their own. Any actor who could initiate change in their part of the system fears that they would then no longer be in harmony with the rest of the system. Therefore, they are committed to behaviours that they know are not optimal and overcoming these lock-ins can only take place slowly. Collaborative reflection at industry level, led by breeder's associations, vets, and advisors, and the further development of the existing decision support tools, may lead to optimisation of the system, and to a longer productive life of dairy cows.

Providing outdoor access to pigs: what are the profiles of farmers working in those systems?

S.B. Brajon, C.T. Tallet, E.M. Merlot and V.L. Lollivier

INRAE, Institut Agro Rennes-Angers, PEGASE, Le clos, 35590 Saint-Gilles, France; sophie.brajon@agrocampus-ouest.fr

Societal expectation for the provision of outdoor access to farm animals is growing, mainly for questions of natural behaviour expression. It is thus important to understand the farmers motivational factors to engage in this type of farming in order to increase the job attractiveness and develop strategies to encourage and support farmers in moving towards such systems. This study aimed at identifying the motivational profiles of farmers choosing a trajectory of pig farming with outdoor access. A total of 24 pig farmers providing outdoor access (from indoor with outdoor access to free-range) participated in a semi-structured interview. Questions concerned historical context, farm and practices description and perception of the impact of outdoor access on the farmer, pigs, technico-economic performances, environmental and societal aspects. Qualitative data were analysed using thematic analysis which identified four motivational profiles. Farmers providing 'Outdoor access for the animals' were particularly concerned by the animals' welfare and mainly based their decision to provide an outdoor access on the importance of allowing them to express their natural behaviour and have control over their environment. Farmers providing 'Outdoor access for environmental principles' were motivated by the search of low-input, circularity, and autonomy. Those two profiles included farmers working in full outdoor and indoor farms with outdoor access. Farmers developing 'Outdoor access for economic reasons' were able to seize the opportunity to go toward a differentiated market along with welfare quality scheme to meet societal expectations. This profile was exclusively constituted by farmers managing indoor farms with outdoor access. Finally, the last profile concerned farmers giving 'Outdoor access by tradition' for whom the outdoor access was the result of maintaining traditional familial and regional breeding practices, and this concerned farmers rearing local breeds. The present study highlighted the motivational factors that guided pig farmers in their choice to provide an outdoor access, and the relation to the type of access given.

Session 45

Poster 23

The explosion of sustainability indicators in the European livestock sectorB. Van Der Veeken¹, M. Carozzi², C. Barzola Iza³ and F. Accatino²¹Science, Management & Innovation, Radboud University, Redboud, 1081 AR, the Netherlands, ²UMR SADAPT INRAE, AgroParisTech, Université Paris-Saclay, Palaiseau, 91120, France, ³Wageningen University and Research, Wageningen, 6705, the Netherlands; francesco.accatino@inrae.fr

Sustainability of the European livestock sector needs indicators to be measured. Over the last decades, several studies defined sustainability indicators covering the three different pillars of sustainability, namely the environmental (ENV), economic (ECO) and social (SOC) pillar. However, due to an increasing number and diversity of indicators, it is possible to speak about an 'indicator explosion' and the development of indicators was not balanced over the three pillars. By means of a systematic literature review, we aimed at studying the quantity and diversity of indicators used in each pillar and for different livestock systems defined in the last decades. We started from a search result and, after a systematic screening, we selected 44 studies that defined and measured sustainability indicators in Europe at the farm scale. Indicators used in these studies were harmonized (in case they named differently but describing the same thing) and classified into pillars and themes (sub-pillars). They were counted as total (T) or unique (U) (according to whether the same indicator, used in different studies, was counted multiple times or once), quantitative or qualitative. Out of a total of 736 indicators, most were used in ENV (n=282), followed by SOC (n=271) and ECO (n=183). ENV showed a low diversity of indicators used (U/T=0.52), with the most representing themes being emissions, nutrient balance, and non-renewable resources; ECO showed greater diversity of indicators used (U/T=0.64) but the great majority (65.5%) of them regarded profitability and were mostly quantitative (94%). SOC showed the higher diversity of indicators (U/T=0.72), most of them in the animal welfare theme, with the highest percentage among the pillars of qualitative indicators (50%). The review showed that most indicators (38.9%) were used for dairy cattle systems. This study enhanced that more efforts should be used to expand the study of indicators of positive impacts of the livestock system and to make the social indicators more uniformly assessed.

Pig farmers' and citizens' opinions on outdoor access for livestock

S.B. Brajon, C.T. Tallet, E.M. Merlot and V.L. Lollivier

INRAE, Institut Agro Rennes-Angers, PEGASE, Le clos, 35590 Rennes, France; sophie.brajon@agrocampus-ouest.fr

The proportion of French citizens in favour of outdoor access for farm animals is increasing, but farmers are sometimes hesitant or reluctant to do so. Two surveys based on semi-structured interviews were performed among 32 French citizens and 36 pig farmers (who worked in all types of farming systems, from conventional to free-range) (1) to better understand citizens' expectations and specify acceptable practices of outdoor access for livestock and (2) to identify the barriers and motivations of farmers to provide outdoor access to pigs. The main theme addressed with the citizens concerned their perceptions of livestock farming and outdoor access. The main theme addressed with farmers concerned perceptions about the impact of outdoor access for pigs on farmers, animals, technico-economic performance and society. Qualitative data were analysed using thematic analysis. Our study reaffirms that citizens interviewed are generally in favour of outdoor access which is synonymous of freedom in vast fields, although they believe that the ability for animals to choose whether to shelter or go outside is important. For farmers, the coherence of the breeding system with their values is crucial. Farmers providing outdoor access have pleasure to work outside and consider the life conditions better for animals. Most indoor farmers do not imagine breeding pigs outdoor mainly due to their job conception and they often mention the disconnection between citizens perception and farming reality. Despite their lack of knowledge on the topic, citizens were aware about main challenges of outdoor access such as the risk of disease transmission by wildlife, land availability and farmers working conditions. In addition, a main limitation for farmers with outdoor access concern the lack of support and technical references to manage the system and face climatic hazards, but experienced farmers mention that knowledge exist and should be shared. Finally, citizens are not able at characterising practical modalities of outdoor access due to a lack of knowledge of livestock but they trust farmers. Communicating about their work and receiving a positive feedback from citizens is a source of pride for farmers and this could be a lever to promote farms with outdoor access acceptable for society.

Session 45

Poster 25

Short food supply chains and food safety issues: HACCP utilization, opportunities and limitsR. Rafiq¹, O. Boutou², M.P. Ellies-Oury^{1,3} and B. Grossiord¹¹Bordeaux Sciences Agro, Feed &Food, 1 cours du Général de Gaulle, 33170 GRADIGNAN, France, ²Groupe AFNOR, Délégation Nouvelle-Aquitaine, 3 Avenue Rudolph Diesel, 33700 Mérignac, France, ³INRAE, UMR1213 Recherches sur les herbivores, Vet AgroSup Clermont-Ferrand, 63122 Saint Genès Champelle, France; benoit.grossiord@agro-bordeaux.fr

In order to maintain and develop their activities, but also to bring an appropriate answer to the expectations of the consumers and the society, farmers develop new ways to valorise their productions. One of those consists in shortening the distance between producers and consumers by developing new strategies allowing a direct producer-consumer relation, like the so called short food supply chains (SFSCs). When developing SFSCs, producers have to reinvent their own job as new skills are necessary to manage and control all the steps involved in the processing, storing, marketing or transport of the end products they put on the market. If considering animal husbandry, the slaughter is a key step in the process. Throw the whole process, from living animals to end products, the producer who becomes an entrepreneur has to face many stakes related to those new activities. One of the main stake is the management and control of the food safety all along the chain. Like all the other food business operators, producers involved in SFSCs must respect the EU regulation on food safety (Food Law). Here we focus on Article 6 of the Food Law and its application in SFSCs. Article 6 deals with risk analysis, which consists in three successive actions: risk assessment, risk management and risk communication. The HACCP method (Hazard Analysis and Critical Control Point) is universal and we report here on its utilization in SFSCs. The HACCP allows a full analysis of all the steps involved in the elaboration of the end products, from the production of the raw materials to the commercialization. It is therefore a very powerful tool in order to make the operators be conscious of the many hazards (physical, chemical, biological) they have to manage all along the food chain and to help them identify and apply the proper good hygiene practices (GHPs). A better understanding and utilization of the HACCP could then contribute to the improvement of the food safety culture (FSC), as it is expected all along the food chain.

Feeding strategy in organic farming as a lever to improve various quality dimensions of porkC. Van Baelen¹, L. Montagne¹, S. Ferchaud², A. Prunier¹ and B. Lebreton¹¹PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France, ²INRAE, GenESI, 86480 Rouillé, France; chloe.van-baelen@inrae.fr

Organic farming is the official quality label in which consumers have the most confidence with. Its specifications evolved in 2022 to reinforce animal welfare and enhance the link to the soil for feeding resources. We considered the feeding strategy as a lever to improve various quality dimensions of organic pork. Pork quality includes intrinsic dimensions (commercial, nutritional, organoleptic, sanitary) and extrinsic dimensions related to animal farming (image). The experiment was conducted with 77 organic non-castrated male pigs (Piétrain NN (non-carrier of the n allele) × Large White) distributed in two batches. Within batch, littermates were divided into two groups at 33 kg body weight (BW). One group received a control feed (C) corresponding to the organic specifications. The other group received a test feed (Bio+) mainly based on French raw materials and contained more fibre (faba bean) and omega-3 fatty acids (linseed, camelina) and had access to fodder (rack). Each group was reared in a pen from the same building on deep straw bedding (1.3 m²/pig) with free outdoor access (1.0 m²/pig). Pigs were fed *ad libitum* until slaughter at about 125 kg BW. Average daily gain, feed intake and feed efficiency, and carcass weight and lean meat content were similar between C and Bio+ pigs. Compared to C, loin meat (longissimus muscle) from Bio+ pigs had higher ultimate pH associated to lower glycolytic potential ($P < 0.05$), and tended to have lower drip loss ($P < 0.10$), meaning an improvement in technological quality. Meat from Bio+ vs C pigs was less light ($P < 0.05$) and had a more intense red colour ($P < 0.01$). It was judged with a lesser aromatic persistency ($P < 0.05$) by a trained sensory panel, whereas odour intensity, tenderness and juiciness did not significantly differ. With Bio+ diet, loin had lower n-6:n-3 fatty acid ratio ($P < 0.001$). Backfat skatole and androstenedione concentrations were low in most C and Bio+ pigs. However, skatole was slightly lower in Bio+ than C pigs ($P < 0.05$) whereas androstenedione did not differ. Altogether, the Bio+ diet had positive impacts on nutritional, technological and some sensory qualities of organic pig meat from entire male pigs, while contributing to the relocation of feed resources.

Session 45

Poster 27

Body reserve dynamics using metabolites and hormones profiles of Romane ewes in two farming systemsA. Nyamiel¹, D. Hazard¹, D. Marcon², F. Tortoreau¹, C. Durand³, A. Tesnière⁴ and E. González-García⁴¹INRAE, UMR1388 GENPHYSE Université de Toulouse, ENVT, 31326 Castanet-Tolosan, France, ²INRAE, UEP3R Bourges, 18390 Osmoy, France, ³INRAE, UE321 La Fage, 12250 Roquefort-sur-Soulzon, France, ⁴INRAE, CIRAD, SELMET Institut Agro Montpellier, Univ Montpellier, 34060 Montpellier, France; agnes.nyamiel@inrae.fr

The objective was to monitor the main effects affecting body reserve (BR) mobilization and accretion, using metabolites and hormones profiles, in Romane ewes reared under two contrasting farming systems (FS; (indoor, IND; extensive, OUT)). The ewes (n=173 IND; n=234 OUT) belonged to two genetic lines selected for low or high residual feed intake. They were monitored during their two first productive cycles at five key physiological stages (Mating, M; mid-Pregnancy, P; 2 weeks Pre-Lambing, bL; 3 weeks Post-Lambing, aL; Weaning, W). Parameters included body condition score (BCS) and metabolic profiles for plasma concentrations on non-esterified fatty acids (NEFA), β -hydroxybutyrate (BHB), Triiodothyronine (T3) and insulin (INS). The relevant fixed effects and their interactions were investigated through analyses of variance using R. Physiological stage, parity, cohort, genetic line, and litter class were fixed effects while ewe and residuals were random effects. Depending on the parameter evaluated, the fixed effects and their interactions, with the exception of the genetic line, were statistically significant ($P < 0.05$). Regardless of the FS, results showed that BCS increased until P and declined thereafter. Highest NEFA concentrations were found from bL until W and at W in ewes reared IND or OUT, respectively. Significantly higher BHB levels than those found in M, P, and W were found in bL and aL ewes in both FS. T3 displayed a similar high trend throughout the stages with a peak at aL, and INS increased from P to aL before declining thereafter whatever the FS. These findings indicate that BR mobilization was displayed between P and W, as evidenced by BCS and blood parameters, whereas BR accretion occurred between W to P. Overall, there seems to be a consistent trend in Romane ewes' capacity to mobilize and recover their BR irrespective of the FS. Plasma concentrations of metabolites and hormones at different physiological status can be an indicator of the ewe's metabolic plasticity.

Inclusion of macroalgae in high forage beef cattle diets

S.A. Terry, T.W. Coates, R.J. Gruninger, D.W. Abbott and K.A. Beauchemin

Agriculture and Agri-Food Canada, 5403 1 Ave S, T1J4B1, Lethbridge, Alberta, Canada; stephanie.terry@agr.gc.ca

Supplementing ruminant diets with macroalgae has gained global interest because bromoform-containing macroalgae (e.g. *Asparagopsis* sp.) have been shown to be highly effective enteric methane (CH_4) inhibitors. Due to concerns with production costs, animal and human health, as well as regulatory restrictions, alternative macroalgae were examined for their impact on ruminant CH_4 production. Study 1 examined 33 Atlantic macroalgae on *in vitro* fermentation, and gas and CH_4 production. Study 2 examined the effect of two macroalgae extracts on rumen fermentation, nutrient digestibility, and CH_4 emissions from beef cattle fed high forage diets. All macroalgae were included at 2% of diet dry matter (DM) for each study. Most of the novel macroalgae examined in Study 1 did not have an inhibitory effect ($P>0.05$) on *in vitro* CH_4 production when included in a high forage diet; however, *Battersia* sp. and a shore blend (*Fucus vesiculosus*, *Furcellaria lumbricalis*, *Laminaria longicuris*, *Chondrus crispus*) linearly decreased ($P\leq 0.05$) *in vitro* CH_4 production expressed on a dry matter degraded basis. There was no effect ($P\geq 0.35$) of macroalgae extract on dry matter intake, feeding rate, or enteric CH_4 production (Study 2); however, apparent total tract digestibility of neutral and acid detergent fibre was increased ($P<0.01$) by both extracts compared to the control. In conclusion, these studies demonstrated the ability of the rumen environment to effectively degrade various macroalgae, with only limited species showing potential to decrease CH_4 production. Further screening efforts and testing using *in vivo* experiments are needed to continue the discovery of novel macroalgae with the potential to inhibit enteric CH_4 production.

Theatre 2

Rumen protected potassium gluconate increases average daily gain of beef

A. Santos, J.G.H.E. Bergman, J.A. Manzano and M. Hall

Nutreco, Selko, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands; alberto.santos@trouwnutrition.com

Calcium gluconate is a prebiotic that improves hindgut health. Trials in dairy cattle have shown that feeding rumen protected calcium gluconate (RPCG) improved hindgut health and increases milk production. A trial in steers sowed that feeding RPCG increases the amount of volatile fatty acids in the caecum and colon. In this trial, the impact of RPCG (LactiBute, Selko) on faecal starch levels and pH and on ADG gain in beef was tested. Beef calves on a commercial beef farm in Spain, housed in 6 pens of 20 calves each were included in the trial. Half of the animals (1 pen with females, 2 with males) were fed RPCG, the other half (1 pen with females, 2 with males) served as untreated controls. The fattening period lasted 111 days, RPCG was fed for 43 days. Bodyweight and starch levels and pH of faeces were measured at the start of the trial and at day 43. Faecal pH was reduced from 6.2 in the controls to 5.8 in the RPCG group. Average faecal starch declined from 19.7% in the controls to 15.6% for the RPCG group. ADG in the females increased by 8% or 94 g/day, ADG in males increased by 7% or 95 g/day.

Impact of additives and forage levels on performance and enteric methane emissions of Nellore bullsE. Magnani¹, T.H. Silva¹, L.B. Tosetti¹, A. Berndt², E.M. Paula¹, P.R. Leme³ and R.H. Branco¹¹Institute of Animal Science, Beef Cattle Research Center, Rod. Carlos Tonani km94, 14.174-000, Brazil, ²Empraba Pecuaría Sudeste, Beef cattle, Rod. Washington Luiz, Km 234, 13560-970, São Carlos, SP, Brazil, ³University of São Paulo, Department of Animal Science, R. Duque de Caxias, 225, 13635-900, Pirassununga, SP, Brazil; rhbarnandes@gmail.com

This study was carried out to evaluate the effect of additives and increasing levels of neutral detergent fiber from forage (NDFf) on performance and enteric methane (CH₄) emissions in finishing Nellore bulls. Sixty Nellore bulls [408.4±14.4 kg of body weight (BW) and approximately 24 months of age] were allocated into 6 diets in a factorial 2×3 arrangement during 105 days in an individualized feedlot system. The treatments were the combination of monensin (MON; 30 mg/kg DM), essential oils (EO; 500 mg/kg DM; essential oil was a mixture of castor oil and cashew nut) and 3 levels of dietary FDNf (6, 9, and 15% total diet, DM basis). The diet was composed by *Brachiaria brizantha* cv. Marandu hay, finely ground corn, soybean meal, ground citrus pulp, urea, potassium chloride, sodium chloride and trace minerals + vitamins. For CH₄ emission measurements, 5 random bulls per treatment were evaluated. Methane emissions were measured using the sulphur hexafluoride (SF₆) tracer technique. Additives and dietary NDFf levels were analysed in a complete randomized design according to a factorial arrangement. When NDFf levels were statistically significant, linear and quadratic responses were assessed (software SAS 9.4). Greater dry matter intake (DMI) was detected for MON vs EO treatments. Also, DMI increased linearly as NDFf levels increased. Monensin treated bulls had greater final BW and ADG compared to EO. Essential oils reduced CH₄ emission (g/d) compared to MON. In addition, increased CH₄ emission was detected with increasing dietary NDFf levels. These effects reflected on CH₄ emission by carcass unit, where EO reduced CH₄ emissions and increasing NDFf levels increased. Monensin was effective in improving the performance of finishing Nellore bulls compared to EO, in which EO reduced CH₄ emission at performance expense. Further, dietary NDFf may increase enteric CH₄ emission in a level-dependent manner.

Session 46

Theatre 4

Differences in digestive traits of young bulls fed contrasted diets and diverging in feed efficiencyM. Coppa¹, C. Martin², A. Bes², L. Ragionieri³, F. Ravanetti³, P. Lund⁴, G. Cantalapedra-Hijar² and P. Nozière²¹Independent Researcher, Turin, 10100, Italy, ²INRAE, UMR-Herbivores, Saint-Genès-Champanelle, 63122, France,³Università di Parma, Department of Veterinary Science, Parma, 43126, Italy, ⁴Aarhus Universitet, Nordre Ringgade 1, Aarhus, 8000, Denmark; mauro.coppa@inrae.fr

This research aimed to: (1) identify digestive traits that differed on bulls that phenotypically diverged in residual feed intake (RFI) and their relationships with RFI; and (2) explore the hierarchy among digestive traits in discriminating divergent RFI bulls fed contrasted diets. Extreme and phenotypically divergent RFI animals were selected within 100 Charolais growing bulls fed either grass silage (GS, n=50), or maize silage (MS, n=50) diets (8 efficient RFI- and 8 inefficient RFI+ bulls selected per diet). The 32 bulls selected on a first feed efficiency test (84 days) were measured for digestibility, digestive transit rate, rumen pH, behaviour and gas emissions (CH₄, CO₂, H₂). They were also measured for visceral organ weight and reticulo-omasal orifice (ROO) size, rumen particle size, and rumen and ileum histology after slaughter. A feed efficiency test was performed on the whole trial (180 days); RFI were recalculated and regressed by GLM to digestive traits. Irrespective of the diet, efficient bulls (RFI-) tended to have higher CH₄ and CO₂ emissions (g/kg DMI), spent longer time of rumen pH below 5.8 and had lower rumen size, proportion of small particle size in the rumen, less ileum nuclei, than non-efficient ones. The RFI was negatively related to time spent in activity other than ingestion, rumination, and resting, and positively related to abomasum size, and number of cells in the ileal crypts. Diet-dependent relationships were noted: with GS, RFI- bulls showed a slower transit rate, whereas with MS, RFI- bulls tended to have shorter resting events and smaller ROO than RFI+. Transit rate was positively related to RFI only in GS diet. Among digestive traits monitored, rumen size appeared as the major discriminating variable between RFI divergent bulls. These results should be validated on a larger population.

Effect of solid feed intake on feeding behaviour and energy metabolism in growing calvesE. Labussiere^{1,2}, L. Montagne², Y. Le Cozler², C. Martineau³ and D. Bastien³¹UE3P, INRAE, Le Clos, 35590 Saint-Gilles, France, ²PEGASE, INRAE, Institut Agro, Le Clos, 35590 Saint-Gilles, France, ³Idele, Monvoisin, 35650 Le Rheu, France; etienne.labussiere@inrae.fr

In growing calves reared for the production of veal meat, milk replacers (MR) and solid feeds (SF) are fed simultaneously to support high growth rate and address welfare issues. The combination of these diets is associated with modified feeding behaviour, digestion and metabolic processes that may change the utilization of dietary energy for growth compared with the use of MR alone. Present experiment aimed to determine the effects of increasing levels of SF as substitutes to MR on feeding behaviour, physical activity and energy metabolism in growing calves. Twenty Holstein male calves were affected to four dietary treatments in which SF were substituted to MR from 10 to 100%. SF were composed of 87% concentrates, 5% chopped wheat straw and 8% chopped hay. The calves were first adapted to their respective treatments during 100 days until their body weight reached 159±10 kg. MR was given twice daily whereas SF were provided once in the morning. Water and SF were available 18 h 45 min per day. Thereafter, calves were housed individually in an open-circuit respiration chamber during one week to measure their feeding behaviour, physical and energy balance from total collection of faeces and urine, and measurements of gas exchanges (CH₄, O₂ and CO₂) to calculate heat production (HP). The latter was partitioned between components due to basal metabolism, physical activity and thermic effect of feeding (TEF). Water evaporation was measured to determine latent heat losses. Intake of SF increased from 404 to 3,630 g dry matter (DM)/d while MR intake decreased from 2,029 to 0 g DM/d between dietary treatments. When increasing SF intake, number of meals, feeding rate and time spent standing while eating increased whereas total time spent standing decreased. Total HP increased with increasing SF intake because of increased TEF. The proportion of HP lost via latent route decreased from 45 to 32% when SF increased. Energy balance was not affected suggesting that the lower metabolic efficiency of SF was compensated for by behavioural adaptations. These results suggested that calf behaviour and nutrition can adapt to contrasted sources of dietary energy.

Session 46

Theatre 6

Effects of dietary inclusion of willow leaves on feed intake and methane emission in sheepJ.J. Thompson¹, S. Stergiadis², O. Cristobal-Carballo³, T. Yan³, S. Huws¹ and K. Theodoridou¹¹Institute of Global Food Security, Queen's University Belfast, 19 Chlorine Gardens, Belfast, BT95DL, United Kingdom,²University of Reading, School of Agriculture, Policy and Development, Earley Gate, P.O. Box 237 Reading, RG6 6AR, United Kingdom, ³Agri-Food and Biosciences Institute, Large Park, Hillsborough, BT266DR, United Kingdom; k.theodoridou@qub.ac.uk

The present study aimed to investigate the effects of feeding two varieties of fresh-cut willow leaves on feed intake and enteric methane (CH₄) emissions in sheep. Twelve ewe hoggets (Texel, 12 months old) were allocated in a 3 (diets) × 3 (periods) Latin Square design study with 4 weeks/period. The diets were (DM basis): 100% grass silage (Control), 85:15 grass silage:Terranova leaves (TL) and 85:15 grass silage:Beagle leaves (BL). Each sheep also received concentrate at 180 g/day offered through a GreenFeed unit (5 visits/d). Sheep were housed as a single group with 6 auto-feeders (2 feeders/treatment) with CH₄, H₂ and CO₂ emissions and O₂ consumption measured using a GreenFeed unit during day 14 to 21 of each period. Sheep were then placed in individual metabolism crates for 7 days, with total faeces and urine outputs recorded in the final 6 days. Willow leaves were harvested daily and chopped to a length of 3 cm, totally mixed with grass silage for TL and BL diets and offered to lambs twice a day with a residual rate of 5%. Willow treatments had no effect on CH₄ (g/d) ($P=0.933$), CO₂ ($P=0.898$) and O₂ production ($P=0.925$). H₂ production increased, during period 1 for BL compared to the other two treatments. Dietary willow did not affect ($P=0.061$) urinary nitrogen (N) excretion (g/d), but faecal N excretion (g/d) was higher ($P<0.01$) for both willow treatments compared to control. In conclusion, feeding fresh willow leaves of Terranova or Beagle at 15% (DM basis) had no effect on feed intake and methane emissions of lambs. Further animal trials are needed to quantify the effect of willow fodder of different varieties and at different inclusion rates.

Effect of supplementing Omega-3 rich oil on ruminal fermentation and dietary digestibility in lambsO. Cristobal-Carballo¹, F. Godoy-Santos², S. Huws², S. Morrison¹, A. Aubry¹, E. Lewis³ and T. Yan¹¹AFBI, Hillsborough, BT26 6DR, United Kingdom, ²Queen's University of Belfast, Belfast, BT9 5DL, United Kingdom,³Devenish Nutrition, Belfast, BT3 9AR, United Kingdom; omarcristobal.carballo@afbini.gov.uk

This study assessed the effect of feeding microalgae oil, rich in Omega-3, at different levels on ruminal fermentation, methane emissions, and feed digestibility in finishing lambs. A group of 24 male lambs, Texel/Scottish black face, was selected from a performance study of 64. All lambs were balanced by body weight (BW), and randomly assigned into one of four treatments. Treatments were fed TMR diets of 50:50 grass silage and concentrate. Concentrate meals included 0.00% (Control), 0.54% (Low), 1.08% (Medium) and 1.62% (High) of microalgae oil (DM basis); oil inclusion was balanced with soyabean oil. Daily DMI and weekly BW were recorded. At 70 d of treatment, lambs were gradually introduced at 4 d intervals in 4 groups of 6 into digestibility crates for 7 d and respiration chambers for 4 d. Urine and faeces were collected daily during the final 6 d of crates. Methane emissions were measured in the final 48 h of chambers. Rumen fluid was collected at slaughter (95 d of treatment). Response variables were analysed using linear mixed models via the REML method, with treatment as fixed effect and Run and Chamber as random effects. Pairwise differences between treatments were examined using Fisher's LSD test at $P=0.050$. GenStat (version 19) was used to carry out all analyses. DMI tended to decrease ($P=0.068$) as the microalgae oil dose increased in the diet. Digestibility of DM, OM, NDF, ADF and Energy did not differ ($P>0.255$) between treatments. Total VFA concentration was greater ($P=0.018$) in High and Low when compared to Medium lambs. Acetate and propionate proportions were higher ($P<0.001$) and lower ($P=0.003$), respectively, in Control when compared to microalgae oil treatments. Methane production ($P=0.009$) and yield (CH_4/DMI ; $P=0.041$) were reduced in 21.5 and 20.3%, respectively, in High when compared to Control lambs. It is concluded that microalgae oil can be included in the diet of finishing lambs at doses of 1.62% without affecting the nutrient and energy digestibility, while increasing the total VFAs and propionate proportions, and reducing the acetate proportions and CH_4 emission.

Session 46

Theatre 8

Essential oils and integral diets to optimize rumen function and decrease methanogenesis in lambsN. Ghallabi¹, G. Gonzalo¹, A. Garcia², O. Catalán³, P. Romero⁴, M. Hassan⁴, A.I. Martín-García⁴, D.R. Yáñez-Ruiz⁴ and A. Belanche¹¹University of Zaragoza, Animal Production and Food Science, Miguel Servet 177, Zaragoza, 50013, Spain, ²Los Chengos SL, Maxima Ladron de Guevara 5, Mula, 30170, Spain, ³INZAR, Julio García Condoy 41, Zaragoza, 50018, Spain,⁴Estación Experimental del Zaidín (CSIC), Profesor Albareda 1, Granada, 18008, Spain; belanche@unizar.es

This study aims to explore if feeding lambs with fibrous concentrate feeds without forage and their supplementation with feed additives could help to minimize the labour costs and environmental footprint. After receiving artificial milk feeding, a total of 56 male lambs were divided into 28 pens (in pairs) and allocated to 4 experimental treatments ($n=7$) following a 2×2 factorial design. Lambs were fed *ad libitum* with a conventional concentrate feed and barely straw (CTL) or with a fibrous concentrate feed without forage (FIB), either non-supplemented (-) or supplemented (+) with a commercial blend of essential oils (200 mg/kg DM). Concentrate feed intake was similar across treatments but CTL lambs tended to have higher total DMI than FIB lambs, the difference being the straw consumption. No differences were noted in the feeding pattern. The FIB diet promoted lower glucose / β -hydroxybutyrate ratio during the post-weaning period suggesting an accelerated rumen physiological development. The FIB diet also promoted higher rumen fermentation activity characterized by higher AGV concentration and methane yield and lower rumen pH and acetate/propionate ratio. On the contrary the CTL lambs had higher blood urea concentration suggesting a lower N utilization by the host. Essential oils supplementation tended to increase rumen propionate proportion and decreased the blood urea, blood glucose and methane yield indicating a lower environmental footprint. No differences were noted across treatments in productive parameters or carcass performance. In conclusion, the use of integral diets without forage can represent a successful strategy to increase the rumen fermentation and simplify the animal feeding labour without having negative productive implications. The supplementation with essential oils led to a propionic fermentation and could be considered as a strategy to minimize the environmental footprint in fattening lambs.

Novel water based delivery of seaweed extracts to improve the sustainability of ruminant production

A. Casey, T. Boland, Z. McKay and S. Vigers

University College Dublin, Animal and Crop Sciences, School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, D4, Ireland; staffordvigers1@ucd.ie

The use of seaweed derived additives has potential to improve the sustainability of ruminant production but dosage rates and delivery need further evaluation. One of the major issues constraining the incorporation of rumen modifiers in grass based production systems is issues in relation to delivery. The objective of this study was to evaluate the inclusion of an extract derived from *Ascophyllum nodosum* on nitrogen use efficiency (NUE) and methane emissions delivered through water. The extract was included through the water at 0.75 and 1.5% of total feed intake and fed to 10 Spring calving mid-late lactation Holstein Friesian dairy cows (182 days in milk, 27.5 kg/day, 3.86% fat, 3.64% protein) in a 3×3 Latin Square design. The experiment compromised three 21 d experimental periods (16 days dietary acclimatization and 5 days data and sampling collection). The inclusion of the seaweed had no effect on dry matter intake or water intake ($P>0.05$). The inclusion of the seaweed extract at 1.5% increased milk solids compared to the control ($P>0.05$), while milk yield was unaffected by seaweed inclusion. Of the constituents milk protein was increased in the cows fed seaweed extract at 1.5% ($P<0.05$) while milk fat and milk lactose were unaffected ($P>0.05$). The seaweed extracts had no effect on urinary or faecal nitrogen (N) but milk N was increased in the cows supplemented with seaweed included at 1.5% compared to the control group ($P<0.05$). This increase in milk N led to an improvement of NUE in the group fed the high dose rate compared to the control. The seaweed extracts had no impact on rumen fermentation measures such as ammonia and volatile fatty acids and had no impact on methane production. This research provides interesting data on the mode of action of brown seaweeds with further research ongoing on their potential benefit and use in pasture based production systems.

Session 46

Theatre 10

Supplementation of Ca gluconate improves fertility and time to peak milk yield in dairy cattle

D.J. Seymour, M.V. Sanz-Fernandez, J.B. Daniel, J. Martin-Tereso and J. Doelman

Trouw Nutrition R&D, P.O. Box 299, 3800 AG Amersfoort, the Netherlands; dave.seymour@trouwnutrition.com

Transitioning from pregnancy through parturition to lactation imposes a significant amount of physiological stress and inflammation on dairy cattle, which can, when excessive, negatively impact health and performance. The gastrointestinal tract is a key site of inflammation during the transition period and represents a potential target for prophylactic dietary interventions. Increased milk productivity has been reported in dairy cattle when a fat-embedded prebiotic compound, Ca gluconate (HFCG), was supplemented to mid-lactating dairy cows. The objectives of this study were to evaluate responses in health, fertility, and lactation performance in multiparous dairy cattle supplemented with HFCG during the transition period and early lactation. Holstein cattle in a commercial herd ($n=164$) were randomly assigned to a 2×2 factorial, receiving either HFCG or control incorporated into a pelleted feed for approximately 21 d prepartum and/or 100 d postpartum. Incidence of culling was monitored as a proxy for animal health, while days to first observed heat, first service, and confirmed pregnancy were used to evaluate fertility. Individual lactation curves were modelled, and the fitted parameters were compared statistically to evaluate production response. No differences in incidence of culling were observed. Animals supplemented with HFCG, both prepartum and postpartum, tended to return to oestrus earlier and reach peak lactation earlier relative to animals that switched to negative control postpartum. No other effects on production performance were observed. Animals supplemented with HFCG postpartum, regardless of prepartum treatment, tended to be serviced earlier and were confirmed pregnant earlier than those receiving control postpartum. While the precise mode of action of HFCG remains unclear, we hypothesize that these findings are driven in part by a combination of reduced inflammation and improved energy status during the transition period and early lactation.

DFM supplementation during the gestation and dry periods on postpartum performance in dairy cows

O. Ramirez-Garzon¹, D.G. Barber², J. Alawneh³, L. Huanle¹ and M. Soust¹

¹Terragen Biotech Pty Ltd, Unit 6/ 39-41 Access Cres, Coolumb Beach QLD, 4573, Australia, ²DairyNEXT, Marburg, 4346, Australia, ³GCP Veterinary Consulting Ltd Pty., Kenmore, Brisbane, 4069, Australia; orlandor@terragen.com.au

This study aimed to test the hypothesis that daily supplementation of dairy cows with a direct-fed microbial (DFM) during gestation and the dry period would have a carry-over effect on milk production and reproductive performance in the first 100 days in milk (DIM) of the subsequent lactation. The study was conducted at a commercial dairy farm in Harrisville (Queensland, Australia) from October 2021 to January 2023 with 150 multiparous Holstein cows randomly selected based on parity (2.0 ± 0.8) and days in milk (126.9 ± 55.4 DIM). Group A (control $n=75$) received the basic diet, while Group B (DFM, $n=75$) received a basic diet supplemented with a DFM (top dressed) consisting of three strains of *Lactobacillus* sourced from a commercial product (Mylo®, Terragen Biotech, Australia). During the calving season (March to July 2022) a subset of 82 cows (40 control, 42 DFM) was monitored to assess postpartum performance. Serum metabolic profile and uterine health were evaluated before calving (-4 w to -2 w prepartum) and after calving, (week 1, week 3, and week 6 postpartum). Results showed that cows supplemented with DFM had higher average milk yield and peak milk than the control group (24.0 vs 22.0 l/cow; $P < 0.007$ and 34.0 vs 31.2 l; $P < 0.014$, respectively). Moreover, the days to first insemination were lower in the DFM group (64.7 d vs 74.3 d; $P = 0.03$). Serum levels of albumin, glucose, NEFA, and Mg were higher in DFM cows ($P < 0.05$) while total protein, urea, and BOH were higher in the control group ($P < 0.05$). No significant differences were observed in uterine health. In conclusion, supplementing cows with DFM during gestation and dry periods can improve their subsequent productive and reproductive performance after calving, providing evidence for the use of DFM as a potential strategy to enhance the performance of dairy cows.

Session 46

Theatre 12

In vivo evaluation of tannins and essential oils mixtures as additives for dairy cows

G. Foggi¹, L. Turini¹, F. Dohme-Meier², A. Muenger², L. Eggerschwiler², J. Berard², G. Conte¹, A. Buccioni³ and M. Mele¹

¹University of Pisa, Department of Agriculture, Food and Environment, via del Borghetto, 80, 56124, Pisa, Italy, ²Agroscope, Ruminant Nutrition and Emissions, Route de la Tioleyre 4, 1725 Posieux, Switzerland, ³University of Florence, Dipartimento di Scienze e Tecnologie Agrarie, Alimentari, Ambientali e Forestali, Piazzale delle Cascine 18, 50144 Florence, Italy; giulia.foggi@phd.unipi.it

Several studies have focused on the use of feed additives to modulate ruminal fermentation and metabolism. Most of these studies adopted *in vitro* or *in vivo* approach considering pure substances, whereas only a minor part reported the effect of additive mixtures. This study aimed to evaluate the *in vivo* low dosage effects of 3 additives formulated with tannins and/or different blends of essential oils compounds (BEOC) previously tested in RUSITEC. The trial was conducted in a free-stall barn at Agroscope, Posieux (Switzerland), for 12 weeks. A total of 32 lactating Holstein cows were assigned to 4 groups balanced by milk yield (35 ± 5) and days in milk (62 ± 27): negative control, K; positive control, PC; group A; and B. The Basal diet was common to all groups and contained corn and grass silages, grass hay and a concentrate mix (forage:concentrate=62:38). The PC was supplemented with Agolin Ruminant®; A, with a chestnut extract and a BEOC_A; B, with a quebracho extract and a BEOC_B. Gross composition of milk and feed were analysed weekly, feed intake and milk production daily, and ruminal pH and ammonia on weeks 2, 5, 8, 10 and 12. All data were analysed with a mixed model with repeated measures. Cows consumed on average 22.4 ± 0.8 kg/day of DM regardless of group. The fat-corrected milk yield did not differ between groups and averaged 36.5 ± 1.8 kg/day. The ruminal pH (7.04 ± 0.04) and ammonia (9.97 ± 0.60 mM) were not affected by the additive addition, even though ruminal ammonia decreased by 25% ($P < 0.001$) in weeks 10 and 12 compared to week 8. Regarding milk composition, there were significant interactions of group and period for milk urea, protein and fat (all $P < 0.001$). In conclusion, the use of the selected additives did not affect animal performance and most of the parameters considered, but further evaluations, particularly on ruminal fermentation profile are needed.

Palmitic to oleic ratio in fat supplement influenced the digestibility and production of dairy cowsJ. Shpirer^{1,2}, L. Lifshitz², H. Kamer², Y. Portnick² and U. Moallem²¹The Hebrew University of Jerusalem, ²Department of Animal Science, Rehovot, Rehovot, Israel, ²ARO, Volcani Institute, Department of Ruminant Science, HaMaccabim Road, 7505101, Israel; uzim@volcani.agri.gov.il

The form of fat supplements, degree of saturation, and the fatty acids (FA) profile influence the cows' productive response. The objective was to examine the effects of supplemental fats in the form of calcium salts of fatty acids (CSFA) in different ratios between palmitic (PA) and oleic (OA) acids on nutrient digestibility and cows' performance. Forty-two dairy cows were assigned into 3 groups and fed for 13 wks rations contained 2.2% of CSFA (on DM basis) consisting of: (1) CS45:35–45% PA and 35% OA; (2) CS60:30–60% PA and 30% OA; and (3) CS70:20–70% PA and 20% OA. Rumen and faecal samples were taken for VFA and digestibility measurements, respectively. Production data were analysed with PROC MIXED, and rumen and digestibility data with GLM models of SAS. Milk yields were the highest in the CS45:35 (52.0 kg/d), intermediate in the CS60:30 (51.1 kg/d), and lowest in the CS70:20 cows (47.3 kg/d; $P=0.002$). Milk fat content was ~0.35 percentage units lower in the CS45:35 cows than in the other two groups (3.55, 3.94, and 3.87% in the CS45:35, CS60:30, and CS70:20 groups, respectively; $P=0.001$), and fat yields were higher in the CS60:30 than in other groups ($P=0.001$). The FCM 4% and ECM yields were higher in the CS60:30 than in other groups. Feed intake was highest in the CS60:30 group (33.5 kg/d) and lowest in the CS70:20 group (31.3 kg/d; $P=0.001$). The milk-to-DMI ratio was the highest in the CS45:35 ($P=0.001$), with no differences in the efficiency for 4% FCM or ECM production. In conclusion, increasing the PA proportion in the fat supplements greatly increased the milk-fat content, and a high OA ratio increased the milk yields. The digestibility of most nutrients was lower in the CS70:20 than in other groups; however, the total fat digestibility was similar between all groups, indicating that the form more than the FA profile influences the fat digestibility. The different impacts of the PA-to- OA ratio in the fat supplements indicates that in the future the FA profile of the provided supplement will be determined according to the defined goal: milk or milk-fat.

Session 46

Theatre 14

Xylooligosaccharides and enzyme increased milk yield and reduced methane emissions of Jersey cows

L.F. Dong and Q.Y. Diao

Institute of Feed Research, Chinese Academy of Agricultural Sciences, No. 12 Zhongguancun South Street, 100081, China, P.R.; donglifeng@caas.cn

Sustainable strategies for enteric methane (CH_4) mitigation of dairy cows have been extensively explored to improve production performance and alleviate environmental pressure. The present study aimed to investigate the effects of dietary xylooligosaccharides (XOS) and exogenous enzyme (EXE) supplementation on milk production, nutrient digestibility, enteric CH_4 emissions, energy utilization efficiency of lactating Jersey dairy cows. Forty-eight lactating cows were randomly assigned to one of 4 treatments: (1) control diet (CON), (2) CON with 25 g/d XOS (XOS), (3) CON with 15 g/d EXE (EXE), and (4) CON with 25 g/d XOS and 15 g/d EXE (XOS + EXE). The 60 d experimental period consisted of a 14-d adaptation period and a 46-d sampling period. The enteric CO_2 and CH_4 emissions and O_2 consumption were measured using the GreenFeed system, which were further used to determine the energy utilization efficiency of cows. Compared with CON, XOS and EXE synergistically ($P<0.05$) increased milk yield, fat concentration, and energy-corrected milk yield (ECM)/DM intake, which could be reflected by the significant improvement ($P<0.05$) of dietary NDF and NDF digestibility. The gaseous results showed that XOS and EXE synergistically ($P<0.05$) reduced CH_4 emission and CH_4 emissions intensities (e.g. CH_4 /DM intake, CH_4 /milk yield, and CH_4 /ECM yield), whereas CO_2 emission and O_2 consumption remained similar among the treatments ($P>0.05$). Furthermore, the synergistic effects of XOS and EXE was observed ($P<0.05$) for metabolizable energy intake and CH_4 energy output as a proportion of gross energy intake, whereas lowest values ($P<0.05$) of CH_4 energy output and CH_4 energy output as a proportion of gross energy intake was observed for cows fed XOS compared with the remaining treatments. Dietary supplementary of XOS and EXE contributed to the improvement of lactation performance, nutrient digestibility, and energy utilization efficiency, as well as reduction of enteric CH_4 emissions of lactating Jersey cows. More research is also needed to investigate the long-term effect and mode of action of these additives for Jersey cows.

Defatted black soldier fly larvae meal as substitute of soybean meal in Kenyan dairy cow rationsD.J.M. Braamhaar¹, D.J. List², S.J. Oosting¹, D. Korir³, C.M. Tanga⁴ and W.F. Pellikaan²

¹Wageningen University & Research, Animal Production Systems Group, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ²Wageningen University & Research, Animal Nutrition Group, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ³International Livestock Research Institute, Livestock, System and Environment, P.O. Box 30709, 00100 Nairobi, Kenya, ⁴International Centre of Insect Physiology and Ecology, P.O. Box 30772, 00100 Nairobi, Kenya; dagmar.braamhaar@wur.nl

Soybean meal (SBM) is worldwide the most used protein source in livestock production. However, SBM is expensive and the availability is limited in Kenya. Additionally, this feed has a limited contribution to circular food systems, since it is associated with feed-food competition. Therefore, there is a demand for alternative feed ingredients. Black soldier fly larvae (BSFL) can be considered an alternative feed because of its contribution to the circular food system by converting bio-waste into high quality feed ingredients. To the best of our knowledge, to date no *in vivo* study has been done with lactating dairy cows. The aim of the experiment was to investigate the effect of replacing SBM with defatted black soldier fly larvae meal (DBSFLM) in diets of lactating Holstein-Friesian (HF) cows on milk production and composition, feed and nitrogen use efficiency, and apparent total-tract digestibility. The experiment was conducted at a commercial dairy farm in Molo, Kenya. Twelve lactating HF cows were blocked by milk production, parity and days in milk into 4 squares in a replicated 3×3 Latin square trial. The basal diets contained 52% corn silage, 4.6% barley straw, 17% maize germ, 8.6% wheat bran, 2.4% sunflower meal, 0.4% urea, 3.6% molasses, 1.6% mineral and premix, and 9.4% protein treatment. The protein treatments were: (1) 92% SBM and 8% soybean oil; (2) 46% SBM, 4% soybean oil and 50% DBSFLM; and (3) 100% DBSFLM. The amount of concentrate was adjusted to milk yield per Latin square and basal diet mixtures were offered *ad libitum*. Data were analysed using the Mixed procedures of SAS. No treatment effect was found for milk production and milk quality (i.e. protein, fat and lactose). Lab results to calculate feed and nitrogen use efficiency, and apparent total-tract digestibility are expected soon.

Classifying lipogenic and glucogenic diets in dairy cows based on metabolomics profilesX. Wang^{1,2}, S. Jahagirdar¹, W. Bakker³, C. Lute², B. Kemp², E. Saccenti¹ and A.T.M. Van Knegsel²

¹Wageningen University & Research, Department of Agrotechnology and Food Sciences, Systems and Synthetic Biology, Helix, 6700 EJ Wageningen, the Netherlands, ²Wageningen University & Research, Department of Animal Sciences, Adaptation Physiology Group, Zodiac, 6700 AH Wageningen, the Netherlands, ³Wageningen University & Research, Department of Agrotechnology and Food Sciences, Toxicology, Helix, 6700 EA Wageningen, the Netherlands; xiaodan.wang@wur.nl

The objective of this study was to investigate the ability of plasma metabolomic profiles to differentiate between early lactation cows based on their diet. Holstein-Friesian cows were randomly assigned to a glucogenic (n=15) or lipogenic (n=15) diet in early lactation. Plasma was collected in week -2, 2, and 4 relative to calving. Metabolomics profiles in plasma were detected using liquid chromatography-mass spectrometry (LC-MS). A total of 37 metabolites were identified. For each cow per timepoint two metabolomics profiles were available: (1) extinction values for metabolites (extinction dataset); and (2) ratios between extinction values for metabolites (ratio dataset). Classification performance of dairy cows to the two diets was done using the XGBoost algorithm. The ratio dataset resulted in better classification performance compared with the extinction dataset for cows fed a lipogenic diet and cows fed a glucogenic diet. Model performance as measured by the area under the ROC curve (AUC) of lipogenic diet and glucogenic diet improved from 0.606 to 0.753 and from 0.696 to 0.842 in week 2 and 4, respectively. The top features to classify the lipogenic and glucogenic treatment were the ratio of arginine to tyrosine and the ratio of aspartic acid to valine in week 2 and 4, respectively. For cows fed the lipogenic diet, choline and the ratio of creatinine to tryptophan were top features to classify cows in week 2 and 4. For cows fed the glucogenic diet, methionine and the ratio of 4-hydroxyproline to choline were top features to classify cows in week 2 and 4. Carnitine and the ratio of asparagine to carnitine were top features to classify week -2 and 4 both for cows fed a lipogenic diet or a glucogenic diet. This study shows that the ratios of metabolites better classify diets in dairy cows in early lactation compared with absolute extinction values.

Comparative study of digestibility of safflower varieties*M. Besharati, N. Khoshnam and D. Azhir**University of Tabriz, Animal Science, 29th Bahman Blv., 51666, Iran; m_besharati@hotmail.com*

The purpose of this project was to compare the laboratory digestibility of safflower varieties and the effect of radiation on digestibility and gas production parameters. Experimental treatments include: 1:seed of Gol Mehr variety, 2:seed of Parnian variety, 3:seed of Goldasht variety, 4:seed of Sefa variety, 5:Gol Mehr variety Meal, 6:Parnian Meal, 7:Goldasht Meal, 8:Sefa Meal, 9:Gulmehr fodder, 10:Parnian fodder, 11:Goldasht fodder, 12:Sefa variety fodder, 13:irradiated seed of Gol Mehr variety, 14:irradiated seed of Parnian variety, 15:irradiated seed of Goldasht variety, 16:irradiated seed of Sefa variety, 17:irradiated flour Gol Mehr variety, 18:irradiated meal of Parnian variety, 19:irradiated meal of Goldasht variety, 20:irradiated meal of Sefa variety. Gas production of different safflower cultivars at different incubation times showed that there is a significant difference between the treatments in terms of gas production at different incubation times. The amount of gas production of different varieties of safflower flour in different hours of incubation showed that Mehr flower meal has the highest amount of gas production among different varieties at 2,6,8,12,6 and 24 hours of incubation. Also, the irradiated Gol Mehr flour cultivar had the lowest amount of gas production in the rumen liquid during the mentioned hours of incubation, and it has a significant difference with other cultivars. In the subsequent times of incubation, the irradiated Parnian meal variety had the highest gas production rate compared to other varieties of safflower meal. The results showed that irradiation has improved the percentage of laboratory digestibility of dry matter and organic matter of different varieties of safflower seeds and flour compared to varieties without irradiation, although this performance improvement is different in different varieties and times. The results show that the irradiated Goldasht seed has the highest NDF digestibility in all incubation hours compared to other treatments. According to the obtained results, it can be concluded that radiation can increase the nutritional value of food, which has been proven in several studies, and among them, factors such as different types of food and method Radiations can be considered important factors in achieving effective results.

Session 46

Poster 18

Effect of different levels of propolis, nitrate, thyme and mint essential oil on digestibility*M. Besharati and M. Mousavi**University of Tabriz, Animal Science, 29th Bahman Blv., 51666, Iran; m_besharati@hotmail.com*

The aim of this study was to investigate the effect of using different levels of bee propolis, calcium nitrate, thyme and mint essential oil on *in vitro* gas production and digestibility by using 3 experiments (gas production, *in vitro* degradability, three-step digestibility) was performed in a completely randomized design with 9 treatments. The experimental treatments included: 1. diet (control), 2.diet containing 500 mg propolis/kg DM 3. diet containing 1000 mg propolis/kg DM 4. diet containing 1.5 g calcium nitrate/100 g DM 5. diet containing 3 g calcium nitrate/100 g DM 6. diet containing 100 mg thyme essential oil/kg DM 7. diet containing 200 mg thyme essential oil/kg DM 8. diet containing 100 mg mint essential oil/kg DM 9. diet contained 200 mg mint essential oil/kg DM. The results showed that the treatment containing thyme essential oil (100 mg) caused a decrease and the propolis (1000 mg) and calcium nitrate (1.5 g) treatments significantly increased the amount of gas produced ($P<0.05$). The treatment containing mint essential oil (200 mg) had a significant effect on digestibility in that it reduced the digestibility of dry matter and insoluble fibres in acidic detergent, but in the kinetics of degradability in the rumen, it increased the degradability of dry matter, insoluble fibres in neutral and acidic detergent ($P<0.05$). Treatments containing propolis increased the degradability of dry matter, insoluble fibres in neutral and acidic detergents, and the treatment containing propolis (1000 mg) increased the degradability of dry matter and insoluble fibres in neutral detergents in the total gastrointestinal tract. Treatments containing thyme essential oil (200 mg) and calcium nitrate (1.5 g) significantly reduced the degradability of insoluble fibres in neutral and acidic detergents in the rumen and the total gastrointestinal tract ($P<0.05$).

Combination of lactic acid bacteria inoculant in difficult to ensile grass after 15 days of ensilingM. Duvnjak¹, L. Dunière², B. Andrieu², E. Chevaux² and C. Villot²¹University of Zagreb, Department of General Agronomy, Faculty of Agriculture, Zagreb, Croatia, ²Lallemand SAS, Blagnac, 31700, France; cvillot@lallemand.com

The main objective was to evaluate the impact of an inoculant combining homofermentative and heterofermentative bacteria on the microbiota and fermentation profile of a sugar rich grass ensiled for only 15 days. Pure Italian ryegrass (1st cut, DM=46.8%, WSC=33.4%) was chopped and ensiled in macro-silos of 40 l. Five replicates were ensiled without inoculant (CTRL), whereas another 5 replicates were inoculated with *P. pentosaceus*, *L. buchneri*, and *L. hilgardii* (INOC). A faster acidification in INOC compared to CTRL samples was observed (4.18 vs 4.58) thanks to the accumulation of lactic acid (103.2 vs 56.0 g/kg DM). A higher level of acetic acid was reported in CTRL compared to INOC (15.0 vs 9.0 g/kg DM) confirming the heterofermentative activity at early stage in non-inoculated silage. A large diversity of LAB (*Lentilactobacillus* and *Latilactobacillus*) was reported in the CTRL silage illustrating the natural fermentation process whereas INOC silage was dominated by *Pedococcus* and *Lentilactobacillus* supporting the fastest pH drop observed. Amplicon sequence variants (ASV) specific of inoculated strains were identified, with inoculated *L. hilgardii* and *L. buchneri* being higher in the INOC silages compared to CTRL. Non-inoculated silage was characterized by two wild ASVs of *L. buchneri/parabuchneri* partly responsible for the highest acetic acid level although no reduction in the total mould development was noted (5.2 vs 4.3 log10 cfu/g). In addition, undesirable bacteria *E. coli* was observed in significantly greater abundance in the CTRL silage than in the INOC samples (0.08 vs 0.03%). The dominant homolactic pattern of the inoculated silages supports lower fermentation losses (3.1 vs 9.9% of DM). The use of homolactic bacteria in difficult to ensile grass helps minimizing fermentation losses early on and may balance the development of dominant heterofermentative epiphytic flora that slows the acidification process without clear effects on antifungal metabolite production. Not all *L. buchneri* strains are metabolically similar and inoculation with selected strains can limit less efficient wild species to drive fermentation profile and silage quality.

Session 46

Poster 20

Effect of whey on *in vitro* ruminal methane formation and digestibility in cowsH. Luisier-Sutter^{1,2}, L. Isele¹, M. Terranova³, S.L. Amelchanka³ and M. Schick^{1,2}¹University Hohenheim, Institute for Agricultural Engineering, Garbenstrasse 9, 70593 Stuttgart, Germany, ²Strickhof, Division Animal Husbandry & Dairy Production, Eschikon 21, 8315 Lindau, Switzerland, ³ETH Zurich, AgroVet-Strickhof, Eschikon 27, 8315 Lindau, Switzerland; helene.luisier@strickhof.ch

The agricultural sector is responsible for a large part of methane emissions worldwide, mainly because of cattle detention. Methane is produced by fermentative processes in the digestive tract of ruminants. Hence, feeding strategies might lower methanogenesis. Whey is a byproduct of caseation. It is available in large quantities, cheap and has a high nutritive value. Whey is rich in water-soluble carbohydrates since it mainly consists of lactose. Water-soluble carbohydrates do modify the fermentative processes in the rumen and might affect methanogenesis. A previous study from Agroscope (unpublished) on whey feeding in heifers observed a methane reduction of 37%. However, further research is needed to investigate the potential of whey as an inhibitory agent on methanogenesis. To this aim, an *in vitro* study was conducted using the Hohenheim Gas Test (HGT) method. A basal diet, consisting of grass-silage and hay (66% : 33%) was supplemented either with Emmentaler cheese whey, whey powder or pure lactose. The latter was added to test if the water-soluble carbohydrates in whey could be responsible for methane inhibition. Ruminal fluid was taken from 3 rumen-cannulated Original Brown Swiss cows and incubated in 4 consecutive runs. For every run the roughage-based diet served as basal diet. Whey, whey powder and lactose replaced the basal diet in 3 different dosages: 5, 15 and 30% of diet DM for whey and whey powder and 1, 10 and 20% of diet DM for lactose to test for an effect of dosage as well. In total, there were 20 replicates per treatment and dosage. Against our expectations, preliminary results suggest that the addition of whey increased *in vitro* ruminal methanogenesis. The same effect, on a smaller scale, was found for whey powder and lactose. *In vitro* organic matter digestibility was also elevated with whey, whey powder and lactose. This finding is in line with previous studies which suggested that whey is an interesting option for replacing concentrate due to its high digestibility and feeding value.

Ellagic acid and gallic acid reduced methane and ammonia in an *in vitro* rumen fermentation modelM. Manoni¹, S. Amelchanka², M. Terranova², L. Pinotti¹, P. Silacci³ and M. Tretola^{1,3}¹University of Milan, Department of Veterinary Medicine and Animal Science, Via dell'Università 6, 26900, Lodi, Italy,²ETH Zurich, AgroVet-Strickhof, Eschikon 27, 8315, Lindau, Switzerland, ³Agroscope, Posieux, Rte de la Toileyre 4, 1725,

Posieux, Switzerland; michele.manoni@unimi.it

Livestock production must meet the growing demand for animal-source food and reduce the impact on the environment. Different strategies are studied to lower greenhouse gas (GHG) emissions in ruminants, and one of them is tannin supplementation. The dietary supplementation with tannins can affect the enteric fermentation, reducing methane emissions. Following a previous screening, we investigated the effect of two hydrolysable tannins, ellagic acid (EA) and gallic acid (GA), in a long-term *in vitro* rumen fermentation. EA and GA were supplemented to a control diet (CTR: ryegrass hay and barley concentrate, 10 g DM/day) in an 8-fermenter rumen simulation technique (Rusitec), for 10 days. Three experimental conditions were investigated: (1) EA 75 mg/g DM; (2) GA 75 mg/g DM; (3) EA 75 mg/g DM + GA 75 mg/g DM. The data were collected in the last 5 days of the incubation time. Total gas production was not altered over the last 5 days, whereas daily methane (CH₄) production was significantly decreased by EA (-45%) and EA+GA (-60%), compared to control. CH₄ production per unit of dietary organic matter (OM) and short-chain fatty acids (SCFA) was also reduced by EA (-48% and -32%) and EA+GA (-65% and -58%), and less by GA (-19% and -22%). Ammonia formation was significantly reduced by EA (-46%), GA (-19%) and EA+GA (-86%). Total SCFA production was decreased by EA and EA+GA (-26%, -16%), but not by GA. Similarly, EA and EA+GA, but not GA, reduced rumen degradability of OM, crude fibre (CF) and crude protein (CP). All the treatments increased the bacterial count and decreased the protozoal count (except for GA). EA and EA+GA modulated the relative abundance of selected rumen bacterial taxa. These data proved that both EA and GA decreased GHG emissions and ammonia formation, with EA being most effective than GA. Nevertheless, GA showed a lower interfering effect on nutrient rumen degradability. Further details on rumen microbiota dynamics and hydrolysable tannins metabolism will complete the outcome of the study.

Effect of toasted soybean on dairy cows milk performancesA. Berchoux¹, M. Duval¹, E. Hermant², M. Legris¹ and M. Jouffroy¹¹Institut de l'Elevage, 149 rue de bercy, 75012, France, ²EPLEFPA Rethel, route de novion, 08300, France;

alice.berchoux@idele.fr

Protein crops can be a way to reduce the use of imported soya meal. However, most of the protein content in crude pea/bean crops deteriorate very quickly in rumen. Heating protection of proteins can be a solution to increase the proportion of feed protein in the intestine (PDIA). This process was tested and evaluated on a mixed-crop dairy farm in French Ardennes. The trial was conducted in 2022 on two groups (control and testing) of twenty-seven dairy cows in complete and balance blocks. The control group received crude soybean and the testing group received toasted soybean. The trial started with a pre-testing period of two weeks and followed by a testing period of ten weeks. An analysis of enzymatic degradability at 1 hour (DE1) was done with crude and toasted soybean. For each cow, milk production, composition (protein and fat contents) and urea rate were analysed each week. Ingestion of dry matter per group was measured each day. The statistical analysis was done on the covariance on the mean data of the testing period, with covariate from the pre-testing period. Toasted soybean had a DE1 of 32% against 83% for crude soybean. PDI increased by 49% and PDIA by 123%. Toasting process did not have significantly impact on milk production and fat contents. Protein contents of the testing group significantly increased of 19 g/day ($P < 0.05$) but protein concentration (g/kg of milk) did not increased. Urea rate did not vary between each group. DM intake was similar between each group (18.3 kg of DM/d). In regard of feeding system INRA07, the toasting process allowed to enhance PDIE intake of 109 g/d for the testing group. With a marginal efficiency of 20%, the response of protein contents (g/d) was in coherence with the result of our trial, but the increase was not enough to impact protein concentration (g/kg of milk) which is in coherence with previous results. The feeding cost of the testing group was higher of 4,1€/1000 l, with a stable milk performance the feeding margin was lower.

The addition of dry ice as an attempt to inhibit proteolysis during ensilage of lucerne

M. Borsuk-Stanulewicz, C. Purwin and M. Mazur-Kuśnerek

University of Warmia and Mazury in Olsztyn, Department of Animal Nutrition, Feed Science and Cattle Breeding, Oczapowskiego 5, 10-719 Olsztyn, Poland; marta.borsuk@uwm.edu.pl

Lucerne (*Medicago sativa* L.) is an important crop plant of economic importance in animal and human nutrition, with a species susceptibility to proteolysis during ensilage. The hypothesis assumes that the addition of carbon dioxide as dry ice would modify the gaseous environment of the ensiled lucerne and improve the fermentation parameters, limiting proteolysis. The aim of the study was to investigate the effect of different levels of dry ice addition on the fermentation profile and protein fractions of ensiled lucerne. Lucerne was harvested in the first cut at the beginning of bud formation stage, at a height of 5 cm. The herbage was cut to a particle with an average length of 25 mm and the one part was allowed to wilted for 12 hours. Lucerne was ensiled in micro silos (1 dm³) with the addition of: 0 g – control, 0.5, 1 and 2 g dry ice. After 50% of the micro silos volume was filled, dry ice was added as granules of a diameter of 16 mm and densiting was continued. The micro silos equipped with fermentation tubes were closed after the densiting was ended. The proximate chemical composition, fermentation parameters and nitrogen fractions were performed according to standard methods described in the literature. According to the literature, the parameters of fermentation were correct. Dry ice (2 g) significantly reduced ammonia nitrogen in both groups of silage (fresh and wilted) and reduced (1 and 2 g) the degradation of true protein in silage regardless of wilting. In unwilted lucerne silage (2g dry ice) the fraction of protein insoluble in neutral detergent increased. According to the CNCPS, the addition of dry ice significantly reduced the PA1 fraction and the proportion of fibre-bound protein (PB2) in wilted lucerne silage. The addition of 1 and/or 2 g dry ice significantly changed the fermentation parameters, limiting ammonia nitrogen and degradation of true protein. This research was funded in whole or in part by the National Science Centre, Poland grant no. 2021/41/N/NZ9/01881. For the purpose of Open Access, the author has applied a CC-BY public copyright licence to any Author Accepted Manuscript (AAM) version arising from this submission.

***In vitro* effects of *Bacillus subtilis* CH201 and *Bacillus licheniformis* CH200 on rumen microbiota**R. Gresse¹, G. Copani², B.I. Cappellozza², A. Torrent¹, D. Macheboeuf¹, E. Forano³ and V. Niderkorn¹¹UCA, INRAE, VetAgro Sup, UMRH, Route de Saint Genes, 63122 Saint Genes Champanelle, France, ²Chr. Hansen, Animal and Plant Health & Nutrition, Boege Alle 10/12, 2970 Hørsholm, Denmark, ³UCA, INRAE, UMR 454 MEDIS, Route de Saint Genes, 63122 Saint Genes Champanelle, France; raphael.gresse@inrae.fr

Direct-fed microbials has improved livestock's performances and overall health status. Several research studies have been undertaken to find new potential probiotics and to gain knowledge about their mechanisms of action in the gut. *Bacillus* species are multifunctional spore-forming bacteria surviving to harsh conditions and thus having numerous potential applications in feed industry and livestock production. The present study aimed to investigate the mode of action of *B. licheniformis* CH200 and *B. subtilis* CH201 (BOVACILLUS™, Chr. Hansen, Denmark) in the rumen using diverse *in vitro* techniques. *In vitro* inoculation of spores showed that both strains were able to germinate and grow in rumen and intestinal contents obtained from dairy cows. Gas composition analysis of *in vitro* cultures in a medium containing 40% rumen juice revealed that germination of CH200 and CH201 strains could reduce O₂ level, thus favouring an anaerobic environment beneficial for rumen microbes. Additionally, we observed that a cocktail containing CH200 and CH201 spores in a rumen fluid medium could survive and grow with a commercial dose of monensin sodium. The effects of CH200 and CH201 on rumen fermentative activity and microbiota were studied using an *in vitro* batch fermentation assay. In fermenters that received a combination of CH200 and CH201, less CO₂ was produced while dry matter degradation and CH₄ production was similar compared to the control condition, indicating a better efficiency of dry matter utilization by the microbiota. Investigation of the microbiota composition in fermenters showed that although no significant effect was observed on alpha and beta diversity, the differential analysis highlighted changes in several taxa in the supplementation condition compared to the control condition. Altogether, these data suggest that the administration of a cocktail of CH200 and CH201 could have a beneficial impact on rumen function and consequently on health and performance of ruminants.

Effect of nitrate and its interaction with starch levels on methane production in continuous culture

Y. Roman-Garcia, S. El-Haddad, S. Van Zijderveld and G. Schroeder

Cargill Animal Nutrition and Health, Innovation Campus, 10383, 165th Ave NW, Elk River, MN, 55330, USA;

yairy_romangarcia@cargill.com

The objective of this study was to evaluate the effect of calcium nitrate (SilvAir®, Cargill Inc.) supplementation and its interaction with levels of starch on methane production and rumen fermentation in *in vitro* continuous culture. Twelve fermenters were used in a randomized block design experiment of 2 periods (10-d each) consisting of 2 diets (21% or 28% starch; LST or HST, respectively) with or without nitrate supplementation at 1% DM in a factorial arrangement. Fermenters (2 l capacity) were fed (~ 100 g) a lactating cow diet once a day. Treatments were made isonitrogenous by adding urea or nitrate and starch levels were modified by replacing fine ground corn with soyhulls. Methane in the headspace was monitored continuously in all fermenters using a Micro-Oxymax Respirometer (Columbus Instrument Inc., Columbus OH). Data was analysed with lmer in R with fixed effects of diet, treatment, and their interaction, and the random effects of period and fermenter. Overall, nitrate supplementation reduced ($P<0.01$) methane production rate by 21% (3.67 vs 2.89 g/d). There was a tendency for an interaction ($P=0.06$) starch level by nitrate supplementation, suggesting that reduction of methane by nitrate was higher in HST than LST (-30 vs -6%, respectively). Treatments with nitrate had lower methane production rate on all 24 hours post-feeding. There was no effect of treatments on starch degradation (98%). Replacing urea by nitrate did not affect NDF degradability, but HST reduced NDF degradation (49 vs 41%; $P=0.03$). Supplementing nitrate did not affect total VFA concentration, but that was higher in LST than HST (111 vs 121 mM, $P<0.01$). Both nitrate and LST increased ($P<0.01$) acetate production and decreased ($P<0.01$) propionate production, resulting in higher acetate:propionate ratio (2.30 vs 2.61, $P<0.01$). Mean daily pH was not affected by nitrate, but the LST diet had a tendency ($P=0.08$) to decrease mean daily pH (6.03 vs 5.99) mostly explained by lower pH between 12 to 24 h after feeding. This study validates that nitrate is an effective strategy to reduce methane production and that the magnitude of the reduction can vary with the type of diet.

Effect of garlic processing method on *in vitro* methane production and rumen fermentationN.F. Sari^{1,2}, S. Stergiadis², P.P. Ray^{2,3}, C. Rymer², L.A. Crompton² and K.E. Kliem²¹National Research and Innovation Agency, Cibinong, 16911, Indonesia, ²University of Reading, Reading, RG6 6EU, United Kingdom, ³The Nature Conservancy, Arlington, VA 22203, USA; nurulfitri.sari@pgr.reading.ac.uk

The effect of garlic processing method (freeze-dried, FD; oil) and origin (China; Spain) at different dietary inclusion rates (3, 6, 12% on dry matter (DM) basis) on gas, methane (CH₄) and volatile fatty acid (VFA) production was assessed in a batch culture *in vitro* system. Garlic was chopped, and stored at -20 °C until processing. One batch from each origin was freeze-dried and milled to <2 mm, and another batch underwent diethyl ether extraction of the essential oil. A total mixed ration (forage:concentrate, 50:50 DM basis) without (Control, CON) or with garlic at each of the three inclusion rates was incubated for 72 h with rumen fluid: incubation medium at 1:9 v/v. Gas pressure was recorded and gas samples were analysed for CH₄ concentration by gas chromatography at intervals throughout the incubation. DM degradability (DMD) and VFA concentrations in the medium were assessed after 72 h. The gas and CH₄ production profiles were fitted to the model of France *et al.* Data were analysed by linear mixed models, using processing method, origin, and their interaction as fixed, and run as random, factors. DMD (g/kg DM) was higher ($P<0.01$) in FD, than in CON, across all inclusion rates (807, 797, and 791 vs 783 at 12, 6 and 3% DM, respectively); and the same was observed for OIL at 12% DM (811) and 6% DM (802). Total CH₄ production (ml/g DM) was higher ($P<0.05$) in OIL, than in CON (10.9 ml), at 6% (12.4 ml) and at 12% (11.9 ml) but not at 3% DM ($P>0.05$). Acetate:propionate ratio (A:P) was lower ($P<0.001$) in both garlic treatments across all inclusion rates (2.4-2.9) compared with CON (3.0). Garlic origin did not affect DMD and A:P ($P>0.05$). Garlic from China resulted in higher total CH₄ production (12.7 ml/g DM) than garlic from Spain (10.0 ml/g DM) at 3% DM ($P<0.05$) but origin had no effect at 6 and 12% DM ($P>0.05$). Garlic from China resulted in higher terminal pH than garlic from Spain across all inclusion rates (6.8 vs 6.5). Adding garlic did not reduce *in vitro* CH₄ production but improved overall diet DMD.

Effects of Red Sorghum and *Rhizoma paridis* on rumen protozoa, fermentation characteristics *in vitro*R. Yi^{1,2}, S. Vigers¹, L. Ma², J.C. Xu² and D.P. Bu²¹University College Dublin, School of Agriculture and Food Science, Belfield, Dublin 4, Ireland, ²Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, State Key Laboratory of Animal Nutrition, Yuanmingyuan West Road NO.2, Haidian District, Beijing, 100193, China, P.R.; ran.yi@ucdconnect.ie

The inclusion of plant-derived supplements in ruminant diets is one potential strategy to modify fermentation and reduce emissions. Rumen protozoa play an important role in lowering nitrogen utilization efficiency (NUE) and are therefore, a target for alterations both in numbers and functionality. This research aimed to examine the potential of *Sorghum bicolor* L. Moench (RS) (0, 10.4, 20.8, 41.6, 83.2 mg/g) and *Rhizoma paridis* (RP) (0, 2.6, 5.2, 10.4, 20.8 mg/g) to inhibit rumen protozoa *in vitro* and impact NUE. Fresh rumen fluid was collected from four cannulated dairy cows and filtered. The effect of RS and RP powder (n=6) was tested on rumen protozoal counts and fermentation characteristics following 18 hours of *in vitro* culturing. Rumen protozoal cells were morphologically identified and counted using microscopy. Ammonia nitrogen (NH₃-N) and microbial protein (MCP) concentrations in the *in vitro* cultures were tested using colorimetric determination, and concentrations of volatile fatty acids (VFAs) were determined using gas chromatography. Data were analysed in a complete randomized design using RStudio (version 1.4.1717). The results demonstrated that, compared with the control group, RS and RP stem powder at 83.2 and 5.2 mg/g decreased *Entodinium* cells by 35.33 and 26.04%, respectively ($P<0.05$). NH₃-N was decreased by 32.15 and 15.27% at 83.2 and 5.2 mg/g inclusion of RS and RP stem respectively. In addition, methane production was predicted to be reduced by 15% with inclusion of 83.2 mg/g of RS, while total VFA production was unchanged. Moreover, after correlation analysis, the number of total protozoa and *Entodinium* are positively correlated with NH₃-N, isobutyrate, A:P ratio and methane, while, negatively correlated with Propionate and MCP. In conclusion, RS and RP may be potential feed additives to enhance NUE in ruminants without impairing fermentation characteristics, but future research is warranted to identify the target phytochemicals and evaluate in animal trials.

Session 46

Poster 28

Phytochemicals can modify the rumen fermentation profile as monensinL. Gonzalez¹, A.C. Dall-Orsoletta², D. Mattiuda¹, A. Daudet¹, T. Garcia¹, P. Chilibraste¹, A. Meikle³, M. Arturo-Schaan², A. Casal¹ and M.A. Bruni¹¹Facultad de Agronomía, Ruta 3 km 363, 60000, Paysandú, Uruguay, ²Deltavit, CCPA Group, ZA du Bois de Teillay, 35150, JANZÉ, France, ³Facultad de Veterinaria, Ruta 8 Km 18, 13000, Montevideo, Uruguay; acdallorsoletta@ccpa.com

To investigate the influence of phytochemicals (PE; containing Trans cinnamaldehyde, Flavonoids, Curcuminoids, and Piperine) and a monensin (MO) on the rumen fermentation parameters rumen liquid samples were collected from 9 fistulated cows 7 d prepartum, 30 and 60 d postpartum from cows that had either received a PE (n=3) or MO (n=3) from 3 weeks antepartum on feed, or a control diet (n=3). The samples were analysed for pH, volatile fatty acid (VFA), ammonia concentrations, and protozoal counts. Before calving cows ate a total mixed ration (70% forage+30% concentrate on DM basis) after calving cows had a daily grazing shift (*Medicago sativa*) and were supplemented with a partial mixed ration (45% forage+55% concentrate on DM basis). In the prepartum ruminal sample, there were no differences in ruminal pH, ammonia, and total VFA as well as the proportion of the main VFA (acetate, propionate, butyrate). However, PE increase the branched-chain fatty acids compared to the control, and MO and PE treatments decreased the number of protozoa by 39% ($P<0.01$). During the postpartum period, there were no differences in ruminal pH, acetate proportion, and acetate: propionate. Ammonia concentration was lower on PE ($P<0.01$). Total VFA is similar between PE and MO, but PE decreases is comparable to the control ($P=0.09$). PE and MO modified the VFA proportion. Propionate proportion was not affected by MO, but was increased by PE treatment ($P=0.08$). PE reduced butyrate and isobutyrate compared to MO and control ($P<0.01$). MO and PE treatments decreased the number of protozoa on average by 38 and 64%, respectively ($P<0.01$). The rumen fermentation profile was affected by physiological conditions, diets, and PE or MO supplementation, additionally, the results suggest that PE can be useful as a rumen fermentation modifier and, considered as a potential alternative to monensin.

***In vitro* fermentation of TMR using rumen fluids from cows supplemented with hemp and savory leaves**S. Arango¹, S. Massaro¹, S. Schiavon¹, N. Guzzo¹, M. Montanari², L. Bailoni¹ and F. Tagliapietra¹¹University of Padova, BCA/DAFNAE, V. dell'Università 16, Legnaro, 35020, Italy, ²Council for Agricultural Research and Economics, V. di Corticella 133, 40128 Bologna, Italy; sheylajohannashumyko.arangoquispe@phd.unipd.it

Industrial hemp (*Cannabis sativa* L.) leaves could be a good source of protein and fibre for ruminants. Summer savory (*Satureja hortensis* L.) is an aromatic plant with antimicrobial and antioxidant activities. The aim was to assess the fermentation parameters during *in vitro* incubations of rumen fluids collected from cows fed a total mixed ration (TMR) supplemented with hemp and savory leaves. Hemp leaves were harvested at the Center for Cereal and Industrial Crops (CREA-CI, Rovigo, Italy) and savory was provided by Agripharma srl (Padova, Italy). Six Italian Simmental lactating cows were divided into 3 groups on a 3×3 Latin square design. Each experimental period lasted 2 weeks. A TMR, based on grass and sorghum silages, was used for the experiment. During the first week, the control group (CTR) was fed with TMR, the hemp leaves group (HL) and savory group (SS) were fed TMR plus increasing amounts of leaves until 1.5 and 1.0 kg/d were reached, resp. Rumen fluid samples were collected after the first week of each period by an oesophageal probe and analysed for volatile fatty acids (VFA). Three rumen fluids were used as inocula on *in vitro* incubations with an automated gas production (GP) equipment. Each run (48 h) used TMR as substrate to test the microbial activity. The fluids were analysed after fermentation for pH, dry matter degradability (DMd), ammonia nitrogen, VFA, GP kinetics and gas composition (CH₄, CO₂, H₂). Results showed that the acetic acid proportion in the rumen fluid was lower in the HL than the CTR group (57.4 vs 59.3% of VFA; $P < 0.10$). The HL rumen fluid did not affect DMd of the TMR or GP kinetics but, it increased the acetic acid proportion (50.0 vs 48.1% of VFA; $P < 0.10$). Despite these, methane production was similar in both groups. Savory supplementation did not show any effect on rumen fluid composition or *in vitro* parameters. To conclude, fresh hemp and savory leaves did not have an inhibitory effect on rumen TMR degradability. It appears that HL have a slight effect on rumen microbial activity by modulating VFA production. Funded: BIRD213117/21.

***Bacillus licheniformis* and *B. subtilis* on *in vitro* ruminal parameters and greenhouse gas emission**B.R. Amancio¹, E. Magnani¹, T.H. Silva¹, A.L. Lourenço¹, B.I. Cappellozza², R.H. Branco¹ and E.M. Paula¹¹Institute of Animal Science, Beef Cattle Research Center, Rodovia Carlos Tonanni, km 94, 14.160-970, Sertãozinho, SP, Brazil, ²CHR Hansen A/S, Research and Development, Boege Alle 10-12, 2970 Horsholm, Denmark; renata@sp.gov.br

Three *in vitro* experiments were conducted to evaluate the effects of increasing levels of *Bacillus licheniformis* and *Bacillus subtilis* (BB) on *in vitro* ruminal parameters and enteric greenhouse gas (GHG) emissions in three different scenarios. For Exp. 1, the basal diet consisted of 25:75 roughage: concentrate ratio (R:C) and was composed by 3 treatments: control (no additive) and 2 levels of BB (3.8 mg and 19 mg). The Exp. 2 consisted of a 40:60 R:C diet and was composed by 3 treatments: control (no additive) and 2 levels of BB (5.6 and 28 mg). The Exp. 3, consisted of a 100:0 R:C diet [*Brachiaria* (syn. *Urochloa brizantha*)] and the same treatments as in Exp. 1. The BB product contained *Bacillus licheniformis* + *Bacillus subtilis* (3.2×10^9 cfu/g). An *in vitro* gas production (GP) system with 12 bottles (AnkomRF) was used in four consecutive fermentation batches each experiment to evaluate total GP (TGP), volatile fatty acids (VFA), enteric methane (CH₄) and carbon dioxide (CO₂). Supplementation levels of each experiment were analysed for linear and quadratic responses using the software SAS 9.4. For Exp. 1, there were no effects of BB on ruminal fermentation and GHG emissions. For Exp. 2, after 48 h of fermentation, TGP and organic matter digestibility (OMD) increased quadratically with increasing BB supplementation. In addition, propionate increased quadratically with increasing doses of BB, which reflected on reduced acetate to propionate ratio. Ammonia-N and CH₄ and CO₂ emissions related to OMD also reduced quadratically according to BB addition. Finally, for Exp. 3, after 48 h of fermentation, TGP increased linearly as BB increased. In addition, butyrate proportion and ammonia-N reduced linearly and quadratically, respectively, as BB increased. Overall, BB supplementation may improve ruminal fermentation and reduce GHG emissions in a dose-dependent manner, but the outcomes are dependent upon diet type.

Bioproduct from royal palm colonized by *Lentinula edodes* on *in vitro* ruminal fermentation

¹Universidade do Estado de Santa Catarina, Beloni Trombeta Zanin street, 680E, 89815-630, Chapecó, Santa Catarina, Brazil, ²Institute of Animal Science, Carlos Tonani Road, km 94, 14160-970, Sertãozinho, São Paulo, Brazil, ³Fundação Universidade Regional de Blumenau, Antônio da Veiga street, 140, 89030-903, Blumenau, Santa Catarina, Brazil, ⁴Washington State University, ASLB, 120, 99164-6310, USA; dasilvath2@gmail.com

The agroindustrial by-products use in ruminant nutrition have a great potential to promote both profitability and sustainability. The king palm (*Archontophoenix spp.*) residue is a high fibre content. Thus, its treatment with fungal (*Lentinula edodes*) colonization produces a more digestible bioproduct that can be an interesting option for ruminant nutrition. Thus, the aim of this study was to evaluate the effect of king palm bioproduct on ruminal fermentation parameters in comparison with corn silage using an *in vitro* gas production system. The treatments were the two feeds (corn silage and king palm bioproduct), which were individually evaluated in three consecutive 48-hour incubations. Each treatment had 8 replicates, plus 3 blanks, totalling 19 observations per incubation. Sixteen 250 ml flasks were used to analyse fermentation parameters, total gas production, and rumen kinetics. Simultaneously, sixteen 100 ml flasks were used for enteric CH₄ and CO₂ evaluation. Data were analysed using the PROC NLMIXED (for gas production models estimation) PROC MIXED (remaining variables) in SAS, with $\alpha=0.05$. King palm bioproduct had lower total gas production, metabolizable energy, organic matter digestibility, and greenhouse gases profile. Regarding the kinetic parameters, king palm bioproduct presented lowest value for the first pool, compared with corn silage. However, treatments did not differ for the other kinetic parameters. These results suggest that king palm bioproduct has as sustainable potential to be used as roughage in feedlot diets.

***Enterococcus faecium* and *Saccharomyces cerevisiae* on *in vitro* rumen parameters and greenhouse gases**

B.R. Amancio¹, T.H. Silva¹, G.M. Wachekowski¹, H. Reolon¹, T.G. Timm¹, B.I. Cappellozza², E. Magnani¹, E.M. Paula¹ and R.H. Branco¹

¹Institute of Animal Science, Carlos Tonani Road, km 94, 14160-970, Sertãozinho, São Paulo, Brazil, ²Chr. Hansen, Boege Alle 10-12, 2970, Denmark; dasilvath2@gmail.com

Three *in vitro* experiments were conducted to evaluate the effects of increasing levels of *Enterococcus faecium* and *Saccharomyces cerevisiae* (ES) on *in vitro* ruminal parameters and enteric greenhouse gases emissions in three different diets. For Exp. 1, basal diet consisted of 25:75 roughage: concentrate ratio (r:c) and was composed by 3 treatments: control (no additive) and 2 levels of ES (1.9 mg and 9.0 mg). The Exp 2 consisted of a 40:60 r:c diet and was composed by 3 treatments: control (no additive) and 2 levels of ES (3.8 and 19.0 mg). Finally, Exp 3. consisted of a 100:0 r:c diet [*Brachiaria* (syn. *Urochloa brizantha*)] and the same treatments as Exp. 1. The ES contained 2.5 and 1.5×10⁹ cfu/g of *Enterococcus faecium* and *Saccharomyces cerevisiae*, respectively. An *in vitro* gas production (GP) system with 12 bottles (AnkomRF) was used in four consecutive fermentation batches each experiment to evaluate total GP (TGP), volatile fatty acids (VFA), enteric methane (CH₄) and carbon dioxide (CO₂). Supplementation levels of each experiment were analysed for linear and quadratic responses using the software SAS 9.4. For Exp. 1, after 24 and 48-h of fermentation, TGP and organic matter digestibility (OMD) increased quadratically with increasing ES. Further, ammonia-N, as well as CH₄ and CO₂ related to OMD decreased quadratically. For Exp. 2, after 24 and 48-h of fermentation, TGP and OMD increased quadratically with increasing ES inclusion. Also, butyrate proportion, ammonia-N, and CH₄ and CO₂ emissions related to OMD reduced quadratically according to ES addition. Finally, for Exp. 3, similar quadratic increase of TGP and OMD were detected after 48 and 72-h of fermentation. Further, quadratic increase of pH and branched-chain volatile fatty acids were detected as ES increased. Ammonia-N was quadratically reduced with increasing doses of ES. Overall, ES supplementation may improve rumen fermentation as well as reduce GHG emissions of different diets in a dose-dependent manner with no detrimental effects on VFA profile.

Rumen protected calcium gluconate improves milk production of cows*J.G.H.E. Bergman, B. Skibba and M. Hall**Nutreco, Selko, Stationsstraat 77, 3800 AG Amersfoort, the Netherlands; jac.bergman@selko.com*

Calcium gluconate (CG) is a prebiotic that increases butyrate in the hindgut, reducing the risk of leaky gut. Trials have shown that abomasal infusion of CG increases milk production and feeding rumen protected calcium gluconate (RPCG) increases fat corrected milk ($P=0.056$) and energy corrected milk ($P=0.086$). Purpose of this trial was to test the effect of RPCG (LactiBute, Selko) on 2 commercial farms. The first farm had 550 cows, 65 were randomly divided in 2 groups, immediately after calving until 120 days into lactation. Both groups were fed TMR with 270 g starch and 180 g crude protein/kg DM. RPCG was added to the TMR of the test group. Milk production and solids were recorded on day 0, day 30, day 60, day 90 and day 120. Average milk production over the entire period was 2.35 kg/cow/day higher in cows fed RPCG ($P<0.05$). Average production of energy corrected milk by 2.77 kg/cow/day ($P<0.05$). The second farm had 240 cows, 71 cows were randomly allocated to one of 2 groups and included at 30 days after calving until they were 120 days into lactation. Both groups were fed TMR with 260 g starch and 170 g crude protein/DM. RPCG was added to the TMR of the test group. Milk production was recorded on day 30, day 60, day 90 and day 120. Milk solids were not measured on this farm. Average milk production over the entire period was 1.85 kg/cow/day higher in the group of cows fed RPCG ($P<0.05$). Conclusion: milk production increased in cows kept under commercial conditions as a result of feeding rumen protected calcium gluconate. These results are in line with the results of earlier trials.

Session 46

Poster 34

Rumen protected calcium gluconate improves lactational performance*J.G.H.E. Bergman, F. Morisset and M. Hall**Nutreco, Selko, Stationsstraat 77, 3800 AG Amersfoort, the Netherlands; jac.bergman@selko.com*

Rumen protected calcium gluconate (RPCG) has a prebiotic effect in the hindgut, increasing volatile fatty acid production, which reduces the risk of leaky gut and improves milk production. Earlier trials have shown that RPCG increases milk production of dairy cows. Purpose of the current trial was to test RPCG (LactiBute, Selko) in 3 French farms. RPCG was fed for 4 months. Milk recordings were compared to predicted production based on genetic potential of each of the 3 dairy herds included in the trial, based on data from all cows using the same supplier of bull semen that also recorded production data on all their farms. Farm 1 had 120 cows, 155 days in milk at the start of the trial. Persistence of milk production was improved as a result of feeding RPCG with a difference in milk production of up to 1.7 kg of milk. Farm 2 had 90 cows, 138 days in milk when the trial started. RPCG resulted in a better persistence of milk production with a difference of up to 1.8 kg of milk per day. Farm 3 had 200 dairy, 170 days in milk when the trial started. Persistence of milk production in cows fed RPCG increased. When the trial was 2 months underway, respiratory disease occurred, leading to a drop in production. When the herd recovered, milk production in the cows on RPCG recovered faster, with a difference of up to 2.7 kg of extra milk per day. Conclusion: before the start of the trial, production on all 3 farms was equal to the predicted production based on genetic potential. Persistence of milk production improved during the period cows were fed RPCG. Once RPCG was stopped, milk production dropped to a level at or even below the predicted genetic potential.

Increase milk production by preserving the nutritional value of the dairy ration*L.L.C. Jansen, J.G.H.E. Bergman and S.J.A. Van Kuijk**Selko, Feed Additives, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands; lonneke.jansen@trouwnutrition.com*

Growth of micro-organisms in a Total Mixed Ration (TMR) for dairy cows reduces both the palatability and feeding value of TMR. Applying a synergistic blend of organic acids to reduce the growth of microbes in TMR is a critical step in proper silage management. The objective of this study was to test the impact of TMR preservation with an organic acid based blend on milk production of dairy cows. The study was carried out with 120 lactating, of which 8 fistulated, dairy cows on the Trouw Nutrition dairy research centre (Kempenshof, the Netherlands). Cows were blocked based on parity and days in milk (DIM). After an adaptation period of 1 week, both groups of 60 dairy cows each were fed the same diet based on a mixture of grass and corn silage, mixed into a TMR. The treatment group received TMR including 2kg/mt of the organic acid blend (Selko® TMR, Selko®, Tilburg, The Netherlands). Both groups were fed once a day for a total study period of 7 weeks. Compound feed was fed according to a standard curve based on DIM. Environmental temperature and humidity were monitored. Individual dry matter intake (DMI) of the TMR was measured daily using automatic feeding bins. Milk production including milk solids was recorded weekly for each animal and the volatile fatty acid (VFA) profile of rumen fluid was measured weekly in the 8 fistulated cows. Average daily temperatures were between 20 and 30 °C during the study. The Temperature Heat Index was above 72 regularly, which suggests that the cows were suffering from heat stress. DMI and VFA profile of rumen fluid did not differ significantly during the study. At the start of the study, there was an insignificant difference of 0.3 kg/day ($P=0.52$) of milk production between the treatment groups. This difference numerically increased towards the end of the study with the cows fed the organic acid blend producing 1.7 kg/day more milk compared to the control ($P=0.07$). Milk fat and protein levels (g/kg) did differ significantly. Although feed intake was not different in this study, dairy cows fed the treated TMR tended to produce up to 1.7 kg/day more milk compared to the controls. This increase of milk production is most likely related to a higher nutritional value of the TMR treated with the organic acid blend.

Session 46

Poster 36

VistaPre-T, a crude fermentation extract to support the sustainable use of forages in dairy rations*V. Blanvillain, E. Bungenstab and G. Gomes**AB Vista, Woodstock Court, Marlborough, United Kingdom; virginie.rivera@abvista.com*

Enteric methane corresponds to approximately 40% of the carbon emissions coming from livestock. While feeding greater dietary starch or fat levels contribute to reducing enteric methane emissions per animal, greater NDF levels have the opposite effect. Under this perspective, forages do not appear to be an alternative to sustainable livestock farming, and the high variability of their quality and nutritional content makes it even more challenging. However, forages have a role to play in the biogenic cycle of methane, and in circular economy models. Along with an accurate forage characterization, nutritional strategies which maximize nutrient utilization from forages are a means to support the use of these inputs while remaining sustainable. VistaPre-T (VPT, AB Vista, UK), a crude fermentation extract, significantly increased NDF and ADF digestibility, by increasing the utilization of hemicellulose and cellulose of forages in an *in vitro* rumen fermentation model ($P<0.05$). It was assumed that the greater digestibility could result in a beneficial impact on the global warming potential (GWP) of milk, thanks to a greater milk yield or a decrease in feed GWP. Two studies were performed in commercial farms to measure and compare the effect of VPT on GWP to a hundred years (GWP100), per kg of fat and protein corrected milk (FPCM) at farm gate. In the first study, VPT was added on top of a ration containing 70% of grass silage. Dry matter intake (DMI) decreased by 9%, with no significant impact on milk yield or composition. In the second study, the ration was reformulated to balance metabolizable energy content of the total mixed ration, by assigning an energy value of 800 kJ/kg of DMI from forage. A 5% reduction in DMI was observed, along with a 9% increase in milk yield. Overall, GWP100 was reduced by 4 and 15% per kg of FPCM, in the first and second study, respectively. Because no experimental data has yet been published, these estimates did not account for the potential beneficial effect of VPT on enteric methane emissions, as fiber digestibility is increased. Measuring GWP at farm gate helped understand the effect of feeding strategies on productivity, ingredient usage, and overall farm sustainability.

Early lactation trial with a blend of fat encapsulated vitamin B*A.D.G. Esselink¹ and C. Gordon²**¹Trouw Nutrition, Global Innovation, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands, ²Trouw Nutrition Canada, Dairy Technology Application, 7504 McLean Rd E, Puslinch, ON N0B 2J0, Canada; allard.esselink@trouwnutrition.com*

Several researchers have shown synthesis of B vitamins can be insufficient in highly productive cows. Supplementation with B-vitamins can improve milk yield and composition in highly productive dairy cows. The effect of a blend of fat encapsulated B vitamins (FEBV, Vivalto, Selko) was studied in an early lactation trial with 54 cows, divided into 2 groups. One group was fed RBBV between day 4 and day 200 of lactation, the other group served as controls. Supplementing dairy cows with FEBV increased milk yield between 75 and 200 DIM by 3 kg/d ($P<0.05$) and protein yield by 0.08 kg/d when fed between 4 and 200 DIM ($P<0.05$). Feed efficiency increased (+8%; $P<0.03$) from 1.63 kg milk/kg DMI to 1.77 kg milk/kg DMI throughout the 200 day experiment.

Session 46

Poster 38

The effect of a blend of fat encapsulated vitamin B on milk production of highly productive cows*M. Hall¹ and C. Gordon²**¹Nutreco, Selko, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands, ²Trouw Nutrition Canada, Dairy Technology Application, 7504 McLean Rd E, Puslinch, ON N0B 2J0, Canada; mark.hall@trouwnutrition.com*

Changes in rumen fermentation can have an effect on apparent synthesis of B vitamins. As a result, diets of highly productive cows, particularly if they have a high cereal content do sometimes not meet the demand for B vitamins. Several researchers have shown that B-vitamin supplements can improve milk yield, composition, and metabolic efficiency in highly productive dairy cows. The effect of a blend of fat encapsulated B vitamins (FEBV, Vivalto, Selko) was studied in a 2×2 factorial design experiment including 260 multiparous cows and 140 heifers. Three groups of cows were fed RBBV from 21 days pre-partum to calving, from calving to 150 DIM or from 21 days pre-calving until 150 DIM respectively. A control group was not fed RBBV. Group dry matter intake and daily milk yield and milk composition were recorded. Supplementing multiparous dairy cows with FEBV increased milk yield by 1.37 kg/d and milk protein yield by 47 g/d ($P<0.05$) with no effect on milk protein concentration. Milk fat concentration tended to decrease ($P=0.067$) due to dilution effects when FEBV was fed post-partum, but there was no change in milk fat yield. There was no significant increase in milk production in heifers fed FEBV.

Evaluation of milk performances and enteric methane emissions on by-products feed baseA. Berchoux¹, M. Jouffroy¹, A. Laflotte¹ and R. Boré²¹Institut de l'Élevage, 149 rue de bercy, 75012 Paris, France, ²Université de Lorraine, ferme de la Bouzule, 54280 Laneuvelotte, France; alice.berchoux@idele.fr

By-products are produced by agrifood industries during process of transformation of raw materials. They have high energetic and protein values and represent a local resource for farmers to feed cattle. Moreover, they are not in competition with human food. By-products are very interesting for the feeding of ruminants and 75% of them are used in cattle feed in France. In the North-East of France, in Grand-Est region, most of by-products generated are wet (<30% of humidity rate) and need to be mixed with other by-products and sometimes with fodders to reduce matter losses and sanitary issues. A trial has been carried out in the experimental farm of the University of Lorraine from the 4th of January to the 29th of March 2023 to evaluate the effects of two types of by-products storage on dairy cows milk performances (quantity and quality) and enteric methane emissions. The trial is conducted on two groups (control and testing) of twenty-three dairy cows in complete and balanced blocks. The control group received a Total Mixed Ration (TMR) mixed every day with fodder and by-products stored separately. The testing group received the same TMR but totally mixed before the beginning of trial and stored in the same silo. The trial has started with a pre-experimental period of two weeks and has been followed by a ten weeks experimental period. For each cow, milk production, milk composition (protein and fat contents) and urea rate are analysed each week and enteric methane emissions are collected continuously by two GreenFeed systems. An analysis of silo conservation was done during the pre-experimental period and at the end of the experimental period. Dry matter intake (DMI) per group is registered each day. At this time, milk performances and methane emissions of two groups seems similar. Statistical analysis will be done in May with R software.

Session 46

Poster 40

Supplementing lambs with plant extract supplement enhances growth and improve feed conversion ratioV. Ballard¹ and P.H. Pomport²¹CCPA, ZA du Bois de Teillay, 35150 JANZE, France, ²Ferme de Grignon, Route de la ferme, 78850 Thiverval Grignon, France; vballard@ccpa.com

The plant extract has been employed in ruminants to optimize the diet formulation and improve the energy and protein utilization in the rumen. The aim of this study was to optimize the diet of lamb by reducing the crude protein (CP) by combining 3 different plant extracts supplements (CCPA, France) on performance, meat quality, and health. For this, 172 male lambs 81 days old Romane breed were randomly distributed among the 4 treatments. The treatments consisted of: without plant extracts supplementation (CTL), supplementation with tannins and spices (Grp A); supplementation with tannin, essential oils and spices (Grp B), and supplementation with essential oils and spices (Grp C). Lambs were fed concentrate and straw *ad libitum*. The plant extracts were added to the concentrate and the treatments differed in crude protein content (CP), 17.5 and 16.8% of CP for the CTL and plant extract supplementation treatments, respectively. The CP content in the concentrate was achieved by reducing the soybean meal inclusion to 16,8% in the Grp A, B, and C instead of 19,8% in the CTL. The concentrate intake, average daily gain (ADG), feed conversion ratio (FCR) and protein conversion ratio was followed. On average lambs were slaughtered 114 days old. The morbidity and mortality did not differ between groups. The concentrate intake was 1.43, 1.47, 1.47, and 1.54 kg/day for CTL, Grp A, Grp B, and Grp C, respectively. The plant extract supplementation increased the ADG during the first 14 days of fattening, on average 437, 460, 443 g/day (Grp A, Grp B, and Grp C, respectively) compared to CTL (340, $P<0.001$). The total fattening period ADG tended to be greater for Grp A, B, C (426, 432, 419 g) compared to CTL (390 g, $P<0.15$). No difference was observed between groups for carcass weight at slaughter and carcass classification. The FCR was higher in the Grp A and B. The protein conversion ratio was improved in Grp A and Grp B (62.4, 62.7 g of CP/kg of growth, respectively) when compared to Grp C (64.7 g of CP/kg) and CTL (67.3 g of CP/kg). This suggests that the diet optimization with specific plants extracts permits reducing CP content and soya utilization improving ADG, FCR, and protein utilization.

Effects of *Artemisia annua* residue on rumen microorganisms and antioxidant function of mutton sheepS.S. Wang¹, C.F. Peng², Y.R. Shao¹, M.M. Bai¹, Y.H. Zhang², M. Zhang³, X. Xiong¹ and H.N. Liu¹¹Institute of Subtropical Agriculture, Chinese Academy of Sciences, Institute of Subtropical Agriculture, Chinese Academy of Sciences, 410125, 644 Yuanda 'er Road, Furong District, Changsha City, Hunan Province, China, China, P.R., ²Hunan Agricultural University, Hunan, Changsha, 410128, 1 Nongda Road, Furong District, Changsha City, Hunan Province, China, China, P.R., ³Vinsce Bio-Pharm Co., Ltd, Jiangsu, Suzhou, 215600, 2 Nanjing Middle Road, Yangzijiang Chemical Industrial Park, Jiangsu Province, China, P.R.; liuhn@isa.ac.cn

Artemisia annua L. (AA) has been widely recognized for its extract artemisinin in the treatment of malaria. At present, the application of AA and its by-products in other fields has gradually attracted people's attention. The purpose of this study is to explore the effects of *A. annua* residue (AAR) as roughage on in ruminant farming. Eighteen Hu sheep with similar body weight (30.50 ± 0.31 kg) and the same body condition were divided into two groups at random, with three replicates per group, and three animals per replicate. The control group was fed a conventional total mixed ration diet and the treatment group was fed 10% AAR instead of partial roughage. The pre-feeding period was 10 days and the experimental period was 60 days. This study showed that the addition of 10% AAR in the diet significantly increased the average daily feed intake (ADFI), muscle storage loss and decreased the ACE index ($P < 0.05$). The levels of aspartate amino transferase (AST) and low density lipoprotein-C3 (LDL-C3), and the activities of glutathione peroxidase (GSH-Px) and superoxide dismutase (SOD) in the serum significantly increased in the treatment group ($P \leq 0.05$). AAR treatment significantly increased the rumen empty weight and the relative abundance of *Firmicutes* and *Rikenellaceae_RC9_gut_group* in the rumen contents ($P \leq 0.05$). The relative abundance of *Verrucomicrobiota*, *Fibrobacterota*, and *Fibrobacter* significantly decreased in the treatment group ($P < 0.05$). In conclusion, our study provides data in support of feeding ruminants with AAR instead of roughage and demonstrates that AAR can reduce feeding costs and improve the economic benefits of sheep farming without affecting the growth performance.

Nutrient rich novel feed supplements for grazing lambs

A.S. Chaudhry

Newcastle University, School of Natural and Environmental Sciences, Agriculture Building, NE1 7RU, United Kingdom; abdul.chaudhry@ncl.ac.uk

Globally, grazed grass is accepted as an affordable and efficient feed resource for ruminant animals. Nevertheless, it is inconsistent in supply and nutritional value depending upon its variety, region, and season. Thus, grass consuming sheep must receive supplements that match their nutrient requirements to achieve variable production targets and vitality. This completely randomised study compared the impact ($P < 0.05$) of *ad libitum* access of grazing lambs to feed blocks containing either Sffmannan (SafM) or no SafM (NSafM) or no blocks (CNT) on their intake, liveweight (LW), LW gain (LWG) and condition score (CS). Two hundred forty weaned Suffolk and Texel cross lambs of both genders with initial LW of 30.6 kg (± 0.34) and CS (1.8 ± 0.038) were split into six uniform groups of 40 lambs each. These lambs were dewormed before group housed on a ryegrass paddock (11.2 MJ ME, 215 g CP/kg DM) that was divided into six uniform fields of 2 hectares each by fencing. The lamb groups were randomly distributed into these replicated fields with plentiful grass and fresh drinking water for 84 days. The lambs had access to either grazed grass alone (CNT) or with either SafM or NSafM blocks enriched with molasses, soybean meal and vitamin-mineral premix. The grass quality and quantity remained uniform across the fields and treatments. However, its quantity and nutrient value during the sampling periods of grass, declined for all treatment groups towards the end of the trial. All lambs remained fit while adapted easily to consume feed blocks with more variable intake of SafM than NSafM. The treatments differed significantly ($P < 0.05$) for their effects on LW, LWG but not CS ($P > 0.05$). While both feed blocks showed better lamb growth than the CNT, the NSafM gave greater increase in lamb growth ($P < 0.01$). The Breed and Gender effect or their interaction was not significant ($P > 0.05$) for any of the parameters. It appeared that the nutrient rich feed blocks as supplements were beneficial for grazing lambs. However, their effect did vary depending upon their constituents and the quality and quantity of grazed grass. Further studies should be conducted over a longer duration while examining their effect on fertility, carcass and meat quality of lambs.

The order of distribution of two forages affects daily intake and diet composition in dairy goatsR. Delagarde¹, J. Belz¹ and B. Bluet²¹PEGASE, INRAE, Institut Agro, 16 Le Clos, 35590 Saint-Gilles, France, ²IDELE, Route de Chauvigny, 86550 Mignaloux-Beauvoir, France; remy.delagarde@inrae.fr

In practice, dairy goats are often fed daily with two separate forages in order to organise the daywork, diversify the diet and stimulate intake. According to their preferences, the order of distribution of these forages could affect goat performance. The objective of this experiment was to investigate the effect of the order of distribution of two forages: fresh herbage cut once daily, and a partial mixed ration (PMR) based on maize silage and soyabean meal (ratio 85:15 on a DM basis). Twenty four multiparous Alpine goats in mid lactation were used in a reversal switchback design ABA-BAB with three 14-d periods in spring 2022. The forage fed in the morning was available during 6h30 (09:45 to 16:15), and the forage fed in the evening was available during 15h45 (17:15 to 09:00). The two forages were given *ad libitum*, with, in both treatments, 12% of refusals for PMR and 14% of refusals for fresh herbage. Each goat also received 400 g/d of a pelleted concentrate based on maize grain (200 g/milking). Feeding behaviour (cameras) and daily intake were measured daily at herd level, and milk production was measured daily at goat level. Fresh herbage and PMR intakes were 1.36 and 0.81 kg DM/d (38% of PMR in forages), respectively, when fresh herbage was fed in the morning. The corresponding figure was 1.70 and 0.39 kg DM/d (19% of PMR in forages) when fresh herbage was fed in the evening. Total DM intake (+0.08 kg DM/d) and milk production (+0.08 kg/d) were greater when fresh herbage was fed in the morning, which is partly a response to the increase in soyabean meal intake (+0.07 kg DM/d). Time spent eating fresh herbage was 235 and 358 min/d when fresh herbage was fed in the morning and in the evening, respectively. The corresponding figure for PMR was 50 and 126 min/d, respectively. In conclusion, the order of distribution affected marginally daily DM intake but more significantly feeding behaviour pattern and diet composition, affecting milk production. Goats showed a clear preference for fresh herbage in both treatments, despite a lower crude protein concentration (102 vs 128 g/kg DM) and a lower intake rate (292 vs 423 g DM/h) for fresh herbage than for PMR.

Session 46

Poster 44

Feeding frequency has no effect on intake and milk production in dairy goats fed on fresh herbageR. Delagarde¹, J. Belz¹ and B. Bluet²¹PEGASE, INRAE, Institut Agro, 16 Le Clos, 35590 Saint-Gilles, France, ²IDELE, Route de Chauvigny, 86550 Mignaloux-Beauvoir, France; bertrand.bluet@idele.fr

According to many goat farmers and their advisors, increasing feeding frequency could be one solution to motivate ruminants to eat more forage and increase milk production. Is this management strategy useful when goats are fed on fresh herbage? The objective of this study was to investigate the effect of the number of fresh herbage distributions (1 vs 2 per day) on dry matter intake, milk production and feeding behaviour. Twenty four multiparous Alpine goats in mid lactation were used in a reversal switchback design ABA-BAB with three 14-d periods in spring 2022. Herbage was cut once daily and fed *ad libitum* either only in the morning (10:00 h) or in the morning (10:00 h) and in the evening (17h30 h). Goats fed once daily were in the milking parlour during the evening feeding period to avoid stimulating them at this moment. Fresh herbage was accessible for the goats all the time without human intervention, except during 1 h in the morning (refusals weighting at 09:00 h). Each goat received as a supplement 500 g/d of a pelleted concentrate based on maize grain, with 250 g at each milking. Feeding behaviour (cameras) and daily intake were measured daily at herd level, and milk production was measured daily at goat level. Herbage was characterised by an unexpected low crude protein concentration (102 g/kg DM). Herbage intake (1.76 kg DM/d), total DM intake (2.16 kg DM/d), milk production (2.58 kg/d), milk fat (34.1 g/kg) and true protein (27.4 g/kg) concentrations, and live weight (53.1 kg) were unaffected by feeding frequency. Goats fed once daily tended to spend more time eating (443 vs 403 min/d, $P<0.07$), and particularly during the afternoon (13:00 to 17:00 h): + 61 min ($P<0.01$). At the reserve, goats fed twice daily ate 30 min longer ($P<0.05$) in the evening (17:00 to 23:00 h). Provided that fresh herbage is accessible throughout the day, increasing the feeding frequency affected daily feeding pattern of goats but not their total dry matter intake, milk production or composition, suggesting possible simplifications of feeding management for dairy goats fed on fresh herbage.

Effects of dietary energy on late-gestation metabolism in prolific ewesM. Plante-Dubé¹, C. Sylvestre¹, R. Bourassa², P. Luimes³, S. Buczinski⁴, F. Castonguay¹ and R. Gervais¹¹Laval University, Department of animal sciences, 2425 rue de l'Agriculture, Québec, G1V0A6, Canada, ²Veterinary Hospital of Sherbrooke, 1771 rue King Est, Sherbrooke, J1G5G7, Canada, ³University of Guelph, 120 Main St E, Ridgetown, N0P2C0, Canada, ⁴University of Montreal, Faculty of Veterinary Medicine, 3200 rue Sicotte, St-Hyacinthe, J2S2M2, Canada; marguerite.plante-dube.1@ulaval.ca

In late gestation, to prevent metabolic disorders in prolific ewes, dietary supplies must be in line with the rapid increase in energy requirements to support the growth of multiple fetuses. The current study was conducted to evaluate the effects of the dietary energy supply and source on the dynamic response of energy metabolism during the last 6 weeks prepartum in F1 prolific breed ewes. Six weeks prior to lambing (wk -6), all 48 mature, crossbred (Dorset × Romanov) ewes were offered grass silage (2.17 Mcal/kg dry matter (DM)) *ad libitum*. Then, ewes were randomly assigned to 1 of 3 dietary treatments (2.62 Mcal/kg DM): a total mixed ration (TMR) based on grass silage and ground corn from wk 4 (GC4) or wk 2 (GC2) or a TMR based on corn silage from wk 4 (CS4). Dry matter intake (DMI) and body condition score (BCS; 1 to 5) were respectively determined daily and twice weekly. Blood concentrations of beta-hydroxybutyrate (BHB) and glucose were monitored twice weekly for wk -6 to -4, then thrice weekly. Treatment affected DMI by wk -4, as DMI for GC2 was lower (1.91^b) than GC4 (2.42^a) with intermediate values for CS4 (2.00^{ab}kg/d). Starting on wk -3, DMI increased for GC2 and CS4 resulting in similar DMI among treatments by wk -2 (2.39 kg/d). No difference over time or among treatments was observed for BCS (3.65). Glucose concentrations were greater for GC4 and CS4 ewes (3.49^a) than GC2 (2.72^bmmol/l) at wk -4 and -3. These differences were no longer significant by wk -2 (3.68 mmol/l). By wk -4 BHB concentrations were greater for CS4 (1.04^a) than GC2 (0.54^b), whereas GC4 presented intermediate values (0.77^{ab}mmol/l). During the last 3 weeks, BHB concentrations for GC2 evolved (0.69^b) to be similar to GC4 by wk -2 (0.70^b) but lower than CS4 (1.21^a). These results suggest that dynamic responses of energy metabolism in late gestation of prolific ewes are influenced by the dietary energy supply and source.

The effect of feeding with hemp seeds addition on physicochemical and sensory properties of beefP. Pogorzelska-Przybyłek¹, C. Purwin¹, M. Modzelewska-Kapitula², M. Borsuk-Stanulewicz¹ and K. Tkacz²¹University of Warmia and Mazury in Olsztyn, Department of Animal Nutrition, Feed Science and Cattle Breeding, ul. M. Oczapowskiego 5/248, 10-719, Poland, ²University of Warmia and Mazury in Olsztyn, Department of Meat Technology and Chemistry, Plac Cieszyński 1, 10-719, Poland; paulina.pogorzelska@uwm.edu.pl

Hemp by-products have the potential to be used as feed ingredients for ruminant. Some studies have already included hemp by-products as protein sources in finishing diets for goats, sheep, cattle. However, there is a gap in understanding the impact of hemp by-products on the quality and sensory properties of meat. The aim of this study was to determine the effect of whole hemp seeds (*Cannabis sativa* L.) inclusion to the diet of Polish Holstein-Friesian bulls (PHF) on the physicochemical and sensory properties of longissimus lumborum muscle (LL). The experiment was performed on 3 groups of PHF bulls (of 8 animals each), characterized by a similar age and body weight. Over a 91-day finishing fattening, bulls were fed *ad libitum* with maize silage and a concentrate (triticale grain, rapeseed meal, mineral-vitamin premix) with a different proportion of *Cannabis sativa* L. seeds, depending on the feeding group: C – without hemp seeds (HS), HS10 – 10% addition of HS, HS17 – 17% addition of HS. After slaughter samples of LL were removal from the left half-carcass of each animal and stored at -20 °C until analyses. According to the standard methods described in the literature, the colour, chemical composition, physicochemical and sensory properties were determined. The addition of hemp seeds in the rations of PHF bulls had a neutral effect on the chemical composition of meat but affected its colour and sensory properties, which is important for consumers. Meat from the HS10 group was the product with the most desirable aroma, juiciness, tenderness and the highest overall acceptability. This study was conducted within the research project No. 2021/05/X/NZ9/00799 financed by the National Science Center, Poland. Project financially supported by the Minister of Education and Science under the program entitled 'Regional Initiative of Excellence' for the years 2019-2023, Project No. 010/RID/2018/19.

Association of feed efficiency with growth and slaughtering performance in Nellore cattle

S.F.M. Bonilha, J.A. Muñoz, B.R. Amâncio, J.N.S.G. Cyrillo, R.H. Branco, R.C. Canesin and M.E.Z. Mercadante
Institute of Animal Science, Beef Cattle Research Center, Rodovia Carlos Tonani, km 94, 14.174-000 Sertãozinho/SP, Brazil; sarah.bonilha@sp.gov.br

Improving feed efficiency (FE) is of major interest for livestock production. This is the case for studies using residual feed intake (RFI). RFI is designed to quantify between-animal variation in FE, with the limitation of being calculated based on short time interval, evaluated in the beginning of the animals' productive life. This study aimed to evaluate growth and slaughtering performance of Nellore males, based on RFI calculated at post-weaning (PW) and pre-slaughter (PS) periods. Sixty-seven animals were evaluated twice: PW with diet formulated for growth; and PS with diet formulated for finishing. RFI was calculated as the residual of dry matter intake (DMI) regression equation as a function of weight gain (ADG), metabolic body weight (MBW) and subcutaneous fat thickness (FT), being animals classified as negative (RFI<0; efficient) or positive RFI (RFI>0; non-efficient) for PW and PS periods. Feed conversion ratio (FCR) and FE were calculated as the ratio between DMI and ADG, and ADG and DMI, respectively. Data was analysed using SAS GLM procedure, considering RFI class as fixed effect and probability of 5%. Pearson's correlation coefficient was estimated for RFI considering both periods. PW RFI values were compared to PS RFI values to determine change in classification. No significant effect was detected for RFI class on ADG, MBW and FT in both periods. However, it was observed that negative RFI animals, when compared to the positive RFI ones, had lower DMI (6.10 vs 7.06 kg/d; $P=0.0001$) and FCR (7.05 vs 7.77 kg/kg; $P=0.0001$), and higher FE (0.14 vs 0.13 kg/kg; $P=0.0001$) at PW period; and lower DMI (7.72 vs 8.30 kg/d; $P=0.0069$) and similar FCR and FE at PS period. The correlation coefficient between PW and PS RFI was 0.22 ($P=0.0740$), indicating no linear association in RFI between both periods. From the 67 evaluated animals, 37% changed RFI classification (13 animals changed from negative to positive, and 12 from positive to negative RFI). RFI can interact with FCR and FE mainly at PW period. DMI is influenced by RFI until slaughter, even with animals being reclassified. Acknowledgments: FAPESP Process 2022/12347-4.

Effects of dietary nitrate on performance and enteric methane production in Hanwoo steers

R. Bharanidharan¹, P. Xaysana², R. Ibdhi³, J. Lee⁴, B.M. Tomple¹, J. Oh⁵, M. Baik⁴ and K.H. Kim^{1,2}

¹*Institutes of Green Bio Science and Technology, Seoul National University, 25354, Pyeongchang, Korea, South,*

²*Graduate School of International Agricultural Technology, Seoul National University, 25354, Pyeongchang, Korea, South,*

³*Agroécologie, INRAE, Institut Agro, Univ. Bourgogne, Univ. Bourgogne Franche-Comté, 21000, Dijon, France,* ⁴*College of Agriculture and Life Sciences, Seoul National University, 08826, Seoul, Korea, South,* ⁵*Cargill Animal Nutrition, 13630, Seongnam, Korea, South; bharanitharshan76@gmail.com*

Nitrate (NO_3^-) has been recognized as an effective dietary additive to reduce enteric methane (CH_4) production in ruminants. The current experiment was aimed to evaluate the effects of NO_3^- on performance, enteric CH_4 production and rumen fermentation characteristics in Hanwoo steers. Twenty Hanwoo steers (348 ± 18 kg) were divided into two groups of 10 steers balanced for body weight and CH_4 yield, and were assigned to one of two diets: (1) Control, 500 g/kg timothy hay and 500 g/kg commercial concentrates; (2) NO_3^- , control diet supplemented with 2.5% calcium ammonium nitrate (1.875% NO_3^- in the dietary dry matter) for 28 days in a completely randomized design. Rumen fluid samples were collected on the last day of the feeding trial. CH_4 measurement was performed for 3 days starting from day 24 using whole body respiratory chambers (RC). Ruminal pH, ammonia concentration and total volatile fatty acid concentration did not differ between treatments ($p > 0.05$), but NO_3^- containing diets increased and decreased ($P < 0.0001$) acetate and butyrate proportions, respectively. No difference ($P > 0.05$) in dry matter intake (DMI) was noted. However, an increase in feed conversion ratio (10.9 vs 13.6; $P < 0.05$) caused by the decrease in average daily gain (0.73 vs 0.58 kg; $P < 0.05$) was found in NO_3^- fed animals located in barn. In RC, animals fed NO_3^- diet exhibited decreased DMI (6.85 vs 5.31 kg/d; $P < 0.005$), CH_4 production (160.7 vs 91.5 g/d; $P < 0.0001$) and yield (22.4 vs 17.7 g/kg DMI; $P < 0.05$) compared to the control. Future studies are aimed at performing haematological analyses and dosage optimization of NO_3^- in order to minimize the negative effects of NO_3^- on animal performance, and also perform untargeted urinary volatiles profiling to identify factors influencing DMI in RC.

Impact of additives and forage levels on nutrients digestibility and sorting index of Nellore bullsE. Magnani¹, T.H. Silva¹, L.B. Tosetti¹, E.M. Paula¹, P.R. Leme² and R.H. Branco¹¹Institute of Animal Science, Beef Cattle Research Center, Rod. Carlos Tonani km94, 14.174-000, Brazil, ²University of Sao Paulo, Department of Animal Science, R. Duque de Caxias, 225, 13635-900, Pirassununga, SP, Brazil; dasilvath2@gmail.com

This study was carried out to evaluate the effect of additives and increasing levels of neutral detergent fibre from forage (NDFf) on digestibility of nutrients and sorting index in finishing Nellore bulls. Thirty Nellore bulls, 5 bulls per treatment, [409.6±6.36 kg of body weight (BW) and approximately 24 months of age] were allocated into 6 diets in a factorial 2×3 arrangement during 105 days in an individualized feedlot system. The treatments were the combination of monensin (MON; 30 mg/kg DM), essential oils (EO; 500 mg/kg DM, essential oil was a mixture of castor oil and cashew nut), and 3 levels of dietary FDNf (6, 9, and 15% of total diet, DM basis). The diet was composed by *Brachiaria brizantha* cv. Marandu hay, finely ground corn, soybean meal, ground citrus pulp, urea, potassium chloride, sodium chloride and trace minerals + vitamins. The particle size distribution of diet andorts were determined weekly using the Penn State Particle separator containing 3 sieves. Additives and dietary NDFf levels were analysed in a complete randomized design according to a factorial arrangement. When NDFf levels were statistically significant, linear and quadratic responses were assessed (software SAS 9.4). The digestibility of dry matter, organic matter, crude protein, and starch reduced linearly as NDFf level increased. For sorting index outcomes, there was sorting against 1.18 mm particles when 15% NDFf level was combined with EO supplementation compared to other levels within EO treated bulls. Sorting against <1.18 mm particles was also detected for EO vs MON treated bulls. Overall, increasing dietary NDFf levels of finishing Nellore bulls reduce the digestibility of nutrients. Further, EO may induce to sorting against particle ≤1.18 in a level-dependent manner.

Feed efficiency traits calculated at post-weaning and pre-slaughter periods in Nellore cattle

S.F.M. Bonilha, J.A. Muñoz, B.R. Amâncio, J.N.S.G. Cyrillo, R.H. Branco, R.C. Canesin and M.E.Z. Mercadante

Institute of Animal Science, Beef Cattle Research Center, Rodovia Carlos Tonani, km 94, 14174-000, Sertãozinho/SP, Brazil; sarah.bonilha@sp.gov.br

Feed efficiency traits have been commonly evaluated in trials performed after weaning with diets formulated for growth, however, its repeatability across stages of production cycle or using different diets is not well known. This study aimed to evaluate the correlations between performance traits of Nellore bulls during two periods (post-weaning-PW and pre-slaughter-PS), and to verify animals' reclassification based on residual feed intake (RFI). Sixty-seven animals were evaluated twice: PW with diet formulated for growth; and PS with diet formulated for finishing in three different years. RFI was calculated as the residual of dry matter intake (DMI) regression equation as a function of weight gain (ADG), metabolic body weight (MBW) and subcutaneous fat thickness (FT), being animals classified as negative (RFI<0; efficient) or positive RFI (RFI>0; non-efficient) for PW and PS periods in each year. Pearson correlation coefficients were estimated between DMI, ADG, MBW, FT and RFI values in both, PE and PS periods. PW RFI values were plotted against PS RFI values to determine change in classification. The correlation coefficients found between PW and PS in year 1, 2, and 3, respectively, were 0.67 ($P=0.005$), 0.36 ($P=0.067$), and 0.48 ($P=0.016$) for DMI; 0.56 ($P=0.020$), 0.12 ($P=0.561$), and 0.21 ($P=0.311$) for ADG; 0.91 ($P=0.001$), 0.89 ($P=0.001$) and 0.75 ($P=0.001$) for MBW; 0.02 ($P=0.930$), 0.40 ($P=0.040$) and -0.04 ($P=0.851$) for FT; and 0.67 ($P=0.005$), 0.35 ($P=0.079$) and 0.55 ($P=0.005$) for RFI. High correlation coefficients within years 1 and 3 indicated that 31 and 36% of animals have changed RFI classification after PW period. For year 2, it was found a trend of 39% of animals to change their RFI classification. There is reclassification of animals based on RFI when changing age of evaluation and/or type of diet. Nelore bulls classified by RFI at PW period can change the efficiency class when tested again at PS period. However, knowing that most of animals keep their PW RFI classification can be decisive for determinations on the animal's productive life. Acknowledgments: FAPESP Process 2022/12347-4.

Environmental protection study on replacing alfalfa with sesbania for feeding ruminants

L.Y. Wang and Y.J. Tian

Tianjin Agricultural University, Tianjin Key Laboratory of Agricultural Animal Breeding and Healthy Breeding, College of Animal Science, Tianjin Agricultural College (East Campus), 22 Jinjing Road, Xiqing District, Tianjin, China, 300384, China, P.R.; wly6888@163.com

Alfalfa has a high protein content and moderate cellulose content, and is generally widely used for feeding ruminants. However, alfalfa has a long growth cycle and requires a large amount of water and nutrients during breeding, which is easy to lead to soil erosion, and a large amount of nitrogen fertilizer is required during growth, which is easy to cause soil degradation. Therefore, Farmers need to find better alternatives to alfalfa. Sesbania has been shown to be a good substitute for ruminants; Sesbania has the characteristics of cold tolerance, drought tolerance, vigorous growth, and high protein content, low fibre content, and the leaves have the effect of clearing heat and detoxifying. Sesbania can grow in saline-alkali land and survive rough breeding, which greatly reduces the cost of artificial breeding, so it becomes an ideal alternative. Some studies have shown that the experimental group of ruminants added sesbania in the total mixed diet, the control group did not add, and the milk yield was recorded every day. After statistical analysis, the average daily milk production of cows in the experimental group was about 1 litre higher than that of cows in the control group. In addition, researchers also found that the use of sesbania to feed cows had no negative effect on the health status of cows. As a feed source, sesbania has a significantly lower carbon footprint than alfalfa. In conclusion, according to the existing scientific research results, alfalfa sesbania has great potential to replace alfalfa as a feed source for ruminants. In addition, growing sesbania can also improve land and protect the environment, reduce greenhouse gas emissions and save economic benefits. More research is therefore needed to more fully understand the substitution potential of alfalfa and the environmental and economic impacts.

Multi performance analysis of soybean self-consumption on a mixed crop-livestock farmM. Jouffroy¹, A. Berchoux¹, M. Duval¹, M. Weens², E. Hermant³ and M. Legris¹

¹Institut de l'élevage, 149 rue de Bercy, 75012 Paris, France, ²Chambre Régionale d'Agriculture Grand-Est, Route de Suippes, 51000 Chalons en Champagne, France, ³Lycée Agricole de Rethel, Route de Novion, 08300 Rethel, France; mathilde.jouffroy@idele.fr

Breeders are currently working on the rise of their protein autonomy to reduce their dependence on imported feed with unstable market prices. The objective of this study was to evaluate the consequences of soybean self-consumption on the multi-performance of a mixed crop-livestock dairy farm. A trial was carried out on two groups of 26 dairy cows complemented with rapeseed meal (control) or toasted soybeans (testing). Animal performances (ingestion, milk production and composition) were measured, and economic and environmental performances were evaluated. It was set up on the herd of the agricultural college of Rethel for 9 weeks of testing period. No significantly differences were observed on ingestion, milk production and fate rate between these two groups. However, cows complemented with toasted soybeans had a milk protein rate of 2 g/kg lower than the control group. The decrease of protein rate and the additional cost of feed decreased the feed profit per cow for the testing group (-15€/1000 l). A new system of production with a self-consuming soybean strategy was modeled on this farm. A total of 10 ha of soybeans was needed to feed the herd during the winter period (150 days), replacing 10 ha of wheat. Effect of soybeans as preceding crop enabled a lower nitrogenous fertilization on subsequent crops (-20 units). Introduction of soybeans in cows feeding generated lower purchases of rapeseed meal (-5,772€) but self-consumption of soybean generates extra-costs for toasting and crushing (+2,000€). The simulation of self-production of soybeans with a stable milk production and fate rate and with a lower protein rate of 2 g/kg led to a loss of Gross Operating Surplus of -16,445€ (-13%). The decrease of charges (-3,020€) did not balance the decrease of products (-19,465€). Economy of fertilization and decline of rapeseed meal purchases enabled to reduce farm-scaled emissions of greenhouse gas (-5%), nitrogen balance (-16%), and the carbon footprint (-3%) at milk-scaled. In this case, self-consumption of soybeans leads to economic lost but improves environmental performances.

Effects of leaf size and harvesting season on nutritive quality of white cloverX. Chen¹, K. Theodoridou², O. Cristobal-Carballo¹ and T. Yan¹¹Agri-Food and Biosciences Institute, Hillsborough, BT26 6DR, United Kingdom, ²Institute of Global Food Security, Queen's University Belfast, Belfast, BT9 5DL, United Kingdom; xianjiang.chen@afbini.gov.uk

The present study aimed to evaluate variations in nutritive values of white clover varieties with different leaf sizes and harvesting seasons. Thirteen varieties of white clover were selected from recommendation lists in the Republic of Ireland and Northern Ireland, including 4 large leaf sizes (Alice, Aran, Barblanca and Gabby), 5 medium leaf sizes (Aberherald, Buddy, Chieftain, Crusader and Iona) and 4 small leaf sizes (Aberace, Coolfin, Galway and Rivendel). Each was sown in a single paddock in 2018 and harvested on 8 June, 23 July and 5 September 2020, respectively. All 39 samples obtained were analysed using 3 techniques: near infra-red spectroscopy (NIRS), wet chemistry and *in vitro* gas production. Results were analysed as a 3 (leaf size) × 3 (harvesting season) factorial design with the variety fitted as a random factor. There was no significant interaction on any variable between leaf size and harvested season except for wet chemistry NDF content with which the interaction was significant ($P=0.034$). Leaf size had no significant effect on any nutrient content determined by NIRS (dry matter (DM), crude protein (CP), acid detergent fibre (ADF), water soluble carbohydrates (WSC) or metabolizable energy (ME)), wet chemistry techniques (DM, Ash, CP, GE, ADF, neutral detergent fibre, lipid or WSC), or *in vitro* total gas production. Organic matter digestibility or ME content was similar between the 3 leaf size categories. However, the majority of variables evaluated were influenced by harvesting date. For example, in comparison with early and middle harvesting dates, late harvesting produced a significantly higher CP, lipid and energy contents while lower ADF and WSC contents when measured by wet chemistry techniques. The NIRS DM, CP and WSC contents each were positively related to their counterparts measured by wet chemistry ($P<0.001$, $R^2=0.57$, 0.55 and 0.61 , respectively). In conclusion, the nutritive value of white clover is similar between leaf size categories although influenced by grazing season. The NIRS technique has potential to be used for predicting DM, CP and WSC contents of white clover.

Session 46

Poster 54

Image analysis of feed boluses collected from cows after ingestive chewingB. Delord¹, M. Berger¹, R. Baumont², P. Nozière², A. Le Morvan², F. Guillon³ and M.F. Devaux³¹Limagrain, Europe, 63360 Saint-Beauzire, France, ²INRAE, UMR Herbivores, 63122 Saint-Genès-Champagnelle, France,³INRAE, UR1268 BIA, 44300 Nantes, France; rene.baumont@inrae.fr

Forage feed value depends on its digestibility and ingestibility, i.e. the quantity of dry matter voluntarily ingested by the animal. Digestibility first depends on the quantity of indigestible cell-walls in the forage. However, for equivalent digestibility, differences are observed in forage ingestibility and consequently in milk production. Forage ingestibility depends primarily on its fill effect in the rumen that is linked to the forage residence time. The latter is determined by the time needed to reduce forage particle size through chewing and microbial degradation to the threshold size allowing feed residues to leave the rumen. Here, we propose to quantify the reduction in particle size due to the ingestive chewing by image analysis. An INRAE homemade macrovision device, the LightBox which allows a large field of view and thus, the imaging of objects several cm long was used, together with image texture analysis to estimate fragment size from the greyscale images. Four Holstein dairy cows hosted at INRAE were fed experimental meals according a Latin square design with four lines of maize selected according to their chemical composition and friability measured by a grinding test. The animals received the maize plants without ear harvested at the silage stage. The feed boluses were collected manually during the meal at the cardia through the rumen canula. Both the offered meals and the boluses were imaged in bulk using the LightBox. The field of view was $113 \times 151 \text{ mm}^2$, with a pixel size of $94 \text{ }\mu\text{m}$. Fragment size was quantified using grey level granulometry that provides with granulometric curves, characteristic of the size of objects even if they are observed in bulk. As expected, the mean fragment size of the offered meals differed between maize lines and a decrease in particle size after chewing was observed. After chewing, the size of the fragments depended first on the cow and then on the maize line. Finally, between maize lines, the size of the fragments after chewing were ranked accordingly to their friability measured by a grinding test, that is promising for further phenotyping of maize lines for friability and ingestibility.

A documented example of the One Health concept

P. Weill, N. Kerhoas and B. Schmitt

Université de Rennes, rue du Tabor, 35000 Rennes, France; pierre.weill@bleu-blanc-coeur.com

One Health concept is based on the principle that human health is linked to the health of its ecosystems. Initially based on the link between animal and human, supported by pandemics and antibiotic resistance, this concept covers very broad fields, sometimes without rigorous demonstration. The synthesis and roles of polyunsaturated fatty acids (PUFA) from soil & plant to man are a good example of One Health that provides measurable markers. Indeed, the precursors of PUFA are exclusively plant-based and participate to plant immunity. Then, only animals elongate these PUFA and incorporate them in their tissues. In animals and in humans, the balance between these PUFA drives inflammation and health prevention. Numerous trials in which the ratio between n-6 and n-3 PUFAs was reduced (from 15 to 5 in average) in animal feed (all other things being equal), provide measurements of environment, animal health and human health impact. n-6 PUFA is mainly provided by corn, n-3 PUFA by grass and linseed. At different levels: environmental. The main effect is the reduction of enteric methane emissions from ruminants. These effects are measurable in milk and meat. Animal health and fertility. A decrease in the frequency of metabolic diseases and an improvement in fertility has been measured in cows and sows. Composition of animal products. They (eggs, meat, milk) contain less saturated FA and n-6 PUFA and more monounsaturated FA and n-3 PUFA. Human health. We note an improvement in the composition of serum and red blood cells in healthy volunteers. A significant improvement of insulin resistance in diabetic patients, an improvement of cardiovascular markers and a lesser weight regain after a hypocaloric diet in obese volunteers are also measured. The decrease of the n-6/n-3 ratio in animal diets is an excellent measurable example of what should be a one health strategy built on the strength of evidence and measurement. Other examples could be built on this measurement scheme from soil to man.

Theatre 2

Dietary lipid supplements affect milk composition and butter properties in dairy cowsM. Landry^{1,2}, Y. Lebeuf^{1,2}, M. Blouin^{1,2}, F. Huot^{1,2}, J. Chamberland^{1,2}, G. Brisson^{1,2}, D.E. Santschi³, É. Paquet², D.E. Rico⁴, P.Y. Chouinard^{1,2} and R. Gervais^{1,2}

¹Institute of Nutrition and Functional Foods, 2440 Bd Hochelaga, G1V0A6, Québec, Canada, ²Université Laval, 2425 Rue de l'Agriculture, G1V0A6, Québec, Canada, ³Lactanet, 555 Bd des Anciens-Combattants, H9X3R4, Ste-Anne-de-Bellevue, Canada, ⁴CRSAD, 120-A Chemin du Roy, G0A1S0, Deschambault, Canada; myriam.landry.8@ulaval.ca

This trial aimed to evaluate the effects of 4 lipid supplements on milk composition and butter manufacture. In a replicated 5×5 Latin square design, 10 multiparous Holstein cows (64±21 days in milk) received a basal diet without supplementation (CTL) or with 2% (dry matter basis) fatty acids (FA) provided as soybean oil (SO), calcium salts of palm FA (CS), hydrogenated/hydrolysed tallow (HT) or palmitic acid-enriched supplement (PA). Treatment periods lasted 21 days and the last 5 days were used for data and sample collection. At each period, milk from consecutive milkings of days 18 and 19 was collected from each cow, pooled by treatment in refrigerated bulk tanks, and transferred to the pilot plant for butter manufacture with a Stephan mixer. Milk yield was increased with SO compared with CTL (+8%; $P<0.01$). Milk fat content was decreased with SO compared with any other treatment (-11 to -17%; $P<0.01$) and increased with PA compared with CS (+7%; $P=0.04$). Milk crude protein content was greater for PA and CTL compared with CS or SO (+4%; $P\leq 0.04$). Casein micelle size in pooled milk was similar among treatments (163±4 nm; $P=0.99$). Milk free FA content was not affected by treatment (0.46±0.07 mEq/100 g fat; $P=0.67$). Fat globule diameter ($D_{4,3}$) in cream before maturation tended to be greater for CS than SO (4.29 vs 3.80 µm; $P=0.10$). The width of the fat globules size distribution after overnight cream maturation was greater for CS than CTL (1.26 vs 1.11; $P=0.03$). Churning time tended to be greater for PA compared with HT and CS (23 vs 11 min; $P=0.08$). At 20 °C, butter made from PA milk was harder and its spreadability lower than any other treatment ($P\leq 0.01$), whereas at 4 °C, PA butter was only harder and less spreadable than CS and SO ($P\leq 0.03$). Compared with CTL, SO butter was softer at 20 °C ($P<0.01$) and its spreadability was higher at both temperatures ($P<0.01$).

Decreasing GHG footprint while improving nutrition value in ruminant product: a new challengeS. Mendowski¹, G. Chesneau¹, G. Mairesse^{1,2} and N. Kerhoas²¹Valorex, La Messayais, 35210 Combourtille, France, ²VALOREX, La Messayais, 35210 Combourtille, France; s.mendowski@valorex.com

Dairy products are the main source of saturated fatty acids (SFA) in human nutrition. Consumed in excessive amounts, SFA may increase the risk of cardiovascular diseases. Moreover, enteric methane (CH₄) emissions from dairy cows is the most important greenhouse gas in agriculture. Despite other nutritional benefits of dairy products, these two defaults are a brake for dairy industry. As milk fatty acid (FA) profile is linked to dairy cow diets, and CH₄ can also be mitigated by changing diets, is animal feeding a solution to improve both nutritional and environmental quality of dairy products? Two technical webtools, Visiolait and Lait Durable, designed to monitor dairy herds performances and health for the first, and performances and environmental impact for the second, were used to answer this question. The data extracted from these tools gathers 44,217 milk FA profiles analysed between 2021 and 2022 and their associated predicted CH₄ emissions (thanks to the equation used by Bleu-Blanc-Coeur). Data were divided in 6 groups according to the content of linolenic acid (ALA) in milk, which reflects the content of ALA in dairy cow diets. Results show that both SFA and CH₄ decrease in milk when ALA increase. Indeed, for milks containing less than 0.5% of total FA of ALA, SFA and CH₄ average 73.0% of total FA and 16.1 g/l of milk, respectively; while for milks containing more than 0.9% of total FA of ALA, SFA and CH₄ reach averages of 63.6% of total FA and 13.5 g/l of milk, respectively. In conclusion, changing dairy cow diets by increasing the amount of ALA in their feed (spring grass, alfalfa, linseed, etc.) lead to an improvement of both nutritional and environmental milk quality, by increasing the level of unsaturated FA while decreasing both SFA amount and the greenhouse gas footprint.

Session 47

Theatre 4

Effect of dietary protein source and *Saccharina latissima* on milk fatty acids profiles and bromoformB. Wang^{1,2}, S. Ormston², N. Platos³, J.K. Parker⁴, N. Qin², D. Humphries², Á. Pétursdóttir⁵, A. Halmemies-Beauchet-Filleau⁶, D. Juniper² and S. Stergiadis²¹China Agricultural University, College of Animal Science and Technology, 100193, Beijing, China, P.R., ²University of Reading, School of Agriculture, Policy and Development, Reading, RG6 6EU, United Kingdom, ³Polish Academy of Sciences, Institute of Animal Reproduction and Food Research, Olsztyn 10-748, Poland, ⁴University of Reading, Department of Food and Nutritional Sciences, Reading RG6 6DZ, United Kingdom, ⁵Matis, Vínlandsleið 12, Reykjavík, 113, Ireland, ⁶University of Helsinki, Department of Agricultural Sciences, Helsinki, 00014, Finland; b.wang6@reading.ac.uk

16 Holstein cows were allocated in four 4×4 Latin squares with four 4-week periods (7 d washout, 14 d adaptation, 7 d measurements). Diets (forage:concentrate 75:25 in dry matter (DM)) were: (1) wheat distillers' grains (WDG)-based without seaweed (C-WDG); (2) WDG-based with *Saccharina latissima* (S-WDG); (3) rapeseed meal (RSM)-based without *S. latissima* (C-RSM); (4) RSM-based with *S. latissima* (S-RSM). *S. latissima* was offered at 38.6 g/cow/d. Fresh-cut grass or grass silage (as buffer) was fed *ad libitum* and concentrates were iso-nitrogenous (16% CP in DM). Linear mixed models used protein source, seaweed supplementation, and their interaction as fixed effects; and animal ID and period as the random effects. Compared to WDG, RSM milk had higher ($P<0.05$) concentrations of total SFA (+1.7%), C12:0 (+4.7%), C14:0 (+3.3%), C16:0 (+3.8%) in milk fat. Compared to RSM, WDG milk had higher ($P<0.05$) concentrations of C18:1 t11 (+16.9%), C18:1 c9 (+5.2%), C18:2 c9c12 (+30.7%), C18:2 c9t11 (+12.9%), C18:3 c9,c12,c15 (+6.5%), total MUFA (+3.6%), *trans* MUFA (+7.4%), PUFA (+13.3%), *cis* n-3 PUFA (+4.9%), and *cis* n-6 PUFA (+25.3%) in milk fat. Atherogenicity and thrombogenicity indices were lower ($P<0.05$) in WDG than in RSM. Seaweed did not affect the nutritionally-relevant milk FAs ($P\geq 0.05$); while bromoform concentrations were negligible and unaffected by the dietary treatments ($P\geq 0.05$). Feeding WDG, instead of RSM, enhanced concentrations of nutritionally-beneficial FA and reduced the nutritionally-undesirable SFA, while feeding *S. latissima* at 38.6 g/cow/d does not pose any risk around bromoform contamination of milk.

Human health markers improvements in clinical trials when animal feed is the only variable

N. Kerhoas, P. Weill and B. Schmitt

Bleu-Blanc-coeur, 8 rue J Maillard de la Gournerie, 35000 Rennes, France; pierre.weill@bleu-blanc-coeur.com

A lot of trials measure the impact of differences in human diets on human health biomarkers (lipidic, glycaemic or anthropometric markers) for prevention of chronic diseases such as cardiovascular diseases, obesity or diabetes. We present results of another type of trial when human diet remains unchanged, but the diet of animal that produce eggs, milk and meat were changed. In all trials, animal diet composition was the only experimental variable, and we introduced 5% of extruded linseed in experimental diets in substitution of corn and soy on an iso caloric, iso proteic basis. In the first trial, human volunteers are healthy volunteers and we measure cardiovascular risks markers. In the second trial, human volunteers were diabetic. In the third trial, we recruited obese volunteers. The first trial measured an improvement in cholesterol markers, in correlation with a decrease of stroke risk by 9%. The second trial measured a significant decrease in insulin resistance. In the third one, with obese volunteers, a 90 days hypocaloric regimen caused weight loss of 3 kg in both groups, but 5 months later, we measured a weight re-gain divided by 5 in the experimental group. The nature of animal diets is associated with the quality of animal products and in particular their lipid composition. It is also associated with human health prevention by improving, (all other things being equal), the value of recognized markers of chronic diseases prevention, when the n-6 / n-3 ratio of animal feed is reduced.

The impact of combination of Inulin fibre with the 4 major PAHs present in meat on colorectal cancerL. Abdennebi-Najar^{1,2}, M. Zaoui³, N. Ferrand³, L. Louadj³ and M. Sabbah³¹CRSA, Sorbonne University, INSERM, UMR_S_938, 184 rue du faubourg Saint-Antoine, 75571 Paris cedex 12, France,² IDELE Institute, Quality and Health Department, 149 Rue de Bercy, 75012, Paris cedex 12, France, ³CRSA, Sorbonne University, INSERM, UMR_S_938, 184 rue du faubourg Saint-Antoine, 75571 Paris cedex 12, France; latifa.najar@idele.fr

Evidence suggests that processing and heat treatment of meat may increase cancer risk through exposure to potentially carcinogenic compounds, the polycyclic aromatic hydrocarbons (HAPs) and heterocyclic aromatic amines (AAHs). Inulin-rich foods is known to be potent preventive agents against colorectal cancer. The current study aims to examine the effect of the 8 major (4-HAPs, 4 AAHs) meat contaminants in colorectal cancer and to test whether supplementation with inulin limits cancerogenic process in mice model. Healthy colon cell line (HCEC-1T) and colon cancer cell lines showing different aggressiveness (HT-29, HCT116 and LS174T) were incubated 24 and 48 hours in the presence of the 4-PAHs, 4-AAHs and the mixture. We measured cell proliferation and the expression of genes involved in the metabolism of xenobiotics (CYP1A1, CYP1A2, CYP1B1). We Evaluated in BALB/c DSS mice receiving 3 times/week 50, 100 and 150 mg of the 4-HAPs/kg of body weight, the effect of inulin (1mg/ml in drinking water) on the initiation and development of colon cancer. The 4-PAHs have no effect on healthy colon cells but were able to decrease the viability of tumour colorectal cells and activate the CYP1A1 and CYP1B1 genes involved in the metabolism of xenobiotics. *In vivo*, the 4-PAHs group mice supplemented with inulin did not reveal any changes in carcinogenesis as compared to the one without inulin. However, we did observe a significant ($P < 0.05$) decrease of the loss of body weight in mice receiving PAHs+ inulin as compared to the HAPs group. As conclusion, PAHs b are capable of significantly modifying the activity of several colic cancer cell lines and the expression of key genes related to colorectal cancer. In mice, inulin supplementation did not protect against HAPs induced colorectal carcinogenesis. All these results underscore the importance of considering biological association between HAPs exposure at low doses and diet-related tumours in the colon.

Animal feeding strategy: a move towards giving strategic direction to East African countriesH. Makkar¹, K. Agyemang², D. Balikowa³, A. Sebsibe⁴ and R. Mondry⁵¹Sustainable Bioeconomy, Lammaschg, Vienna, Austria, ²Agriculture, NRM & Policy, 85233, Gilbert, USA, ³EAC Secretariat, EAC Road, Arusha, Tanzania, ⁴ICPALD, Kapenguria Road, Nairobi, Kenya, ⁵Subregional Office for Eastern Africa FAO, CMC Road, Addis Ababa, Ethiopia; ricarda.mondry@fao.org

Inability to feed animals adequately to meet their nutrient requirements round-the-year is a major constraint in East Africa. Despite animal feed and feeding being the foundation of livestock systems, and food and nutrition security being heavily interlinked with feed security, it has received limited attention so far. Most challenges in feed and feeding area are common to countries of the Intergovernmental Authority on Development (IGAD) and East African Community (EAC). Concerted efforts are needed to address them. This prompted the Subregional Office for Eastern Africa of the Food and Agricultural Organization (FAO) in collaboration with IGAD and EAC, to take lead in developing an Eastern Africa Livestock Feed and Feeding Strategy (2023-2037). It has been developed through multi-stakeholders participation from the region, and covers technological, institutional and policy dimensions under 4 pillars in the form of 4 strategic objectives: (1) take stock of the feed and water availability and accessibility, and formulate and put in practice technical solutions to enhance their availability and accessibility; (2) develop and implement appropriate feed processing, feeding strategies, and water provision approaches; (3) develop and strengthen agri-feed businesses; and (4) develop and strengthen institutional, policy-formulation and-research and human capacities on feed production and feeding. The strategy also presents 3 to 6 strategic outcomes under each 4 strategic objectives, with activities under several key focal areas of action. It embraces all the prevalent livestock production systems in East Africa: pastoral, agro-pastoral, mixed-crop livestock and intensive systems; and is inclusive of smallholder, pastoralists and industrial farmers. Recently countries in the region validated this Strategy. It will guide FAO and IGAD to update the East Africa Animal Feed Action Plan, and the countries to develop country-specific feed-focused action plans and embed them in their livestock development agenda and action plans.

Session 47

Theatre 8

Macrominerals and trace elements in retail milk: their variation and nutritional implicationsS. Stergiadis¹, E.E. Newton¹, S. Beauclercq¹, J. Clarke¹, N. Desnica² and Á. Pétursdóttir²¹University of Reading, School of Agriculture, Policy and Development, Reading, RG6 6EU, United Kingdom, ²Matis, Vinlandsleið 12, Reykjavík, 113, Iceland; s.stergiadis@reading.ac.uk

This study investigated the effect of dairy production system (conventional, CON; organic, ORG; channel island, CHA) and seasonal variation (January-December) on the concentrations of macrominerals and trace elements in retail milk and assessed the potential nutritional implications on mineral intakes for consumers. 42 milk brands (26 CON, 12 ORG, 4 CHA) were sampled monthly from retail outlets between January-December 2019 (n=473) and analysed for mineral concentrations by ICP-MS. Data were analysed by linear mixed models using production system, month and their interaction as fixed factors and brand ID (nested within the production system) as a random factor. Compared with CON and ORG, CHA milk contained (respectively) more Ca (+111 and +116 mg/kg milk), Mg (+9 and +12 mg/kg milk), P (+48 and +60 mg/kg milk), Cu (+7.3 and +8.6 µg/kg milk), Mn (+6.7 and +7.0 µg/kg milk), and Zn (+0.67 and +0.32 µg/kg milk); and less K (-127 and -125 mg/kg milk) and I (-109 and ORG -100 µg/kg milk). Although macrominerals did not show a clear seasonal pattern (with both lowest and highest values been within the cows' indoor period), trace elements were at lower concentrations in summer, when cows are typically grazing. For example, the months with the higher milk concentrations for Ca, P, I and Zn had 1.7, 1.4, 1.6, and 4.8 times more of these minerals, respectively, than the months with the lower concentrations. In terms of nutritional implications, milk was an excellent source of Ca, P, I, and Mo across all UK demographics, and a very good source of K, Mg, and Zn for children. Seasonal variation was greater than variation due to milk production system. The seasonal variation, and to a lesser extent milk production system, may have implications for Ca and P supply in children; and I and Zn supply across all consumer demographics. Targeted mineral supplementation in production systems and seasons with reduced milk concentrations in certain minerals (i.e. I during the grazing season), could minimise variation and ensure an optimum supply of minerals to the population throughout the year.

Effect of a spice feed additive on behaviour, saliva composition, and ruminal pH in fattening bullsC. Omphalius¹, J.-F. Gabarrou², G. Desrousseaux² and S. Julliard¹¹Lab To Field, 26 bd Dr Petitjean, 21000 Dijon, France, ²Phodé, ZI Albipôle, 81150 Terssac, France; cleo.omphalius@lab-to-field.com

The acid buffering capacity (aBC) of saliva contributes to maintaining ruminal homeostasis in fattening bulls fed acidogenic diets. Both production and aBC of saliva can be modulated by feeds. Eight fattening bulls (427±40 kg BW) were distributed in a 4×4 Latin square design, with 21-d experimental periods separated by 7-d wash-out periods to evaluate the impact of a spice feed additive (SFA) on behaviour, saliva composition, and ruminal pH. Bulls were fed a controlled diet (in DM: 62% corn silage, 22% barley, 16% soybean meal, 1% minerals, at 1.88% BW DMI) in 2 equal meals (8:30am and 4:15pm) without (CTRL) or with the SFA included at 0.5 g/d (SFA0.5), 1.0 g/d (SFA1.0), or 2.0 g/d (SFA2.0). Ruminal pH was continuously recorded with boluses. During experimental periods, feeding duration and ingestion speed were determined from video records at d16 and d17. At d18, rumination behaviour was recorded from 7am to 7pm (2-min scan sample intervals). Saliva was sampled at d21 (3-h after morning meal) to measure aBC and minerals and HCO₃⁻ concentrations. Spice effect on saliva composition was assessed using multidimensional descriptive analysis (PCA, R) and through analysis of variance and regressions (SAS). Correlations between variables were calculated (SAS). Saliva composition seemed to differ gradually with the dose on the PCA graph, and [HCO₃⁻] and [Na⁺] were numerically higher with SFA2.0. These concentrations were positively correlated to saliva aBC ($r \geq 0.87$; $P < 0.001$). The higher aBC was associated with numerically lower amplitude of ruminal pH over 24-h (0.54 for SFA2.0 vs 0.60 for other diets). Ruminal pH drop after morning meal was longer when bulls were fed the CTRL diet compared to the SFA-containing diets (6.0h vs 3.7-4.2h; $P = 0.080$). The shorter the drop, the faster the ingestion ($r = -0.32$; $P = 0.034$) and the longer the rumination ($r = -0.37$; $P = 0.013$). Yet, ingestion speed rather followed a quadratic than a linear regression with SFA dose ($P = 0.051$). It was faster for CTRL and SFA2.0 than SFA1.0 (9.7, 9.6, and 10.9 min/kg DM, respectively). The bell curve suggests that the effect of this SFA could be optimal with 1.0 g/d in fattening bulls although saliva was more buffered with 2.0 g/d.

Theatre 10

Role of niacin in regulating intestinal health in piglets

H.B. Yi

Institute of Animal Science of Guangdong Academy of Agricultural Sciences, 1 Dafeng 1st street, Guangzhou, 510640, China, P.R.; yihongbo@gdaas.cn

How to effectively enhance the expression of antimicrobial peptides (AMPs) without triggering intestinal inflammation is currently an challenge in nutritional regulation in weaned piglets. We found that niacin (NA) could induce AMPs expression in the intestinal epithelium of weaned piglets without increasing the expression of pro-inflammatory cytokines, thereby enhancing its own resistance to disease and alleviating diarrhoea, intestinal damage and inflammation caused by *E. coli* infection. Furthermore, the expression of AMPs was associated with activation of SIRT1 and inhibition of HDAC7, while NA enhanced the levels of pH3S10, H3K9ac and H3K27ac modifications in intestine. We further explored the potential mechanisms by which histone modifications induce the expression of APMs. Firstly, we found that NA combined with sodium butyrate increased piglet daily weight gain, reduced feed-to-weight ratio and diarrhoea significantly improved growth performance of piglets. On the one hand the combination of the two increased the expression of ZO-1, Occludin, MUC2 and AMPs, improved the barrier function in weaned piglets. On the other hand, it regulated the changes of colonic metabolites and increased the concentration of butyric acid and propionic acid in the colon. Acetylation modification results suggested that differential proteins affected by the combination of NA and NaB were significantly enriched in the TCA pathway. We have verified it. The results showed that the combination of NA and sodium butyrate significantly increased the enzymatic activities of HK, PK, and SDH as well as the concentration of NADH, and increased the modification level of H3K27ac in piglet intestine. In addition, Chip-qPCR results demonstrated that the combination of NA and sodium butyrate significantly enhanced the modification level of H3K27ac in the promoter region of porcine intestinal epithelial cells, thereby inducing the expression of antimicrobial peptides in epithelial cells. This study further revealed the mechanism of niacin-induced intestinal AMPs expression in piglets. In conclusion, the addition of NA to the diet can be a safe and efficient way to promote intestinal healthy of weaned piglets.

Effect of maternal nutrition on thymus development in Wagyu (Japanese Black) foetusO. Phomvisith¹, S. Muroya² and T. Gotoh^{1,3}¹Hokkaido University, Faculty of Environmental Science, Sapporo, Hokkaido, 060-0811, Japan, ²NARO, Animal Products Research, Tsukuba, Ibaraki, 305-0901, Japan, ³Kagoshima University, Faculty of Agriculture, Kagoshima, 890-0065, Japan; ouanh80@gmail.com

The rapid growth of the global population involves accumulated pressure on animal-source food. Enlargement of meat and milk production inevitably engage to increase the risk of animal epidemics. The strength of immunity at birth greatly affects the subsequent health of calves. Understanding the biological mechanism of cattle immune development is imperative to support ideal tools to combat existing and potential pathogens for enhancing global food security. Maternal nutrition is crucial for the growth trajectory and development of the structure and physiology of the visceral organs in the foetus. The thymus is a primary lymphoid organ, it has important functions in immune homeostasis during foetal development and after birth. The study aimed to determine the effect of different maternal nutrition on the alteration of immune-related properties in the thymus of foetuses in Wagyu which is a fatty breed. After the conception was proved, 12 pregnant cows were assigned to 2 groups (n=6 for each group), the low-nutrition (LN) group received 60%, and the high-nutrition (HN) group was fed 120% of their nutrient requirement (NARO, 2008). At 260 days of gestation, foetuses were removed; thymus samples were collected and frozen with liquid nitrogen and stored at -80 °C until used for analyses. Relatively, the LN group revealed lighter foetal thymus weight than the HN group ($P<0.01$). The haematoxylin and eosin staining found a larger section of the interlobular segment, and immature Hassall's corpuscles in the LN group, whereas the HN group exhibited a clear zone of cortex and medulla, and apparent Hassall's corpuscles panels. The immunohistochemical analysis displayed a higher CD8 detection in the LN foetal thymus. Furthermore, concentrations of His, Ser, and Thr were higher in the LN foetal thymus compared to the HN group ($P<0.05$) in the metabolome analysis. In summary, the levels of maternal nutrition influenced foetal development, which affected the immunohistochemical properties and tissue metabolism in the foetal thymus of wagyu cattle.

Session 47

Poster 12

***Bacillus* sp. strains protect the intestinal barrier from oxidative stress and deoxynivalenol**

G. Copani, B.I. Cappellozza and E.J. Boll

Chr. Hansen A/S, Animal and Plant Health & Nutrition, Boege Alle 10/12, 2970 Hoersholm, Denmark; dkgico@chr-hansen.com

Oxidative stress can have a major impact on performance and health of livestock animals. In ruminants, there is a potential negative impact of oxidative stress during transportation and weaning. Mycotoxins present in the feed can cause decreased nutrient utilization/performance and impairment of the intestinal barrier. These stressors can cause intestinal barrier damage (leaky gut), which in turn may facilitate the passage of potential toxins and other luminal content into the bloodstream. The objective of this study was to evaluate *in vitro* beneficial effects of probiotic *Bacillus licheniformis* (CH200) and *B. subtilis* (CH201) (part of BOVACILLUSTM, Chr. Hansen) on gut barrier integrity using Caco-2 cell monolayers challenged with: (1) hydrogen peroxide (5 mM of H₂O₂) to simulate oxidative stress (Exp. 1); or (2) the mycotoxin deoxynivalenol (75 µM of DON) (Exp. 2). The FITC-dextran-20 kDa (FD) was added to the apical side of the Caco-2 cells at the same time as the probiotics. The amount of FD translocated to the basolateral side was quantified upon the termination of the TEER measurements (after 20 h for Exp. 1 and after 14 h for Exp. 2) by measuring the fluorescent signal. In Exp 1, H₂O₂ caused an 82% TEER decrease compared to unstimulated Caco-2 cells over 20 h ($P<0.005$). CH200 and CH201 both significantly alleviate the H₂O₂-induced TEER decrease ($P<0.0002$) and FD translocation ($P<0.05$). In Exp 2, DON caused an 85% TEER decrease compared to unstimulated Caco-2 cells over the 14 h ($P<0.0001$) while CH200 and CH201 significantly reduced the DON-induced TEER decrease to 50% ($P<0.0001$) and 37% ($P<0.0001$), respectively. The addition of both CH200 and CH201 significantly reduced the amount of DON-induced FD translocation (79 and 60% respectively; $P<0.0001$). In conclusion, the tested probiotic strains confer protection against oxidative stress caused by H₂O₂ and alleviate the *in vitro* leaky gut condition caused by DON by counteracting its damaging effect on intestinal barrier integrity.

Production and carcass characteristics of growing-fattening rabbits under three feeding phases*V.C. Resconi, M. López, J.L. Olleta, J. Romero and M.M. Campo**Universidad de Zaragoza, Animal Production and Food Science, Miguel Servet 177, 50013 Zaragoza, Spain; resconi@unizar.es*

Traditionally, rabbit farms use one type of feed after weaning and include a withdrawal feed if medication has been applied previously. On some farms more than one type of feed is used, but their composition, period and mode of administration and names of the phases are not well established. In this study, a three-feeding phase plan was tested on a Spanish farm: from 21 to 35 d old (transition phase), from weaning at 35 to 49 d (post-weaning phase), and from 49 d to slaughter (63-65 d, finishing phase). Percentages of fibre decreased and energy components increased as the feeding phase progressed, while protein was highest in the last feed type and lowest in the second. Daily growth and feed efficiency were calculated weekly in 18 litters with 8 rabbits each allocated in a cage until 63 d. Carcass characteristics were assessed at 21, 35, 49 and 65 d old in 10 animals per age. Growth was higher and feed efficiency lower in the post-weaning phase than in the finishing phase (50.9 vs 45.9 g/d and 2.9 vs 5.0; $P < 0.001$; respectively). Carcass yield was maximum at 21 d, when previous feeding was based on lactation; minimum at 49 d for the high proportion of the digestive tract; and increased to 55.4% at 65 d with 2.1 kg liveweight. Considering the muscle in the carcass at 65 d as a reference, 22.1% of the weight was achieved from 21 to 35 d, 20.1% from 35 to 49 d, and 46.6% in the finishing period. In terms of fat (scapular plus kidney fats), 24.5% of the final weight was achieved in the transition period, only 7.0% during post-weaning and 29.6% in the third phase. Most the liver (40.0%) and kidney (28.4%) weight was also gained in the finishing phase, but the highest percentage of the head was reached at 21 d. These changes reflect the modification of feed composition in the different phases and the development of tissues and organs along the growth of the rabbits. The feeding phases studied are feasible to apply under the conditions of this trial (i.e. animal genetics, slaughter weight and sanitary conditions). All three phases are important, but specially the third because, although daily gain and feed efficiency are disadvantageous, most of the edible weight of the carcass is attained.

Session 47

Poster 14

Niacin improves intestinal health through up-regulation of AQP's expression induced by GPR109A*X. Yang, Y. Qiu, S. Liu and Z. Jiang**Institute of Animal Science, Guangdong Academy of Agricultural Sciences, No. 1, Dafeng 1st Street, Wushan, Tianhe District, Guangzhou, 510640, Guangzhou, China, P.R.; yangxuefen@gdas.cn*

Changes in the expression of aquaporins (AQPs) in the intestine are proved to be associated with the attenuation of diarrhoea. Diarrhoea is a severe problem for postweaning piglets. Therefore, this study aimed to investigate whether niacin could alleviate diarrhoea in weaned piglets by regulating AQPs expression and the underlying mechanisms. 72 weaned piglets (Duroc $\times$ (Landrace $\times$ Yorkshire), 21 d old, 6.60 ± 0.05 kg) were randomly allotted into 3 groups for a 14-day feeding trial. Each treatment group included 6 replicate pens and each pen included 4 barrows ($n=24$ /treatment). Piglets were fed a basal diet (CON), a basal diet supplemented with 20.4 mg niacin/kg diet (NA) or the basal diet administered an antagonist for the GPR109A receptor (MPN). Additionally, an established porcine intestinal epithelial cell line (IPEC-J2) was used to investigate the protective effects and underlying mechanism of niacin on AQPs expression after *Escherichia coli* K88 (ETEC K88) treatment. Piglets fed niacin-supplemented diet had significantly decreased diarrhoea rate, and increased mRNA and protein level of ZO-1, AQP 1 and AQP 3 in the colon compared with those administered a fed diet supplemented with an antagonist ($P < 0.05$). In addition, ETEC K88 treatment significantly reduced the cell viability, cell migration, and mRNA and protein expression of AQP1, AQP3, AQP7, AQP9, AQP11, and GPR109A in IPEC-J2 cells ($P < 0.05$). However, supplementation with niacin significantly prevented the ETEC K88-induced decline in the cell viability, cell migration, and the expression level of AQPs mRNA and protein in IPEC-J2 cells ($P < 0.05$). Furthermore, siRNA GPR109A knockdown significantly abrogated the protective effect of niacin on ETEC K88-induced cell damage ($P < 0.05$). Niacin supplementation increased AQPs and ZO-1 expression to reduce diarrhoea and intestinal damage through GPR109A pathway in weaned piglets.

How can poultry farming systems evolve to meet the major societal and environmental challenges?P. Thobe¹ and P. Van Horne²¹Thuenen Institute, Thuenen-Institute of Farm Economics, Bundesallee 63, 38116 Braunschweig, Germany, ²Wageningen University & Research, the Netherlands, P.O. Box 9101, 6700 HB Wageningen, the Netherlands; p.thobe@thuenen.de

Global poultry meat and egg production showed an impressive increase over the last 10 years. FAO data show that poultry meat production was 131 m ton in 2020 compared to 97 m ton in 2010. In this period, North America and Europe lost market share and Asia and South America increased their share. The largest producers of poultry meat are USA (17%), China (13%), Brazil (12%) and the EU (9%). According to the FAO, egg production in 2020 was 87 m ton compared to 64 m ton in 2002. In egg production, China is by far the largest producer (34%), followed by USA (8%) and the EU (7%). In 2020, total production of pig meat was 110 m ton and of cattle meat was 68 m ton. In 2017, poultry meat surpassed the production volume of pig meat. OECD projection for 2030 show a further increase in eggs and poultry meat. The outlook for 2030 shows a higher annual growth for poultry meat compared to pig meat and cattle meat. As a result of population growth and increasing income of a growing middle class in many developing countries, meat consumption will further grow with poultry meat often being the favoured one. Tradition, no religious barriers, a low price and convenient preparation are factors in favour of poultry meat. The most efficient production system with specific breeds and indoor housing is dominating world-wide. Housing of layers in cage and the use of fast-growing broiler breeds is criticized in the EU for animal welfare reasons. As poultry production is highly cost and price driven, costs incurred from adopting welfare practices are therefore of great importance. In terms of sustainability, besides animal welfare, social as well as environmental and economic aspects need to be included, while minimizing potential trade-offs. For bringing poultry farming to a significantly higher level of animal welfare in a socially and economically sustainable manner, a centrally guided concept becomes indispensable. Policy and business actors are working together to ameliorate animal production systems in the EU to comply with higher animal welfare standards. Several new public and private animal welfare labelling initiatives emerged in the past decade.

Can we enhance environmental impact without compromising bird welfare in broiler systems?

I. Kyriazakis

Queen's University, Institute for Global Food Security, 19 Chlorine Gardens, BT9 5DL Belfast, United Kingdom; i.kyriazakis@qub.ac.uk

As there is a widely recognized need to enhance all aspects of sustainability of livestock systems, the debate about potential trade-offs between reduction of environmental impacts and enhancement of animal welfare has inevitably come into focus. This conundrum is best reflected in the desire to move towards slower growing birds, to overcome some of the health and welfare concerns associated with fast growth and efficiency. Because feed-associated activities, such as feed ingredient production, and manure contribute almost 90% to the various metrics of environmental impact, systems that use slower growing birds which are less efficient in utilizing their feeding resources, will by definition be more environmentally impactful. The reductions in environmental impact that arise from welfare enhancements, such as reductions in mortality, culling, and use of medication will never offset such feed utilization-related impacts. For this reason, instead of entering into comparisons between broiler systems that utilize either fast or slow growing birds, it may be more fruitful to concentrate on practices that have the potential to reduce environmental impacts within a system. In this presentation, examples of such practices and their potential to affect environmental impacts will be given: (1) As the environmental impact of feed ingredient production is associated with land use and land use change, such as in the case of soya production, using home-growing protein sources may reduce the environmental impact of broiler systems. Furthermore, because of the lower amino acid requirements of slower grown strains, in theory it may be possible to replace more of the soya inclusion in the diet with alternative protein sources than in the diets of fast-growing birds and reduce their environmental impacts. (2) A reduction in the stocking density is accompanied with an increase of several environmental impact metrics (e.g. carbon footprint and energy use). However, the use of a heat exchanger applied for ventilation air is able to reduce any increased heating requirements due to low stocking density and offset environmental impact increases.

What is the impact of the farming system on the quality of the chicken breast meat?

J. Albechaalany^{1,2}, S. Yilmaz², M.P. Ellies-Oury^{1,2}, M. Bourin³, Y. Guyot³, J. Saracco⁴, J.F. Hocquette¹ and C. Berri⁵

¹INRAE, UMRH, 63122 Saint-Gènes-Champanelle, France, ²Bordeaux Sciences Agro, F&F, 33170 Gradignan, France,

³ITAVI, INRAE CVL, 37380 Nouzilly, France, ⁴INRIA, IMB, 33400 Talence, France, ⁵INRAE, BOA, 37380 Nouzilly, France; john.albechaalany@doctorant.uca.fr

The study aimed to assess the quality characteristics of the four main types of chicken fillets produced in France. The research was conducted on a set of 7,843 fillets collected from commercial slaughterhouses as part of a survey conducted by ITAVI and INRAE. The four main French production systems – Label Rouge, Certified, Standard and Heavy Broiler – were included in the sample, which varied according to animal type, age and/or weight at slaughter, and rearing practices. These systems have coexisted in France for many years to meet different demands in terms of taste quality and societal expectations, including animal welfare. The study assessed technological quality by ultimate pH, CIELAB colour parameters and curing-cooking yield, sensory quality by juiciness and tenderness after cooking, and nutritional quality by measuring dry matter, protein and fat content. Principal component analysis was performed to identify significant variables that explain chicken fillet quality, and analysis of variance (ANOVA) to investigate relationships between categorical variables. The data also included the time between slaughter and boning of the carcass, which has a significant impact on breast meat tenderness. Label Rouge fillets had the lowest pH and lipid content, but the highest redness and yellowness. The Certified broiler produced the lightest meat. Compared to standard and heavy broilers, Label Rouge and Certified broilers had a higher shear strength, indicating a tougher meat. Heavy broiler breast meat had the highest fat content, but the lowest cooking and processing losses. In addition, the study identified an abattoir effect for each type of broiler, highlighting the significant impact of the slaughter process on breast meat quality. In conclusion, the study highlights the significant impact of the rearing system and genetics on the quality of chicken fillets and the importance of taking into account the characteristics of the animals to optimize the process and ensure optimal meat quality.

Session 48

Improving broiler wellbeing and micro-climate through PLF application

S. Druyan^{1,2}, N. Barchilon^{1,2} and I. Halachmi¹

¹PLF Lab, Agricultural Research Organization, Volcani Institute, 68 HaMakkabbim Road, Rishon Le Ziyon, 7528809, Israel, ²Institute of Animal Science, Agricultural Research Organization, Volcani Institute, 68 HaMakkabbim Road, Rishon Le Ziyon, 7528809, Israel; shelly.druyan@mail.huji.ac.il

The welfare and productivity of broilers are affected by micro-climate conditions. Unsuitable environmental conditions lead to reduced performance, increased morbidity, and even death, resulting in animal welfare concerns and financial losses for farmers. Modern broilers struggle to balance energy expenditure and body water balance, limiting their ability to maintain steady-state mechanisms under sub-optimal environmental conditions. Climate control systems in modern broiler houses are equipped with sensors measuring environmental parameters around the broilers, rather than their actual needs. This study aimed to test and validate a new system that measures individual broiler body temperature using a low-cost infrared camera calibrated by a thermistor, an algorithm for IR image processing, and a Lasso regression model predicting actual body temperature. The system successfully detected a departure from the thermoneutral zone, with both systems detecting broilers crossing the upper and lower critical temperature thresholds on different days. The study identified 16 occurrences where the broilers' body temperature fell below the lower critical threshold, and five cases were detected where the broilers' body temperature exceeded the upper critical threshold. All were identified despite the ambient temperature sensors of the climate control system indicating that the temperature was within the desired range effecting broilers body weight (2,100 grams compared to an average weight of 2,500 as reported by the slaughterhouses for 35-day-old broilers). The results of this study suggest that monitoring individual broiler body temperatures is crucial for ensuring optimal micro-climatic conditions. By using this system as a temperature sensor in the climate control loop in broiler houses, farmers can improve broiler productivity and welfare, leading to better economic outcomes. Overall, this study highlights a practical, low-cost method for achieving optimal micro-climatic conditions for broilers.

Effects of heat stress and spirulina on productive performances of two slow growth broiler strains

E.A. Fernandes¹, C.F. Martins^{1,2}, D.F.P. Carvalho¹, L.L. Martins¹, A. Raymundo¹, M. Lordelo¹ and A.M. And Almeida¹
¹Instituto Superior de Agronomia, University of Lisbon, LEAF – Linking Landscape, Environment, Agriculture and Food Research Centre, Associated Lab. TERRA, Tapada da Ajuda, 1349-017 Lisbon, Portugal, ²Faculdade de Medicina Veterinária, University of Lisbon, CIISA – Centre for Interdisciplinary Research in Animal Health. AL4AnimalS, Avenida da Universidade Técnica, 1300-477 Lisbon, Portugal; eafernandes@isa.ulisboa.pt

Poultry production faces two problems: heat stress (HS) and lack of sustainable feedstuffs. HS affects productive performance and health. Mainly due the high protein content Spirulina are becoming increasingly interesting in poultry nutrition. The aim of this study was to evaluate the effect of 15% Spirulina (SP) dietary inclusion and the impact of HS on growth performance and organ measurements in two slow- growth broiler strains: FF (normally feathered) and Na (naked neck). 40-one-day-old male chicks (20/strain) were individually housed at 30 °C with *ad libitum* access to water and feed. Each strain received either a Control diet (C) or SP diet. Feed intake (FI) and body weight (BW) were monitored weekly and feed conversion ratio (FCR) and average daily gain (ADG) were calculated. After 84 days of trial, all broilers were slaughtered and organs collected, weighed, and measured. The final BW of the animals was 2,741, 2,536, 2,527 and 2,142 g for CNa, SPNa, CFF and SPFF groups respectively. At the end of the trial, FI and ADG were significantly affected ($P < 0.05$). SPNa animals had the highest FI and ADG (145 g/animal/d – 53.34 g/d) and the CFF had the lowest (111 g/animal/d – 39.53 g/d). However, FCR were not significantly affected. Relative crop and gizzard weight ranged between 1.97-2.67 and 10.0-13.0 respectively, highest in SP animals ($P < 0.05$). The relative length (cm/kg) of the ileum was increased by the incorporation of SP, 31.5, 30.1, 27.5 and 25.7 for SPFF, SPNa, CFF and CNa groups respectively. The HS negatively influenced growth performance of broilers especially the normally feathered animals. The Na groups could tolerate HS even when fed with SP. Future information provided by digestibility coefficients and meat quality traits will complement these results, allowing a better knowledge of the nutritional values of Spirulina for broilers under HS.

Session 48

Theatre 6

Evaluating services provided by free-range poultry systems

G. Chiron

ITAVI, 7 Rue du Faubourg, 75009 Paris, France; chiron@itavi.asso.fr

In free-range poultry production, outdoor run is a key element for the multiperformance of the farming system. However, managing the outdoor run can be seen more as a constraint when its potential to provide more global agroecological solutions and meet society's expectations, beyond animal welfare, is not perceived. Thus, it is necessary to provide tools for farmers, adapted to different knowledge levels and context, allowing them to think about an optimized management of the outdoor run or to better take into account the diversity of services it provides. The objective of this study was to develop and test a generic method to assess the services provided by different free-range poultry systems (i.e. species, location, or outdoor run characteristics). First, a conceptual framework was developed through a participatory approach by experts before being challenged by futures users (farmers, advisors, outdoor run management structures, etc.) in three poultry production regions (West, South-East and South West of France). The conceptual framework finally considers of 13 services, being allocated in five different service categories (production of resources and value, farmer's life quality, farmer-consumer-citizen interconnection, territorial integration and environmental quality). For each service, the experts also selected relevant indicators to assess each service in an easy, quick, and cheap way in commercial farms. These indicators are based on either on-farm surveys (e.g. labour time or economic performance) or *in situ* measurements (e.g. assessing animal welfare). In order to validate the feasibility and genericity of the method in practical conditions, 21 commercial houses were studied. These farms differed in their location (West, South-East and South West of France), the production (chicken meat, eggs, duck meat) and the shape, size, and design (trees, bushes, woods, etc.) of the outdoor run. The first results indicates that the method is enough sensible to highlight different bundles of services according to the outdoor run characteristics. Therefore, this method could be used by farmers and their advisors, to evaluate the actual provision of services by a free-range poultry system, and further discuss about the most adequate management of the outdoor run for a maximal provision of services.

Biosecurity gaps in 7 major poultry producers (breeder and layer farms) in EU: a farmers perspectiveA. Amalraj¹, H. Van Meirhaeghe², R. Souillard³, A. Zbikowski⁴ and J. Dewulf⁴¹Faculty of Veterinary Medicine, Ghent University, 9820, Belgium, ²Vetworks BV, Knokstraat, Aalter, Belgium, ³ANSES, French Agency for Food, Environmental and Occupational Health & Safety, Epidemiology, Health, France, ⁴Institute of Veterinary Medicine, Warsaw University of Life Sciences, Nowoursynowska, Poland; arthi.amalraj@ugent.be

Good practices prevent diseases and economic losses, and ensure high production standards in poultry farming. A qualitative assessment was done in poultry breeder (n=46), enclosed layer (n=37) and free-range layer (n=21) farms of the NetPoulSafe project, with a semi-closed questionnaire with focus on 46, 45 and 54 biosecurity measures (BM) respectively in each production. The farmers responded to the frequency of implementation and the reasons for non-compliance. Most measures (75% of all the answers collected) were frequently implemented due to regulatory control. However, a compromise was noticed on implementation of some measures. Wheel disinfection (BM1), cleaning and disinfection of the rendering tank after each collection (BM2) and egg storage room (BM3) after each collection, showering of personnel (BM4), visitors (BM5), and farm-specific clothing and shoes for egg transport drivers (BM6) were less implemented compared to other measures. A descriptive analysis of the collected data showed that from the total respondents, only 78% breeder, 59% enclosed layer and 62% free-range layer farms practiced BM1; only 46% breeder, 67% enclosed layer and 42% free-range layer farms practiced BM2; only 47% breeder, 63% enclosed layer and 69% free-range layer farms practiced BM3 and only 75% breeder, 67% enclosed layer and 56% free-range layer farms followed BM6. In only 65% breeder, 11% enclosed layer and 19% free-range layer farms, farm personnel showered before entering into the poultry house and in only 72% breeder, 24% enclosed layer and 24% free-range layer visitors showered before entering into the poultry house, often reported 'excessive measures' in some productions. The main reasons for non-compliance were 'lack of time', 'not knowing risks/advantages', 'expenses incurred' or 'not considered useful'. This study suggests that intervention is needed in order to further improve biosecurity compliance in the participating farms.

Session 48

Theatre 8

Reducing environmental impact of broiler production: the role of crude protein and soybean mealT. De Rauglaudre^{1,2}, B. Méda¹, S. Fontaine³, W. Lambert³ and M.P. Létourneau Montminy²¹INRAE, BOA, Nouzilly, 37380, France, ²Université Laval, Département des sciences animales, Québec, G1V0A6, Canada, ³METEX Animal Nutrition, Paris, 75017, France; theophile.de-rauglaudre.1@ulaval.ca

Lowering crude protein (CP) content in broiler feeds has the potential to reduce environmental burdens related to nitrogen (N) volatilization. As the main source of CP is generally soybean meal (SBM), this strategy also allows to reduce the environmental impacts (e.g. climate change) associated to feed production, when SBM production is associated with deforestation. Yet, in most low CP trials, the effects of CP and SBM are confounded. Thus, the aim of this study was to investigate the effect of decreasing CP content at various SBM levels on growth performance, and N volatilization. A total of 3,384 one-day-old Ross 308 males were randomly distributed in 63 pens. After receiving the same starter feed, 7 experimental diets were used fed during growing (G; 11-22 d) and finishing (F; 23-34 d) periods: A control diet (C; 20.4 and 19.5% CP in G and F periods, respectively) and 6 experimental diets formulated with 3 levels of SBM (100, 50 and 0%) and two CP reduction levels (-15 and -30 g/kg) were randomly assigned. The body composition used to calculate the N body retention was measured by scanning under anaesthesia one bird per pen (9 per treatment) with dual-X ray absorptiometer at days 23 and 35. During the G period, compared to C, average daily gain and feed intake were linearly decreased with CP independently of SBM content ($P < 0.001$), but feed efficiency was not impacted. In the F period, no effect on performance was observed. On the total trial period (11-34 d), only the growth and feed intake in the soy-free diet at -30 g CP/kg were lower than C (-5%; $P < 0.01$). Reducing CP linearly decreased N intake and excretion independently of SBM content while N retention efficiency was linearly increased ($P < 0.001$). This decrease in N excreted led to a decrease of N lost through volatilization (N volatilized = $-0.44 + 0.58 * \text{N excreted}$; RMSE=0.20; $P < 0.001$). The current results show that it is possible to simultaneously decrease CP content by 30 g/kg and SBM content by 50% without impairing animal performance. CP and SBM reduction strategies can therefore be used together to improve the sustainability of broiler production.

Elevated platforms for broilers on commercial farms: usage and effects on health and performanceJ. Stracke¹, F. May², J. Müsse³, N. Kemper² and B. Spindler²¹University of Bonn, Farm Animal Ethology, Institute for Animal Science, Endenicher Allee 15, 3115 Bonn, Germany,²University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany, ³Chamber of Agriculture Lower Saxony, Mars-la-Tour-Straße 1-13, 26121 Oldenburg, Germany; jenny.stracke@itw.uni-bonn.de

Barren barns as standard housing systems for broiler chicken can lead to serious welfare problems. Environmental enrichment does not only allow the animals to perform species-specific behaviour, but might also improve other welfare aspects such as health. In the present study, one of two barns in each of three broiler farms was equipped with an elevated platform (90×1.20 m). Video cameras were installed above the elevated platforms, recording the number of animals in three locations (front, middle, back) during fattening (about 42 days). For one day per week (n=6) of the fattening period (n=3), screen shots were taken every 30 minutes for a time period of 24 hours. The number of animals on the elevated platforms was evaluated. Furthermore, each farm was visited three times (beginning, middle end) per fattening period (n=5). Data of animals' performance (weight) and health (food pad dermatitis (FPD), hock burns (HB), injuries and plumage pollution (PP)) was collected per barn for 50 animals each. Generalized linear mixed models were calculated. The animals used the elevated platform frequently with a maximum of 14 broilers per m². Significant effects of farm, week and interaction between both (week and farm) was found. Effects of treatment were found for HB and PP, and a significant effect of the interaction between farm and treatment was revealed (HB, FPD, PP). The results of this study indicate the benefits of elevated platforms for broilers' well-being. However, positive effects on health depend on the respective management and need further research. This work (Model- and Demonstration Project for animal welfare MaVeTi) is financially supported by the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE); grant number 'FKZ 2817MDT301'.

Mutation effects as key driver of maintaining genetic variation for long-term selection in broilersB.S. Sosa-Madrid^{1,2}, N. Ibañez-Escriche¹, G. Maniatis³ and A. Kranis^{2,3}¹Institute for Animal Science and Technology, Universitat Politècnica de València, P.O. Box 2201, Valencia 46071, Spain,²The Roslin Institute, University of Edinburgh, EH25 9RG, Midlothian, United Kingdom, ³Aviagen Ltd., Newbridge, Midlothian, EH28 8SZ, United Kingdom; v1bsosa@exseed.ed.ac.uk

Maintaining genetic variation in a population is important for long-term genetic gain. Theoretically, selection process leads to reducing genetic variation over time in populations undergoing intense directional selection pressure. Mutations are variation sources arising in the genome randomly, and those contributing to the genetic variance of the traits under selection would partly compensate for the loss of genetic variation. In broiler breeding, the breeding goals have been expanding through time to include traits related to biological performance and welfare. Body weight is a trait that has been part of broiler breeding goals historically. The aim of this study was to quantify the contribution of mutational variance for body weight trait in a broiler line, over 23 years of selection and 2 million animal records. Bayesian inference was carried out to estimate the variance components using two models: one with- and other without-mutational effects. The parameterization of Wray's relationship matrix by Casellas and Medrano was used to model the mutational matrix. Mutation variance is regarded as the variation originating from a mutation effect arising from an animal until the last generation. Namely, the genetic effect build-up segregating from a mutation event to the youngest relative is deemed a mutation effect and contribute separately to additive genetic variance. The trajectory of variances was inferred according to Sorensen's method clustering animals by egg hatching period (3 weeks). Results showed that mutational variance (0.71) and mutational heritability (0.0027) estimates are lower in the base population, compared to the additive genetic variance (100.96) and heritability (0.39). However, mutational variance bears an important role over time, as the mutational effects accumulate and thus, their contribution tends to increase. Overall, albeit the contribution of mutation effects is small in the first generation of selection, its role has been essential to ensure genetic variation in a long-term broiler selection programme.

Early interventions during incubation and impact on a muscle of locomotory relevance in broilers

T. Kettrukat¹, A. Dankowiakowska², M. Mangan³, E. Grochowska³, K. Stadnicka⁴ and M. Therkildsen¹

¹Aarhus University, Dept of Food Science, Agro Food Park 48, 8200 Aarhus N, Denmark, ²University of Science and Technology Bydgoszcz, Dept of Animal Physiology & Zoophysiotherapy, ul. Mazowiecka 28, 85-084 Bydgoszcz, Poland,

³University of Science and Technology Bydgoszcz, Dept of Animal Biotechnology & Genetics, ul. Mazowiecka 28, 85-084 Bydgoszcz, Poland, ⁴Nicolaus Copernicus University, Faculty of Health Sciences, ul. Łukasiewicza 1, 85-821 Bydgoszcz, Poland; tobias.kettrukat@food.au.dk

Early intervention through temperature manipulation and *in ovo* microbiome programming can potentially alleviate challenges in broiler production like heat stress and gut health. In contrast to the breast muscle, the impact on leg muscles has rarely been examined. A positive effect on such muscles could improve locomotory ability in broiler chickens, a persistent concern brought on by singular selection on breast muscle growth that compromises welfare. We investigated the effects of temperature manipulation and microbiome programming *in ovo* on *M. gastrocnemius* in Ross 308 broilers. In experiment one, temperatures ranging from 36.5 to 39.0 °C were applied during embryonic day 4 to 7, and *M. gastrocnemius* was sampled for histology at hatch and 35 days of age. In experiment two, a combination of an IBD vaccine with a prebiotic (*Astragalus polysaccharides*), a probiotic (*B. lactis*) or a synbiotic (both) was applied *in ovo* on embryonic day 18. *M. gastrocnemius* of 42-day-old females was sampled for histological analysis. Fibre dimensions, fibre type and intramuscular fat were determined by H+E, myosin ATPase, and Oil Red O – staining. Absolute and relative muscle weights were influenced by the interventions, but the fibre dimensions seem to be largely unaffected, suggesting no negative effect on the development of leg muscle fibres through the interventions. The findings could be used to develop these early interventions into tools to alleviate negative effects of the intensive selection for body weight. The experiments were funded by the European Union's Horizon 2020 research and innovation program (grant N° 955374), the National Science Centre, Poland (grant N° 2019/35/B/NZ9/03186, OVOBIOM) and the Polish National Agency for Academic Exchange (grant N° PPI/APM/2019/1/00003).

Session 48

Theatre 12

Summary of the posters in session 48 by the chairs

B. Méda¹ and K. Stadnicka²

¹INRAE, Université de Tours, BOA, 37380 Nouzilly, France, ²Nicolaus Copernicus University, Collegium Medicum, Łukasiewicza 1, 85-821 Bydgoszcz, Poland; katarzyna.stadnicka@cm.umk.pl

A summary of the posters in session 48 will be presented by the chairs of the session. The aim is to increase the visibility of the relevant research topics that address challenges and solutions related to poultry farming systems in the context of major societal and environmental challenges.

Effect of gallic acid supplementation to corn-soybean-gluten meal-based diet in broilers performance*J.H. Song¹, C.B. Lim¹, S. Biswas¹, Q.Q. Zhang¹, J.S. Yoo² and I.H. Kim¹**¹Dankook University, Department of Animal Resource and Science, Cheonan, 31116, Korea, South, ²Daehan feed company, 13 Bukseongpo-gil, Jung-gu, Incheon, 22300, Korea, South; thdwnsh@naver.com*

Gallic acid (GA) is an endogenous plant polyphenol found in fruits, nuts, and plants that has antioxidant, antimicrobial, and health-promoting effects. Broilers were fed graded doses of GA to assess growth efficiency, nutrient retention, footpad lesion score, tibia ash, and meat quality. In a 32-days feeding trial, 576 1-day-old Ross 308 broiler chicks (mixed sex) with an average body weight of 41 ± 0.5 g were arbitrarily assigned to 1 of 4 dietary treatments with 8 repetitions of 18 birds per cage and a basal diet administered with 0, 0.02, 0.04, and 0.06% of GA. Linear and quadratic effects were used to examine the polynomial contrast of increasing level of GA inclusion. Feeding broilers with a graded dose of GA increased body weight gain (BWG) ($P=0.003$) and feed intake ($P=0.012$) linearly on days 9-21. BWG also tended to linearly increase on days 21-32 ($P=0.092$) and the overall period ($P=0.051$), respectively. In addition, the nutrient digestibility of dry matter ($P=0.003$) and gross energy ($P=0.014$) were linearly increased. However, the faecal score, footpad lesion score, and tibia ash reveal no significant effect ($P>0.05$). By feeding broilers a graded level of GA, relative organ weights including breast muscle and spleen tended to increase linearly ($P=0.081$ and 0.067 , respectively), meat colour of yellowness increased linearly ($P=0.005$), and pH value tended to decrease ($P=0.068$). Briefly, adding GA at increasing doses to broiler diets increased growth efficiency, nutritional absorption, and meat quality, so we infer that adding 0.06% of GA could be beneficial for broiler performance.

Poster 14

Veterinary coaching to stimulate biosecurity compliance*A. Amalraj¹, H. Van Meirhaeghe², M. De Gussem² and J. Dewulf¹**¹Faculty of Veterinary Medicine, Ghent University, 9820, Belgium, ²Vetworks BV, Knokstraat, Aalter, Belgium; arthi.amalraj@ugent.be*

Farmers' readiness to accept changes is pivotal to biosecurity application and therefore improving biosecurity requires changes in the attitudes and behaviour of farmers. Coaching is a method to help farmers find their short term and long term goals through non-directional questioning with more interaction and is different from previously used advisory techniques where the process is more unidirectional. Veterinary 'coaching' was tested to assess their efficacy in stimulating compliance. A longitudinal study is ongoing on 18 pilot farms (part of NetPoulSafe project) in Belgium: broiler (n=5), enclosed layer (n=2), free-range layer (n=2), turkey (n=2), breeder (n=4), and hatcheries (n=3). The hygiene evaluation tool – Biocheck.Ugent (www.biocheck.ugent.be) and ADKAR® change management model were used as supporting tools for coaching. For ADKAR, whenever the farmers scored low (<3) for the element 'Awareness', the risk factors arising from poor hygiene was discussed. For the element 'Desire' (<3), to provoke an interest, the benefits of the change were explained. For the element 'Knowledge', depending on the specific problem in the farm, an educative approach was used in the form of visual aids and PowerPoint presentations. For the element 'Ability' lower scores were dealt with by discussing topics such as making structural changes and investments towards better biosecurity. An action plan is drawn for the following 6 months and is reviewed by the coach and the veterinarian through a phone call. The biosecurity status was re-evaluated after 6 months. The total biosecurity score obtained by the pilot farms were: broiler (65%), enclosed layer (65%), free-range layer (68%), turkey (70%), and breeder (71%). Breeder farms in Belgium scored highest for external biosecurity (70%) and turkey and free-range layer farms had the highest internal biosecurity scores (80%). The mean ADKA scores for the participating farms were 3.8, 4, 3.8 and 3.9 for the elements Awareness, Desire, Knowledge, and Ability, respectively. Farm biosecurity scores and profiling helped the coach and veterinarian to design an intervention plan specific to each pilot farm.

Establishing elevated perforated platforms in broiler chicken housing – is hygiene a barrier?B. Sake¹, J. Müsse², F. May¹, J. Stracke³, N. Kemper¹, J. Schulz¹ and B. Spindler¹¹University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTn), Bischofsholer Damm 15, 30173 Hannover, Germany, ²Chamber of Agriculture Lower Saxony, Mars-la-Tour-Straße 1-13, 26121 Oldenburg, Germany, ³University of Bonn, Farm Animal Ethology, Endenicher Allee 15, 53115 Bonn, Germany; bjoern.sake@tiho-hannover.de

In Europe, broiler chickens are usually raised in littered barns without structuring elements. Elevated perforated platforms (EPP) might have positive effects on animal welfare by providing additional space, and elevated structures to rest. This study aimed to analyse the efficiency of the cleaning and disinfection process (C&D) during the service period. Therefore, microbiological samples were taken during two to three service periods from three farms with barns equipped with an EPP. For sample collection, sterile sponges were taken, and wiped over a defined area at three different locations: the top of the perforated plastic floors of the platform, the metal rack and the barn floor for comparison. At each location five samples were taken and pooled. Three different time-points (TP) at the service period were considered (TP1: before cleaning, TP2: after cleaning and drying, TP3: after disinfection). Samples were analysed microbiologically for the occurrence of *Enterococci* (ET), *Enterobacteriaceae* (EB), and the total bacterial counts (TBC). The results showed that samples from the EPP at both locations contained less TBC compared to the barn floor. At TP3, neither ET nor EB were detected at both locations of the EPP and all tested locations showed a TBC below 1,000 per cm², indicating a reduction of 4 to 6 log levels. Although C&D of the EPP took considerably more time and required additional cleaning tools, the procedure was performed efficiently. It can be concluded that the applied hygiene measures are suitable to reduce the risk of pathogen transmission to the next production cycle. This work (Model- and Demonstration Project for animal welfare MaVeTi) is financially supported by the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE); grant number 'FKZ 2817MDT301'.

Session 48

Poster 16

What's going on outside? Use of winter gardens by rearing hens of different geneticsA. Riedel^{1,2}, N. Kemper² and B. Spindler²¹University of Veterinary Medicine Hannover, Foundation, WING (Science and Innovation for Sustainable Poultry Production), Heinestraße 1, 49377 Vechta, Germany, ²University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany; anna.katharina.riedel@tiho-hannover.de

In German laying hen husbandry, it is required that pullets are accustomed during rearing to the husbandry system in the laying hen farm. For organic farms, the offer of a winter garden (WG) as a transit area between henhouse and free-range is required, to accustom the pullets to the outdoor climate. In this on-farm study, it was examined how frequently this area was visited by pullets in three flocks of different genetics (H1 NB: NOVOgen Brown, H2 LB: Lohmann Brown-Lite and H3 DW: Dekalb White). They were reared over the same period of 18 weeks of life (LW). The flocks H1 NB and H2 LB were housed in groups of about 4,100 animals each, with 2 WG of about 69 m² each. The flock H3 DW was reared in another farm, including 2,400 animals, with one WG of approximately 68 m². A wildlife animal camera was installed in one WG of each group, automatically taking photographs in a 15-minute interval over the course of the day. These photographs were evaluated for three days in LW 12 and LW 16/18, and the number of animals present in an area of 35 m² (H3 DW), 26.8 m² (H1 NB) and 19.5 m² (H2 LB) was counted. The results showed a good acceptance of the WG in all three flocks with on average of 2.26 (±1.86) hens/m² in the examined area. All flocks showed a significant increase in hens/m² from the first (LW 12) to the second (LW 16/18) observational period ($P < 0.001$). During the first observational period, no significant differences between the flocks were found, while at the end of the rearing period, H1 NB showed a significantly higher use of the WG (3.8 ± 1.8 hens/m²) than H3 DW (2.9 ± 0.5 hens/m²; $P < 0.01$). The results for H2 LB were intermediate (3.1 ± 2.4 hens/m²). This work is financially supported by the Federal Ministry of Food and Agriculture based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (grant number FKZ 2817MDT301/311).

Metabolomic analysis reveal the molecular mechanism related to leg disease in broilers*J. Zheng, G. Zhang, Q. Li and G. Zhao**Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Yuanmingyuan West Road No.2, Haidian, Beijing, 100193, Beijing, China, P.R.; liqinghe@caas.cn*

White feather broilers are characterized by fast growth and high production efficiency. Rapid weight gain causes the body metabolism to be in an overload state, triggering leg disease, which has economically affected the welfare and development of broilers. However, the relationship between changes in metabolites during the dynamic metabolism and leg disease remains unclear. The results of serological biochemical indices in normal and leg bone deformed broilers showed that the serum calcium to phosphorus ratio was highly reduced in diseased broilers. In addition, serum lipid indices were abnormal, indicating a disturbance in lipid metabolism. Based on extensive targeted metabolomics analysis, 1,005 and 997 metabolites were detected in serum and cartilage tissue samples, respectively. Orthogonal partial least squares discriminant analysis and weighted gene co-expression network analysis were used to screen for important metabolites associated with leg disease, serum calcium and phosphorus levels. As a result, a total of nine key metabolites were screened, which included carnitine C16:0, carnitine C18:1, 3-oxy-methyl-L-tyrosine, cis-4-hydroxy-D-proline, cis-L-3-hydroxyproline, and trans-4-hydroxy-L-proline. The top 20 metabolic pathways enriched in the KEGG pathway for differential metabolites in the two tissue samples included fatty acid degradation and arachidonic acid metabolic pathways. Metabolite analysis on these two pathways showed that prostaglandin D_2 , prostaglandin J_2 , prostaglandin A_2 , 15- keto- prostaglandin $F_{2\alpha}$ were significantly different between normal and disease groups. Collectively, the results suggest that the occurrence of leg disease in broiler chickens is associated with metabolic disorders in the organism. Serum calcium to phosphorus ratio can be used as an *in vivo* predictor of leg disease in broiler chickens.

Session 48

Poster 18

Housing conditions do not influence the effects of a nutritional challenge for broilers*V. Michel, C. Deschamps, N. Regrain, E. Devillard and J. Consuegra**Centre of Expertise and Research in Nutrition, Adisseo, 03600, France; virginie.michel@adisseo.com*

In vivo experimentation is essential for animal science research. However, the large number of animals and repetitions required to obtain biological and statistical differences limits the flexibility of designs and heavily impacts animal welfare. For a sustainable animal experimentation, it is pivotal to develop new designs and experimental structures allowing both the reduction of animal use and biological events. Here, we tested the possibility of reducing the number of animals in nutritional challenge thanks to an adaptable system composed of 24 modular broilers cages. This system allows a flexible experimental design in terms of birds per cage and repetitions. A total of 108 one-day-old male Ross 308 chicks were randomly allocated to 4 experimental conditions with a 2×2 factorial arrangement. Two diets were tested: Control (CTL, standard diet with wheat/soybean meal) and Dysbiosis (DYS, an unbalanced feed enriched in rye and saturated fat). Two types of cages were used: small (S) with 3 birds/cage and large (L) with 9 birds/cage. The experimental conditions in the S cages were repeated 9 times and those in L cages were repeated 3 times to obtain 27 birds per treatment. Body weight (BW), feed intake (FI) and feed conversion ratio (FCR) were measured on days 14 and 28. No interaction between diets and cage sizes was observed. At 28 d, DYS significantly decreased broilers body weight by 5.6% in S cages and by 7.4% in L cages compared to CTL ($P<0.05$). Moreover, FCR was significantly degraded with DYS diet by 8% on 0-14 d and 6% on 0-28 d periods ($P<0.01$). However, housing conditions did not affect these parameters. The FI during 0-14 d and 0-28 d wasn't impacted by any experimental factor. Altogether, our results show that both tested housing conditions allow to reproduce the DYS negative impacts on BW, FI and FCR. Moreover, the deterioration of performances is at the same level as the one previously reported on the same challenge using around 2,000 animals on floor (at least -6% of BW at 28 d). Thus, our S cages model allows to increase the number of experimental replicates and to reduce the numbers of animals which offers a larger panel of experimental designs and improves the sustainability of our experimental facilities.

Compliance of biosecurity in poultry farms in France: remaining obstacles and levers for improvementN. Rousset¹, A. Battaglia¹, J. Puterflam¹, J. Marguerie², R. Souillard³, S. Le Bouquin-Leneveu³ and A.-C. Lefort¹¹ITAVI, 7 rue du faubourg Poissonnière, 75009 PARIS, France, ²SNGTV, 5 rue Moufle, 75011 Paris, France, ³Anses, BP 53, 41 rue de Beaucemaine, 22440 Ploufragan, France; rousset@itavi.asso.fr

The successive outbreaks of avian influenza in France underline more than ever the importance of complying with biosecurity measures in poultry farms. Although the concepts of biosecurity are increasingly well known, it is nevertheless observed that they are not always well applied. The European NetPoulSafe network, launched in 2020, aims to sustainably improve compliance of biosecurity in the poultry sector. In order to make a state of the art of current compliance of these measures, the technical and psychosocial obstacles that remain, and to identify ways of strengthening support, a study was conducted in France with 25 broiler, turkey, laying hen and duck farmers, with different production systems (indoor, outdoor, different sales ways), as well as with 24 technical and veterinary advisors. The study reveals that only a minority of measures are actually applied by all farmers. As for the rest of the measures, a very high degree of heterogeneity was observed depending on the species produced and the production system. The obstacles mentioned by the farmers are often the inconvenience in the work, or even in the organisation of the work that some measures can generate. This is the case in particular for complex production systems in farms with direct sales, with the presence of several species, and multiple flocks. Structural obstacles were also mentioned, e.g. the presence of specific equipment (aviaries, cages) can generate difficulties in applying complete cleaning and disinfection protocols. Finally, many farmers still have doubts about the effectiveness or relevance of some measures, which indicates a need to continue raising awareness and training on the risks. Personal advice, discussion groups within farmers and training based on concrete cases were widely favoured by the interviewees. Although an improvement in biosecurity compliance was generally observed, this study confirms the need to strengthen personalised support, by proposing very operational solutions to overcome the specific obstacles of some production systems.

Session 48

Poster 20

Untrimmed beaks in turkey hens: Effect on injuries and mortality rateM. Kramer¹, K. Skiba¹, P. Niewind², F. Von Rüden², N. Kemper¹ and B. Spindler¹¹University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTN), Bischofsholer Damm 15, 30173 Hannover, Germany, ²Agricultural Chamber of North Rhine-Westphalia, Haus Duesse, Haus Düsse 2, 59505 Bad Sassendorf, Germany; Marie.Kramer@tiho-hannover.de

Beak trimming is a common non-curative intervention to minimize severe pecking injuries in poultry. This study aimed to show the effect of untrimmed beaks on injuries and mortality rate of turkey hens in an optimized housing environment. Therefore, turkey hens with untrimmed (UT: 5,400 hens) and trimmed beaks (T: 5,400 hens) were housed in one barn each, on one farm and were observed during two fattening batches. To minimize injurious pecking, the UT herd received enrichments such as elevated platforms, hay baskets, metal mobiles and feed dispensers. In the 1st, 5th, 9th and 13th week of life, in both batches, 60 birds per group were scored to detect injuries. Losses due to mortality and separation were recorded daily. Overall, there were 28% hens with injuries in the UT sample and 6% in the T group. The highest prevalence of injured birds in both batches (UT: 72% | 52%; T: 13% | 10%) was recorded in the 13th week of life. The injuries occurred mainly to the snood and head area (80%). Animals with fresh injuries were removed from the herd to a separation compartment. Thus, in the first run, 1,546 animals (29%) were separated in the UT group, while 331 animals (6%) were separated in the T group. In the second run, 718 hens (13%) were separated in the UT group, while 203 hens (4%) were separated in the T group. The cumulative mortality rate in UT herds was 8.65% in the first, and 4.39% in the second run, while in T herds it was 3.98% in the first, and 2.26% in the second run. Concluding, keeping UT hens showed mortality rates nearly twice as high and a higher prevalence of injuries despite the enriched housing environment and the extensive separation management. This work (Model- and Demonstration Project for animal welfare #Pute@Praxis) is financially supported by the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE; grant number FKZ 2817MDT611).

Habitat affects egg characteristics of Libyan local pigeon (domestic vs feral pigeon)*F. Akraim, M.F. Idrees and M.M. Sghieyer**Omar Al-Mukhtar University, Animal Production Department, University campus, 1118 Al Bayda, Libyan Arab Jamahiriya; fowad.akraim@omu.edu.ly*

Domestic pigeon is descended from rock pigeons (*Columba livia*), that inhabit North Africa. The majority of the pigeon population in Libya are domestic or feral pigeons, in addition to a smaller number of wild pigeons. This study aimed to investigate the effect of habitat on some external and internal quality characteristics of eggs collected from feral and domestic Libyan pigeons. Measurements were done on 62 feral pigeon eggs collected from different urban locations and 37 eggs collected from a domestic pigeon farm. Across habitats, the mean egg weight was 15.72 g. Yolk, albumin, and shell represent 67.85, 23.72 and 8.22% of egg weight, respectively. Egg shape index was 74.88%, and shell thickness was 0.26 mm. Feral pigeon eggs were heavier (16.73 vs 15.16 g), bigger (15.82 vs 14.76 cm³), wider (28.57 vs 27.46 mm), and had a more favourable shape index (76.34 vs 72.30%) than domestic pigeon eggs ($P<0.05$). The yolk percentage was lower (21.51 vs 26.09%) and the albumin percentage was higher (71.07 vs 64.36%) in feral compared with domestic pigeon eggs ($P<0.05$). Those differences could be attributed to nutritional factors linked to the diverse feeding regimes of feral pigeons. A study of multiple domestic pigeon farms is needed to confirm this conclusion.

Effects of heat stress and spirulina on meat traits of two slow growth broiler strains*E.A. Fernandes, J.R. Sales, L.L. Martins, M. Lordelo, A. Raymundo and A.M. And Almeida**Instituto Superior de Agronomia – University of Lisbon, LEAF – Linking Landscape, Environment, Agriculture and Food Research Centre, Associated Lab. TERRA, Tapada da Ajuda, 1349-017 Lisboa, Portugal; eafernandes@isa.ulisboa.pt*

Heat stress (HS) and lack of sustainable feedstuffs are two of the most severe problems faced by poultry production systems. Heat stress negatively affects productive performance and health. Due to its high protein content, the incorporation of spirulina (SP) is becoming increasingly interesting in poultry nutrition and can play an important role in minimizing the problems associated with HS. The objective of this study was to evaluate the impact of 15% SP dietary inclusion and the effect of HS on different meat quality parameters in normally feathered (FF) and naked neck (Na) slow growth broiler strains. Forty-day-old chicks were distributed in 4 different groups of ten animals: Control diet + Naked neck (CNa), Diet with 15% SP + Naked neck (SPNa), Control diet + Normally feathered (CFF) and Diet with 15% SP + Normally feathered (SPFF). Each animal had *ad libitum* access to water and feed. During the 84 days of the experiment, the temperature was kept at 30 °C. At the end of the trial, all broilers were slaughtered, and breast muscle was collected, weighed, and used for subsequent analysis. Carcass yield was 69.0, 67.3, 66.6 and 65.8% for CFF, CNa, SPNa and SPFF groups, respectively. Carcass yield was decreased ($P<0.05$) with the incorporation of SP regardless the strain. Breast muscle yields were not significantly different between groups ($P>0.05$). SPFF animals had the highest percentage of drip loss (40.7%), while CNa had the lowest (34.8%). Thawing and cooking losses were not significantly affected ($P>0.05$). Regarding colour parameters, lightness (L*) and redness (a*) were not significantly affected ($P>0.05$) but yellowness (b*) was significantly highest ($P<0.001$) in SP groups, when compared to control diet groups. This alteration is associated with a more intense yellow in the groups fed with SP, resulting from the presence of high levels of carotenoids. The incorporation of Spirulina in the diet didn't affect the majority of the meat traits, independently of the strain used.

How does broiler range use impact forage intake, outdoor excretion and gaseous emissions?

C. Bonnefous¹, B. Méda¹, K. Germain², L. Ravon², T. De Rauglaudre¹, J. Collet¹, S. Mignon-Grasteau¹, M. Reverchon³, C. Berri¹, E. Le Bihan-Duval¹ and A. Collin¹

¹INRAE, Université de Tours, BOA, 37380 Nouzilly, France, ²INRAE, UE EASM, Le Magneraud, CS 40052, 17700, Surgères, France, ³SYSAAF, 37380, Nouzilly, France; anne.collin@inrae.fr

Free range enables broiler chickens to express natural behaviours, eat grass, worms or insects outdoors, but also induces excretion outside the poultry house. To understand how the outdoor run is impacted by range use, we studied three strains of intermediate to slow-growing chickens: JA757 (734 animals, average daily gain (ADG): 36 g/day, outdoor density (OD): 0.26-0.29 chicken/m², rearing duration (RD): 86 days), S757N (735 animals, ADG: 26 g/day, OD: 0.26-0.29 chicken/m² and RD: 100 days) and a dual-purpose (DP) crossbreed (771 animals, ADG: 16 g/day, OD: 0.27-0.31 chicken/m² and RD: 121 days). Birds had access to a grassy outdoor run with mature trees from 36 days of age. We collected data on the time spent outdoor by broilers using Radio Frequency Identification (RFID) chips, on the composition and amount of manure and on grass growth to evaluate the impact of range use on grass consumption and outdoor nitrogen (N) / phosphorus (P) excretions. RFID showed that S757N chickens spent about twice as much time outdoor per day than the JA757 and DP ones. Similarly, the S757N chickens also consumed about twice as much grass per day than JA757 and the DP ones. Consistently, S757N chicken outdoor excretions of N and P per day of outdoor access were about twice as much as that of the DP chickens while only about 30% greater than that of JA757. Therefore, we confirmed the relationship between range use and foraging, but we showed strain-dependant outdoor excretion in relation to growth rate and feed intake. A finer understanding of how genetics impact foraging behaviour can help maximize the use of the outdoor run without compromising resource intake and excretion on outdoor areas. The project PPILOW has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N°816172.

Heritability of the number of crossovers as proxy of recombination rate in chicken

V. Riggio¹, E. Tarsani¹ and A. Kranis^{1,2}

¹The Roslin Institute and R(D)SVS, University of Edinburgh, Easter Bush, EH25 9RG Midlothian, United Kingdom,

²Aviagen Ltd., Newbridge, EH28 8SZ Midlothian, United Kingdom; valentina.riggio@roslin.ed.ac.uk

Recombination has a direct impact on evolution by shuffling genetic diversity. Avian species appear to have higher rates of recombination than mammals. The variability in recombination observed between chicken breeds is consistent with extensive findings in other species that show it is a heritable trait. However, in mammals, the genetic control of recombination is better studied and it has been shown that some genes have a major effect, whereas in avian species, there is less information about the genetic architecture of the trait. In this study, we aimed at estimating the heritability of the number of crossovers, as proxy of recombination rate. The data consisted of 39,108 genotyped chicken, of which 299 were sires and 1,780 were dams. The pedigree file included 41,189 individuals. Chickens were genotyped with a customised 50k genotyping array, for a total of 48,367 SNP across 28 chromosomes. Sex chromosomes were not included in the analysis. The number of crossovers per offspring for both sires and dams were calculated using the FindHap software v.3 (<https://aipl.arsusda.gov/software/findhap/>), and then analysed as repeated measurements of the parents. Variance components, heritability and repeatability were estimated using ASReml v.4, fitting a repeatability animal model with sex as fixed effect, age (calculated as difference in weeks between parents and their offspring) as covariate, and the animal (i.e. either the sire or the dam) and the permanent environmental effect as random, using the pedigree. Both heritability and repeatability estimates were moderate and significant, being equal to 0.25±0.02 and 0.55±0.01, respectively, confirming that the recombination rate, expressed as number of crossovers, is heritable and it can potentially be used to make predictions of their incidence and impact on genetic variation. Further studies are being carried out using random regression models to investigate how the recombination rate is affected by the individuals ageing (i.e. whether the more an individual ages, crossovers increase, hence being a proxy of recombination rate).

The potential of early warning system at health issues in poultry by soundI. Halachmi¹, T. Lev-Ron^{1,2,3}, Y. Yitzhaky³ and S. Druryan^{1,2}¹PLF Lab, Agricultural Research Organization (A.R.O.), Volcani Institute, 68 HaMakkabbim Road, Rishon Le Ziyon, 7528809, Israel, ²Animal Sci Inst., Agricultural Research Organization (A.R.O.), Volcani Institute, Poultry and Aquaculture Department, 68 HaMakkabbim Road, Rishon Le Ziyon, 7528809, Israel, ³School of Electrical And Computer Engineering, Ben-Gurion University of the Negev, Be'er Sheva, 8410, Israel; halachmi@volcani.agri.gov.il

Sound analysis has a potential to detect health issues such as a respiratory disease. To test the feasibility of the above hypothesis, poultry sound analysis was performed. Two consecutive experiments were conducted, each with 80 chickens exposed to different stressors (sub-optimal acute environmental conditions – cold, heat, and windy conditions), and a control group kept under recommended environmental regime. Data were collected using audio recordings, and ANN models were trained and tested on two different datasets. Among three ANN model sizes, ranging from 6 million to 88 million parameters. The ‘base’ model (which is the largest) resulted in the highest mAP scores of 0.97, 0.80, and 0.96 for the first dataset, the second dataset, and the combined datasets. The ‘small’ model yielded mAP scores of 0.96, 0.78 and 0.95 for the first, second and combined experiments accordingly. ‘Tiny’ model resulted in mAP scores of 0.95, 0.75, and 0.93 for the first, second, and combined experiments, respectively. Further research is recommended applying induced-illness, not only cold, heat and wind stressors.

Poster 26

Pre-slaughter fasting changes the *ante mortem* muscle proteolysis levels and *post mortem* meat qualityS. Katsumata¹, M. Kamegawa², A. Katafuchi², A. Ohtsuka² and D. Ijiri²¹Okayama University, Graduate School of Environmental and Life Science, 1-1-1, Tsushima-naka, Okayama, 7008530, Japan, ²Kagoshima University, Faculty of Agriculture, 1-21-24, Korimoto, Kagoshima, 8900065, Japan; s.katsumata@okayama-u.ac.jp

Pre-slaughter fasting is a routine practice in commercial broiler production and it elevates stress levels with muscle protein degradation (proteolysis). The aim of this study was to investigate the effects of pre-slaughter fasting times on the relationship between *ante mortem* muscle proteolysis level and *post mortem* breast meat quality of broilers. Twenty-four broiler chicks (Ross 308) at 0 days of age were provided water and a semi-purified diet with no animal protein *ad libitum* until 27 days of age. At 27 days of age, the chicks were assigned to four treatments: 0-hour of fasting (0H), 8-hours of fasting (8H), 16-hours of fasting (16H), or 24-hours of fasting (24H). Then, they were slaughtered at 28 days of age. Blood samples were collected from the wing vein before the fasting and just prior to slaughter. A portion of the left breast muscle was immediately stored in liquid nitrogen, and the right breast muscle was stored at 4 °C for 48 hours. Plasma N^ε-methylhistidine concentration, which is an index of muscle proteolysis level, and muscle free amino acids contents were analysed by the UHPLC system. To evaluate the taste characteristics, chicken soup was made from each breast muscle, and its taste traits were determined by the taste sensing system. *Ante mortem* change in individual plasma N^ε-methylhistidine concentration was significantly increased in 8, 16, and 24H compared to that in 0H ($P<0.05$). After 48 hours of *post mortem* storage, glutamic acid (Glu) content in breast muscles was increased with the length of fasting time ($P<0.05$), and umami taste (the fifth basic taste) of chicken soup in the fasting group (8, 16, 24H) was higher than 0H ($P<0.05$). The *ante mortem* change plasma N^ε-methylhistidine concentrations were correlated with the Glu contents in breast muscles ($r=0.57$, $P<0.05$), and umami taste ($r=0.66$, $P<0.05$). These results suggest that *post mortem* changes in the Glu contents of chicken meat during storage reflect *ante mortem* muscle proteolysis levels exerted by pre-slaughter fasting.

Host-microbiota interactions in swine and poultry: disentangling causes and effects

J.F. Pérez

Universitat Autònoma de Barcelona, Animal and Food Science, Travessera dels Turons. Edifici V, 08193, Spain; josefrancisco.perez@uab.es

Main concerns of the swine and poultry production reside on the high morbidity and mortality of animals during early periods, and the high within lot BW variability. Mortality and slow growing animals are particularly relevant for the industry, as these animals bring inefficiencies in term of feed and resources, increasing the final variability of the market group. The progressive movement towards a more sustainable livestock industry, with a required lower use of medicines, also means a strong interest for understanding host microbiota interactions aimed to improve overall wellbeing and health. Many solutions are being studied, including the use of additives with prebiotic or probiotic functions, but there is no 'silver bullet' to guarantee animal health in this new scenario. The failure of these strategies may likely derive from our difficulties on understanding the complex relation and interactions established among causes and consequences involved on the health, and productivity of the animals. Characterizing the intestinal microbiota of highly feed-efficient (FE) pigs could help to define an 'optimal' microbial profile for improved FE. In pigs, low residual feed intake was associated to: higher fermentation of carbohydrates, higher release of butyrate, lower mucin secretion. In poultry, it has been also described a genetic control by the host of its microbiota. However, several studies suggest that early life experiences and environmental conditions have a critical role in the growth and development of mammals. On the one side, the early life microbial colonization of the gut, shaped by factors such as host genetics, environment, diet, immunological pressure, and antibiotics, may influence the programming of the mucosal immune response and the development of the gut barrier function, conditioning the microbiota profile and their propensity to develop certain health disorders. Evidence suggests that a disruption of microbial colonization, and events occurring during the early periods, might also cause lifelong deficits in growth and development. Better knowledge of these interactions will allow the design of a holistic approach aimed to improve overall wellbeing, health and feed efficiency in swine and poultry.

Glutamine and glucose metabolism in suckling low birth weight piglets supplemented with glutamine

D. De Leonardis, Q.L. Sciascia, S. Goers, A. Vernunft and C.C. Metges

Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany; de-leonardis@fbn-dummerstorf.de

Glutamine (Gln) supplementation has been shown to be beneficial in growing piglets. To study the effect of glutamine supplementation on metabolic pathways in suckling piglets, male German Landrace piglets with low (L; 0.8-1.2 kg) and normal birthweight (N; 1.5-1.9 kg) were selected. At 24 h after birth, 10 L and N piglets/group were allocated to daily Gln (1 g/kg BW/d; L-Gln, N-Gln) or water (W, 6 ml; L-W, N-W) supplementation. At age 14 d, piglets received orally Gln (0.33 g/kg BW) plus $^{13}\text{C}_5$ Gln (10 mg/kg BW), and at 16 d, glucose (Glc; 0.4 g/kg BW) plus $^{13}\text{C}_6$ Glc (10 mg/kg BW). Blood was collected before (-15 min, basal) and half-hourly until 300 min after tracer administration via a jugular catheter. Mass spectrometry was used to measure red blood cell $^{13}\text{CO}_2$ enrichment (E) derived from oxidation of $^{13}\text{C}_5$ Gln and $^{13}\text{C}_6$ Glc, plasma $^{13}\text{C}_5$ Gln E, and plasma $^{13}\text{C}_3$ Glc E, newly synthesized from $^{13}\text{C}_5$ Gln tracer carbon. Area under the ^{13}C enrichment-time-curve (AUC), maximum enrichment (Emax) and time to maximum enrichment (Tmax) were computed by curve fitting. Statistical evaluation was performed by Student t-tests. Preliminary results show that $^{13}\text{CO}_2$ E Tmax from $^{13}\text{C}_5$ Gln and $^{13}\text{C}_6$ Glc oxidation was greater in N-Gln than in L-Gln and N-W ($P<0.05$). Plasma $^{13}\text{C}_5$ Gln E AUC tended to be lower (141.4 vs 174.4 mole % excess (MPE)*min; $P=0.1$) and Emax was lower (0.95 vs 1.24 MPE; $P<0.05$) in N-Gln than in N-W. Plasma $^{13}\text{C}_3$ Glc E AUC derived from $^{13}\text{C}_5$ Gln metabolism tended to be greater in L-Gln than in L-W and N-Gln piglets (14.9 vs 8.5 vs 9.2 MPE*min; $P=0.1$). The $^{13}\text{C}_3$ Glc Tmax was greater in N-Gln than in L-Gln and N-W groups (91.1 vs 57.9 vs 55.9 min; $n=3/\text{group}$; $P<0.05$). Our data suggest that L piglets supplemented with Gln oxidized Gln and Glc faster than N piglets. This agrees with greater utilization of glutamine carbon for Glc de novo synthesis in L-Gln piglets. The lower plasma $^{13}\text{C}_5$ Gln E in N-Gln piglets might indicate a greater dilution by endogenous Gln production. These results must be confirmed by further investigations of Gln and Glc metabolism. This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement no. 955374.

Creep feeding (dry, liquid) and pen hygiene (low, high) impacts pre-weaning growth in pigsS.R. Vasa^{1,2}, G.E. Gardiner¹, K. O'Driscoll², G. Bee³ and P.G. Lawlor²¹South East Technological University, Dept. of Science, Waterford X91Y074, Ireland, ²Teagasc, Pig Development Dept., Fermoy P61R966, Ireland, ³Agroscope, Swine Research Unit, Posieux 1725, Switzerland; shivramveer.vasa@teagasc.ie

Increasing pre-weaning creep feed intake can increase pig weaning weight (WW) and better prepare pigs for weaning. The objective was to evaluate the effect of providing creep feed in dry or liquid form to suckling pigs housed in a low or high hygiene environment, on their growth and intestinal structure. Eighty seven sows, blocked by parity, number of pigs weaned and live-weight, were randomly allocated to one of the four treatments in a 2×2 factorial arrangement. The factors were creep feeding (dry or liquid) and pen hygiene (low or high). Pigs were provided with dry pelleted starter diet from day (d) 10-28, or a mixture of liquid milk and starter diet from d3-28. Either a sub-standard cleaning protocol (water wash, no detergent or disinfectant and no drying) or an optimal cleaning protocol (detergent application, water wash, disinfectant application and thorough drying) was used to obtain a low or high hygiene environment, respectively in the farrowing rooms. Pigs were weighed and feed disappearance recorded on d4 and 28 (weaning) of age. On d4 post-weaning (PW), 10 pigs/treatment were euthanized to collect tissue samples for histological analysis. Data were analysed using PROC MIXED (v9.4, SAS Institute Inc.). There was a creep feeding × hygiene interaction on WW. Liquid feeding increased WW in both high and low hygiene environments ($P < 0.05$). Liquid-fed pigs had 0.5 kg heavier WW than dry-fed pigs ($P < 0.05$). There was a creep feeding × hygiene interaction on ADFI from d3-28. Liquid feeding increased ADFI in the high hygiene but not in the low hygiene environment ($P < 0.05$). High hygiene pigs had 43% higher ADFI than low hygiene pigs ($P < 0.05$). From d4-28, ADG was increased by liquid feeding ($P < 0.05$) but was not affected by pen hygiene ($P > 0.05$). On d4 PW, jejunal villus height and crypt depth were increased by high hygiene in farrowing rooms ($P < 0.05$) but were not affected by creep feeding ($P > 0.05$). In conclusion, high pen hygiene increased pre-weaning feed intake and improved intestinal structure, whereas liquid creep feeding increased growth and WW. Funded by EU Horizon 2020 under grant agreement No 955374.

The impact of early incubation temperature on broiler walking ability and final meat quality

T. Kettrukat and M. Therkildsen

Aarhus University, Department of Food Science, Agro Food Park 48, 8200 Aarhus N, Denmark; tobias.kettrukat@food.au.dk

With a rearing time of only 5-6 weeks from hatch until slaughter for fast-growing broiler strains, the portion of the life spent in the egg becomes increasingly important for interventions. The incubation temperature has been shown to affect muscle development, bone development, performance, meat quality and possibly walking ability. The latter is a persistent animal welfare issue in commercial broiler flocks around the world leading to concern among consumers and economic losses. Studies on the relationship between these aspects and the possibility to develop temperature manipulation into a tool to improve walking ability and subsequent welfare without compromising meat quality are limited. In the studies presented here, we changed the temperature of ROSS 308 fertile eggs during embryonic day 4 to 7, testing 36.5, 38.5 and 39.0 °C against 37.5 °C. Then, we followed the development of the locomotory system by gene expression analysis and histology in different muscles, as well as bone strength analysis, while documenting performance parameters and meat quality. The walking ability was assessed by gait scoring and its association with different parameters of the locomotory system was examined. Temperature manipulation affected the walking ability of 5 weeks-old broilers: a temperature of 36.5 °C led to higher gait scores than all other treatments. Furthermore, a higher temperature seems to favour the growth of *M. pectoralis* over *M. gastrocnemius* compared to a lower temperature, as indicated by the ratio between the muscles. Analysis of gene expression in the muscles by qPCR suggests more changes in the breast muscle than in the leg muscle. The sex influenced almost all parameters measured, most notably performance, muscle weights and bone dimensions, with males reaching higher weights. An effect on final meat quality is suggested by differences in muscle glycogen content and drip loss. The results give a comprehensive overview about the changes in the locomotory system of broilers induced by early temperature manipulation and their subsequent effects on performance and welfare. This project received funding from the European Union's Horizon 2020 research and innovation program under grant agreement no. 955374.

***In vitro* and *in vivo* analysis of bioactive substances growth and antioxidant activities**M. Mangan¹, C. Metges² and M. Siwek¹¹Bydgoszcz University of Science and Technology, 85-084 Bydgoszcz, Poland, Department of Animal Biotechnology and Genetics, Mazowiecka 28, Bydgoszcz, Poland, 85-084, Poland, ²Research Institute for Farm Animal Biology, Wilhelm-Stahl-Allee 2, Dummerstorf, 18196, Germany; modou.mangan@pbs.edu.pl

Heat stress is a major problem in the poultry industry, causing severe economic loss due to its adverse effects on chickens' health and performance. Thus, the main aim of this study was to screen *in vitro* bioactive substances to find those most suitable for *in ovo* modulation of chicken microbiota and heat stress mitigation in chickens. To achieve this, we first determined the kinetic growth curve of the selected probiotics (*Lactocaseibacillus casei*, *Lactiplantibacillus plantarum*, *Limosilactobacillus reuteri*, *Lactocaseibacillus rhamnosus*). Subsequently, these probiotics were combined with prebiotics (raffinose, galactooligosaccharide (GOS), long-chain inulin) and plant extracts (green tea, turmeric, garlic extract). The growth curve of the probiotics in the presence of prebiotics or plant extracts was determined by optical density (OD) at 600 nm. Finally, the antioxidant activities of these bioactive substances were assessed using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay. From the results obtained, *L. plantarum* and *L. rhamnosus* had the highest growth curve (OD 2). From the DPPH results, *L. plantarum* exhibited antioxidant activity of 69% and thus was selected for *in ovo* injection on day 12 of embryonic development. The second bioactive used for *in ovo* injection and microbiota modulation was prebiotic GOS which was selected due to its positive effects in mitigating heat stress in poultry. These bioactive substances were delivered *in ovo* to test their effects on hatchability and zootechnical parameters on day-old chicks. Preliminary results show that the hatchability was higher in the negative control (not injected) and GOS treatment. The day-old chick body weight was higher ($P < 0.05$) when treated with *L. plantarum* compared to the other groups. The day-old chick length was lowest in the negative control. There was no difference between the treatments for Pasgar score. This research is funded by the European Union's Horizon 2020 research and innovation program, grant N° 955374.

Session 49

Theatre 6

Prophybiotics, a novel approach for *in ovo* gut microbiome reprogramming of broilersR.N. Wishna-Kadawarage¹, R. Hickey² and M. Siwek¹¹Bydgoszcz University of Science and Technology, Department of Animal Biotechnology and Genetics, Faculty of Animal Breeding and Biology, Mazowiecka 28, 85-084 Bydgoszcz, Poland, ²Teagasc Food Research Centre, Department of Food Biosciences, Moorepark, Fermoy, Co. Cork P61 C996, Ireland; ramesha.wishna-kadawarage@pbs.edu.pl

Bioactives administered *in ovo* may reprogram the gut microbiome of chickens before they are exposed to environmental pathogens. Although the antimicrobial and gut microbiome modulation potential of probiotics and phytobiotics alone have been studied intensively, their combined use in *in ovo* model has yet to be investigated. We coined the term Prophybiotics (probiotic + phytobiotics) to describe such a combination. The current study aims to screen and validate the effects of prophybiotics in an *in ovo* model to determine if their application can mitigate pathogenic stress in broilers. Six lactic acid bacteria, *Lactiplantibacillus plantarum*, *Lactocaseibacillus casei*, *Limosilactobacillus reuteri*, *Lactocaseibacillus rhamnosus*, *Leuconostoc mesenteroides* and *Pediococcus pentosaceus* and three plant extracts, turmeric, green tea and garlic were included for *in vitro* screening. Growth curves with plant extract supplementation and antimicrobial assays against *Salmonella* and *Campylobacter* were performed to select the most effective anti-pathogenic and synergistic combination for *in ovo* validation. *L. mesenteroides* (LM) with garlic (G) presented as the most promising prophybiotic *in vitro*. Therefore, this prophybiotic and its probiotic component alone were injected to ROSS308 broiler hatching eggs on day 12 of incubation to validate the beneficial effects on the gut microbiome *in vivo*. The hatchability of LM+G and LM alone treated groups were higher and lower, respectively than that of positive control (injected with physiological saline). The weight of chicks on day one was highest in LM group followed by LM+G group ($P < 0.05$). The chick length and Pasgar score were not significantly different between the groups although LM+G treatment resulted in the highest chick quality (Pasgar score 9). Moreover, the impact of LM+G and LM on the gut microbiome and physiology of the chickens will be presented. This project is funded by European Union's Horizon 2020 research and innovation program (Grant agreement N° 955374).

Antibacterial plant blends modulate gut microbiota in organic piglets challenged with *E. coli* F18K. Jerez-Bogota^{1,2}, M. Jensen², O. Højberg¹ and N. Canibe¹¹Aarhus University, Department of Animal and Veterinary Sciences, Tjele, 8830, Denmark, ²Aarhus University, Department of Food Science, Aarhus N, 8200, Denmark; jerezbogota@food.au.dk

The study investigated the use of combinations of garlic and apple pomace, or blackcurrant as potential in-feed alternatives to antibiotics and zinc oxide in combating postweaning diarrhoea caused by enterotoxigenic *E. coli* (ETEC) in organically raised piglets. These blends had previously demonstrated *in vitro* synergistic antibacterial activity against ETEC. Here we present the effects on ETEC shedding, diarrhoea incidence, gut microbiota composition (16S rRNA), and oxidative stress markers. For 21 days, 32 piglets (7-weeks old) were randomly assigned to one of four groups: non-challenge (NC); ETEC-challenged (PC); ETEC-challenged receiving garlic and apple pomace (3%+3%; GA); ETEC-challenged receiving garlic and blackcurrant (3%+3%; GB). A strain of ETEC F18 was administered (8 ml; 10⁹ cfu/ml) on days 1 and 2 after weaning. Faecal samples were collected daily the first week, and every other day thereafter for diarrhoea assessment; microbiota composition was analysed on days 1, 3, 7, 14 and 21. At the end of the experiment, digesta and mucosa samples from the gastrointestinal tract (GIT) were collected. NC pigs had no ETEC F18 shedding nor diarrheal symptoms. PC group had diarrhoea and ETEC shedding, which were reduced in the GA and GB groups. On day 7, the GA, GB, and NC pigs had a greater ($P<0.05$) Shannon and 1-Simpson α -diversity index than the PC pigs. The PC group had a greater ($P<0.05$) microbiota volatility (compositional change) than all other groups on days 7 and 14. The *Escherichia*, *Campylobacter*, and *Erysipelothrix* genera were less abundant in the NC, GA, and GB than in the PC group ($\log_2FC>2$; $P<0.05$), whereas *Catenibacterium*, *Dialister*, and *Mitsoukella* were more abundant ($\log_2FC>2$; $P<0.05$). The GB group had the highest abundance of *Prevotella* and *Lactobacillus* ($\log_2FC>2$, $P<0.05$). Overall, adding GA or GB to the weaning feed of organic piglets maintained a healthier gut microbiota profile and overall gut health, that reduced the incidence of diarrhoea. Results on microbiota along GIT and gut mucosa oxidative stress markers will be further presented. The study received funding from the EU H-2020 program (grant # 955374).

Theatre 8

Role of caecal microbiota in flock weight heterogeneity

M.Z. Akram, E.A. Sureda, L. Comer and N. Everaert

KU Leuven, Department of Biosystems, Kaastelpark Arenberg 20, 3001, Leuven, Belgium; muhammad.akram@kuleuven.be

Despite improved genetics and farm practices, body weight (BW) heterogeneity yet exists within broiler flocks, causing operational inefficiencies and challenges in processing and marketing. Chicken performance is also linked to the gut microbiota, however specific microbiota affecting BW within a flock remains elusive. This study examined caecal microbiota's role in BW differences among birds from two hatching systems (HS: HH, hatch in hatchery and HOF, hatch on-farm). The 454 male broiler chicks for each HS were raised together until day (d) 7 before being split into low (L, n=147) and high (H, n=140) BW groups, made two factorial design (HS $\times$ BW) and four groups (HH-L, HH-H, HOF-L, & HOF-H). On d 7, 14 and 38, ten birds from each group were sampled for 16s rRNA gene sequencing of the caecal microbiota. α -diversity was analysed by 2-way ANOVA and β -diversity with 2-way PERMANOVA. The differential abundance of taxa was analysed using LEfSe. α -diversity was largely influenced by BW with low BW chickens having higher α -diversity on day 38. β -diversity was solely influenced by BW, not HS, and the PCoA plot had distinct BW group clusters on day 7. The interaction of HS $\times$ BW had no significant effect on α - and β -diversities. LEfSe analysis revealed that high BW chickens had caecal microbiota enriched with SCFA-producing and health-promoting genera e.g. *Unclassified Lachnospiraceae*, *Faecalibacterium* and *Clostridia* family. Interestingly, *Ruminococcaceae* members and *Lactobacillus* were abundant in low BW chickens along with *Escherichia-Shigella*, *Enterococcus*, *Streptococcus* and *Akkermansia*. Little HS-related differences in caecal microbial composition were observed, including an increased level of *Escherichia-Shigella* in HH system chickens. The study revealed that caecal microbiota diversity and composition were less influenced by HS and differences in taxa abundances were more associated with chicken BW differences. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N° 955374.

1H-NMR metabolomics reveals alterations in the metabolism of ascarid-infected laying hensO.J. Oladosu¹, B.S.B. Correia², B. Graff³, D. Liebhart³, C.C. Metges¹, H.C. Bertram² and G. Daş¹¹Research Institute for Farm Animal Biology (FBN), Institute of Nutritional Physiology, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, ²Aarhus University, Department of Food Science, Agro Food Park 48, 8200, Aarhus, Denmark,³University of Veterinary Medicine Vienna, Clinic for Poultry and Fish Medicine, Veterinärplatz 1, 1210, Vienna, Austria; oladosu@fhn-dummerstorf.de

Nematode infections with *Ascaridia galli* and *Heterakis gallinarum* are associated with impaired performance in laying hens. Furthermore, *H. gallinarum* is a vector of *Histomonas meleagridis*, and is often co-involved in the infections. Here, we provide the first insight into alterations in plasma and liver metabolome of laying hens due to ascarid infections with concurrent histomonosis. ¹H nuclear magnetic resonance (¹H-NMR) metabolomics was applied to explore the variation in the metabolite profiles of the liver (n=105) and plasma (n=108) from laying hens experimentally infected with *A. galli* and *H. gallinarum* (+ *H. meleagridis*), and compared with uninfected hens at 2, 4, 6, 10, 14 and 18 weeks post infection (wpi). The hens were killed after a 3-hour feed withdrawal for sample collection. In total 31 and 54 metabolites were quantified in plasma and liver extracts, respectively. Data analysis showed no significant difference ($P>0.05$) in any of the 54 liver metabolites between the two groups. In contrast, 20 plasma metabolites showed significantly elevated concentrations in the infected hens ($P<0.05$). Alterations of plasma metabolites occurred in wpi 2, 6 and 10, covering the pre-patent period of worm infections. Plasma metabolites with the highest variation at these time points included glutamate, succinate, trimethylamine-N-oxide, myo-inositol, acetate, and glucose. Pathway analysis suggested that infection induced changes in: (1) phenylalanine, tyrosine, and tryptophan metabolism biosynthesis; (2) alanine, aspartate and glutamate metabolism; and (3) arginine and proline metabolism. In conclusion, ¹H-NMR metabolomics revealed significant alterations in the plasma metabolome of infected hens. The alterations suggested upregulation of key metabolic pathways mainly during the patency of infections. This project has received funding from EU-Horizon 2020 under the Marie Skłodowska-Curie grant agreement No 955374.

Validated machine-learning model to detect IUGR pigletsR. Ruggeri^{1,2}, G. Bee¹, P. Trevisi² and C. Ollagnier¹¹Agroscope, Pig Research Unit, Animal Production Systems and Animal Health, Töllelyre 4, 1725 Posieux, Switzerland, ²University of Bologna, Agricultural and Food Sciences, G Fanin 44, 40127 Bologna, Italy; roberta.ruggeri@agroscope.admin.ch

Intrauterine growth restriction (IUGR) is defined as the impaired development of the foetus during gestation. Piglets affected by IUGR have prioritized brain development as part of an adaptive reaction to placental insufficiency. This mechanism results in a higher brain-to-liver weight ratio (BrW/LW). The aim of this study was to develop a machine-learning model to predict the BrW/LW from a piglet's image and accurately diagnose IUGR. Two days (± 1) after birth, brain and liver weight of each piglet were assessed with computed tomography scan (n=299) or by weighting the organs after euthanasia (n=65). A threshold value of 0.94 ± 1 (mean + SD) was chosen to divide the piglets into NORM (BrW/LW < 0.94) and IUGR (BrW/LW ≥ 0.94). Videos of the piglets were taken using a RealSense camera. Selected frames of piglets were then used to predict the IUGR status through a convolutional neural network (CNN) developed in Python. The available data was split in two datasets. One dataset was used for training (80% of the data) and the other to validate the model and assess its performance (remaining 20% of the data). The CNN was trained five times and the results were expressed as average recall, precision and F1 score. Recall represents the percentage of IUGR piglets the CNN correctly predicted, over all the IUGR cases. Precision is a measure of how many of the IUGR predictions made were correct. F1 score is the harmonic mean of precision and recall. The CNN performed in the training dataset with a recall, precision and F1 score equal to 97, 53 and 65%, respectively. In the validation phase, recall, precision and F1 score were reduced to 88, 50 and 64%, respectively. The present results showed that the CNN was able to identify most of the IUGR piglets in both the training and the validation phase. However, 32 and 27% of the NORM piglets were classified as IUGR in the training and in the validation dataset, respectively. In conclusion, the model is highly sensitive in detecting the IUGR cases but precision could still be improved. This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement N°955374.

In vivo validation of a non-invasive tool to collect intestinal content in pigs – CapSa-I. García Viñado^{1,2}, F. Correa¹, P. Trevisi¹, G. Bee² and C. Ollagnier²¹University of Bologna, Department of Agricultural and Food Sciences (DISTAL), Viale Giuseppe Fanin 40-50, 40127 Bologna, Italy, ²Agroscope, Pig Research Unit, Rue de Tioleyre 4, 1725 Posieux, Switzerland; ines.garciavinado@agroscope.admin.ch

Pig microbiome has become a focus of intense research in recent years, because its modulation can greatly impact pigs' health. So far, stool samples have been the only non-invasive mean to study the gut microbiome. However, microbiome in the gut differs from the one in the stool. Capsule for Sampling (CapSa) is a swallowable device that transits through the natural digestive pathway, collects small intestine content, and is excreted in faeces. In this validation study, 93 pigs (ranging from 6 to 67 kg bodyweight (BW)) were administered 2 CapSas each and monitored for 3 days until recovery of the CapSas in the faeces. Upon retrieval from faeces, CapSa contents were extracted, their pH were measured, and they were stored at -80 °C until microbiota analysis. Three days after administration, pigs were euthanized and content from small and large intestine, and faeces were collected for microbiome analysis. In total, 38 CapSas were retrieved from 28 pigs (n=9; 12±3.4 kg BW fed a starter diet; n=19; 50.5±12.3 kg BW fed a standard grower diet). Bacterial composition of CapSas were compared with the microbiota extracted from 3 segments of the small and large intestine, and the faeces of the same pig. Pairwise Adonis contrast demonstrated that CapSa sample composition was different ($P<0.001$) from the large intestine and faeces, while it was more similar to the composition of the segment 1 and 2 of the small intestine for lighter pigs fed with a starter diet ($P_{\text{adj}}=0.32$ and $R^2=0.10$; $P_{\text{adj}}=0.06$ and $R^2=0.12$) but not ($P_{\text{adj}}=0.001$ and $R^2=0.12$; $P_{\text{adj}}=0.001$ and $R^2=0.14$) for heavier pigs, fed with a grower diet. The CapSa samples were consistently characterized by the abundance of certain bacteria like *Terrisporobacter* (LDA=4.42, $P=0.002$ and LDA=4.61 and $P<0.01$; in lighter and heavier pigs respectively). CapSa has been validated for repeated collections of the gut microbiota in postweaning pigs, but needs to be confirmed in grower pigs with more precise *post-mortem* samplings. This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement N° 955374.

Effect of creep feeding (liquid milk, dry and liquid diet) on pig growth and intestinal structureE.A. Arnaud^{1,2}, G.E. Gardiner¹, M. Chombart², J.V. O'Doherty³, T. Sweeney³ and P.G. Lawlor²¹South East Technological University, Dept. of Science, X91Y074, Waterford, Ireland, ²Teagasc, Pig Development Dept., Animal & Grassland Research & Innovation Centre, Moorepark, P61R966, Fermoy, Co. Cork, Ireland, ³University College Dublin, Belfield, D04C7X2, Dublin, Ireland; elisa.arnaud@teagasc.ie

Increasing early post-weaning (PW) feed intake in pigs is necessary to improve intestinal structure and function and maximise growth. This study aimed to determine the effect of creep feeding (dry pelleted starter diet, liquid milk replacer, liquid starter diet) suckling pigs on pre- and post-weaning growth and PW intestinal structure. After farrowing, 104 sows were blocked on parity, number of pigs weaned in previous parity and body weight (BW) and randomly assigned to one of 4 treatments: (1) CTL; no creep; (2) DRY; pelleted starter diet provided to piglets from day (d)10-28; (3) MILK; liquid milk [150 g of Swinco Opticare milk powder/l of water] provided from d3-28; and (4) MIX; mixture of liquid milk and starter diet which increased as a proportion of the mixture as lactation progressed (152 g DM/l of water) from d3-28. At weaning, 566 pigs were grouped by sow treatment and formed into single sex groups of 10-12 pigs of even weight (12 pens/treatment). Group weights and feed disappearance were recorded at intervals up to slaughter. At d7 PW, 40 pigs were euthanized and intestinal tissue sampled for histological analysis. Data were analysed using the mixed models procedure in SAS (Version 9.4; SAS Institute Inc). The litter was the experimental unit prior to weaning and the pen group PW. Weaning weight was 7.87^c, 8.10^b, 8.27^a and 7.99^{b,c} (SEM 0.064 kg; $P<0.05$) for CTL, DRY, MILK and MIX, respectively. From d0-6 PW, average daily gain was 208^a, 198^a, 159^b and 191^a (SEM 12.2 g/pig/day; $P=0.03$), gain to feed was 1.00^a, 0.94^a, 0.83^b and 0.90^a (SEM 0.035 g/g; $P<0.001$) and slaughter weight was 120.8^b, 120.1^b, 119.5^b and 122.7^a (SEM 0.70 kg; $P<0.01$) for CTL, DRY, MILK and MIX, respectively. Villous height in the ileum was 242^B, 284^A, 248^B and 283^A (SEM 14.0 µm; $P=0.07$) for CTL, DRY, MILK and MIX, respectively. In conclusion, providing a liquid mixture of milk and starter diet to suckling pigs increased PW villous height, likely explaining the heavier BW found at slaughter.

In vitro* anthelmintic evaluation of Greek oregano against *Ascaridia galliI. Pouloupoulou¹, E. Sarrou², E. Martinidou³, L. Palmieri³, D. Masuero³, S. Martens³ and M. Gauly¹¹Free University of Bolzano, Faculty of Agricultural, Environmental and Food Sciences, Piazza Università 5, 39100 Bolzano, Italy, ²Institute of Plant Breeding and Genetic Resources, Hellenic Agricultural Organization DEMETER, Thessaloniki, Greece, ³Edmund Mach Foundation, Food Quality and Nutrition Department, Via E. Mach 1, 38010 San Michele all'Adige Trento, Italy; ioanna.pouloupoulou@unibz.it

This study aims to assess the *in vitro* anthelmintic activity of five different *Origanum vulgare* (OV) sbsp. hirtum accessions with different composition of carvacrol, and thymol from two different years (2019 and 2020). *Ascaridia galli* eggs isolated from the worm uterus were exposed *in vitro* to OV essential oils (EO), in dimethyl sulfoxide (1%) from the accessions originated from Evia 1 (OvH4) Taygetos-Peloponnese (OvH14), Gokceada (Turkey) (OvH15), Evia 2 (OvH17), Thessaloniki (OvH19). Untreated control, negative control petri dishes with 0.5% formalin and positive controls, flubendazole, thymol and carvacrol were also tested at 0.500 mg/ml in duplicate. Eggs' embryonic development (ED) was evaluated every third day (160 eggs/replicate) from the day of egg isolation until day 28 resulting in the examination of 12,160 eggs. The examined eggs were classified as either undeveloped or developed and the percentage of the eggs corresponding to each development class was calculated. Analysis performed using generalized linear mixed model, stating a negative binomial distribution, having plant accession, and year as fixed effect. OvH14 showed significant lower ($P < 0.05$) ED compared to all other samples estimated at approximately 38%. The samples OvH14, OvH15 and OvH19 from the year 2020 had lower ($P < 0.05$) ED, compared to the year 2019. The phytochemical analysis showed that the sample OvH14 had a high concentration of thymol for both years that estimated approximately at 790 mg/ml EO while carvacrol concentration was low (64 mg/ml EO) while taxifolin a flavonoid with antiparasitic activity was also determined. EO extracts obtained from the reported OV species have promising results in inhibiting ED, contributing to the identification of alternative anthelmintic treatments against *A. galli*.

Session 50**Theatre 1****Genetic diversity and improvement of the black soldier fly**

C.D. Jiggins and T. Generalovic

University of Cambridge, Downing Street, CB2 3EJ, United Kingdom; c.jiggins@zoo.cam.ac.uk

To improve food security, sustainable agricultural practices are needed due to threats posed by climate change and population growth. Insect livestock, specifically the black soldier fly, is a promising organism for circular food production by feeding on organic waste. However, knowledge of the fly's evolution, genetics, and potential for genetic improvement is lacking. We have been studying the domestication and genomics of *H. illucens*, revealing evidence of considerable genetic diversity around the globe, and for selective sweeps in the genome associated with domestication. Domestication has likely occurred independently multiple times but is associated with genetic changes in the same regions of the genome. We have used experimental evolution to select for increased pupal size, with correlated improvements in many industrially important traits. We have also developed CRISPR/Cas9 approaches for genetic modification that hold considerable promise for the future. This work lays the foundation for *H. illucens* as an important global agricultural organism.

Selection for larval weight in the black soldier fly – empirical evidenceK. Shrestha¹, E. Facchini², E. Van Den Boer¹, P. Junes¹, G. Sader¹, K. Peeters² and E. Schmitt¹¹Protix. B.V., Research and Development_Genetics, Industriestraat 3, 5107 NC, Dongen, the Netherlands, ²Hendrix Genetics Research, Technology & Services B.V, Spoorstraat 69, 5831 CK, Boxmeer, the Netherlands; kriti.shrestha@protix.eu

Black soldier fly (BSF; *Hermetia illucens*) industrial farming has increased in the last ten years. Interest in the species arises from its ability to convert low-grade organic materials into high-value ingredients. In addition to its use in aquaculture and pet food diets, the European Commission has recently authorized the use of insects derived processed animal proteins in monogastric livestock diets. The demand for insect protein is expected to grow 50 times more by 2030 globally. Therefore, there is a need to improve the efficiency of production further. One means of improvement is selective breeding, which has been widely applied in plants and other animal species. Results on other instances reflecting a focused, multi-year selective breeding effort in BSF is yet to be seen. In 2019, a genetic improvement program for increased larval weight of BSF larvae was started. We present the outcomes of this breeding program after 16 generations of selection. The performance of the selected body weight line was compared to the base population line over six experimental rounds under different environmental conditions. Under automated production settings, an average improvement of +39% in larval weight, +34% in wet crate yield, +26% in dry matter crate yield, +32% in crude protein per crate and +21% crude fat per crate was achieved in the selected line compared to the base population line. The selection in the context of the genetic improvement program translated into improvements in industrial production settings. This research demonstrates the potential contribution of selective breeding to improve production when farming BSF.

Session 50

Theatre 3

Full-sib group records as a practical alternative to individual records in insect breedingL.S. Hansen¹, A.C. Bouwman², H.M. Nielsen¹, G. Sahana¹ and E.D. Ellen²¹Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus, Denmark,²Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands; lsh@qgg.au.dk

Selective breeding in insects has predominantly been utilising information on phenotypic variation which does not require records on relatedness. Selection based on estimated breeding values would require: (1) tracking a pedigree over multiple generations; and (2) tracking individuals over their development to link phenotypic records for multiple traits. Most farmed insect species experience several life stages of occasionally distinct morphology, and the entire exoskeleton including any exterior identifier is shed regularly. These aspects of the insect metabolism make tracking of individuals essentially impossible unless they are reared individually. However, rearing insect species such as black soldier fly or housefly in isolation is impractical for large-scale production, and suboptimal for larval development. When tracking and isolation are impossible, we cannot correlate individual phenotypic records collected throughout development, or relate early life phenotypic records to mature selection candidates. To overcome these limitations, an approach would be to use group records. For flies, the genetic relationship of individuals grouped together cannot be tracked unless they are all full-siblings. This has consequences for the accuracy of breeding values estimated using family-level information, since phenotypic covariance will be caused by both genetic similarity and common environmental effects, and this environment could vary dramatically between families. In this study, we use stochastic simulation to investigate the potential for genetic improvement in insects using family records for breeding value estimation in a two-trait breeding scheme. We simulate scenarios with varying ratio of genetic to common environmental variance, and consider the effect of using full-sib subgroups to estimate and correct for the non-genetic sources of variance. The group-based breeding scheme is not limited to applications in multi-trait systems, but also applicable when breeding for traits that cannot be measured at the individual level.

Simulating breeding programs based on mass selection in black soldier fly (*Hermetia illucens*)M. Slagboom¹, H.M. Nielsen¹, M. Kargo¹, M. Henryon² and L.S. Hansen¹¹Aarhus University, Centre for Quantitative Genetics and Genomics, C. F. Møllers Allé 3, 8000 Aarhus, Denmark, ²Danish Agriculture and Food Council, Axelstorv 3, 1609 København, Denmark; margotslagboom@qgg.au.dk

Interest in black soldier fly production for feed has increased greatly in recent years. Selective breeding can improve chosen traits in the desired direction. Mass selection is the selection on phenotypic performance, i.e. something that is measurable on the individual itself. In this study, we simulated mass selection breeding programs aimed at improving larval body weight (LBW). We tested if more complicated breeding program designs that increase manual labour increase genetic gain while maintaining inbreeding. Specifically, we looked at housing families separately after a female lays eggs, housing larvae individually after weighing, and controlling mating, which resulted in 8 different breeding programs. Each time step, 35,000 larvae were produced, of which 3,000 were phenotyped for LBW. These larvae were either randomly selected from the whole population, or a fixed number per family was selected when families were housed separately. The 400 heaviest larvae were kept alive to emerge as adult flies (when they could be sexed), and they were either individually or group housed. When group housed after phenotyping, it was impossible to connect the phenotype for LBW to individual flies. Therefore, the selection of 200 females and 100 males for breeding was random in this case (selected from the 400 heaviest larvae that were kept alive). Alternatively, larvae were housed individually until development into flies to connect the phenotype for LBW to individual flies. In this case, breeding animals were selected based on LBW. Mating was either controlled in a vial with 2 males and 1 female, or in a group with all breeding animals. Preliminary results show that housing families separately after egg-laying did not have a large effect on either inbreeding or genetic gain, housing larvae individually after weighing to connect the phenotype for LBW to individual flies increased genetic gain by up to 8%, and controlled mating decreased inbreeding at the same level of genetic gain.

Session 50

Theatre 5

Effects of artificial selection in the black soldier fly – a Pool-seq approachE. Facchini¹, A. Vereijken¹, D. Bickhart¹, A. Michenet¹, K. Shrestha² and K. Peeters¹¹Hendrix Genetics Research, Technology & Services B.V., Villa 'de Körver', Spoorstraat 69, 5831 CK Boxmeer, the Netherlands,²Protix Biosystems B.V., Industriestraat 3, 5107 NC Dongen, the Netherlands; elena.facchini@hendrix-genetics.com

Black soldier fly (*Hermetia illucens*) is used to convert low-grade organic waste materials into high-quality products. The European Commission has recently authorized the use of insects derived processed animal proteins in monogastric livestock diets, expanding the destination of use that already included aquaculture and pet food diets. In 2019, we started a genetic improvement program to increase larval body weight. Results show how genetic improvement can help the sector improve production. Under commercial conditions, an average gain of +39% in larval weight was achieved after two years of artificial selection. This study aimed to evaluate the effects of artificial selection on genetic variability. The flies enrolled for this study were sampled at the beginning of the program and after eight generations to form three study populations. Population A represents the starting base population at generation zero, population B represents the selection line for body weight at generation eight, and population C is the control line at generation eight. The control line (population C) was derived from the same starting population and was used to benchmark the genetic progress in the selection line. DNA was individually extracted from 30 random flies and aliquoted in equal amounts to form one pooled DNA sample per population. The three DNA pools were sequenced using paired-end next-generation sequencing with a target coverage of 30 Gbp (i.e. 30× coverage). Allele frequencies at single nucleotide polymorphisms and Wright's Fixation index were estimated on a genome-wide scale. Based on differences in allele frequencies, the impact of the breeding program on genetic variability was evaluated. Differences in allele frequencies were detected between the three studied populations, and fixation indexes showed moderately low genetic differentiation. Pool sequencing is an affordable and viable approach for investigating allele frequency changes due to natural or artificial processes.

Adaptive responses of black soldier fly to simple low-quality diets

A. Gligorescu and J.G. Sørensen

Aarhus University, Department of Biology, Section for Genetics, Ecology and Evolution, Ny Munkegade 116, Building 1540, 8000, Aarhus, Denmark; angl@bio.au.dk

The production of black soldier fly larvae (BSFL) is rapidly expanding because of the ability of BSFL to bioconvert cheap and low-quality substrates into high quality insect biomass. Despite this, the consequences of growing BSFL on low-quality substrates during multiple generations are largely unknown. We used three lines of BSF kept on a low-quality diet (wheat bran, WB) or on a high-quality diet (chicken feed, CF), respectively, for more than 30 generations. BSF lines were maintained on either the original or the interchanged diets for three generations, during which we investigated the response in a series of performance parameters (i.e. larval weight at harvest, larval growth rate, survival rate, pupa weight, sex ratio and egg production). As expected, the BSF was found to perform best when kept on high quality diets, irrespective of original maintenance diet. The BSF lines originally maintained on a low-quality diet had a higher growth rate than BSF lines reared on high quality, but shifted to a low quality diet during the first generation. Subsequently, this difference disappeared during the following two generations. Our study has implications for understanding the evolutionary and phenotypic consequences of maintaining BSF lines on single sourced, low-quality substrates. Differences between original diets seems to rely mainly on phenotypic plasticity rather than evolutionary adaptation, and low-quality diets have limited implications for BSF performances.

Session 50

Theatre 7

Molecular sexing of black soldier fliesR.S.C. Rikkers¹, E. Van Der Valk¹, A.A.C. De Wit¹, L. Kruijt¹, E.D. Ellen¹, J. Van Den Heuvel² and B.A. Pannebakker²¹Wageningen Livestock Research, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands, ²Laboratory of Genetics, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands; elianne.vandervalk@wur.nl

The use of black soldier flies (BSF; *Hermetia illucens*) has exponentially increased the past decade because of their ability to efficiently convert waste products into high value proteins for humans as well as feed for livestock. There is a need to further improve the efficiency of BSF production to meet the rising demands for high-value proteins in human food and livestock feed industries. To set up well functioning breeding programs it is crucial to sex the BSF at an early stage, however in BSF it is only possible to determine the sex phenotypically once they reached the adult phase. Additionally, female larvae are heavier than male larvae, thus selecting larvae on body weight would result in a biased sex ratio. Therefore, the objective of this study was to develop a tool to sex BSF, using molecular sexing. BSF have six autosomes, and additionally females have two sex chromosomes and males have one sex chromosome. DNA from six male and six female adult BSF was isolated and with the use of quantitative Polymerase Chain Reaction (qPCR) we tested nine sex genes and three autosomal genes (reference genes). For males, the qPCR product of the sex genes should be half of the amount relative to the females. Furthermore, the qPCR product of the reference genes should be equal for both sexes. Raw qPCR results were corrected for DNA quantity differences with the Pfaffl method. Results showed that (within this small sample size) we could identify the male and female BSF with a 100% accuracy, based on the differences in qPCR product between the sex genes. Of the nine sex genes, five genes resulted in 100% accurate identifications. Three genes showed higher variation, but also resulted in a 100% accuracy, whereas one gene gave inconclusive identifications. To conclude, we identified genes and developed a tool that could be used to molecular sex BSF which could be used for future applications on e.g. exuviae of larvae. However, validation in a higher sample size and on exuviae is necessary.

Biomarker discovery for the black soldier fly (*Hermetia illucens*)*E.M. Espinoza**EnviroFlight, Genetics R&D, 2100 Production Dr, 27539, USA; eespinoza@enviroflight.net*

One of the overarching goals at EnviroFlight Genetics R&D is to create elite black soldier fly (BSF) (*Hermetia illucens*) populations that meet target values for the commercial production of our insect ingredients. Identifying desirable traits throughout the life history of the BSF will help us track phenotypes and aid in the selection of individuals for breeding. We strive to identify potential biomarkers for studying various biological processes important in the farming of BSF. Defining these measurable indicators, we hope to better understand breadth of limiting factors critical to the improved production of elite BSF populations.

Session 50

Theatre 9

Improving black soldier fly genetics by CRISPR/Cas9 gene editing*I.N.Y. Nevo Yassaf, A.G. Goren, R.A. Adler and I.A. Alyagor**FreezeM, Genetics, Nachshonim 1, Nachshonim, 7319000, Israel; inbar@freeze-em.com*

The shortage of protein resources is becoming more and more severe as the global population is increasing. Finding new environment-friendly and sustainable protein sources is a necessity to replace the traditional ones. The black soldier fly (BSF), *Hermetia illucens* (Diptera: Stratiomyidae), is one of the most efficient insects in converting organic waste into biomass. To generate improved genetic strains with beneficial features, we utilized the CRISPRIL platform to develop an efficient BSF genome editing platform. Applying a unique gRNA design system developed during the CRISPRIL consortium, we generated 400 genome editing events with an average efficacy of 74%. Additionally, we generated 10 deletion events by applying CRISPR on two adjacent editing sites simultaneously. Later, this technique was applied to generate modified BSF strains with enhanced industrial performance. One of these strains resulted in significantly larger larvae than the wild-type origin. This strain has a better feed conversion ratio (FCR) while maintaining its nutritional values. Our study provides valuable technical and genomic resources for improving BSF lines for industrialization.

Expected response to selection on larval size and development time in the housefly (*Musca domestica*)H.M. Nielsen¹, T.N. Kristensen², G. Sahana¹, S.F. Laursen², S. Bahrndorff², J.G. Sørensen³ and L.S. Hansen¹¹Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus, Denmark, ²Aalborg University, Section for Bioscience and Engineering, Department of Chemistry and Bioscience, Fredrik Bajers Vej 7H, 9220 Aalborg, Denmark, ³Aarhus University, Department of Bioscience, Ny Munkegade 116, 8000 Aarhus C, Denmark; hannem.nielsen@qgg.au.dk

The demand for protein will increase dramatically in the future. At the same time, we face major challenges related to e.g. greenhouse gas emissions causing climate changes, where the agricultural sector is a large contributor. Proteins from insects can be produced more sustainable compared to other animal protein sources because they generally have higher nutritional value, higher feed conversion efficiency, and produce less ammonia and greenhouse gases than conventional livestock. However, commercial production of insects for food and feed is still in its early stage, and little has been done to improve quantity and quality of products from insects through selective breeding. The expectation is that implementation of selective breeding programs for traits of economic importance in insect production can lead to tremendous genetic progress and further optimize the production. In this study, we present expected selection response in the houseflies *Musca domestica*. The traits were; larval size and development time for which we have estimated heritabilities of 0.1 and 0.3, respectively. In our simulations we select 80 dams and 40 males and each dam produced 10 offspring. Candidates were evaluated purely on sib information. Because the genetic correlation between larval size and development time is presently unknown but expected to be unfavourable, the correlation was varied from 0 to 0.6. With equal economic values on the two traits, it was possible to improve both traits simultaneously. With a correlation of e.g. 0.3, response in larval size was 0.72 mm², whereas response in development time was -10.4 hours. This study shows that there is a large potential for selecting for important production traits in insects such as the housefly. The knowhow from this study will help to design breeding plans for insect species used for food and feed production.

YnFABRE: design of reference populations for genomic selection in *Tenebrio molitor*E. Sellem¹, A. Donkpegan², Q. Li¹, K. Paul¹, A. Masseron¹, F. Gagnepain-Germain¹, K. Labadie³, B. Vacherie³, P. Garrabos⁴, M.A. Madoui⁵ and T. Lefebvre¹¹Ynsect, R&D Biotech, 1 rue Pierre Fontaine, 91000 Evry, France, ²SYSAAF, UMR BOA, Centre INRAE Val de Loire, 37380 Nouzilly, France, ³CEA, Genoscope, Institut de biologie François Jacob, Université Paris-Saclay, 91057 Evry, France, ⁴Thermo Fisher Scientific, 16 Av. du Québec, 91941 Villebon-sur-Yvette, France, ⁵CEA, Service d'Etude des Prions et des Infections Atypiques (SEPIA), Institut François Jacob, Fontenay-aux-Roses, France; qi.li@ynsect.com

Tenebrio molitor is a promising alternative to produce high-quality protein products with low environmental impact. Industrial scale production concentrates an important number of individuals, leading to consider population management to account for genetic diversity conservation and performance improvement. YnFABRE project was designed to address the required innovations in genetics/genomics and automated phenotyping for insect industries. This project aims to develop all the required tools to implement a genomic selection scheme adapted to industrial farming conditions. Four main traits will be selected: reproduction, growth, food efficiency, and disease resistance. A reference population of 4,000 phenotyped individuals was generated over 3 generations of unrelated single-pair matings (700 pairs were mated per generation). Several phenotypes have been assessed, a part of them characterized the couple (daily or total egg laying count, hatching rate, larval growth, or feed efficiency), and the other part described the individual (pupae-imago-adult weight, sex, or developmental time egg to pupae). A subset of 136 adults has been sequenced, identifying all the SNP candidates to produce the genotyping HD array (~700K), and then the rest of the adults will be genotyped. The genetic study quantified the part of the phenotype variability explained by the additive genetic effect. Heritabilities ranged between 0.21 to 0.45 for reproduction phenotypes, 0.12 to 0.57 for growth parameters and 0.20 to 0.46 for developmental time according to the parameter studied. These results show the potential for the selective breeding of these various traits, which will allow us to establish the first selected yellow mealworm lines of interest.

The potential of instrumental insemination for honeybee breeding*M. Du, R. Bernstein and A. Hoppe**Institute for Bee Research Hohen Neuendorf, Friedrich-Engels-Str. 32, 16540 Hohen Neuendorf, Germany; manuel.du@hu-berlin.de*

Mating control constitutes a crucial part of honeybee breeding. In Germany, it is currently mostly ensured by the use of isolated mating stations, where geographic remoteness allows only drones from drone producing queens with a selected dam to participate in the mating process. However, for many burgeoning breeding programs in Europe, this method of mating control is not feasible, because suitable locations are scarce. Instrumental insemination appears as a viable alternative that is independent of geography and comes with several theoretical advantages. Due to increased control over the mating process, breeding values can be estimated more accurately. Furthermore, a greater variety of sires can be selected, thus enhancing the genetic variance, and, finally, by the direct selection of drone producing queens, the paternal generation interval between selected individuals can be reduced from five to four years. We used computer simulations to quantify the benefits of instrumental insemination for different population sizes and traits with different heritabilities. In instrumental inseminations, queens were paired with 12 drones that all came from the same drone producing queen. When we did not reduce the generation interval, we found that instrumental insemination could indeed generate higher genetic gain at lower inbreeding rates. Only five insemination stations, each with 8 drone producing queens, were needed to conserve as much genetic variance as could be maintained with 20 isolated mating stations of the same size. In contrast, when reducing the paternal generation interval, we observed substantially higher inbreeding rates. By selecting dams and sires from the same generation, the probability of pairing closely related queens and drones was greatly increased. The ideal strategy thus appeared to allow sires to be selected from two consecutive birth cohorts, thereby reducing the paternal generation interval only for a part of the population. In conclusion, we think that instrumental insemination can serve as a great alternative and that its theoretical aspects should be further investigated.

Session 50

Theatre 13

Genetic analysis of production and behavioural traits of French honeybees*T. Kistler^{1,2}, C. Kouchner^{1,3}, C. Dumas^{1,4}, R. Dupain^{1,4}, A. Vignal^{1,5}, F. Mondet^{1,4}, P. Jourdan^{1,3}, B. Basso^{1,4} and F. Phocas^{1,2}*

¹UMT PrADE, Avignon, 84000, France, ²Université Paris-Saclay, INRAE, AgroParisTech, GABI, Jouy-en-Josas, 78350, France, ³ADAPI, Aix-en-Provence, 13100, France, ⁴Abeilles & Environnement, INRAE, Avignon, 84000, France, ⁵GenPhySe, INRAE, ENVT, Université de Toulouse, 31320, Castanet-Tolosan, France; tristan.kistler@inrae.fr

Genetic parameters were estimated for traits of interest in a honeybee population reared by professional beekeepers in south-eastern France. Around eight hundred open mated queens from 32 maternal families of instrumentally inseminated dams were tested on 14 apiaries. In 2021 and 2022, respectively 429 and 379 honey production records were collected. Hygienic behaviour was measured by the pin-killed brood method in spring (May). During this visit and a second one in early summer (June), the total sealed brood surface, gentleness, calmness, and the phoretic varroa load, were also measured. BLUP animal models were used considering the workers' genetic effects and the fixed effects of apiaries×year, the open mating area, and observation technicians×year to describe performances. The software BLUP90 was used with a bee specific inverse relationship matrix. Heritabilities were high to very high for honey production (0.50 ± 0.21), hygienic behaviour (0.68 ± 0.40), phoretic varroa load measured in summer (0.66 ± 0.24), and both sealed brood surface measures (spring: 0.74 ± 1.06 , summer: 0.53 ± 0.24). Moderate heritabilities were obtained for gentleness, calmness and phoretic varroa load in spring (from 0.20 ± 0.17 to 0.33 ± 0.24), except for gentleness in summer with a null heritability. No significant genetic correlations could be estimated (due to a small dataset), but strong positive correlations were found between repeated measurements during the season. These results were obtained thanks to the Carnot France Futur Elevage project 'BeeMuSe' and promise that the ADAPI starting breeding plan can bring significant genetic progress in the future.

SIMplyBee: R package for simulating honeybee populations and breeding programsJ. Obšteter¹, L.K. Strachan², J. Bubnič¹, J. Prešern¹ and G. Gorjanc²¹Agricultural Institute Of Slovenia, Hacquetova Ulica 17, 1000, Slovenia, ²The Roslin Institute and Royal (Dick) School of Veterinary Studies, University of Edinburgh, Easter Bush, Midlothian, EH25 9RG, Edinburgh, United Kingdom; jana.obsteter@kis.si

The Western honeybee is a globally important species, contributing to pollination and food production, but has been experiencing colony losses that lead to economical damage and decreased genetic variability. This situation has increased interest in honeybee breeding and conservation programs. Stochastic simulators are essential tools for rapid and low-cost testing of breeding programs and methods, yet no existing simulator allows for a detailed simulation of honeybee populations. To close this gap, we have developed a holistic simulator of honeybee populations and breeding programs, SIMplyBee. SIMplyBee is an R package, freely available for installation from CRAN at <http://cran.r-project.org/package=SIMplyBee> and SIMplyBee.info. SIMplyBee builds upon the stochastic simulator AlphaSimR that simulates individuals with their corresponding genomes and quantitative genetic values. To enable a honeybee-specific simulation, SIMplyBee extends AlphaSimR by developing: (1) a class for modelling honeybee colonies, Colony, that holds multiple castes of honeybee individuals with their individual- and colony-level quantitative genetic values; and (2) a class for modelling multiple colonies, MultiColony. SIMplyBee also includes functions to address major specificities of the honeybees: honeybee genome, haplo-diploid inheritance, social organisation, complementary sex determination, polyandry, colony events, and quantitative genetics of honeybees. We have additionally addressed simulating the spatially dependent mating of honeybees. SIMplyBee is a holistic simulator of honeybee populations and breeding programs, including individual honeybees with their genomes, colonies with colony events, and selection on individual- or colony-level quantitative values. SIMplyBee provides a research platform for testing breeding and conservation strategies and their effect on future genetic gain and variability.

Demonstrating the principles of genetic inheritance in honeybees using SIMplyBeeL. Strachan¹, J. Bubnič², G. Petersen³, G. Gorjanc¹ and J. Obšteter²¹Edinburgh University, Roslin Institute, Edinburgh, United Kingdom, ²Agricultural Institute of Slovenia, Hacquetova ulica 17, Ljubljana, Slovenia, ³AbacusBio Ltd, Moray Place, Dunedin, New Zealand; s2122596@ed.ac.uk

Recently, there has been an increased interest in honeybee genetic variation and in establishing breeding programmes. A key metric in studying genetic variation is the level of genetic relationships between individuals of a population. Here we used SIMplyBee to demonstrate the principles of honeybee genetic inheritance and show the genetic relatedness amongst individual honeybees. SIMplyBee is a stochastic simulator dedicated for the design and optimisation of honeybee breeding programmes. It is available as an open-source R package from CRAN at <http://cran.r-project.org/package=SIMplyBee> and at <http://SIMplyBee.info>. A base population of 800 *Apis mellifera carnica* (Car) and 1,600 *Apis mellifera mellifera* (Mel) founder queens underwent a 10-year cycle, simulating a closed Car and a closed Mel population as well as a semi-open MelCross hybrid population by continuous mating of a proportion of Mel queens with drones from Car colonies. Various genetic relationships across the whole genome and at the complementary sex determiner (*csd*) locus were computed between individuals within a single colony, queens of the same population, and queens of different populations. We computed three types of relationships: expected identity-by-descent (IBD, pedigree) and realised IBD (genomic) relationships relative to the founder population, and identity-by-state (IBS) relationships. For the latter, we used different allele frequencies. Summarising the expected IBD relationships we recovered the well-known pedigree expectations, while realised IBD showed variation due to recombination and segregation. Summarising the IBS relationships showed even more variation due to older ancestries. IBS relationships varied substantially in values depending on which allele frequencies we used, suggesting that we must be careful when comparing genomic relatedness between studies. Our comparison of closed and hybridised populations can guide such comparisons. The *csd* locus showed smaller relationship values than the whole genome due to balancing selection. This work will help interpret the regional population genetic diversity of honeybees in many populations.

Exploring the potential for artificial selection in the black soldier fly, *Hermetia illucens*

T. Generalovic and C. Jiggins

University of Cambridge, Zoology, Downing Street, Cambridge, CB2 3EJ, United Kingdom; tng23@cam.ac.uk

Artificial selection has dramatically shaped the genomes of many species resulting in phenotypic diversification across the tree of life. In an agricultural context, the rising insect livestock industry shows great potential for artificial selection due to large population sizes and short generation times. The black soldier fly, *Hermetia illucens*, has been the focus of this industry over the past decade due to its efficient bioremediation and nutritional properties. Recent studies have identified significant genetic diversity in *H. illucens* populations around the globe. However, capturing and shaping this diversity for optimal industrial application requires further understanding on the phenotypic variation within strains. Here, we genome sequenced domesticated populations of *H. illucens* and explored phenotypic variation within and between strains across several diets. Our experimental assays of domesticated *H. illucens* revealed substantial variation between strains across several life-history traits, suggesting that there may be benefits to using specific strains for waste applications. Exploring genetic and phenotypic variances within strains and families enabled estimates of heritability suggesting several avenues for genetic improvement through artificial selection. We also performed experimental evolution for increased pupal size. Response to selection in *H. illucens* was strong and repeatable over time. Body size showed complex interactions with life-history traits vastly improving biomass yields and larval growth rates over nine months. However, increasing pupal body size had the unintended consequence of significantly reducing the development time of female pupae, revealing a previously undetected trade-off. This work highlights the importance for genetic and phenotypic characterisation of *H. illucens* strains to be incorporated into insect farming practices. We also demonstrate the potential impact of artificial selection in this growing sector. However, further assessment for trade-offs should be explored further prior to mass uptake of selection regimes in this novel industry.

Poster 17

Weight of *Hermetia illucens* eggs from breeding and wild individualsJ. Lisiecka¹, Z. Mikołajczak¹, M. Dudek¹, K. Dudek¹, B. Kierończyk² and D. Józefiak^{1,2}¹HiProMine S.A., Poznańska, 12F, 62-023 Robakowo, Poland, ²Poznań University of Life Sciences, Department of Animal Nutrition, Wołyńska 33, 60-637 Poznań, Poland; monika.dudek@hipromine.com

The aim of the research was to define the differences between *Hermetia illucens* eggs weight from breeding and wild individuals. Additionally, differences between the time of eggs harvest were compared. In current research, individuals from two lines were compared: breeding, which was HiProMine (HPM) standard genetic material, and wild, from Malaysia (M line). In the beginning of experiment, the generation of lines in production condition was: F26 for HPM line and F1 for M line. During the cycle, eggs were collected on different days. Eggs were placed on microscope slides tared on scale, and weighed (PR223/E, OHAUS Corporation, USA). After that, a microscope preparation using physiological saline was prepared. Prepared slides were observed using a microscope (Stemi 508, Carl Zeiss, Jena, Germany) and ZEISS ZEN Microscopy Software, and the pictures of eggs were taken using Axiocam 208 colour (Carl Zeiss, Jena, Germany). Eggs counting was performed using the ImageJ Software v.1.53. Egg weight (g) for HPM line was estimated to 0.00002528, while for M line to 0.00002598. Statistical analysis showed no significant differences between the groups. However, both lines showed a significant decrease in egg weight with harvesting in the later days of the reproductive cycle (HPM line $P=0.007$; M line $P<0.001$). This work was supported by an grant titled 'InnHatch: Innovative Technology for Industrial Insect Reproduction' no POIR.01.01.01-00-0898/19. The project is co-financed from European Funds by the National Center for Research and Development, under Measure 1.1 'R&D projects of enterprises', Sub-measure 1.1.1 'Industrial research and development works carried out by enterprises' of the Innovative Economy Operational Program.

Paternity assignment tool in honey bees (*Apis mellifera*)

Mating control, a key element in honey bee (*Apis mellifera*) breeding programs, is often not, or only partially implemented. Consequently, the genetic gain is not as desired, prompting beekeepers to consider purchasing queens from non-local populations or even commercial hybrids. BeeConSel project aims to establish tailor-made effective mating control in Croatia, Macedonia, and Slovenia. Several approaches to obtain controlled natural matings have been tested for suitability, e.g. geographical isolation, isolation by drone saturation (biological isolation), and temporal isolation. The analysis of patriline and paternity assignment explores genetic tools in estimating patriline composition. In every approach, we have collected samples of drone-producing queens and their drone brood, and young mated queens, and their brood. In these samples, the DNA was isolated, and 5 micro-satellites (A0007, A0013, Ap043, Ap055, and B0124) were genotyped, resulting in a total of 81 alleles. The readouts were analysed with a custom-developed Linux script. The analysing process had three steps: data verification by confirming that all brood samples originated from the queen of the colony; reference genome composition by calculating all possible combinations of the five loci in combinations of the queen and present known drones at the spot; paternity assignment by matching brood genotypes with the combinations in the reference genotypes. It also includes logical controls and gives summary statistics. Later the script was upgraded to calculate different alleles frequencies for each subpopulation. The tool was tested on *A. m. carnica* and *A. m. macedonica* in mating seasons 2021 and 2022.

Single-step genomic BLUP allows for the genetic evaluation of commercial honeybee queens

G.E.L. Petersen^{1,2}, F.S. Hely², M. Araujo², P.F. Fennessy² and P.K. Dearden^{1,3}

¹FutureBees NZ Ltd, 442 Moray Place, 9016 Dunedin, New Zealand, ²AbacusBio Ltd, 442 Moray Place, 9016 Dunedin, New Zealand, ³University of Otago, Biochemistry, 710 Cumberland Street, 9016 Dunedin, New Zealand; gertje_petersen@gmx.de

Although honeybees play a large role in modern food production systems through their role as an abundant and readily manageable generalised pollinator, beekeeping systems in most western countries have remained small scale, with a strong influence of traditional management techniques and low uptake of new technologies. This has led to a generalised absence of historically grown structures for structured genetic improvement (such as the breed societies often present in other livestock species), so the majority of honeybee queens is currently still selected based on ad hoc quality assessments. However, use of a centralised genetic evaluation for European honeybees (Beebreed) has shown that selection based on BLUP-based estimated can significantly increase genetic gain. Simultaneously, where large-scale beekeeping businesses are present (e.g. in North America and Oceania), their selection decisions impact on the population structure and genetic diversity of the honeybee population. These commercial beekeeping businesses are often operating under a cash- and time-poor business models and can only support the most basic of performance and pedigree recording systems. Through the use of genomics, commercial queen selection schemes can be developed that support large-scale beekeeping and contribute significantly to the sustainable improvement of honeybee populations. By blending a historic pedigree-based relationship matrix with a genomic relationship matrix based on non-invasive drone pool genotypes, we were able to calculate preliminary genomic estimated breeding values (gEBVs) for 1,200 honeybee queens in commercial beekeeping businesses in New Zealand. Although prediction accuracy for these is still quite low (as expected for such an early-stage genetic evaluation), these gEBVs will enable more informed selection decisions and empower beekeepers to improve their own populations without having to rely on queen suppliers who often operate in very different environments and under less demanding conditions than commercial honey producers.

Deformed wing virus quantification: effect of selection and correlation with varroa related traitsM.G. De Iorio¹, S. Ottati², G. Molinatto², D. Bosco² and G. Minozzi^{1,3}¹University of Milan, Via dell'Università 6, 26900, Italy, ²Università degli Studi di Torino, Grugliasco, DISAFA, Largo Paolo Braccini, 2, 10095, Grugliasco, Italy, ³CNR-IBBA, Via Alfonso Corti 12, 20133, Italy; giulietta.minozzi@unimi.it

Together with the parasitic mite *Varroa destructor*, viral infections are threatening the health of honeybee hives. One of the main viruses studied today is the deformed wing virus (DWV). DWV is an RNA virus that affects honeybees and other hymenopterans often in latent form. Disease outbreaks may occur when virus replicates at high levels and/or in presence of other stressors, such as heavy varroa infestations. Furthermore, varroa mite is the main vector of DWV. Therefore, selecting for varroa resistance traits should indirectly reduce the DWV presence in hives. In this study we quantified the viral load by rtPCR in 69 hives belonging to a population of bees under selection with the aim to test correlation of DWV load with different varroa related traits and with the genetic lineage. The selected population belonged to a well melted stock including Ligustica, Carnica and Buckfast selected over several years by the same beekeeping farm located in North Italy. Selection was based on three traits: honey yield, gentleness and hygienic behaviour. Since 2015, phenotypic data from 90 hives have been annually registered. In 2021, after six years of selection, 69 out of 90 hives have been tested for DWV load. In the same year other varroa related traits were measured. DWV was present in all the hives showing a good variability in load, which ranged from 2.32E+11 to 5.44E+14 viral genome copies/bee. We found high correlations between DWV load and varroa growth rate (0.80) and between DWV load and the total quantity of phoretic mites (0.84). Furthermore, out of the 8 genetic lines used in the selected population, we identified a higher viral load in line 1 compared to line 8. Further research will be conducted in the next years on the genetics underlining DWV infection in this population.

Monitoring the distribution of *Apis mellifera* genetic resources in Italy using mtDNA information

V. Taurisano, A. Ribani, K.E. Johnson, D. Sami, G. Schiavo, S. Bovo, V.J. Utzeri and L. Fontanesi

University of Bologna, Department of Agricultural and Food Sciences (DISTAL), Viale Fanin 48, 40127, Italy; luca.fontanesi@unibo.it

The genetic integrity of *Apis mellifera* subspecies and populations is a matter of concern all over Europe. Honey contains environmental DNA (eDNA) traces from all organisms that directly or indirectly were involved in its production, including the DNA of the honey bees that produced it. Specific mitochondrial DNA (mtDNA) lineages (i.e. mitotypes) characterize several *A. mellifera* subspecies. Different mitotypes can be detected using honey as source of honey bee DNA, providing approximate population genetic information useful to estimate the diffusion and frequency of honey bee mitotypes. In this study, we combined two approaches based on the analysis of: (1) honey eDNA; and (2) DNA extracted from honey bee workers of many different colonies to monitor the distribution of *A. mellifera* mtDNA lineages all over Italy. DNA was extracted from a total of about 2,300 honey samples produced over five years (2018-2022) in several regions of the Italian peninsula and Sicily. In addition, worker bees from 1,100 colonies were analysed to compare the distribution map of the mtDNA lineages in a region of the North of Italy (Emilia-Romagna). PCR products were analysed using a fragment size-based assay followed by Sanger sequencing. Results from the two approaches confirmed that the C lineage was the most frequent mitotype all over Italy except in Sicily where the A lineage was highly represented across all years. Other mtDNA haplotypes (A and M lineages) were present in almost all Italian regions. The obtained results are useful for designing conservation strategies for *A. mellifera* genetic resources in Italy and evaluating the efficacy of previously adopted measures. Moreover, we demonstrated that eDNA from honey can be exploited to design cost-effective non-invasive and simple methods to obtain information on the genetic distribution of honey bee mitotypes at large geographic scale.

How does the cow's microbiome respond to physiological challenges?J. Seifert^{1,2}

¹University of Hohenheim, HoLMiR – Hohenheim Center for Livestock Microbiome Research, Leonore-Blosser-Reisen Weg, 70593 Stuttgart, Germany, ²University of Hohenheim, Functional Microbiology of Livestock, Emil-Wolff-Str. 10, 70593 Stuttgart, Germany; jseifert@uni-hohenheim.de

Dairy cows face several outstanding challenges during their production life span. This includes the calving period with painful parturition and a significant impact on energy metabolism and nutrient requirements at the start of the lactation period. In addition, infections can induce inflammatory reactions such as fever, reduced rumination activity and feed intake. Although cows are of similar genetic background and receiving same feed at equal housing conditions, the response to the described challenges varies individually. The changes of the rumen and intestinal microbiome are studied in respect to feeding changes, etc. but can we link the microbiome composition and its functional response to the individual challenges described above? And does this correlate with individual animal performance? These questions were addressed in a previous study, where the individual variability and long-term changes of the microbiome and metabolome of dairy cows were studied. We found a significant impact in the rumen microbiome after parturition characterized by a bloom of *Bifidobacteria*. Fibrolytic bacteria seem to support the animal with energetic metabolites during the acute phase of an induced inflammatory event. Overall animal microbiomes were clustered into three microbial clusters (enterotypes) based on faecal microbiome sequence information. They are characterized by different diversity indices and dispersion pattern over the complete experimental period. Correlation analyses showed clear links between microbiome clusters and performance, residual energy intake, and health of the animals. This indicates that a certain microbial composition should be considered for future selection and breeding strategies.

Meath, C15PW93, Ireland, ³Agri-Food and Biosciences Institute, Veterinary Sciences Division, Stormont, Belfast, Northern Ireland, BT4 3SD, United Kingdom; stephanie.odonoghue@teagasc.ie

Bovine respiratory disease (BRD) is a leading cause of morbidity and mortality in cattle of all ages. The bovine respiratory microbiome plays a critical role in respiratory health. Despite current research, a lack of data exists surrounding the impact of viral infection on the bovine nasal microbiota. A key BRD virus, Bovine Respiratory Syncytial Virus (BRSV) is an enveloped, single stranded RNA virus of the order Mononegavirales, and a significant viral agent in BRD cases in Ireland. The study objective was to characterise the nasal microbiota of dairy calves following experimental challenge with BRSV. Holstein-Friesian bull calves (mean age(SD)120.7 days(14.15); mean weight(SD)154.7(13.6 kg)) were administered either BRSV inoculate ($10^{3.5}$ TCID₅₀/ml × 15 ml)(n=12) or sterile phosphate buffered saline (n=6). Nasal swab samples were collected prior to euthanasia on day (d) 7 post-challenge. Microbial DNA was extracted from swabs using the Powerlyzer PowerSoil extraction kit. Sequencing libraries were prepared using the Nanopore 16S barcoding kit (SQK-16S024) and amplicons purified using AmPureXP beads. Libraries were pooled and sequenced on a MinION flow cell (9.4 chemistry) using the Mk1C Device. Raw FASTQ files were uploaded to the EPI2ME platform and analysed using the Fastq 16S workflow(v2022.01.07). The top genera identified in BRSV challenged animals were *Pasteurella*, *Moraxella* and *Mannheimia* spp. with *Pasteurella multocida*, *Moraxella nonliquefaciens* and *Mannheimia varigena* identified as the most common species. *Moraxella*, *Pasteurella* and *Mannheimia* spp. were the most common genera identified in controls on d7, while *Moraxella nonliquefaciens*, *Pasteurella multocida* and *Mannheimia varigena* were the most common species identified. In conclusion, differences were identified in the top genera between BRSV infected and non-infected calves, suggesting that BRSV infection causes a dysbiosis of the nasal microbiome.

Differential effects of *Ostertagia ostertagi* vaccination and infection on the rumen microbiome

J. Lima¹, T.N. McNeilly², P. Steele², M. Martínez-Álvarez³, M.D. Auffret⁴, R.J. Dewhurst¹, M. Watson⁵ and R. Roehe¹
¹SRUC, West Mains Road, EH9 3JG, United Kingdom, ²Moredun Research Institute, Pentlands Science Park, EH26 0PZ, United Kingdom, ³Universitat Politècnica de València, Camí de Vera s/n, 46022, Spain, ⁴AgriFirm Belgium, Baarleveldstraat 8, 9031 Drongen, Belgium, ⁵Royal (Dick) School of Veterinary Studies, Easter Bush Campus, EH25 9RG, United Kingdom; joana.lima@sruc.ac.uk

The abomasal parasitic nematode *Ostertagia ostertagi* leads to lower performance and welfare in cattle, but its impact on the rumen microbiome is unclear. Two groups of 10 animals received a vaccine against the parasite (V) or an adjuvant-only control (AD) and were then orally administered 1000 *O. ostertagi* L3 larvae 5 times a week for 5 weeks. We sampled the rumen digesta of AD animals identified based on high (H, n=4) or low (L, n=4) cumulative parasite faecal egg counts (FC), 4 VC animals with low FC, and 4 unvaccinated uninfected animals (UN) at *post-mortem* 3 weeks after the last infection, and shotgun sequenced to obtain abundances of microbial genera (MT) and genes (MG). Microbial profiles were centred log-ratio transformed and pairwise compared (H, L, V vs UN) using permutations within discriminant partial least squares models, and the most important MT/MG were identified by the variable importance in projection. A total of 36, 38 and 21 MT and 91, 31, and 57 MG in H, L, and V, respectively, differed from UN. Of these, 26, 29 and 13 MT and 74, 19 and 41 MG exclusively differed between UN and H, L, or V, respectively, suggesting that the parasite influence on the microbiome depends on the degree of infection. MT enriched in H, L, and V included e.g. opportunistic pathogen *Listeria* (H), *Tsukamurella* (L) and *Pseudopropionibacterium* (L, V), which include pathogens *T. paurometabolum* and *P. propionicum*. Methanogens e.g. *Methylocystis* (H, L) and *Methyloversatilis* (L, V) were enriched in H, L, or V. The microbiome functional potential in H, L and V also differed from UN. MG enriched in H, L and V were involved in, e.g. bacterial secretion system (*gspD*), biosynthesis of nucleotide sugars (*evaA*) and fructose and mannose metabolism (*rhaB*), respectively. These results suggest that the abomasal parasite changed the composition of MT and MT in the rumen microbiome.

Novel ruminal microbiome solutions to reducing enteric methane emissions

T.A. McAllister¹, L.L. Guan² and R.I. Mackie³

¹Agriculture and Agri-Food Canada, Lethbridge Research and Development Centre, 5403 1st Ave South, Lethbridge, AB T1K 4R5, Canada, ²University of Alberta, Department of Agricultural Food and Nutritional Science, 410 Agriculture Forestry Center, Edmonton, AB T6G 2P5, Canada, ³University of Illinois, Animal Science, 1207 W. Gregory Drive, 61801 Urbana, USA; tim.mcallister@agr.gc.ca

Methane (CH₄) is the second most important greenhouse gas (GHG) contributing to climate change, and the most significant emission source from ruminants. Presently, 150 countries have signed the Global Methane Pledge, which targets reducing global CH₄ emissions by 30% from 2020 by 2030. Furthermore, the comparatively short-lived atmospheric duration of CH₄ makes it a logical target if global warming is to be limited to 1.5 °C. The rumen microbiome can have both beneficial and detrimental impacts on cattle productivity and GHG emissions. The rumen microbiome plays a vital role in carbohydrate, protein and fat metabolism and the production of volatile fatty acids, microbial protein and vitamins for use by the cattle host. Changes in the presence/absence/abundance and activity of select microbes within the rumen affects fermentation, alters nutrient supply and enteric CH₄ emissions and thereby the efficiency of meat and milk production. Despite considerable effort, few CH₄ mitigation strategies are available for immediate implementation on farm. The paucity of mitigation solutions suggests that we still lack a fundamental understanding of the complexity and nature of hydrogen (H₂) transfer within the rumen ecosystem. Recent studies suggest that even if all known enteric CH₄ mitigation strategies were implemented, they would be insufficient to limit global warming to current targets. Consequently, new strategies that reduce enteric CH₄ emissions are needed, but they must be anchored by a understanding of the fundamentals of H₂ flow in the rumen. The current presentation will describe some of the gaps in our current understanding of fermentation and how they may be potentially filled. Tools such as genomics, metagenomics, metatranscriptomics, proteomics and metabolomics of both the host and the rumen microbiome, with integration through machine learning, will play a key role in identifying new approaches to reducing enteric CH₄ emissions in ruminants.

Relationship between feed efficiency and rumen microbiota in feedlot bulls fed contrasting diets

A. Ortiz-Chura, M. Popova, G. Cantalapiedra-Hijar and D. Morgavi

Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores Theix, 63122 Saint-Genes-Champanelle, France; abimael.ortiz-chura@inrae.fr

Improving feed efficiency in ruminants contributes to the environmental and economic challenges facing the livestock sector. Although the rumen ecosystem plays an essential role in feed digestion, there is no defined pattern between rumen microbiota and feed efficiency. The goal was to find if there is a relationship between divergent residual feed intake (RFI) phenotypes (RFI= efficient and RFI+= non-efficient) and the rumen microbiota in feedlot Charolais bulls fed contrasting diets. In this experiment, we used the 32 most extreme bulls based on their RFI from 100 animals fed corn-silage (CS; n=50) or grass-silage (GS; n=50) based diets. Rumen fluid samples were obtained at slaughter for fermentation analysis, bacteria and methanogens quantification by qPCR and meta-taxonomic analysis. In this study, total VFA concentration and profiles showed no differences between diets and RFI groups ($P>0.05$). Total bacteria and methanogen populations did not differ between RFI groups ($P>0.05$), although methanogens expressed per total weight of rumen content tended to decrease in efficient bulls compared to non-efficient ones ($P=0.10$). Total bacteria did not differ between diets, but methanogens increased in the GS compared to the CS ($P<0.05$) diet. Rumen microbial community structure differed between diets (Adonis test, $R^2=0.18$, $P<0.001$), but also between RFI groups within each diet. Although we found no RFI $\times$ Diet interaction on microbial abundance, different microbial families were associated with the RFI phenotype in a diet-dependent manner. Efficient bulls receiving the CS diet had a higher abundance of the *Lachnospiraceae* and *Veillonellaceae* families ($q<0.05$), while in the GS diet, the *Acidobacteriaceae* family was more abundant compared to non-efficient ones ($q<0.05$). In conclusion, diet-related factors were the main drivers of rumen microbiota variation. Furthermore, the RFI phenotype in each diet revealed the establishment of different microbial consortia. However, whether these microbiota rearrangements originate from the RFI phenotype or are associated with the interaction of the multiple variables involved in rumen fermentation remains unclear.

Session 51

Theatre 6

Establishment and evolution of ruminotypes of lactating Lacaune ewesT. Blanchard¹, C. Marie-Etancelin¹, Y. Farizon¹, C. Allain² and A. Meynadier¹¹INRAE, ENVT, GenPhySE, 24 Chem. de Borde Rouge, 31326, Castanet Tolosan, France, ²INRAE, Experimental Unit of La Fage, 12250, Saint-Jean et Saint-Paul, France; tiphaine.blanchard@inrae.fr

Ruminal microbiota of sheep is being studied to evaluate its impact on animals' energy balances in early lactation stage. The establishment of ruminotypes could be a useful tool to summarize the large dataset of ruminal microbiota abundances. The feasibility of directional selection of gut microbiota enterotypes has been demonstrated in pigs, proving the existence of genetic determinism of the host on enterotypes. Sixty-five Lacaune dairy sheep were studied and their ruminal contents and blood were sampled at 2 weeks (D1), 3 weeks (D2), 4 weeks (D3) and 6 weeks (D4) after lambing. Ewes were weighed on each date and were fed the same diet with hay, grass silage and concentrates. During the first month, lambs remained with the ewes: milk recording (milk quantity, fat and protein contents, somatic cell count) were performed at D4. Ruminal microbiota was analysed by sequencing the 16S rRNA gene for bacteria and sequences were computed with the FROGS pipeline to obtain relative abundances of ASVs which were then labelled according to genus level. Clustering of microbiota genera abundances using Jensen-Shannon divergence and partition around medoids clustering algorithm has led to 2 groups. Spls-da of these two clusters revealed a first ruminotype characterised by *Mogibacterium*, *Lachnospiraceae* NK3A20 group and *Acetivomaculum* genera (RuM) and a second one by *Prevotella*, *Prevotella_9* and *Lachnospiraceae* NK4A136 group genera (RuP). Over time, a significant shift towards RuP is noted (D1: 22%, D2: 34%, D3: 58%) which becomes a minority again after weaning (D4: 14%). At D1, RuM is associated with higher non esterified fatty acids ($P=0.04$), beta-hydroxybutyrate ($P<0.01$), isobutyrate ($P=0.01$) and lower total volatile fatty acids ($P<0.01$) compared with RuP. At D2, RuM is associated with lower weekly weight loss ($P=0.03$) compared to RuP. At D3, ruminotypes were not associated with zootechnical traits. At D4, RuM was associated with lower milk protein and fat contents ($P<0.02$). Characterization of the specific metabolic pathways of these 2 clusters is underway via a functional inference approach, in order to make links with the zootechnical traits.

Effect of colostrum source and calf breed on diarrhoea incidents in pre-weaned dairy calvesS. Scully^{1,2}, P.E. Smith², B. Earley², C. McAloon¹ and S.M. Waters²¹University College Dublin, School of Veterinary Medicine, Belfield, Dublin, Ireland, ²Teagasc, Animal and Bioscience Research Department, Teagasc Grange, Dunsany, Co. Meath, Ireland; sabine.scully@teagasc.ie

Neonatal calf diarrhoea is a multifactorial condition and a major cause of economic loss to producers. Several pathogens are reported to cause or contribute to calf diarrhoea. Other factors include environmental and management practices that influence disease outcomes. The study objective was to evaluate effect of colostrum source (CS) and calf breed (CB) on diarrhoea incidents in 51 spring born Holstein (HO; n=29, birth weight (BW) 34.7 (SE 0.69) kg) and Jersey (JE; n=22, BW 25.9 (SE 0.81) kg) heifer calves from birth (day (d) 0) to weaning (d83 (SE 1.04)). Calves were fed 8.5% BW in colostrum, from either, the dam (n=28) or a pooled source of colostrum (≤ 2 cows, ≤ 1 d; n=23) within 2 hours of birth. A modified Wisconsin-Madison calf health scoring system was used and rectal temperature (RT) measured for clinical assessment at d0, d7, d21, and day-of-diarrhoea incident, and day-of-weaning. Live weights were recorded at d0, d21, and weaning. Diarrhoea incident was assessed using faecal scores (0=normal, 1=semi-formed, 2=moderate, 3=severe diarrhoea), and health status was defined as calves having diarrhoea (n=27), or healthy (n=24). Faecal scores were analysed using the Wilcoxon Mann-Whitney U-test and RT data were analysed using the PROC MIXED procedure in SAS (9.4). The model included CS, CB, and health status and their interactions as fixed effects, and shed as random effect. The mean day post-birth for diarrhoea was d23 (SE 1.04) and d22 (SE 0.88) for HO and JE calves, respectively; 53% of calves had a diarrhoea incident. There was no CS $\times$ CB interaction ($P>0.05$) for diarrhoea incident from d0 to weaning. On the day of diarrhoea detection, faecal scores were greater ($P<0.0001$) for diarrhoeic calves (median score 3; range 2-3) than healthy calves (0; 0-1) while RT of diarrhoeic calves was elevated ($+0.37$ °C (SE 0.01); $P=0.004$). Health status had no effect ($P>0.05$) on ADG from d0 to weaning. Faecal samples from healthy and diarrhoeic calves at d7, d21 and the day-of-diarrhoea incident, and day-of-weaning are currently undergoing microbial metataxonomic analysis using 16s rRNA amplicon sequencing.

Metagenome strain deconvolution and abundance estimation enabled by low-error long-read DNA sequenceD. Bickhart¹, M. Kolmogorov², E. Tseng³, P. Pevzner⁴ and T. Smith⁵¹Hendrix Genetics, Spoorstraat 69, 5831 CK Boxmeer, 5830 AC Boxmeer, the Netherlands, ²National Institute for Health, Center for Cancer Research, Building 41, Room A100C, 20892 Bethesda, Maryland, USA, ³Pacific Biosciences, 1305 O'Brien Drive, 94025 Menlo Park, California, USA, ⁴University of California San Diego, Jacobs School of Engineering, 9500 Gilman Drive, 92093 La Jolla, California, USA, ⁵United States Department of Agriculture, Meat Animal Research Center, State Spur 18D, 68933 Clay Center, Nebraska, USA; derek.bickhart@hendrix-genetics.com

The sequencing of microbial isolates is considered the gold standard means to generate high quality reference genomes for individual species in lieu to metagenome sequence assembly. We present new methods and tools to generate isolate-quality reference genomes for metagenome assembled genomes (MAG) using the latest in DNA sequencing technologies that achieve lower error-rates ($<1\%$) with longer read sizes (>9 kbp). Using 255 Gbp of PacBio HiFi sequence, we assembled 428 MAGs that had completeness estimates higher than 90%. We then developed a novel strain deconvolution tool, MAGPhase, that identifies SNP haplotypes within assembled MAGs that are representative of lower abundance strains by using read-phasing. Within our sheep MAG dataset, MAGPhase predicted that 220 of our MAGs (51%) were devoid of any phased SNP haplotypes and represented lineage- or strain-resolved reference genomes. We also identified strain haplotypes in several MAGs that had $>99\%$ predicted nucleotide identity with the reference MAG. This suggests that a closely related strain was present in the same sample as the MAG and that the proportion of reads that contain the SNP haplotypes could be used to derive relative abundance of the strain to the reference assembly haplotype. Such insights were difficult to derive from MAGs created using shorter or error-prone DNA sequencing reads, as such assemblies were more likely to collapse strain-level variation into chimeric assemblies. We demonstrate that metagenome assemblies generated with lower-error, long-read sequencing methods are most likely to generate lineage-resolved MAGs. Coupled with the use of our MAGPhase algorithm, these reads can be used to identify cohabiting strains prevalent in the sample or in other orthologous samples of the same type.

Stakeholders views regarding new practices to control microbiomes

F. Bedoin¹, A. Ait-Sidhoum², E. Vanbergue¹, A. Stygar², T. Latvala², Á. MacKen-walsh³, S. Waters³, P. Smith³ and J.K. Niemi²

¹Institut de L'élevage, 149 Rue de Bercy, 75012 Paris, France, ²Natural Resources Institute Finland (Luke), Latokartanonkaari 9, 00790 Helsinki, Finland, ³Teagasc, Oak Park, Carlow R93 XE12, Ireland; jarkko.niemi@luke.fi

Microbes play an important role when farmers are aiming at sustainable and viable livestock production, and farmers and other stakeholders play a key role in adopting practices that utilize microbiomes. The aim of this study was to gain understanding on the perceptions and expectations farmers and other supply chain stakeholders regarding microbial ecosystems and adoption of innovations that benefit from microbiome. A review of decision-making to explain the adoption of innovations and farming practices and five focus group discussions involving farmers, advisors and other stakeholders in five European countries were carried out. The themes considered were: (1) identification of microbiomes on farms; (2) Stakeholders' knowledge; and (3) opinion on the role of microbiomes in animal production, health and greenhouse gas emissions; and (4) Opinions on innovations relating to early life, dietary transition and environmental issues. Although financial aspects are strong drivers for the adoption of practices, endogenous factors such as the perceived impact of diseases, the lack of knowledge, and technical skills were found barriers for the adoption of new practices. The importance of early establishment of a 'good' microbiome for young animals was understood well. However, many participants were reluctant towards feed additives for the reduction of methane emissions especially because of doubts about their long term effects.

Session 51

Poster 10

Temporal establishment of the colon microbiota in angus calves from birth to post-weaning

M. Stafford^{1,2}, P. Smith², S. Waters², F. Buckley¹, E. O'Hara³ and D. Kenny²

¹University College Cork, School of Biological, Earth, and Environmental Sciences, Distillery Fields, North Mall, University College Cork, T23 N73K, Ireland, ²Teagasc Grange, Animal and Bioscience Research Department, Teagasc Grange, Meath, C15 PW93, Ireland, ³University of Alberta, Department of Agricultural, Food, & Nutritional Sciences, Department of Agricultural, Food, & Nutritional Sciences, University of Alberta, Edmonton, AB T6G 2P5, Canada; michelle.stafford@teagasc.ie

During the peri- and early post-partum period, the gastrointestinal tract (GIT) of the calf is colonised by a combination of commensal and pathogenic microbes. Current understanding of the temporal microbial establishment of neonatal colon is, however, limited. This study focused on the ontogeny of colon microbiota establishment in Angus Beef calves from birth through weaning. Colon digesta contents were collected from Aberdeen Angus calves reared on two farms. Calves were euthanized at birth (n=7), day (D) 7 (n=7), D14 (n=6), D21 (n=7), D28 (n=6), and D96 (n=7) of life. Microbial DNA was extracted from colon samples and subjected to 16S rRNA amplicon sequencing. The effect of time on alpha (GLM procedure of SAS; 9.4) and beta (PERMANOVA) diversity of the colon microbiota was assessed with age and farm included as fixed effects. Differential abundance (*Maaslin2*) analyses were conducted with the same fixed effects. The alpha-diversity of the bacterial community progressed from birth onwards (D0 H' mean=0.59 and D96 H' mean=5.33) with apparent stabilisation between D14 v D21 ($P=0.21$). Weaning had a further statistically significant effect on the diversity of the colon microbiota (D28 v D96; $P<0.001$). Similarly, PERMANOVA analysis indicated stabilised colonisation of the colon microbiota from D14 to D21 ($P=0.22$), albeit weaning altered the colon microbiota (D28 v D96; $P<0.001$). This study is amongst the first to describe the ontogeny of colonisation of the colon microbiota, from birth to weaning in beef calves and provides fundamental information to support the establishment of beneficial microbes in the lower GIT of ruminants.

Preliminary study of faecal microbiota in a selection experiment for birth weight variability in mice

L. El-Ouazizi El-Kahia¹, N. Formoso-Rafferty², J.P. Gutiérrez¹, C. Esteban Blanco³, J.J. Arranz³ and I. Cervantes¹
¹Facultad de Veterinaria, UCM, Producción Animal, 28040 Madrid, Spain, ²E.T.S.I.A.A.B, UPM, Producción Agraria, 28040 Madrid, Spain, ³Facultad de Veterinaria, ULe, Producción Animal, 24007 León, Spain; lailaelo@ucm.es

A divergent selection experiment for environmental variability of birth weight in mice was carried out successfully for 31 generations. Two divergent lines were created having different variability at birth weight, the high variability line (H-line) and the low variability line (L-line). Further studies showed that the L-line is more advantageous in fertility with higher reproductive longevity. Also, it showed benefits in traits considered welfare and robustness indicators such as feed efficiency and longevity. It has been reported that the microbiota plays a key role in the host phenotypes through the interactions that occur with the host by influencing several physiological functions. Thus the microbiota can have beneficial or detrimental effects leading to differences in animal productivity and welfare. The aim of this study was to evaluate the differences in the microbial composition from the two lines obtained by a divergent selection experiment for birth weight environmental variability. In order to analyse the faecal microbiota, samples from 77 pregnant females from four generations of selection (22-25) were collected, 43 of which correspond to the L-line and 34 to the H-line. The V4 region of the 16S rRNA was sequenced, the amplicon sequence variants (ASVs) were determined using the DADA2 pipeline, and the taxonomic assignment was performed using the SILVA database. After the trimming and quality control, 11.5 million sequences were used for further analysis. These sequences were grouped in 45,783 ASVs corresponding to 12 phyla, being *Firmicutes* (48%) the most representative, and 143 genera. There were significant differences in relative abundance at the genus level when comparing the two divergent lines. We observed a marked increase in *Lactobacillus* and *Helicobacter* and a decrease in *Turicibacter* in the L-line compared to the H-line. The selection experiment led to differences in the microbiota composition between lines; studying these three genera could be the first step to analysing the microbiota linked to higher welfare and robustness.

The effects of crude protein levels on rumen microbiome and CH₄ of the fattening Hanwoo steers

H. Kim¹, H. Cho², S. Jeong², K. Kang², S. Jeon², M. Lee², H. Kang², S. Lee³, S. Seo² and J. Seo¹

¹Pusan National University, Department of Animal Science, 3339, 1268-50 Samrangjin-ro, Miryang, 50463, Korea, South, ²Chungnam National University, Division of Animal and Dairy Sciences, 99, Daehak-ro, Yuseong-gu, Daejeon, 34134, Korea, South, ³National Institute of Animal Science, Animal Nutrition and Physiology Division, 1500, Kongjipatjiwi-ro, Iseo-myeon, Wanju-gun, Jeollabuk-do, 55365, Korea, South; khb3850@pusan.ac.kr

Enteric methane (CH₄) emissions are a significant concern in livestock science, due to their substantial impact on global warming potential. The CH₄ is generally produced by diverse microbiota in the rumen. In this study, we aimed to evaluate the effects of crude protein (CP) levels in concentrate on rumen microbiome and CH₄ emissions of Hanwoo steers during the early fattening period. Twenty-four Hanwoo steers (average 27-month-old, 504±33.0 kg) were randomly allocated to one of four treatment groups and fed their respective diets for 16 weeks: (1) low crude protein (12.00%; LCP); (2) lower middle CP (15.50%; LMCP); (3) higher middle CP (17.25%; HMCP); and (4) High CP (19.00%; HCP) levels in concentrate. In the final week of the experimental period, rumen fluid was collected and 16S rRNA gene amplicon sequencing was performed using PacBio Sequel II. There was no significant difference in CH₄ concentration (ppm-m; *P*>0.10). Based on the weighted UniFrac distance, HCP group showed a significant difference compared to LCP group (*P*<0.05). At the family level, *Succinivibrionaceae* was significantly decreased with increasing levels of CP (*P*<0.05), whereas unclassified family *Bacteroidales* tended to increase (*P*<0.10). At the species level, *Succinivibrio dextrinosolvens* tended to decrease with increasing levels of CP (*P*<0.10). Functional modules related to amino acids biosynthesis (Cysteine biosynthesis [M00021], tyrosin biosynthesis [M00025], methionine salvage pathway [M00034]) were linearly decreased (*P*<0.05) with increasing levels of CP. Our findings provide a fundamental understanding of the relationship between CP levels and rumen microbiota in beef cattle during the finishing period.

Rumen metabolites of periparturient cows varying in SARA susceptibility modify fermentation *in vitro*H. Yang^{1,2}, S. Heirbaut², J. Jeyanathan², X.P. Jing^{2,3}, N. De Neve², L. Vandaele⁴ and V. Fievez²¹School of Animal Science and Technology, Jiangsu Agri-animal husbandry vocational college, Taizhou, China, P.R.,²Laboratory for Animal Nutrition and Animal Product Quality, Department of Animal Sciences and Aquatic Ecology,Ghent University, Coupure Links 653, 9000, Gent, Belgium, ³State Key Laboratory of Grassland and Agro-Ecosystems,

Melle, Belgium; jeyamalar.jeyanathan@ugent.be

The rumen metabolic environment from either SARA susceptible (S) or unsusceptible (U) cows, was hypothesized to alter the fermentative capacity and bacterial community composition. This was evaluated *in vitro* at pH 5.8 and 6.8 through exposure for a period of 24 h of the microbial inoculum of three donor cows to sterile ruminal supernatant obtained from 15 early lactating dairy cows which were either SARA S (n=8) or U (n=7) (2×2 design). Compared to exposure to sterile supernatant from S cows, microbiota exposed to sterile supernatant from U cows produced more total volatile fatty acids, irrespective of the *in vitro* pH (6.8 or 5.8). Specifically, branched-chain volatile fatty acids (BCVFA), such as iso-butyrate and total BCVFA were elevated/tended to be elevated in incubations with the sterile supernatant from U cows. Net lactate accumulation in incubations with U cows' supernatant at pH 6.8 was higher than with S cows' supernatant, whereas no difference was observed between groups when microbiota were exposed to a pH 5.8 buffer. Nevertheless, the gene copy numbers of bacteria were higher at pH 6.8 than at pH 5.8, irrespective of the origin of the sterile supernatant. Also, the bacterial richness and diversity did not differ between incubations exposed to S or U sterile supernatants. Nevertheless, a lower relative abundance of Lachnospiraceae_UCG-008, and *Mogibacterium*, as well as a higher relative abundance of *Prevotella* were observed after incubation with sterile supernatant from S cows as compared with U cows.

Prevalence of resistant *E. coli* and their transmission among dairy cattle in Swiss tie stalls

B. Köchle, V. Bernier Gosselin and J. Becker

Vetsuisse Faculty, Bremgartenstrasse 109a, 3012 Bern, Switzerland; jens.becker@unibe.ch

Dairy cattle are the production branch of Swiss animal husbandry where most antimicrobials are administered. This study was conducted to: (1) describe the prevalence of rectal *E. coli* resistant to antimicrobials; and (2) to investigate whether there are indications for transmission of resistant *E. coli* among tie-stalled dairy cattle that are tied next to each other. During farm visits, triplets of cows were swab sampled to isolate *E. coli* from the rectal mucosa and perform susceptibility testing using microdilution. Triplets included treated and untreated cows: cow A: treated parenterally with antimicrobials within 3-7 days prior to sampling; cow B: untreated neighbouring cow of cow A; cow C: untreated cow not neighbouring cow A or B. A total of 281 farms were visited. Prevalence of resistant *E. coli* was moderate to low in untreated and moderate in treated cows. Overall, resistance was exhibited most frequently to sulfamethoxazole (31.8%), tetracycline (8.5%) and ampicillin (6.3%). Being cow B, i.e. being exposed to treated cow A was not associated with higher prevalence of resistant *E. coli* in comparison to cow C. In our study population, there is no indication that parenteral antimicrobial treatment in tied dairy cows increases the risk of carrying resistant *E. coli* for cows tied at the neighbouring stand. For practitioners, separation of cows that undergo treatment may not be necessary to avoid spread of resistant bacteria and therefore to comply with the standards of prudent use of antimicrobials.

Stability of a *Bacillus*-based DFM following preparation of a milk replacer and premix

G. Copani, A. Segura, N. Milora, M. Schjelde and B.I. Cappellozza

Chr. Hansen A/S, Animal and Plant Health & Nutrition, Boege Alle 10/12, 2970 Hørsholm, Denmark; dkigico@chr-hansen.com

The ability of spore-forming bacteria, such as *Bacillus* spp., to tolerate challenging environments allows its inclusion in different types of supplements often fed to calves and mature animals. We hypothesized that the inclusion of a *Bacillus*-based direct-fed microbial (DFM) in milk replacer and mineral-vitamin premix would provide adequate recovery following supplement preparation. Hence, our objective was to evaluate the recovery of a *Bacillus*-based DFM following its inclusion in milk replacer after 1 hour (Exp. 1) and premix over 12 months (Exp. 2). In Exp. 1, a commercial milk replacer was dissolved in water either at 37 or 50 °C and a *Bacillus*-based DFM (*Bacillus licheniformis* and *B. subtilis*; BOVACILLUS™; Chr. Hansen A/S) was included in both mixtures at 1.0×10^6 cfu/ml of milk replacer (n=3 samples/temperature). Following DFM inclusion, milk replacers were incubated for 1 hour at room temperature (25 °C), and samples were enumerated after 30 and 60 min. In Exp. 2, two independent batches of the *Bacillus*-based DFM were included at a commercial premix at a rate of 3.2×10^7 cfu/gram of premix. Samples were stored at 25 °C and analysed at 1, 3, 6, and 12 months following DFM inclusion into the premix. In Exp. 1, no differences were observed in the recovery of the *Bacillus*-based DFM (log cfu/gram of premix, $P=0.68$) vs time 0 ($P>0.49$) following its mixture in milk replacers at 37 or 50 °C ($P=0.62$). Moreover, no differences were observed between the temperatures evaluated herein. In Exp. 2, the recovery of the *Bacillus* spores in the premix averaged (log cfu/g) 99.5, 100.8, 100, and 98.6% at 1, 3, 6, and 12 months, respectively, and did not differ from time 0 ($P>0.17$). In summary, our results support the hypothesis that this *Bacillus*-based DFM thrives and survives under different environments for feed manufacture, including the ones observed for milk replacer preparation (different temperatures) and mineral-vitamin premix. These results provide additional evidence of the range of opportunities for *Bacillus*-based DFM that could be used in ruminant production systems.

Session 51

Poster 16

Effects of a *Bacillus*-based direct-fed microbial on performance and digestibility of lactating cowsM. Terré¹, N. Prat¹, D. Sàbria¹ and B. Cappellozza²¹Institute of Agrifood Research and Technology (IRTA), Finca Camps i Armet, Edifici D, 17121 Monells, Girona, Spain,²Chr. Hansen A/S, Commercial Development, Animal and Plant Health and Nutrition, Bøge Allé, 10-12, 2970, Denmark; marta.terre@irta.cat

Direct-fed microbials (DFM) have been used to support health and performance of dairy calves, and to improve health, nutrient utilization, milk production, and milk production efficiency in lactating dairy cows. Therefore, we hypothesized that a *Bacillus*-based DFM would improve performance and nutrient digestibility in lactating dairy cows. Hence, our goal was to evaluate the effects of supplementing a *Bacillus*-based DFM on milk production traits and nutrient digestibility of lactating dairy cows. Seventy-six early-lactating Holstein cows (days in milk 43 ± 6) were blocked by calving date and parity in 1 of 2 treatment groups: (1) partial mixed ration (PMR) without DFM supplementation (n=38; CON) or (2) PMR with the addition of 3 g/head per day of a *Bacillus*-based DFM (BOVACILLUS™, Chr. Hansen A/S, Hørsholm, Denmark; n=38; DFM) for a 105-day experiment. The PMR contained ryegrass hay, wheat silage, corn silage, ryegrass silage, alfalfa hay, and concentrate feed. A pelleted soybean-based supplement was used as a carrier for DFM. Milk yield, composition (%), dry matter intake (DMI), and milk production efficiency were evaluated daily. Moreover, faecal samples were collected on week 15 of the experimental period for nutrient digestibility determination. No treatment effects were observed on DMI and milk yield ($P>0.16$), but DFM-supplemented cows had a greater milk production efficiency when compared with CON cohorts (1.54 vs 1.59 kg milk/kg DMI; SEM=0.02; $P=0.03$). No differences were observed on milk composition (% or yield; $P>0.12$), as well as on energy- or fat-corrected milk production and efficiency ($P>0.18$). Lastly, DFM supplementation tended ($P=0.10$) to increase DM digestibility (71.4 vs 72.9%, respectively; SEM=1.13), without further treatment effects being detected ($P>0.24$). In summary, feeding BOVACILLUS improved milk production efficiency, and tended to improve dry matter digestibility in lactating dairy cows. These data highlight the opportunity of using BOVACILLUS to promote milk production efficiency in dairy production settings.

Stability of a *Bacillus*-based direct-fed microbial post-palletisation under different temperaturesB. Cappellozza¹, C. Galschiot² and G. Copani²¹Chr. Hansen A/S, Commercial Development, Animal and Plant Health and Nutrition, Bøgle Allé, 10-12, 2970, Denmark, ²Chr. Hansen A/S, Innovation, Animal and Plant Health and Nutrition, Bøgle Alle 10-12, 2970, Denmark; brbrie@chr-hansen.com

Spore-forming bacteria, such as *Bacillus* spp., are known to support challenging environments, such as high-temperature. We hypothesized that the inclusion of a *Bacillus*-based direct-fed microbial (DFM) in pellet supplements would provide the expected recovery under three temperatures. Hence, our goal was to evaluate the recovery of a *Bacillus*-based DFM in pellets prepared under 75, 85, and 95 °C. Three independent batches of a *Bacillus*-based DFM (BOVACILLUS™; Chr. Hansen A/S) were evaluated. The supplement was composed of (as-fed basis) 29.0% wheat, 20.0% barley, 15.0% corn, 10% beet pulp, 10% rapeseed cake, 9.5% high-protein soybean, 3.8% soybean oil, 1.0% limestone, and 1.7% vitamin-mineral premix. The *Bacillus*-based DFM was included at a recommended commercial dose (9.6×10^9 cfu/head per day). Its recovery was evaluated following the pellet preparation under 75, 85, and 95 °C. Mash samples (pre-pellet) were taken from the horizontal mixer in 10 different locations. Moreover, meal with the product was mixed for 10 minutes before sampling and pelleting. For each temperature, pellet samples were taken approximately between 9 and 11 minutes post-pelleting to ensure enough time to get a stable environment in the conditioner and to give a homogeneous sample. The expected cfu/g was 3.80×10^5 . Following pellet manufacturing, cfu/g (3.89, 3.91, and 4.46×10^5 cfu/g for 75, 85, and 95 °C, respectively) and deviation from expected (102, 103, and 117% for 75, 85, and 95 °C, respectively) were not affected by the temperatures evaluated herein ($P > 0.21$). When the results were transformed to log cfu/g, no differences were observed by the temperature of the pellet preparation ($P = 0.25$), given that the mean counts represented 100, 100, and 101% of the expected count for 75, 85, and 95 °C, respectively. In summary, these data support our hypothesis that BOVACILLUS™ is thermoresistant, given that its recovery in a pellet supplement prepared under different temperatures (75, 85, and 95 °C) was achieved when calculated in cfu/g, log cfu/g, or deviation from expected (%).

Poster 18

Microbial signals in peripheral blood mononuclear cells of Australian Angus cattleP. Alexandre¹, A. Wilson², T. Legrand¹, R. Farr², S. Denman¹ and A. Reverter¹¹CSIRO, Agriculture & Food, St Lucia, Queensland, 4067, Australia, ²CSIRO, Health & Biosecurity, Geelong, Victoria, 3220, Australia; pamela.alexandre@csiro.au

A key aspect of developing sustainable livestock production systems is selecting for improved productivity while considering welfare outcomes. Immune competence is critical to animal health and welfare and can be described as an animal's ability to mount both a cell-mediated (cell-IR) and an antibody-mediated (Ab-IR) immune response. While the beneficial impacts of microbiomes on livestock health and performance are becoming increasingly apparent, major knowledge gaps remain around how their function can be exploited to deliver beneficial outcomes. With that in mind, 51 Angus heifers and steers were evaluated for cell-IR and Ab-IR at weaning and had blood samples collected by jugular venipuncture. Peripheral blood mononuclear cells (PBMC) were isolated using density gradient centrifugation and RNA was extracted using a Qiagen miRNeasy Mini kit. Ribosome depleted RNA libraries were sequenced in an Illumina NovaSeq 2×150 bp. Filtered reads were aligned to the bovine reference genome ARS-UCD1.2 using STAR. Unmapped reads corresponding to ribosomal RNA (rRNA) were identified using SortMeRNA with the reference databases SMRv4.3sensitive and Greengenes2. Considering all samples, an average of $113M \pm 22M$ reads were sequenced and around 16% of those were unmapped. Unmapped reads can be attributed to technical sequencing artifacts, unknown transcripts, RNA editing, trans-splicing, gene fusion, circular RNAs, and of particular interest, the presence of non-host RNA sequences (e.g. bacterial, fungal, and viral organisms). Most of the identified rRNA across the samples (~2.9% of unmapped reads) aligned to mammals and other eukaryotes. However, the most present bacteria were Proteobacteria. In humans, Proteobacteria represents the most frequent phylum present in blood and an increasing number of studies identifies them as a possible microbial signature of disease. We also identified a small portion of archaea present in our samples. Our ongoing research is now focused on understanding the relationship between microbial rRNA in PBMCs and immune competence measures to identify possible biomarkers that can inform both animal selection and management decisions.

Metabarcoding of milk, faeces and ruminal fluid of Sarda ewes fed with Alfalfa (*Medicago sativa*)

A. Vanzin¹, D. Giannuzzi¹, G. Zardinoni¹, A. Cecchinato¹, N. Macciotta², F. Correddu², A. Atzori², S. Carta², A. Ledda², S. Schiavon¹, L. Gallo¹ and S. Pegolo¹

¹University of Padua, DAFNAE, Viale dell'Università 16, 35020, Italy, ²University of Sassari, Dep. of Agricultural Sciences, Viale Italia 39/a, 07100, Italy; diana.giannuzzi@unipd.it

Precision livestock feeding can decrease livestock environmental impacts by optimizing the use of dietary nutrients and animal nutrient utilization efficiency. Diet is also a key factor influencing rumen and gut microbiota compositions, which have a strong relationship with animal health and welfare. The present study aims to investigate the effects of different diets on rumen, faeces and milk microbiota of Sarda ewes. A group of 24 Sarda ewes with low milk cheese-making ability was divided into two groups fed for 22 days with two diets similar for net energy (1.48 Mcal/kg DM), crude protein (175 g/kg DM) and NDF (343 g/kg DM), but differing for alfalfa hay which was introduced (534 g/kg DM) in partial replacement of soybean meal, meadow hay and corn grain. Individual milk, faeces and ruminal fluid samples were collected at day one (T0) and at day 22 (T1) from the beginning of the trial. The microbiota of these matrices was characterized by sequencing the V2-4-8 and V3-6, V7-9 hypervariable regions of the 16S rRNA gene with the Ion GeneStudio S5 technology. To process amplicon sequencing data from raw reads to taxon abundance tables, DADA2 was used. Then, α - and β -diversity indices were calculated using the Phyloseq package. The results obtained from the ruminal fluid did not show significant differences in relative abundances between the control group (low – alfalfa, L-Alf) and the treated one (high – alfalfa, H-Alf). Alpha-diversity analysis showed a tendency for a higher taxonomic diversity in rumen fluid of animals belonging to the H-Alf diet. The predominant phyla were Bacteroidetes, Proteobacteria and Firmicutes. The most abundant families were Prevotellaceae and Succinivibraceae, which are associated with feed conversion efficiency. The upcoming integration with milk and faeces data will allow a more complete picture, which will shed new lights on the relationships diet – animal health and welfare – quality of animal products. Acknowledgments: the research was part of the PRECISLAT project funded by MIPAAF (Italy).

An experimental approach for assessing causal microbes in early life diarrhoea in lambs

L. Voland¹, D. Graviou¹, K. Vazeille², A. Ortiz-Chura¹, D.P. Morgavi¹ and M. Popova¹

¹Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Rte de Theix, 63122 Saint-Genès-Champanelle, France, ²Unité Expérimentale Herbipôle 1414 Les Razats, Laqueuille, 63820, France; laurianne.voland@inrae.fr

In sheep production, separating lambs from dams at birth is common. However, this causes a late and random colonization of the gastrointestinal microbiota in newborn lambs, leading to a higher incidence of digestive disorders like diarrhoea, and neonatal mortality. Understanding the etiology of digestive dysbiosis will allow proposing better prevention and management plans, achieving a balance between welfare and production. We hypothesized that the incidence of diarrhoea would be linked to unbalanced colonization of the gastrointestinal tract in early life. To infer causality of early life scouring, we used triplet lambs allotted into three groups, M: lambs reared with their ewes, AA: artificially reared, no contact with adults, AAC: AA with some contact with adults. All lambs were sampled weekly for rumen contents, with additional sampling if diarrhoea was detected. The sampling times intended to address the first criteria of temporality for establishing causality. The three rearing conditions were designed to obtain different sequences of microbial colonization and thus address the non-spurious criterion of causality (comparing the microbial communities between groups, before and after diarrhoea). In this study, the average daily gain in the M group was 3 times higher than AA and AAC groups in the first week of life; but decreased to a 1.5 fold in week 8. Throughout the study, scouring episodes were recorded in 83, 66 and 35% of the lambs in the AA, AAC and M groups, respectively. The incidence of severe diarrhoea was more frequent at 4 weeks of age and at weaning in the three groups; however, symptoms were recorded in only 5% of M lambs compared to 21% in AA and 28% in AAC. The experimental setup allowed us to obtain different disease phenotypes per group (AA had more diarrhoea than AAC and M). Currently, the genomic DNA of rumen contents, fermentation parameters and immunity status (blood IgG) are under analysis. Integration of these data should allow determining factors driving diarrhoea occurrences in early life.

Mycotoxin-deactivating feed additive supplementation in dairy cows fed *Fusarium*-contaminated diet

Limited scientific evidence on *Fusarium* mycotoxins impact is available in dairy cow performance and health, especially after longer exposition time. Also information on the effects of these mycotoxins on milk cheese-making parameters is very poor. The objective of this study was to evaluate a commercially available mycotoxin deactivating product (MDP, TOXO® XXL, Selko, Tilburg, the Netherlands) in lactating dairy cows fed a *Fusarium*-mycotoxin contaminated diet, and the repercussions on cows' health status and feeding behaviour, milk yield and quality, in term of cheese-making traits. The MDP contains smectite clays, yeast cell walls and antioxidants. In the study, 36 lactating Holstein cows were grouped based on days in milk, milk yield, body condition score and randomly assigned to specific treatments. The study ran over 2 periods (March/May – May/July 2022). In each period, six animals/treatment were considered. Experimental periods consisted of 9 days of adaptation and 54 days of intoxication. Physical activity, rumination time, daily milk production and milk quality was measured. Cows were fed once daily with the same TMR mixed composition. Experimental groups consisted of CTR diet, TMR with low contaminated high moisture corn (HMC), C-B mix and beet pulp; MTX diet, TMR with high contaminated HMC, C-B mix and beet pulp; TOXO XXL diet, MTX diet supplemented with 100 g/cow/day of TOXO XXL. MDP TOXO XXL reduced mycotoxin negative effects on milk yield and quality (protein, casein, lactose, and clotting parameters). The MTX diet had a lower milk yield and feed efficiency than the CTR and TOXO XXL diets. These results provide a better understanding of mycotoxin risk on dairy cows' performances and milk quality. Further analyses should be carried out to evaluate MDP outcome on immune-metabolic responses and diet digestibility.

Effects of 3-NOP on enteric methane production in growing beef cattle offered a forage based diet

S.F. Kirwan¹, L.F.M. Tamassia², N.D. Walker², A. Karagiannis², M. Kindermann² and S.M. Waters¹

¹Teagasc, Animal Bioscience Research Centre, Grange, Dunsany, Co. Meath, C15PW93, Ireland, ²DSM Nutritional Products, Animal Nutrition and Health, Wurmisweg 576, 4303 Kaiseraugst, Switzerland; stuart.kirwan@teagasc.ie

There is an urgent requirement internationally to reduce enteric methane (CH₄) emissions from ruminants. Enteric CH₄ from ruminants accounts for 6% of global anthropogenic greenhouse gas emissions. Numerous nutritional interventions including feed additives have been suggested as potential CH₄ mitigating strategies, however, the efficacy of some of these strategies varies and are difficult to implement at farm level. The CH₄ inhibitor 3-nitrooxypropanol (3-NOP) is seen as a potential strategy at reducing methane emissions in ruminants, but to date the effects have mainly been observed in adult beef cattle and dairy cows mainly fed high energy concentrate diets. Therefore, the objective of this study was to investigate the effects of 3-NOP inclusion in growing beef cattle offered a forage based diet. A total of 68 Dairy × Beef male calves (≤6 months; BW: 147±38 kg) were assigned to 1 of 2 treatments over a 12-week period, in a completely randomized block design. Dietary treatments were: one of two groups: (1) control, placebo (no 3-NOP), and (2) 3-NOP applied at 150 mg/kg dry matter (DM). Methane, H₂ and CO₂ were measured using the GreenFeed system. Total weight gained, dry matter intake, average daily gain, and animal health variables were not affected by the inclusion of 3-NOP ($P>0.05$). The inclusion of 3-NOP decreased ($P<0.001$) CH₄ emissions: (g/d; g/kg DMI) by 29.87 and 26.41% respectively, and was consistent throughout the course of the study. This reduction in methanogenesis resulted in a 223.2% increase in H₂ emissions (g/d) ($P<0.001$). Concentrations of ruminal total VFA and individual VFA were not affected by the inclusion of 3-NOP ($P>0.05$). However, ruminal acetate:propionate tended to be lower in animals that received 3-NOP ($P<0.10$). Incorporating 3-NOP into growing beef cattle diets is a potential solution to decrease CH₄ emissions in growing cattle offered a forage based diet.

COWFICIENCY project: a field attempt to increase nitrogen use efficiency of dairy cattle

A. Foskolos, A. Plomaritou, M.E. Hanlon and D. Kantas

Department of Animal Sciences, University of Thessaly, 41500 Larisa, Greece; andreasfosk@hotmail.com

Nitrogen (N) extended use in the food chain led to the N cascade phenomenon with considerable environmental impacts. The European Union has been taken several initiatives at either research or legislative level to reduce N pollution, including applied projects to further implement these strategies at the dairy sector. The CowficieNcy project aims to further develop and implement the mathematical models Cornell Net Carbohydrate and Protein System (CNCPS; a cow-based model) and Cattle Nitrogen Efficiency (CNE; a herd-based model) to improve N use efficiency (NUE) in dairy cattle farming. The first step involved training staff on the CNCPS feed fractionation scheme, chemical analysis of feedstuffs, and models use. The second step described the current situation at the farm level in specific areas in each country, namely Thessaly in Greece (GR), Emilia Romagna in Italy (IT), Catalonia in Spain (SP), and Wales in the United Kingdom (UK). An intensive outreach program was performed to describe the N status in 64 dairy farms (20 in GR, 20 in IT, 14 in UK and 10 in SP). Following farm sampling and management evaluation, data collected for each farm were inputted into the CNCPS to further evaluate dietary performance. Rations at the feeding group level were evaluated and studied to highlight their limitations in terms of NUE, that were discussed with the farmers and/or the nutritionists to inform on solutions to improve their diets. A third step included the implementation of the suggested changes that was at the discretion of the farmer. Farmer's acceptability was on average 20.5%. A significant improvement of milk nitrogen use efficiency (MNE = N in milk / N intake, %) from 30.0 to 34.0% was recorded. In conclusion, the CowficieNcy project developed a set of pilot farms with improved NUE and consequently decreased environmental impact. Furthermore, it revealed the importance of developing links between Universities and the dairy and feed industries to promote trust and increase farmers' acceptability to new strategies. This project received funding from the European Union's Horizon 2020 research and innovation program, under grant agreement No 777974.

Dairy heifers intake capacity: are estimated values still correct?J. Jurquet¹, Y. Le Cozler², D. Tremblais¹, F. Launay³ and L. Delaby²

¹Institut de l'Elevage, 149 rue de Bercy, 75595 Paris, France, ²INRAE, L'Institut Agro, UMR PEGASE, 16 le Clos, 35590 Saint Gilles, France, ³INRAE, Unité expérimentale du Pin, Borculo, Exmes, 61310 Gouffern en Auge, France; julien.jurquet@idele.fr

On-farm heifers feeding practices often challenge on-going recommendations, some advisors hypothesizing that equations developed in early 80's to predict heifers intake capacity (IC) are no longer suitable for current animals. Three complementary approaches were performed to test this hypothesis. First, a survey on 21 advisors in 2020 indicated that 16 of them considered that algorithms they were using adequately predicted heifers IC. These algorithms were based on information regarding body weight and ration composition, but advisors indicated that most farmers do not weigh heifers or analyse feed. In a second approach, feed intake from 58 groups of heifers, from 4 experimental farms, was analysed. The groups size averaged 15 heifers (± 7), weighing 400 (± 84) kg and aging 15 (± 3.5) months. The main forages used were corn silage, hay and wrapped haylage. Differences between predicted dry matter intake (DMI) and measured DMI was in average -0.3 kg, difference being less than 1 kg DMI/day in 2/3 of the cases. Finally, in a third trial, individual DMI were measured during autumns 2019 and 2020, on respectively 47 and 42 heifers of Holstein (n=54) and Normande (n=35) breeds, aged 17 months on average. They were fed *ad libitum* with grass silage in 2019 and hay in 2020. IC was evaluated thanks to the determination of fill value of forage, through the DMI of the heifers or from an alternative method using DMI measured on adult sheep fed *ad libitum*. IC was also determined thanks to the equation $IC = aBW^b$. The 'a' coefficient was adjusted in both approaches by setting the coefficient 'b' to 0.9, as previously recommended. In the first approach (heifers intake), 'a' value was similar to previous published results (0.03915, vs 0.03729 and 0.03749 for silage and hay, respectively). Similar results were observed in the second approach with the sheep intake and the forages fill value estimations. It was concluded that the intake prediction equation used since the 80's remains valid. The lack of heifers weighing and/or of knowledge of forages values probably resulted in wrong initial hypothesis.

Current status of feed nitrogen use efficiency in dairy replacement heifers in Greece

A. Plomaritou, M.E. Hanlon, K. Gatsas, S. Athanasiadis, K. Droumtsekas, D. Kantas and A. Foskolos

University of Thessaly, Department of Animal Science, Campus Gaiopolis, Larissa, 41222, Greece; anplomaritou@uth.gr

The aim of the study was to assess management conditions and define the current nitrogen use efficiency (NUE) status of dairy replacement heifers in Greece. Data were collected from 14 dairy farms in the region of Thessaly, Macedonia and Thrace. Information about the overall farm and heifer rearing management were obtained during a 2-day visit. Three data sets were developed on: (1) reproduction performance (RP), (2) growth performance (GP) and (3) ration evaluation (RE). For the RP data set, reproduction records of all cows and heifers of the herd were retrieved to determine time of first service (T1stSer), services/heifer and time of first calving (T1stCal). For the GP dataset, 15-20% of all heifers and cows were tape measured to estimate body weight (BW) and average daily gain (ADG) in different stages and mature BW (MBW) of cows in each herd. Growth targets based on farm's MBW were set as follows: (1) double birth weight at weaning, (2) 55% MBW at first service, (3) 85% MBW at calving (Target85) and (4) 95% MBW (Target95) at calving and the respective ADG targets for each growth stage were set. For the RE data set, a description of the total mixed ration was recorded and feed samples were collected and chemically analysed for nutrient composition. The rations were evaluated with the Cornell Net Carbohydrate and Protein System (v6.5). It was found that T1stSer and T1stCal was 15.4 (± 2.4) and 25.3 months (± 2.65), respectively and pregnancy was achieved with 1.54 services/heifer. Heifer BW at T1stSer and T1stCal was 437.1 kg and 692.8 kg, respectively that was within the targets of 55 and 85% of MBW (404 and 625 for T1stSer and T1stCal, respectively) but achieved with a delay of 1.3 months. In all farms, Metabolizable Energy (% of requirements) was the first limiting factor, while Metabolizable Protein was supplied above heifers' requirements and was progressively increasing along with heifers age ($P < 0.0001$). Regarding NUE, was higher in the period from 3 to 12 mo (on average 25.1%); and was decreasing as the growing period, from 15 to 24 mo) was progressing (on average 12.5%).

Session 52

Theatre 4

Impact of feed-grade and slow-release ureas on dairy cattle performance and nitrogen efficiencyM. Simoni¹, G. Fernandez-Turren², F. Righi¹, M. Rodríguez-Prado³ and S. Calsamiglia³

¹University of Parma, Department of Veterinary Science, Via del Taglio, 10, 43126 Parma, Italy, ²Universidad de la República, Departamento de Producción Animal y Salud de los Sistemas Productivos, Instituto de Producción Animal, Facultad de Veterinaria, Ruta 1 km 42, CP 80100 San José, Uruguay, ³Universitat Autònoma de Barcelona, Animal Nutrition and Welfare Service (SNIa), Departament de Ciència Animal i dels Aliments, 08193 Bellaterra, Spain; federico.righi@unipr.it

The aim of the present study was to assess the effects of feeding feed-grade urea (FGU) or slow release urea (SRU) as a replacement for true protein sources (control; CTR) in high-producing dairy cattle diets. The selected research papers (n=44) were published between 1971 and 2021 and included dairy breed, detailed description of the isonitrogenous diets fed, provision of FGU or SRU (or both), high-producing cows (>25 kg/cow/d), and milk yield as minimum output. Most of the studies compared only 2 treatments, thus a generalized linear mixed model network meta-analysis was employed to compare the effects among CTR, FGU, and SRU. Milk production was 32.9 ± 5.7 l/d with 1.18 ± 0.03 and 1.05 ± 0.02 kg/d of fat and protein while dry matter intake was 22.1 ± 3.45 kg. Average diet composition was $16.4 \pm 1.45\%$ CP, $30.8 \pm 5.91\%$ NDF, and $23.0 \pm 4.62\%$ starch. Average supply of FGU and SRU were 209 and 204 g/cow/d respectively. No differences were detected on performance. The SRU and FGU tended to reduce the MUN ($P=0.09$) and tended to reduce the 4% fat corrected milk ($P=0.10$), protein ($P=0.07$) and lactose ($P=0.06$) yield, probably for a lower energy intake in the 2 treatments. A further analysis was conducted on a subset of articles (n=7) reporting both CP intake and milk CP yield. No difference in milk nitrogen efficiency was found between treatments ($P=0.122$). Among the treatments the use of FGU is less expensive and can be justified. This project received funding from the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement no. 777974.

Current nitrogen status and management of dairy farms in GreeceM.E. Hanlon^{1,2}, A. Plomaritou², E. Tsiplakou¹, I. Vakondios², T. Michou², D. Kantas² and A. Foskolos²¹Agricultural University of Athens, Department of Animal Science, Iera Odos 75, 11855 Athens, Greece, ²University of Thessaly, Department of Animal Science, Campus Gaiopolis, Larissa, 41222, Greece; mikenziehanlon@gmail.com

Dairy farming plays a major role in nitrogen (N) emissions causing environmental impacts. Nitrogen emissions and losses can vary largely between farms due to differences in N management practices. Nutritional strategies can be developed to mitigate N losses; however, management and efficiency performance of farms must be determined prior. The objective of this study was to determine the current nitrogen status of dairy farms in Greece. Sixteen dairy farms (202±105 lactating cows, 690±25 kg of BW, 33±6 kg of milk yield, 23±3 kg of DMI) were sampled using a 2 d sampling period. Sampling consisted of a detailed description and collection of the total mixed ration (TMR) offer andorts, feed ingredients, milk yield and composition of each group and a farm questionnaire. To determine the nitrogen efficiency on an animal level, milk nitrogen use efficiency (MNE; milk nitrogen/nitrogen intake) was calculated. Each diet was further evaluated using the Cornell Net Protein and Carbohydrate system (CNCPS) to determine model predicted nitrogen performance. Offered TMRs on dairy farms had a Crude Protein (CP) ranging from 14 to 23% of DM (M=18; SD=3). Nitrogen intake ranged from 441 to 845 g/d (M=610; SD=111) and MNE from 25 to 34% (M=31; SD=3). Model evaluation suggested that the first limiting nutrient for 62% of farms was metabolizable energy. Moreover, rumen ammonia levels, as defined by the CNCPS, ranged from 104 to 319% requirements (M=153; SD=46), suggesting that in some cases CP was oversupplied loading the rumen with soluble N. For all the TMRs limited in metabolizable protein, rumen ammonia levels averaged 145±17%, oversupplying ruminal N. Thus, in Greek dairy farms, N is being oversupplied or accurate sources are not fed. Therefore, indicating potential to improve nitrogen efficiency.

Session 52

Theatre 6

Dairy cattle holistic nutritional management for reduced nitrogen pollution

A. Foskolos, A. Plomaritou, M.E. Hanlon and D. Kantas

University of Thessaly, Department of Animal Science, Campus Gaiopolis, Larissa, 41222, Greece; afoskolos@uth.gr

Nitrogen (N) pollution from agricultural activities has been a central social and scientific issue for at least the last three decades. Within the N cascade theory, there is a sequential transfer of reactive N through environmental systems, and particularly to the transformations of N that make it either to move from one system to another or to be stored within each system. For the European Union (EU) we calculated that: (1) the overall involvement of lactating dairy cattle in N consumption is 26.3% of total N directed to animal feed, and (2) approximately 10% of the virgin N entering into the EU ecosystem is deposited in cattle manure. Several strategies have been proposed to mitigate N pollution referring to the system, the herd or/and the animal. Within these strategies, nutrition has a key role at the animal and herd levels and it is mainly focused on improving milk N use efficiency (MNE = N in milk / N intake). Even though the theoretical maximum MNE is estimated at 40-43%, farm surveys around the world suggest that it is currently between 25 and 30%. To overcome this limitation at the farm level, we developed a Holistic Nutritional Management (HNM) scheme that includes: (1) dairy cattle group formation strategies based on farm's equipment and facilities, (2) diet formulation with sensitive to low crude protein diets systems, such as the Cornell Net Carbohydrate and Protein System, (3) on farm data collection protocols relative to model inputs, and (4) a feed preparation and delivery monitoring scheme to assure that the formulated diet is actually fed. First step evaluation of 20 dairy cattle farms in Greece suggested that current MNE is on average 30.4%, while crude protein overfeeding is in most cases overcame. However, this was done by limiting cows' productivity due to inadequacy of metabolizable protein intake and by supplementing sources of protein that the cow couldn't use efficiently. In a second set of five pilot farms, the HNM was implemented and resulted in MNE improvement (from 30.2 to 34.0%; $P=0.02$). In conclusion, an improved nutritional management as suggested by the HNM scheme may be applied in dairy farms to improve MNE and consequentially to reduce N excretion into the environment.

Manure management practices of dairy farms in Greece*L. Makridis, D. Vouzaras, D. Kantas and A. Foskolos**University of Thessaly, Department of Animal Science, Campus Gaiopolis, Larissa, 41222, Greece; leandros.makridis@gmail.com*

Manure management practices play a significant role in the environmental impact of dairy farming. Prior to developing key mitigation strategies, a detailed description of dairy farms and current practices must be identified. The objective of this study was to determine current manure management practices of dairy farms in Greece with the purpose of collecting the baseline information required for the development of further tools and evaluation methods. This study consisted of an on-farm questionnaire of 48 dairy farms describing herd size, bedding used, manure collection and storage type, land owned, manure treatment with anaerobic digestion (AD) and digestate usage for fertilization. Data collected was first categorized based on farm size (small = 0 to 100 lactating cows; medium = 101 to 200; large ≥ 201). Herd size of lactating cows averaged 67 ± 21 for small farms ($n=13$), 148 ± 30 for medium farms ($n=24$), and 335 ± 109 for large farms ($n=11$). The majority of all farms (81%, $n=48$) did not provide any bedding for the lactating cows and (82% $n=39$) of them used bedding only for the dry cows and heifers, creating the need for both liquid and solid manure handling and storage techniques. The farms with access to mechanical manure separator was 8% for small, 38% for medium and 64% for large. The data was then categorized based on availability of storage type to slurry, solid and a combination of both. The most common storage system was the combination of both with 62, 75, 91% followed by solid 23, 17, 0%, and slurry 15, 8, 9%, for small, medium, large farms, respectively. For land possession, 70, 86, and 73% of small, medium, and large farms, owned land for cultivation, while the hectares to number of lactating cows averaged, 0.40 ± 0.36 , 0.37 ± 0.45 , 0.17 ± 0.05 respectively. AD was used by 64% of all farms as a treatment method for manure, and only 33% of the farms utilized the digestate for land fertilization on their land.

Session 52

Theatre 8

peNDF modulates chewing activity, rumen fermentation, plasma metabolites, performance in dairy cow*Y.C. Cao, L.M. Wang and J.H. Yao**Northwest A&F University, Yangling, Shaanxi, 712100, China, P.R.; caoyangchun@126.com*

Subacute ruminal acidosis (SARA) continues to be a common and costly metabolic disorder in high-producing cows worldwide. In order to evaluate if increasing physically effective neutral detergent fiber (peNDF) in diet can prevent SARA in cows fed high concentrate diets. Thirty second-parity Holstein cows were randomly allocated to three treatment groups: H-peNDF8.0, M-peNDF8.0, and L-peNDF8.0, which were prepared by mixing the same total mixed ration for 10, 18, or 60 min, respectively. The peNDF8.0 intake was positively correlated with the peNDF8.0 contents in the diets. Total chewing and ruminating time was lower for the L-peNDF8.0 diet than for the H-peNDF8.0 and M-peNDF8.0 diets ($P < 0.05$). Rumen pH was higher in the H-peNDF8.0-fed cows than in the other two groups ($P < 0.05$). The H-peNDF8.0 and M-peNDF8.0 diets corresponded with higher acetate concentration, acetate:propionate ratio than the L-peNDF8.0 diet ($P < 0.05$), while H-peNDF8.0 and M-peNDF8.0 resulted in lower propionate and valerate concentrations than L-peNDF8.0 ($P < 0.05$). Lowering the peNDF8.0 content decreased the activities of ruminal carboxymethyl cellulase, avicelase, and β -glucanase ($P < 0.05$). H-peNDF8.0 resulted in lower total plasma antioxidant capacity, γ -glutamyl transpeptidase, albumin, and creatinine compared to M-peNDF8.0 and L-peNDF8.0 ($P < 0.05$). Somatic cell counts in milk were positively correlated with the dietary peNDF8.0 content. The feed and milk energy efficiencies were unaffected by the treatments. In conclusion, increasing the content of peNDF8.0 in diet could help alleviate SARA and improve animal health among early lactation cows fed a high concentrate diet by increasing peNDF8.0 intake, chewing activity, and rumen pH.

Impact on milk production of feeding organic acids during pre and post-partum periodL. Jansen¹ and C. Gordon²¹Nutreco, Selko, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands, ²Trouw Nutrition Canada, Dairy Technology and Application, 7504 McLean Rd E, Puslinch, ON N0B 2J0, Canada; lonneke.jansen@trouwnutrition.com

Organic acids have been used in dairy diets to stabilize ruminal pH, reduce methanogenesis, and stimulate ruminal bacterial growth and activity, which results in enhanced ruminant performance. The impact of a mixture of organic acids (MOA, Renergy, Selko) on milk production was tested in a trial with 4 groups of 18 cows. MOA was fed to a pre-partum group from day -21 until calving, to a post-partum group from calving until 28 days in milk (DIM) and continuously from -21 to 28 DIM, whereas 1 group served as controls. There was a significant ($P < 0.05$) increase of 5.3 kg of energy corrected milk as a result of feeding MOA continuously from -21 to 28 DIM. Feeding MOA in pre- or post-partum periods did not show a significant benefit in energy corrected milk yield. Treatment did not affect dry matter intake in the first 28 days in milk. Liveweight and body condition score were used to assess whether the additional milk was coming from cows losing more bodyweight or body-condition. Similarly, the milk fat and protein concentrations, together with somatic cell count were assessed, but no statistically significant differences were observed.

Peptide profile as fingerprinting of the ripening period of Alpine Asiago cheeseS. Segato¹, S. Khazzar¹, G. Galaverna², A. Caligiani², G. Riuzzi¹, L. Serva¹, F. Gottardo¹ and G. Cozzi¹¹Padova University, Dept. of Animal Medicine, Production and Health, Viale dell'Università, 16, 35020 Legnaro (PD), Italy,²Parma University, Dept of Food and Drug, Parco Area delle Scienze, 27/A, 43124 Parma, Italy; severino.segato@unipd.it

The biochemical cheese ripening process is characterized by an intensive microbial proteolytic activity on milk curd caseins (CN) originating a broad range of oligopeptides. The study was undertaken to evaluate the proteolysis process with the main goal of identifying a potential pool of oligopeptides to be used as molecular markers of cheese ripening time. Samples ($n=32$) of protected designation of origin (PDO) Asiago were manufactured with mountain raw bulk milk according to the rules defined by the European Community Regulation and then aged for 6 or 12 months (12 ± 2 °C, $82 \pm 4\%$ of relative humidity). The detection of peptides in the water-soluble extracts of cheese samples was carried out by a liquid chromatography/electrospray ionization mass spectrometry (LC-ESI-MS) analysis. The peptides were identified according to their molecular weight and significant fragment ions. All identified peptides were semi-quantified by comparison with a Phe-Phe internal standard as ratio between areas in the extract ion chromatogram. A total of 76 peptides were identified and most of them derived from the N-terminal or C-terminal part of α_{s1} -CN and β -CN, while only a small number from α_{s2} -CN and none from κ -CN. A principal component analysis showed that the most representative peptides were β -CN f(10-14), α_{s1} -CN f(17-21), β -CN f(8-14), α_{s1} -CN f(10-16) and α_{s1} -CN f(3-13) at 6-mo of ageing, and β -CN f(193-209), α_{s2} -CN f(189-207), α_{s1} -CN f(6-28) and α_{s2} -CN f(183-207) at 12-mo. The outcomes of this research confirmed that the peptides profile could be a useful molecular benchmark to discriminate cheeses according to their ageing time.

Producing sustainable milk in agroecology with Normande breed and grassland in NormandyB. Rouillé¹, F. Lepeltier² and L. Morin²¹Institut de l'Élevage, 149 rue de Bercy, 75595 Paris, France, ²Association de la ferme expérimentale de La Blanche Maison, La Blanche Maison, 50880 Pont-Hébert, France; benoit.rouille@idele.fr

Normandy is an important cattle breeding region in western France. It ranks second among French regions with 17% of dairy cows. Its territory is largely covered with meadows and is therefore valued primarily by ruminants. La Blanche Maison experimental farm is located in the heart of this territory with an annual rainfall of approximately 1,100 mm. A dairy system, based on the principles of agroecology, was studied for 5 years (2017 to 2021). The system is built with 90 dairy cows of the Normande breed and an area of 97 hectares dedicated solely to fodder production for the herd. A specificity of the system is the conduct of reproduction in 4 periods of artificial insemination of 6 weeks each (one every three months) to rationalize the labour demand. The ambition of the research program was to improve the production system on three major axes: (1) zootechnics by increasing the delivery of milk from the farm with a constant number of cows; (2) the environment by reducing the footprint carbon of the milk produced; and (3) labour and the economy by improving income and work organization for farmers. Over the 5 years of the study, milk production increased by 1,500 kg of milk/cow/year, in particular by improving feed strategy with better grazing management, better quality for harvested fodder and an additional supply of concentrates. This also led to improve milk composition in fat and protein. On the environment, the efficiency of the use of nitrogen in the system has increased from 39 to 46%. At the same time, the carbon footprint calculated with CAP2ER® has decreased by 12% in 5 years. Finally, the cost of milk production went down from €653/1,000 l to €524/1,000 l, thus improving the economic performance of the farm. The system has therefore evolved favourably on zootechnics, the environment and the economy, thanks to simple levers accessible to breeders.

Session 52

Theatre 12

Hepatic metabolome of grazing dairy cows with or without feed restriction during early lactation

M. Carriquiry, M. García-Roche, A.L. Astessiano, D. Custodio, G. Ortega and P. Chilbroste

Facultad de Agronomía, UdelaR, Department of Animal Sciences and Pastures, Ave. Garzón 780, 12400, Uruguay; mcarriquiry@fagro.edu.uy

Six multiparous early lactation (29±10 days in milk (DIM)) Holstein cows (477±73 kg body weight and 2.75±0.16 body condition score (BCS) units) were selected to assess the effect of a five-day feed restriction on the hepatic metabolome. From 29 to 38 DIM cows went through an adaptation period where they were *ad libitum* fed (36.5 kg/DM/cow/d pasture allowance and 5.3 kg/DM/cow/d of an energy concentrate), from 38 to 43 DIM cows were fed restricted (16.5 kg/DM/cow/d pasture allowance and 2.6 kg/DM/cow/d of an energy concentrate) and from 43 to 54 DIM cows went through a flushing period when they were again *ad libitum* fed. Milk yield was recorded daily and milk composition was analysed twice during every period while liver biopsies were collected at the end of every period. Milk yield and components were analysed using a model with period as a fixed effect and metabolomic data analysis including Partial Least Squares Discriminant Analysis (PLS-DA) and Metabolite Set Enrichment Analysis (MSEA) was done using Metaboanalyst 5.0. Energy corrected milk yield was lower during the feed restriction than the adaptation or flushing periods (27.1 vs 33.4 and 33.7±1.9 kg/d, $P<0.01$). The PLS-DA model showed that the periods that differed the most were the feed restriction and flushing periods as components 1 and 2 accounted for 47% of the variation. The PLS-DA model plots showed there were 28 metabolites with Variable of Importance Projection scores >1.2. Differentially abundant metabolites were determined using a volcano plot with fold change >1.5 and $P<0.01$, relative concentrations of beta-hydroxybutyrate, D-glucose-1-phosphate and ribose were higher while relative concentration of malate was lower during the restriction period. Results of MSEA showed that the tricarboxylic acid (TCA) cycle was differently expressed (false discovery rate (FDR) adjusted $P<0.05$) and one-way ANOVA identified that only malate had FDR<0.05. Our results suggest that feed restriction changed the availability of TCA cycle intermediates in the hepatocyte and non-intake energy precursors such as beta-hydroxybutyrate and D-glucose-1-phosphate were used.

Nitrogen balance of lactating cows from herds fed hay-based diets in Northern ItalyT. Danese¹, M. Simoni¹, R.G. Pitino¹, G. Mantovani¹, M.C. Sabetti¹, F. Righi¹ and M.E. Van Amburgh²¹University of Parma, Veterinary Science, Strada del Taglio 10, 43126, Italy, ²Cornell University, College of Agricultural and Life Science, Morrison Hall, 14850, NY, USA; tommaso.danese@unipr.it

The aim of this study was to measure nitrogen balance (NB) of Holstein dairy herds fed hay-based diets in Northern Italy. For this purpose, 20 dairy herds (60-367 animals, 34±3 kg MY, 26±1.7 kg DMI, 678±33 kg BW), located in Emilia Romagna's Parmigiano cheese region and fed a total mixed ration (TMR), were involved in this study. Group feed intakes were measured twice a day, and representative TMRs and bulk milk samples were collected, while individual samples of faeces and urine were collected from 10% of the lactating cows. TMRs and faeces were analysed to determine the following parameters: DM, N, aNDFom, ADFom, NDIN and ADIN. Undigested NDF was determined at 240 h *in vitro* fermentation and used as a marker to estimate total faecal output. Urine samples were collected by perineal massage from the same cows as faecal sampling and acidified to obtain a pH 2, pooled per TMR group and then analysed for creatinine content, employed as marker to calculate the total urine output. Faecal, urine and bulk milk samples were analysed for N content. Milk nitrogen, urine nitrogen, and faecal nitrogen outputs ranged between 147 and 211 g/d (mean 180±14), 191 and 423 g/d (mean 272±57), 128 and 422 g/d (mean 235±64) respectively, while nitrogen intake resulted in the interval between 448 and 768 g/d (mean 627±72). Therefore, NB was on average -60±93 g/d. Overall, NB appears to be consistent with ranges reported in literature but shows a wider variability, probably related to the type and quality of the forage employed. The negative values of NB are likely due to partial collection of faeces and urine and the reliance on markers to estimate total excretion as the negative value is within the standard deviation of the measurement and spans zero however the high end of the excretion for urine and faeces is high compared to literature values. Thus, the cattle are likely excreting excess nitrogen, and this approach was not sensitive to those differences. This project has received funding from the European Union's Horizon 2020 research and innovation program, under grant agreement No 777974.

Theatre 14

Assessing sward managements on nitrogen fixation from a white clover high sugar grass mixtureM. Verbeeck^{1,2}, C. Segura², A. Louro-Lopez², N. Loick², P. De-Meo-Filho², S. Pulley², J. Hood², B.A. Griffith², L.M. Cardenas² and D. Enriquez-Hidalgo^{2,3}¹Soil Service of Belgium, Willem De Croylaan 48, 3001 Heverlee, Belgium, ²Rothamsted Research, Net zero and resilient farming, EX20 2SB North Wyke, United Kingdom, ³University of Bristol, Bristol Veterinary School, BS405DU Langford, United Kingdom; daniel.enriquez@bristol.ac.uk

Biological nitrogen fixation (BNF) in mixed swards can be reduced by poor management or unfavourable soil conditions. In this study, the BNF of a grass-white clover pasture was examined under set-stocking conditions with different grazing management. A split-plot block experiment was run at the North Wyke Farm Platform. Plot treatments were: (1) grazing in unfenced plots; (2) pasture for silage; and (3) simulated grazing, the latter two in fenced plots. The split-plot treatments were either or not application of 14 ton/ha of farmyard manure (FYM). Three replicate blocks were with ewes and lambs grazing from April until October, the other three blocks with pasture reserved for silage production with a cut in June, afterwards cattle grazed from July until October. Samples were taken monthly to assess herbage production, species composition and BNF (assessed with the ¹⁵N natural abundance method). The herbage was analysed for macro- and micronutrients in July. The herbage production ranged between 4-10 ton dry matter (DM)/ha, higher in the silage compared to the grazed and simulated grazing treatments (9.1 vs 6.5-6.1 ton DM/ha). The clover content in the herbage ranged from a few percentages to 40% (DM basis), was lower in the grazing treatments than in the other treatments (10 vs 17-18% DM). The estimated %N derived from the atmosphere (%Ndfa) ranged between 84-93%, but was not determined by management or FYM addition. The BNF ranged between 7-76 kg N/ha, was higher in the silage treatments compared to the other treatments (52 vs 32-23 kg N/ha). The BNF was strongly determined by herbage production ($p=0.72$) and clover content ($p=0.68$) but not by the %Ndfa. The FYM addition had a positive effect on the mineral N concentration in the soil and on the K and Mo concentration in the herbage, however the FYM at the tested rate did not affect the BNF nor the herbage mass of the white clover-grass pasture under set-stocking conditions.

Amino acid intake of hay-based diets and the relationship with milk production and urea contentM. Simoni¹, R. Pitino¹, T. Danese¹, G. Mantovani¹, E. Tsiplakou² and F. Righi¹¹University of Parma, Department of Veterinary Science, Strada del taglio, 10, Parma, 43126, Italy, ²Agricultural University of Athens, Laboratory of Nutritional Physiology and Feeding, Department of Animal Science, School of Animal Bi, Iera Odos, 75, Athens, 11855, Greece; giorgia.mantovani@unipr.it

This study aimed at evaluating the effects of amino acid intake (dAA) of Holstein dairy herds' hay-based diets on milk yield (MY) and composition. A total of 20 dairy herds located in the Parmigiano-Reggiano area were involved in the trial (185±89 cows; 678±33 kg BW). The diets were collected in 2 consecutive d, their composition and AA profile was determined. At the same time, dry matter intake (DMI) and MY were measured and 2 bulk milk samples were collected every 12 h during the 2nd monitoring day. The diets were on average 15.1±0.7% CP, 38.1±3.3% NDF and 21.8±2.2% starch (DM basis). The dAA were determined after acid hydrolysis, except for sulphur AA which were pre-oxidized with performic acid. Barium hydroxide was used for Trp. The procedure was optimized for sample homogenization and substrate to solvent ratio. Samples were analysed by RP-UPLC/ESI-MS in the SIR scan mode. The AA content was estimated using the internal standard method (Trp), and an external calibration curve (all other AA). Casein, fat and urea yield (CY, FY, UY) were determined by MilkoscanTM, milk total protein yield (CPY) was determined by Dumatherm. Correlations were tested between dAA and milk composition parameters using SPSS v.28. The CPY was related to Ala, Val, Thr, Ile, Leu, Asp, Glu, Arg (g/d; $r=0.60$, $r=0.47$, $r=0.44$, $r=0.59$, $r=0.47$, $r=0.50$, $r=0.51$, $r=0.62$, $P<0.05$); ECM to Pro, Glu, Arg and Met (g/d, $r=0.45$, $r=0.49$, $r=0.46$, $r=0.52$, $P<0.05$). The milk nitrogen efficiency was correlated with Val intake (g/d, $r=-0.47$, $P=0.04$). The FY was correlated with Pro, Ile, Leu, Glu, Arg, Met, Trp (g/d, $r=0.47$, $r=0.50$, $r=0.48$, $r=0.54$, $r=0.46$, $r=0.59$, $r=0.50$, $P<0.05$). The UY was found to be affected only by Arg (g/d, $r=0.47$, $P=0.03$). This project received funding from the European Union's Horizon 2020 research and innovation program, under grant agreement No 777974.

Poster 16

Does acidification affect urinary creatinine in dairy cattle?

T. Danese, M.C. Sabetti, M. Simoni, R.G. Pitino, G. Mantovani and F. Righi

Università di Parma, Dipartimento di Scienze Medico-Veterinarie, Strada del taglio 10, 43126, Italy; tommaso.danese@unipr.it

Creatinine is a marker commonly employed to quantify the amount of urine produced by dairy cattle. Combined with urine nitrogen content, the latter allows to measure the urinary nitrogen excretion which is needed when nitrogen balance must be calculated. However, when urine is sampled, a quota of ammonia nitrogen tends to volatilize potentially leading to an underestimation of the content of this element. This issue is normally prevented by sample acidification with sulphuric acid which, along with diluting the sample, could chemically alter the creatinine content, leading to bias in N excretion quantification. The objective of this trial was to evaluate the impact of urinary samples acidification on creatinine concentration and analytical detection in dairy cattle urine. A total of 60 urine samples were collected from lactating dairy cows and randomly divided in three groups (n=20), and immediately treated through acidification with H₂SO₄ to obtain pH<2 (group 1), addition of the same volume of distilled water to analyse the dilution effect (group 2) or stored without acid nor water (group 3). Creatinine analyses were conducted with the Jaffe colorimetric method. Kruskal-Wallis test was used to compare urine groups for treatments ($P<0.05$). Bland-Altman's test was used to analyse inter-assay agreement between measurements (group 1 vs group 3). Results show that urinary creatinine it is not statistically different between groups 1 (median 48.5 mg/dl; range 36.9-83.0), group 2 (median 47.5 mg/dl; range 36.5-80.7) and group 3 (median 48.9 mg/dl, range 37.2-84) (overall $P=0.7$). Bland-Altman's analysis showed agreement between the standard method (group 3) and the experimental method (group 1). The measurement of urinary creatinine by Jaffe method is not influenced by sample acidification; therefore, the use of creatinine as a marker for total urine output is still to consider viable under acidification of the samples. This project has received funding from the European Union's Horizon 2020 research and innovation programme, under the grant agreement No 777974.

Effect of an alternative to sodium bicarbonate on performance of dairy cows

V. Leroux, C. Jaffres, A. Budan and N. Rollet

Neolait, Cargill Animal Nutrition, Voie de la ville Louze, 22120 Yffiniac, France; noemie_rollet@cargill.com

Adding sodium bicarbonate (SB) to the diet of dairy cows is a common practice to prevent digestive disorders induced by diets dense in fermentable energy. Acidomix (AC) is a blend of mineral ingredients that have shown to increase rumen pH *in vitro* from 6 to 24 h compared to sodium bicarbonate in a 1:1.5 ratio. A trial was conducted to evaluate the effect of AC compared to SB in 1:1 and 1:1.5 ratios on the performance of dairy cows fed with a diet based on corn silage containing 47.7% fermentable energy. Compared to SB in a 1:1 ratio, AC decreased milk protein (-0.02%, $P<0.01$), improved body condition score (+0.40 during 45 days, $P<0.01$) and margin over feed cost (+0.06€/c/d, $P=0.05$). In a 1:1.5 ratio, milk fat was increased (+0.23%, $P=0.02$) with AC. Dung pH was higher for AC compared to SB with the 1:1 ratio (+0.08, $P<0.01$) and with the 1:1.5 ratio (+0.09, $P<0.01$). These results suggest that compared to BC, AC is a better economical solution with a 1:1 ratio and increase milk fat with a 1:1.5 ratio.

Evaluation of three measuring methods for the ammonia concentration for practical use in pig housesJ. Witt¹, J. Krieter¹, K. Schröder¹ and I. Czzycholl²

¹Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany, ²Department of Veterinary and Animal Sciences, University of Copenhagen, Grønnegårdsvej 15, 1870 Frederiksberg C, Denmark; jwitt@tierzucht.uni-kiel.de

Ammonia negatively affects pig health and productivity. A value of 20 ppm should therefore not be exceeded. Thus, a simple and reliable control of the ammonia concentration (AC) is necessary. This study examines the use of two hand-held measuring devices, the ammonia meter 'basic ammonia meter' (AM) and the 'Dräger accuro®' gas detection pump (DA) as an alternative to the continuously measuring sensor 'DOL53 Ammonia Meter' (DOL) and the factors that influence these measuring methods. The AC on three different farms (farm 1: organic; farm 2,3: conventional) over three to four batches from farrowing to the end of fattening were measured weekly with the AM ($n=284$) and the DA ($n=142$). In addition, the DOL ($n=77,170$) measured the AC every 15 minutes and showed the daily course of the AC. The influence of the farm, which was investigated with the use of a linear mixed model, on the AC was significant ($P\leq 0.05$) for all three measurement methods. The freely ventilated farm 1 showed the lowest AC (mean DOL 0.69 ppm), which could be caused by a lower animal density and lower stable temperatures compared to the mechanically ventilated farms 2 (mean DOL 12.4 ppm) and 3 (mean DOL 10.6 ppm). The season was a further significantly ($P\leq 0.05$) influencing factor for the mechanically ventilated farms 2 and 3, which is reflected in higher AC in the winter compared to the summer months. This could be due to a lower ventilation rate, due to the lower outdoor temperatures in winter. The DOL was also influenced by the barn, higher AC were measured as the production stage of the pigs progressed, with highest values in the fattening barn (farm 2 up to 60.8 ppm, farm 3 up to 58.5 ppm). Moreover, the DOL showed an increase of AC by feeding and activity phases of the pigs. The comparison of the AM and DA with the DOL did not achieve acceptable or good agreements (limits of agreement $>5\%$ or 10% difference, respectively). It can therefore be concluded that the hand-held meters cannot replace the sensor under practical conditions.

The information and communication technologies in livestock production – expectations and concerns

S. Opalinski¹, K. Olejnik¹, E. Popiela¹, A. Jankowska-Makosa², D. Konkol³, M. Korczynski³, D. Knecht², R. Kupczynski¹, I. Tikasz⁴ and T. Banhazi⁵

¹Wrocław University of Environmental and Life Sciences, Department of Environmental Hygiene and Animal Welfare, Chelmonskiego 38C, 51-630, Poland, ²Wrocław University of Environmental and Life Sciences, Institute of Animal Husbandry and Breeding, Chelmonskiego 38C, 51-630 Wrocław, Poland, ³Wrocław University of Environmental and Life Sciences, Department of Animal Nutrition and Feed Management, Chelmonskiego 38C, 51-630 Wrocław, Poland, ⁴Institute of Agricultural Economics Nonprofit Kft., Zsil u. 3-5, 1093, Budapest, Hungary, ⁵AgHiTech LTD, Budapest, Hungary; sebastian.opalinski@upwr.edu.pl

The use of digital innovations in the animal production sector enables the prediction of animal diseases in advance (animal welfare improvement), optimises production processes, develops the environmental sustainability of farms, and reduces the need for manual labour. Despite all these positive aspects resulting from implementing information and communication technologies (ICT) in livestock production, farmers are not open to new technologies. The main goal of the LivestockSense project was to identify the barriers to introducing modern technologies and to support farmers through education and mentoring. The focus group discussion (FGD) with the representatives related to the pig and poultry sector (scientists, policymakers, technology providers, ICT developers and farmers) has been used to identify critical characteristics of farmers' attitudes towards ICT tools. Participants of the FGD stated that ICT tools are a time and money-saving solution, enabling production optimisation and filling staff shortages. These are the main motivations and purposes for using smart technologies. However, the main barriers to ICT adoption were the high financial risk, especially for small farms. Among solutions that might motivate the spread of ICT tools, the most frequently mentioned were subsidies on the cost of installation and maintenance, governmental support programs, pressure from the side of food contractors (fast food chains or supermarkets) and demonstration farms. Research was funded by the National Centre for Research and Development (NCBR), no. ICTAGRIFOOD/I/LIVESTOCKSENSE/01/21, within the EU's Horizon 2020, No 862665 ERA-NET ICT-AGRI-FOOD.

Implementation of a deep learning based system for monitoring farrowing in sows

M. Wutke¹, C. Lensches¹, A. Holzhauser¹, M.A. Lieboldt² and I. Traulsen¹

¹Georg-August University Göttingen, Animal Sciences, Albrecht-Thaer-Weg 3, 37075 Göttingen, Germany, ²Chamber of Agriculture Lower Saxony, Division Agriculture, Mars-la-Tour-Straße 6, 26121 Oldenburg, Germany; martin.wutke@uni-goettingen.de

Monitoring the farrowing process plays an important role in pig production systems, as complications during parturition pose a potential risk to the sow's health status as well as to the newborn piglets. In this study, we propose a system using computer vision and deep learning techniques to monitor the farrowing process in temporarily crated and free farrowing sows. By first determining the sow's orientation and a potential maternity area, the times of birth can then be determined by detecting newborn piglets in the target area. In addition, by analysing the locomotion behaviour of the detected piglets, an early assessment of their respected health status can be computed. We evaluated the performance of our framework using a two-stage approach and two distinct test sets for the detection of target objects and the subsequent identification of critical events during farrowing. As a result, we achieved a Precision, Recall and MAP score of 0.982, 0.989 and 0.993, respectively, for our object detection model and an Accuracy, Recall and Precision score of 0.9, 0.8 and 1, respectively, for the corresponding determination of important events. The findings of this study demonstrate the potential of artificial intelligence systems and computer vision techniques as a useful addition to the farm management process and could contribute to animal welfare through the early identification of critical situations during farrowing.

Who's biting? Detecting pig screams for identifying tail biting events

P. Heseke^{1,2}, T. Bergmann³, M. Scheumann³, S. Ammer¹, I. Traulsen¹, N. Kemper² and J. Probst²

¹Georg-August-University Göttingen, Department of Animal Sciences, Livestock Systems, Albrecht-Thaer-Weg 3, 37075 Göttingen, Germany, ²University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTN), Bischofsholer Damm 15, 30173 Hannover, Germany, ³University of Veterinary Medicine Hannover, Foundation, Institute for Zoology, Bünteweg 17, 30559 Hannover, Germany; philipp.heseke@uni-goettingen.de

Early identification of tail biting and intervention are necessary to reduce tail lesions and its impact on animal health and welfare. Removal of biters has become an effective intervention strategy, but finding them can be difficult and time-consuming. The aim of this pilot study was to investigate if tail biting could be identified by detecting pig screams. The study included 288 undocked weaner pigs that were housed in six pens in two batches. Pigs had coloured ear-tags and each pen was equipped with a video camera and a microphone. Individual tail examinations were carried out biweekly. Once a tail biter (n=7) was identified and removed by the farm staff, the previous days of video recordings were analysed for pig screams (sudden increase in loudness with frequencies from 1 to 4 kHz) and tail biting events until no biting was observed. In total 2,846 screams were detected in four tail biting pens, from which 53.6% were caused by tail biting, 24.9% originated from other pens, 8.7% were not assignable and 12.8% occurred due to other pig manipulation. Biters were identified between 1 and 9 days prior to their removal from the pen. Tail lesions decreased up to 52.3% one week after removal. Detecting pig screams has the potential for identifying tail biting events. Earlier removal of biters is possible and can reduce tail lesions and thus increase animal health and welfare. Possibilities of an automatic evaluation will be analysed in the next steps. The study is part of the project DigiSchwein, which is supported by funds of the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany. The Federal Office for Agriculture and Food (BLE) provides coordinating support for digitalisation in agriculture as funding organisation, grant number 28DE109E18 and 28DE109F18.

Session 53

Theatre 5

Veterinarians' perceptions of using PLF technologies in pig husbandry in the Netherlands and Germany

M.F. Giersberg and F.L.B. Meijboom

Utrecht University, Veterinary Medicine, Yalelaan 2, 3584 CM Utrecht, the Netherlands; m.f.giersberg@uu.nl

As important players in livestock production, veterinarians are confronted with emerging technologies in the field, such as precision livestock farming (PLF). PLF allows for automated monitoring of animals and related environmental processes on commercial farms. Despite their potential for improving animal health and welfare, these technologies may attract public criticism, for instance through substituting human care and transforming the human-animal relationship. The aim of this study is to make sense of how veterinarians perceive the use of PLF in the context of current pig production. Therefore, semi-structured interviews were carried out with pig veterinarians located in the Netherlands and Germany. The interview data were analysed by using an inductive and semantic approach to reflexive thematic analysis. Based on the developed themes, we draw the following main conclusions: (1) Veterinarians agree on broad concepts, such as defining their own role as advisory and framing PLF technologies as supporting tools. What these concepts entail in detail, however, varies within the group of pig veterinarians. (2) The veterinarians' elaborations on relationships among different stakeholders, including themselves, show that they share positions with different groups of society. They are aware of and reflect on competing interests of these groups. (3) Some veterinarians see the development and provision of PLF as part of their professional activities. This demonstrates that they play an active role in the emerging field of sensor technologies in pig production. (4) The veterinarians also have a clear idea of the chances and challenges PLF may pose. The use of PLF technologies in pig husbandry must not ignore the present distance between agriculture and society. According to the veterinarians, PLF should not reinforce the misconceptions resulting from this distance. Applying PLF to improve pig welfare, a topic in which part of society is interested, is seen as a starting point to reconcile the sector and the public. However, external obstacles, such as financial dependencies, may prevent veterinarians to take an active stance in this process in practice.

Automatic detection and quantification of ear biting in pigsA. Odo¹, R. Muns², L. Boyle³ and I. Kyriazakis¹¹Institute for Global Food Security, School of Biological Sciences, Queen's University Belfast, 19 Chlorine Gardens, BT9 5DL, United Kingdom, ²Agri-Food and Biosciences Institute, 18a Newforge Ln, Belfast, BT9 5PX, United Kingdom,³Teagasc, Teagasc, Animal & Grassland Research Centre, Moorepark, Fermoy, Co. Cork, P61 C996, Ireland; a.odo@qub.ac.uk

Ear biting is considered a main risk factor for ear necrosis, a growing and highly prevalent problem in weaned pigs associated with health and welfare challenge, and poor performance in pig production systems. We aimed to develop an automated method for the quantification of ear biting. We collected data samples comprising videos from two farms (experimental and commercial) with diverse management and monitoring settings. The data samples were from different pens and at various times of the day to ensure good representation of pen conditions and scenarios. Video frames with ear biting events were manually annotated. Behaviours targeting the ear of pen mates (gentle manipulation, quick bites, ear pulling, and chewing) were labelled as ear biting. We defined the region of interest using a bounding box that overlay the heads of the interacting pigs. The size of the bounding boxes varied as the orientation of the biter and bitten pig change. We used a deep learning-based object detection network (YOLOv4) to localize these regions and track them over multiple frames. Multiple objects trackers namely the Centroid and DeepSORT associate detected instances to event episodes. The association of events enabled the computation of frequency and duration of ear biting outbreaks. YOLOv4 detected ear biting at average precision (AP@0.5) of 0.98 and 0.86 on the respective datasets, and 0.92 on the combined dataset. Results showed that automated detection and tracking of ear biting was possible. There are 2,113 events on the test set. The Centroid tracker identified 2,040 events but also resulted in higher false-alarm rate of 34% compared to the DeepSORT-based system (14%). Our method quantified ear biting at group-level which means that frequency and duration of ear biting was not considered for individual performer. Identifying individual biter will facilitate fine-grained intervention such as isolation of the offender. We consider this as the first step in the development of an on-farm early warning system for ear biting detection.

Installation modified carbon felt in pig house to control airborne pathogenic microorganisms

X.D. Zhao, F. Qi, H. Li and Z.X. Shi

China Agricultural University, College of Water Resources & Civil Engineering, No.17, Tsinghua East Road, Haidian District, 100083, Beijing, China, P.R.; zhaoxd723@cau.edu.cn

The pathogenic microorganisms in the air have a significant impact on pig health and even biosecurity of pig industry. Carbon material shows great potential in microbial adsorption to reduce the misuse of chemical disinfectants in pig houses. Herein, modified carbon felt was selected for installation in pig houses to control the levels of airborne microorganisms. The distribution law and initial level of air microorganisms in the pig house were determined first, and carbon felts were placed in the areas with high microbial levels in different ways. High-throughput pyrosequencing of the 16S rRNA was used to detect bacterial composition in the pig house before and after the work of carbon felts. The results show that the modified carbon felt was competent to adsorb several pathogenic bacteria commonly found in pig farms, such as *Escherichia coli*, *Staphylococcus aureus*, *Salmonella cholerae*, and *Clostridium perfringens*. It can also achieve a 90.2% removal of mixed flora. The control efficiency to air microorganisms was higher at 2×2 m coverage area per carbon felt in the pens. Specifically, the relative abundance of *Enterobacteriaceae*, *Streptococcaceae*, and other pathogenic bacteria showed a progressively decreasing trend over 18 d. This study provides a promising strategy to control air microorganisms based on modified carbon felt, thus enhancing biosafety and animal welfare in pig farms.

Benefit of caliper use at insemination on different genetic types: impact on farrowing performances

C. Teixeira Costa, C. Chevanne, T. Nicolazo, G. Boulbria, V. Normand, J. Jeusselin and A. Lebrez
 Rezoolution, ZA De Goheleve, 56920 Noyal-Pontivy, France; t.nicolazo@rezoolution.fr

Backfat thickness (BFT) is widely measured and used to adapt the feed ration of sows during gestation to increase the sustainability of pig production and optimize performances. Recently, a tool called Sow Caliper (SC) was developed to assess the physical structure of sows. The aim of this study was to evaluate the interest of the SC to classify the sows according to their body condition to optimize performances and reduce worktime. The SC was tested on six farms of different genetic types (mean of 284 sows per farm). Five categories (C1 to C5) were used to classify the 1,701 measurements realized at insemination. In parallel, BFT of the same sows was measured with an ultrasonic tool (Renco Lean-Meater®). To determine an optimal category of SC measurement, all farrowing performances were collected. Category means were compared for each genetic type. Correlation coefficients between the measurements with the SC and the BFT were calculated by Spearman test correlation and the effects of the SC category on the farrowing performances by litter rank were tested by analysing the variance otherwise using a non-parametric test (R Studio). The SC measurements were positively correlated with BFT, especially for sows of parity 3 or more ($r=0.65$, $P<0.001$). The correlation was weaker for parity 1 and 2 ($r=0.41$, $P<0.001$). Based on performances at next farrowing, category C3 was considered as ideal for sows of parity 3 or more (on average, approximatively +0.5 total born and -0.13 stillborn than other categories). On the opposite, category C4 was optimal for gilts and to a lesser extent for sows of parity 2, depending on the genetic type (for example, for gilts +0.5 total born). For gilts, SC measurement was a better predictor of farrowing performances than BFT alone. According to these results, under certain conditions, SC measurements at insemination can replace BFT particularly for older sows. However, especially for gilts, combining SC and BFT measurements seems more appropriate.

Vaccination is one of the most effective strategies for preventing infectious diseases. However, most vaccines vary in their efficacy. Our objective was to investigate the effect of genetic background, caecal microbiota and housing on vaccine responses and on welfare. We studied a cohort of 400 animals from 2 commercial laying hen lines from the Novogen breeding company: Rhode Island Red (RIR) and White Leghorn (LEG). To study the impact of the microbiota, we modified its composition by giving hens a cocktail of three antibiotics. To study the housing, half of the animals had an access to an outdoor yard from 12 weeks to the end of the experiment while the others not. The vaccine responses were monitored by an indirect ELISA test for 3 vaccines and by hemagglutination inhibition assays for one of them. The behaviour was studied by group evaluation (image analysis and EBENE® method), individual behavioural evaluations and RFID tagging to record animal exits. The caecal microbiota (16S rRNA gene sequences) was performed at the end of the experiment and on subsets of animal batches at 4 time points to study microbiota dynamics through time. For all the vaccines tested, RIR harboured higher antibody levels compared to LEG with a longer persistence. Microbiota perturbation and rearing conditions also moderately altered vaccine responses. Behaviours differed according to the line: LEG individuals were more exploratory and expressed more resting behaviours, whereas RIR individuals expressed more behaviours related to fear and vigilance. The microbiota perturbation also affected the exploratory behaviour, and differently according to the line. These results confirm the triple impact of genetics, microbiota and rearing environment on the vaccine responses and the hen behaviour.

Using triaxial accelerometers to monitor peripartum behaviour of Purebred Spanish mares

M.J. García García, F. Maroto Molina, C.C. Pérez Marín and D.C. Pérez Marín

Universidad de Córdoba, Department of Animal Production, Campus de Rabanales. Ctra. Madrid-Cádiz km. 396, 14071 Córdoba, Spain; g42gagam@uco.es

Behavioural monitoring can provide relevant information on horse health and welfare, as well as on the occurrence of events of interest, such as foaling or oestrus. Direct observation of animal behaviour requires lots of time and effort and often involves subjective decisions. The use of accelerometers to monitor behaviour limits the influence of human presence and makes it possible to record unusual behaviours that would otherwise be difficult to observe. But reliable classification models are needed to convert raw acceleration data into meaningful behaviour classifications. The aim of this study was to develop algorithms able to automatically monitor mare behaviour from acceleration data. Tri-axial accelerometer collars gathering data at 10 Hz were used on 9 Purebred Spanish mares around foaling. Video recordings and BORIS software were used to tag mare behaviour as: 'standing-head down', 'standing-head up', 'lying on belly' and 'lying on side'. Data were processed and analysed using the statistical software R and the package rabc. A total of 26 features were calculated from acceleration data, which were divided into 20-second fragments. A combination of filtering and wrapping methods was used to select the best subset of features. Finally, an XGBoost supervised machine learning model was trained with the selected features. The best subset of features was: mean acceleration on the X axis, mean of absolute values on the Y axis, mean angle on the Y axis, maximum acceleration on the Y axis, variance on the Z axis, variance on the Y axis and standard deviation on the X axis, with XYZ being the longitudinal, transverse, and perpendicular axes to the neck of the mare. The classification model obtained presented an overall accuracy of 82.7%. In terms of class statistics, the model obtained a F1 score of 0.86 for standing-head down, 0.82 for standing-head up, 0.76 for lying on belly and 0.94 for lying on side. The model obtained was able to classify mare behaviour appropriately and may be used to detect behavioural changes around reproductive events, such as foaling.

Session 53

Theatre 11

Relationships between direct and indirect genetic effects of RFI and feeding behaviour traits

M. Piles, M. Mora, M. Pascual and J.P. Sánchez

IRTA, Torre Marimon, Caldes de Montbui, Barcelona, 08140, Spain; miriam.piles@irta.cat

Records from electronic feeders (EF) allow for the definition of new phenotypes that can be used to improve the response to selection for feed efficiency, as well as the behaviour of the animals in the group towards less competitive/aggressive animals. By fitting a set of two-traits social animal models to residual feed intake (RFI) and one feeding behaviour trait (FB) we aimed at identifying: (1) FB traits whose direct genetic effects (d) are genetically associated with d of RFI and can be used to improve the prediction of genetic evaluations for this trait; (2) FB traits whose d are related to the indirect genetic effects (s) of RFI and therefore can be considered as part of the mechanisms involved in the effects that an animal exerts on the RFI of its group mates. Data came from 1,086 rabbits of a line selected for growth rate under feed restriction at fattening (35 to 59 d). They comprised records of body weight at 35 and 59 d, feed intake and 15 FB variables: number of visits to the EF, occupation time, consumption, feeding rate and ratios indicating how those FB traits aggregated per hour are distributed between cage mates. The models included the effects of sex, batch, parity order, litter size at birth, litter and cage, as well as d and s effects. Correlations between d of RFI and ratio traits were very high (range=0.89 [0.04] to 0.93 [0.03]) as it was the correlation with the mean number of meals (0.70 [0.16]), number of visits per meal (0.56 [0.23]) and time interval between meals (-0.66 [0.18]). These correlations indicate that, genetically, the most efficient rabbits are those that eat fewer meals, wait more time between meals, eat the least amount of food consumed in an hour in the cage and occupy the EF the least. The variables whose d were most correlated with s of RFI were the variables related to the distribution of time, feed and feeder visits occurring in each hour between cage mates (-0.85 [0.08] to -0.90 [0.05]), indicating that animals that occupy the EF longer, eat the most feed, and visit the EF more times than their cage mates are the ones that cause their cage mates to be more efficient. Thus, there is a substantial genetic variation on FB traits which is correlated with d and s effects of feed efficiency.

Audio-based event detection and health monitoring in poultry*F. Hakansson and D.B. Jensen**University of Copenhagen, Department of Large Animal Sciences, Groennegaardsvej 2, 1870, Denmark; fh@sund.ku.dk*

With the continuous growth of intensive livestock production systems, health and welfare impairments are increasing challenges in poultry production. Timely identification of developing challenges can enable farmers to take immediate management actions, thus limiting potential negative implications. Previous research has shown that audio data can be utilized as biomarker for health conditions in poultry, but studies and applications of bioacoustics monitoring in intensive livestock systems are rare. This study aims at developing a tool for automated and continuous monitoring of audio data collected within poultry barns, to detect audible signs of stress and disease, such as sneezing, alarm calls or others sounds. This study will utilize video and audio data collected at a single poultry production site, and signal processing and machine-learning models will be implemented to detect and count instances of undesired sounds/noises. In an initial step, it will be explored if transfer learning from existing models to detect coughing in pigs can be utilized to detect signs of respiratory diseases in poultry. Furthermore, combinations of signal processing models such as wavelet filtering, or machine-learning models accounting for temporal features in the data (such as long-short term memory- LSTM models) will be scrutinized to create novel models to detect early signs of diseases or stress. This work was funded by Code Re-farm Horizon 2020 project: 'Consumer-driven demands to reframe farming systems' (Grant No: 101000216; <https://coderefarm.eu/wp-coderefarm/>).

Session 53

First approach of using sows' water consumption data to detect the onset of farrowing*J. Probst¹, N. Volkmann¹, C. Lensches², P. Hesecker², G. Thimm³, M. Lieboldt⁴, I. Traulsen² and N. Kemper¹*

¹University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTN), Bischofsholer Damm 15, 30173 Hannover, Germany, ²Georg-August-University Göttingen, Department of Animal Sciences, Livestock Systems, Albrecht-Thaer-Weg 3, 37075 Göttingen, Germany, ³Johann Heinrich von Thünen Institute, Institute of Agricultural Technology, Bundesallee 47, 38116 Braunschweig, Germany, ⁴Chamber of Agriculture Lower Saxony, Mars-la-Tour-Str. 6, 26121 Oldenburg, Germany; jeanette.probst@tiho-hannover.de

To offer sows individual and timely support at parturition, the present study aimed to predict the onset of farrowing by measuring the sows' water consumption (WC). In a first approach, the hourly WC of five sows (parity 2-5, mean=3.6) was recorded by a magnetic-inductive waterflow meter. WC was analysed 96 hours before and 72 hours after start of farrowing (determined by video analyses) using the sows' individual cumulative sum (CUSUM) control chart. Daily WC ranged between 18.7 and 91.4 litres. All sows retrieved the highest amount of water 24 hours before and the lowest 24 hours after the hour the first piglet was born. Analysing each CUSUM control chart with allowance value ($k=0.1$) and individual smoothing value ($h=4.1$ to 6.5), the onset of farrowing was detected five to nine hours before it started by analysing sows' hourly WC. Further investigations will be carried out to analyse a larger data set and consider potential influences on animals' WC (e.g. fixation, health problems). This first study on using WC data to detect the onset of farrowing in sows shows the potential of this approach. The study is part of the project DigiSchwein, which is supported by funds of the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany. The Federal Office for Agriculture and Food (BLE) provides coordinating support for digitalisation in agriculture as funding organisation, grant number 28DE109E18.

Social network analysis of cattle and horses inferred from sensor ear tag (SET) and GPS based data

U. Heikkilä¹, K. Ueda¹, N. Gobbo Oliveira Erünlü², M. Baumgartner³, M. Cockburn³, I. Bachmann³, M. Roig-Pons³ and S. Rieder¹

¹Identitas AG, Staffacherstrasse 130A, 3014 Bern, Switzerland, ²Agroscope, Posieux, 1725 Posieux, Switzerland,

³Agroscope, Avanches, 1580 Avenches, Switzerland; ulla.heikkilae@identitas.ch

Solar powered sensor ear tags (SET) have been applied on cattle and horses within an accompanying study. Animal social networks give insights of an individual's social integrity within a herd and thus give indications on its welfare state. As energy supply is a limiting factor in animal sensors, it is of interest to see whether social networks can be detected with the low temporal reporting frequency data of the SET. This study thus attempts to analyse the social structures of the herd by building a contact network of the animals by using the location data delivered by the SET (up to 4 data points per day). We define a 'contact' where two animals have dwelled within 5 meters of each other within 1 hour. These constrictions are fairly loose, being restricted by the data transfer frequency of the ear tags. These contacts are then assessed over the period of 3 months and a network is built. Most contacts occur on feeding at a shared haystack and could be coincidental. We therefore conduct a verification study on horses that are equipped with both the SET and a GPS tracker with a recording frequency of 10 s during a period of one month. The feeding spots are ignored in the verification step. Furthermore, we observe the animals in both studies in the field to compare the theoretical networks with the actual behaviour. The main features of the contact network can be confirmed and show that the social contacts in the herd follow a fairly fixed structure.

Modelling adaptation strategies to climate change in Mediterranean small ruminant systems

A. Lurette¹, S. Lobón², F. Douhard³, M. Blanco-Alibes², D. Martin-Collado², A. Madrid⁴, M. Curtil-Dit-Galin¹ and F. Stark¹

¹UMR SELMET, INRAE, Campus de La Gaillarde, 2 place Pierre Viala, 34060 Montpellier, France, ²CITA, Avda. Montañana 930, 50059 Zaragoza, Spain, ³UMR GENPHYSE INRAE, 24, chemin de Borde-Rouge - Auzeville Tolosane, 31321 Castanet Tolosan, France, ⁴IDELE, CS 52637, 31321 Castanet Tolosan, France; amandine.lurette@inrae.fr

Mediterranean livestock farming systems have specific characteristics, such as heterogeneity of animals, diversity in land use and flock mobility, that make them particularly sensitive but also adaptive to climatic hazards. Combining resilient herds and an efficient use of various feed resources is central to develop adapted livestock farming systems to climate change. In the PRIMA AdaptHerd project, this study aims at evaluating the multi-level implications of adaptation levers that can be mobilized by Mediterranean small ruminant farmers. An approach which combined a participatory design of adaptation strategies and a simulation of these strategies on four Mediterranean French and Spanish farm types was used. The farm types differed in their level of herd intensification and in their feeding practices. For the four contrasting situations, groups of experts were consulted to design: (1) the projected impact of climate change on vegetation; and (2) several adaptation strategies. The resulted adaptation levers to climate change were different between farm types and flock management (sedentary or transhumant). We therefore tested the effects of three levers: (1) increasing the part of pastoral area; (2) shifting the grazing periods; and (3) decreasing the number of lambings or the age at first mating to better match with resources availability. The assessment of the effect of adaptation levers on livestock systems was based on their forage autonomy, grazing rate and the number of days when needs are not covered. The simulation of the designed adaption levers showed that they allowed the impacts of climate change to be mitigated, but they did not allow a return to an initial situation with needs covered all year round and a high autonomy and grazing rate.

Feed365: Early findings for sheep grazing novel year-round forage systems

C.E. Payne, D. Real, A. Loi and C. Revell

Department of Primary Industries and Regional Development WA, Nash Street, East Perth WA, 6000, Australia; claire.payne@dpird.wa.gov.au

Grazing systems in southern Western Australia are challenged by climate change with increasingly hotter, drier, and more variable seasons. New forage systems need to be identified and re-designed to sustain livestock grazing all-year-round with limited supplementary feeding. Grazing plots (n=48) of 0.5 ha each are spread across 2 paddocks of varying soil types at the Katanning Research Station. Sheep (merino hoggets) grazing time and density is dependent on total forage mass, estimated pasture growth rate and type of forage available. In winter and spring sheep are grazing plots that contain mostly annual legumes and grasses, whilst in summer and autumn sheep are grazing dry residues, winter crop stubbles, summer crops, and perennial legumes and grasses. A total of 20 forage/ forage mixes were trialled consisting of 30 different forage species. Sheep are weighed and condition scored every three weeks whilst grazing plots. Sheep are not given any supplementary feeding whilst grazing plots. During the 2022 winter/spring period (June-November) sheep on average gained weight and gained or maintained condition on all plots. The exception being one plot of dry slashed oat stubble where sheep lost between a quarter and half of a condition over the period of early October to late November. During the 2021/2022 summer/autumn period sheep also gained or maintained weight on all grazing treatments. Condition was maintained on most plots during the summer months (January-February) however lost condition in the autumn months (March-April), which was expected during the first establishment year. The ability to graze and monitor sheep performance on multiple forage types and mixes will identify forage systems that can successfully maintain livestock productivity all-year-round in a changing climate whilst minimising supplementary feeding.

Theatre 3

Quantifying responses to hot conditions in divergent sheep breeds in South AfricaS. Cloete^{1,2}, S. Steyn², J. Van Zyl² and T. Brand^{1,2}*¹Western Cape Department of Agriculture, Directorate Animal Sciences, Private Bag X1, 7607, South Africa, ²Stellenbosch University, Private Bag X1, 7602, South Africa; schalkc2@sun.ac.za*

Maximum temperatures are expected to increase in future. Although the ovine species is generally resilient to high temperatures, it is important to know the extent of breed differences in heat tolerance. Therefore, 10 ewes each of 2 terminal sire breeds (Dorper and Ile de France), 2 wool breeds (Merino and Dohne), a dual-purpose breed (SA Mutton Merino or SAMM), 2 composite breeds with indigenous content (Dorper and Meatmaster) and an unselected indigenous fat-tailed breed (Namaqua Afrikaner) were studied for their short-term responses to heat. The former 5 breeds were all from temperate regions. Rectal temperature and respiration rate of the ewes, as indicators of heat stress, were recorded over three days, involving 3 morning and 3 afternoon sessions. The mornings were appreciably cooler than the afternoons with a mean thermo-humidity index of 19.8, as compared to 29.1 during the afternoons. Rectal temperature ranged in a narrow band of 38.5°C (SAMM) to 38.8°C (Dohne and Meatmaster) in the mornings. These temperatures increased to between 39.0°C (Dorper) and 39.3°C (Ile de France) in the afternoons. Morning respiration rates of the breeds with indigenous content ranged from 51 (Meatmaster) to 60 (Dorpers). The corresponding range for the temperate breeds were from 77 (SAMM) to 91 (Merino). Afternoon respiration rates were appreciably higher: 132 for the Namaqua Afrikaner, 135 for the Meatmaster, 157 for the Dorper and from 167 (Dohne) to 192 (Dorper and Ile de France) for the temperate breeds. Rectal temperatures were low-moderately repeatable across sessions at 0.16. All between-ewe variance partitioned to a term accounting for the reranking of ewes from the mornings to the afternoons for respiration rate. All breeds maintained their rectal temperature in a relatively narrow band, but the breeds from temperate regions needed a higher respiration rate to do this. If heat stress conditions persist, this additional energy need could compete with energy required for other production functions. It was therefore contended that breeds with indigenous content would adapt better to the anticipated hotter conditions expected in future.

Impacts of heat peaks in France on the performances of dairy goats housed in an insulated roof shedK. Boissard¹, A. Fatet¹, M. Lambert², P. Sales³ and H. Caillat¹¹INRAE UE FERLus, Les Verrines, 86600 Lusignan, France, ²Institut de l'élevage, 23 rue Baldassini, 69007 Lyon, France,³Chambre d'Agriculture de l'Aveyron, Carrefour de l'Agriculture, 12000 Rodez, France; hugues.caillat@inrae.fr

Thermal comfort of animals and breeders is decisive in ensuring the sustainability of goat and sheep farming systems. Climate projections show that summer periods will be increasingly hot and will lead to changes in feeding and breeding management. The objective of this study is to measure impacts of heat peaks on dairy goats housed in an insulated roof shed. Data were collected from June 1st to September 15th, 2022 in the INRAE FERLus Experimental Unit based in Lusignan (New Aquitaine- 46.43°N, 0.12°E). Monitoring was conducted on 3 batches of animals: 1 group is grazing and breeds during sexual season, 1 group is grazing and breeds during the off-season and 1 group is housed inside year-round and breeds in the off-season. Recorded data included precise description of housing and zootechnical data: feed (distributed and refusal), milk production (collective and individual quantity and quality), watering, sanitary, behaviour, grazing time, panting score (16 goats per batch). Sensors were used to record hourly temperatures and humidity in 2 places in the building, then calculate the temperature hygrometry index (THI). Meteorological data were collected by a 300 m-distant station. In conditions defined like hot (>27 °C), the temperature inside the shed was lower by 1.6 °C than outside, and when the temperature was >36 °C, the temperature inside was lower by 3.2 °C. In neutral condition (<27 °C), the temperature inside was higher by 3.7 °C which means that this building buffers the impact of high temperatures but also when the temperature drops. In 2022, 3 periods of 1 or 2 days with a THI above 77 were observed. Milk production was 6.6% lower during 3 days following the THI>77 period than the preceding 3 days (3.76 vs 3.51 kg/d). This drop was still significant over a period of 5 days. The mean THI was not different (72±2.4) between the 3 or 5 day-periods before or after THI>77, and no differences were observed on the dry matter intake (2.74±0.24 kg/d) or the water consumption (7.3±2.4 l/d). This study will be repeated in 2023 after the addition of a ventilation system.

Session 54

Theatre 5

Cortisol level in sheep wool underwent to three different pasture managementL. Turini¹, A. Ripamonti¹, A. Silvi¹, E. Giua¹, A. Mantino¹, G. Conte¹, F. Bonelli² and M. Mele¹¹University of Pisa, Dipartimento Scienze Agrarie, Alimentari, Agro-ambientali, Via del Borghetto 80, 56124 Pisa, Italy,²University of Pisa, Dipartimento Scienze Veterinarie, Via Livornese snc, 56122 Pisa, Italy; luca.turini@unipi.it

Cortisol has been used as a biomarker to evaluate different sources of stress in livestock (i.e. heat stress, lameness, water restriction, and tail docking). In sheep, wool cortisol concentration is a more reliable predictor of stress compared to serum cortisol and is not influenced by acute stress as sampling. The aim of this study was to evaluate cortisol concentration in the wool of 20 healthy sheep bred into 3 dairy sheep farms with different characteristics of pasture management (Farm A, B, C). Pasture area of Farm A had no shade allowance, neither drinking water sources, whereas farm B had water sources, but no shade and farm C had both water sources and shade allowance. Twenty animals in early lactation were randomly chosen from each flock and underwent to a clinical examination for health evaluation. Wool samples were monthly collected from March to June (T1, 2, 3, 4, respectively). Wool cortisol was analysed by an ELISA kit. The average temperature humidity index (THI) was recorded for each sampling time and classified as 'absence of heat stress', 'moderate heat stress', 'severe heat stress', and 'extreme severe heat stress'. Data about wool cortisol concentrations showed a non-Gaussian distribution so a Log10 transformation was applied to normalize it. A linear mixed model was used to evaluate the difference in wool cortisol throughout T1 to T4, between Farm A, B, C and the interaction between them. All the farms showed a 'no stress' THI at T1 and T2, 'severe heat stress' at T3 and 'extreme severe heat stress' at T4. The highest wool cortisol levels were recorded at T4, while the lowest at T1 ($P<0.001$). The effect of season in increasing wool cortisol levels could be related to the rise of THI values from March to June, suggesting that sheep may suffer of heat stress during the warm season. Farm B showed lower wool cortisol concentrations ($P<0.001$), suggesting that management factors at pasture different to water and shade availability, such as predator attacks and the nutritional quality of the pasture concur to affect wool cortisol levels.

How sheep sectors do face environmental, social and economic issues in French Pyrenees region?A.-L. Jacquot¹, P.-G. Marnet² and Y. Le Cozler¹¹PEGASE, INRAE, Institut Agro, 35590 Saint Gilles, France, ²Institut, Agro, 35000 Rennes, France; anne-lise.jacquot@agrocampus-ouest.fr

French Pyrenees Mountains are traditional territory for sheep production with two different areas: Pyrénées-Atlantiques dedicated to milk and Hautes-Pyrénées to meat production. As other livestock sectors, the French sheep sector is facing environmental, economic, and social issues (climate changes, limitation of environmental impacts, renewal of farmers, lack of attractiveness, etc.). In present study, we explored the responses and adaptations of this sector to these multiple issues, thanks to a survey performed during fall 2022 by 23 'master 2' students. In practice, they individually surveyed 33 stakeholders located in Pyrenees, including 13 farmers. The interview guide consisted of exploring major themes (environmental impacts, climate changes, remuneration, market influences, farm transfer, sector relations, societal expectations, working conditions, etc.) and aimed at designing to better understand actual situation and precise stakeholders' perceptions concerning the those major issues. Results indicated that sheep systems are considered as environmentally friendly, due low green gas emissions and grasslands-use. Sheep sector has an important role in the patrimonial identity of both territories, mainly through the preservation of pastoral lands and landscapes, highly supported by subsidies, and the presence of quality label products. Transhumance, i.e. moving flocks towards other available feed resources, such mountain pastures, is considered to be of importance to adapt to climate changes and is in line of societal expectations, but labour and predation issues might negatively affect this practice. Transmission to new generation is a major concern for all stakeholders, especially for meat farms. Quality labels such as protected designation of origin (PDO), have a key-role in the structuration of milk sector, enabling to maintain high-prices, sufficient incomes and support stakeholder activities. Both sectors are highly depending on subsidies and export market (feed and lamb to Spain), and this is considered as a huge threat for the sustainability. For all stakeholders, regardless of their production and activity, communication is crucial for the future of these productions.

Theatre 7

Aligning carbon footprint estimates from different tools across EuropeA.S. Atzori¹, O. Del Hierro², B. Lyubov³, R. Vial⁴, C. Buckley³, M.G. Serra⁵, M. Habeanu⁶, R. Ruiz², L. Lanzoni⁷, M. Acciario⁵, T. Keady³ and S. Troude⁴¹University of Sassari, Sassari, Italy, via DeNicola 9, 07100, Italy, ²Neiker, Victoria, Spain, ³Teagasc, Athenry, Co Galway, Ireland, ⁴Institut de l'Elevage, France, France, ⁵AGRISS Sardegna, Loc. Bonassai, Sassari, Italy, ⁶Institutul National de Cercetare-Dezvoltare, Romania, ⁷University of Teramo, Italy; asatzori@uniss.it

LIFE Green Sheep (LIFE19 CCM/FR/001245) has been targeting a common Carbon Footprint (CF) methodology at European level. The aim of the study was to align estimates of 4 tools, already available in Europe CAP'2ER (C2E; Institute de l'Elevage, France); ArdiCarbon (AC; Neiker, Spain); CarbonSheep (CS; Univ. of Sassari, Italy) and Sheep LCA (S-LCA; Teagasc; Ireland), for carbon footprint of dairy and meat sheep farms. The comparison was performed gathering data from 12 dairy and 12 meat sheep farms (from France, Spain, Ireland, Romania, Italy). Data included a broad range of characteristics in semi-extensive farming systems. The tools performed a simplified life cycle assessment with different approaches to estimate enteric methane, N excretion while different emission coefficients were used for feed purchased, crop and fertilizers, energy and fuel. Enteric emissions were aligned using the same methane emission formula (dry matter intake, DMI * Ym/55.65; DMI as from Pulina *et al.*), the emission coefficients for each hotspot were standardized. Evaluations consisted of 24x4 model runs before and after tool alignment. After a first comparison the mean farm CF estimated in Dairy farms was 4.69, 3.20 and 3.43, and 3.34 kg CO₂eq/kg of milk and 31.1, 16.4, 21.3 and 17.2 kg CO₂eq/kg of meat for C2E, AC, CS, S-LCA, respectively. Large differences (more the 30% among tools) were observed among tools often due to enteric methane and manure emissions. After the building app phase the mean CF was equal to 4.1±1.3 kg CO₂eq/kg of milk, being 4.21, 3.98, 4.14, and 4.1 kg CO₂eq/kg of milk for C2E, AC, CS, S-LCA, respectively. For meat farms it was equal to 22.9±7.1 kg CO₂eq/kg of carcass weight (CW) with small variations among farms being 22.9, 26.2, 22.1, 21.9 and 21.3 kg CO₂eq/kg of CW.

Determining carbon footprint of sheep farms in Europe: first results of the LIFE Green Sheep project

Small ruminants farming generates greenhouse gas (GHG) emissions accounting for 6.5% of livestock emissions. To reduce the environmental impact of this sector, it is important to know and understand its level of emissions in order to identify areas of improvement. This is one of the objectives of the LIFE GREEN SHEEP project which aims at reducing the carbon footprint of meat and milk sheep by 12% while ensuring farms' sustainability. One of the project's actions is to create an observatory of the carbon footprint of sheep production as well as its sustainability performances. Data from 1,355 sheep farms (935 meat and 420 dairy) representing various rearing systems in 5 European countries (France, Ireland, Italy, Romania, Spain), the project provides a good overview of the average EU sheep milk and sheep meat carbon footprint. Preliminary results indicate an overall GHG emissions from milk and meat sheep of 3.98 kg CO₂e/kg FPCM (fat and protein corrected milk) and 21.5 kg CO₂e/kg carcass, respectively. These results differ between countries and rearing systems. Nevertheless, the variability is mainly observed within each type of system. For instance, within the French grassland-based dairy sheep system, the average GHG emissions of the 10% farms with the lowest emissions is 71% lower (2.13 kg CO₂e/kg FPCM) than the average emissions of the group (2.58 kg CO₂e/kg FPCM). This reflects the farms' differences in productive efficiency. The variations on the carbon footprint are strongly related to herd management: the farms with the lowest emissions have the highest productivity (prolificacy and fertility) rates, the lowest consumption of concentrates and spend more days grazing. These first results enable a better understanding of the correlation between carbon footprint and farms' practices and to identify areas of improvement.

Greenhouse gas emission intensity of milk production in three Slovenian goat breeds

M. Bizjak¹, Ž. Pečnik² and M. Simčič¹

¹University of Ljubljana, Biotechnical faculty, Department of animal science, Groblje 3, 1230 Domžale, Slovenia, ²The Agricultural Institute of Slovenia, Hacquetova 17, 1000 Ljubljana, Slovenia; marko.bizjak@bf.uni-lj.si

The aim of the study was to determine the intensity of greenhouse gas (GHG) emissions from milk production of three goat breeds in Slovenia, to identify the trends, and to determine the main impacts on greenhouse gas emissions. Based on information on milk yield, protein and fat content, average body mass of each breed, litter size, and kidding interval, we estimated methane and nitrous oxide emissions for the period 2008-2021. Emissions were estimated for 9,890 lactations. GHG emissions were expressed in carbon dioxide equivalents. Emission intensity was expressed as emissions per kg of milk produced. Differences in GHG emission intensity among goats were fourfold, ranging from about 0.4 to more than 1.5 kg of CO₂ equivalent per kg of milk. On average, the emission intensity expressed in kg CO₂ equivalent per kg milk was 0.756 for the Slovenian Saanen goat, 0.740 for the Slovenian Alpine goat, and 0.873 for the autochthonous Drežnica goat. The highest emission intensity was found for goats at the first parity (0.809 kg CO₂ equivalent per kg milk), while goats at the fifth parity had the lowest emission intensity (0.733 kg CO₂ equivalent per kg milk). Emission intensity decreased with increasing litter size. The average emission intensity expressed in kg CO₂ equivalent per kg milk was 0.811 for goats delivering single kids, 0.726 for goats delivering twins, and 0.680 for goats delivering triplets. Emission intensity increased with increasing kidding interval. For goats with extended kidding interval, total milk yield was not high enough to compensate for the higher maintenance requirements of these goats. The intensity of GHG emissions from milk production in herds with controlled goats varied over the years (ranging from 0.803 to 0.688 kg of CO₂ equivalent per kg of milk), but decreased overall by about 14% during the study period. We concluded that some fertility traits are correlated with milk production and consequently with the intensity of GHG emissions as well. In particular, relatively short kidding interval could reduce the intensity of GHG emissions through higher daily milk production.

No difference in PAC methane emission corrected for milk yield in three Norwegian dairy goat farmsJ.H. Jakobsen¹, T. Blichfeldt¹, K. Dodds² and J.C. McEwan²¹The Norwegian Association of Sheep and Goat Breeders, Box 104, 1431 Ås, Norway, ²Research Limited, Invermay Agr. Centre, PB 50034, Mosgiel 9053, New Zealand; jj@nsg.no

Use of portable accumulation chambers (PAC) for capturing enteric methane (CH₄) emissions in sheep is spreading globally, while the usage for goats has been limited. Technically the equipment is equally suitable for both species. The Norwegian agricultural sector has made an agreement with the government to reduce the greenhouse gas emissions from agriculture by a cumulative five-million-ton CO₂-eq by 2030, relative to 2020. The agreement is expressed as per kg product. The Norwegian goat milk industry is small and absolute contribution to the national emission is relatively minor. However, dairy goats may act as a model for dairy cattle in dose-response mitigation trials. The aim of the current study was to compare weight corrected CH₄ and milk corrected CH₄ for three farms. Thirty goats participated in each trial, repeated on three different farms. The thirty goats were divided into three lots of ten, with four goats from first, three goats from second and three goats from third parity. All goats were in their early lactation, on average 70 days from kidding and fed indoor on silage and concentrate. Each lot of 10 goats were measured simultaneously three times during 24-hours and at the same time of the day during the three consecutive days, yielding a total of nine PAC visits per goat. Sixty-minute CH₄ concentrations were captured for each visit. Goats were weighed prior to measurement and ID's merged with latest official milk recording. Average CH₄ emission was 1.94, 1.37 and 1.34 g/hr for each of the three farms respectively with corresponding average body weights of 64.1, 49.9, and 49.5 kg, indicating higher emission at higher body weight, and significant differences between farms. Average daily milk yield for the goats with methane emission on the three farms were 3.75, 2.73 and 2.88 kg/day. CH₄ emissions g/hr / kg-milk/day were 0.52, 0.51, and 0.50, respectively, with no significant difference between farms. Based on this study and experimental design, milk yield explains a larger part of the between farm variation in CH₄ emission than live weight in dairy goats and this should be considered as part of on farm calculations.

Sustainability of Irish sheep production

C. Buckley, L. Bragina and T. Keady

Teagasc, Mellows Campus, Athenry, Ireland; lyubov.bragina@teagasc.ie

The paper assesses the economic, environmental and social sustainability of sheep farming across the Republic of Ireland using data from the EU Farm Accountancy Data Network. Results are based on a sample of 111 specialist sheep farms, which are population weighted to represent 13,979 on a national basis. *Economic Sustainability Indicators* The average gross output per hectare for sheep farms was €1,476 in 2021, and the average gross margin was €623 per hectare. Across all sheep farms, 39% were defined as economically viable. The average income per labour unit on sheep farms was €18,725. Approximately 66% of output was generated from the market, with the remaining 34% derived from direct payments. The average family farm income per hectare on sheep farms was €445 in 2021. *Environmental Sustainability Indicators* In 2021, the average sheep farm produced 166 tonnes CO₂ equivalent of Agricultural GHG emissions. In all, 54.1% of these emissions were generated by the sheep enterprise, with the remaining emissions (45.5%) generated by a cattle enterprise present on specialist sheep farms, with the remainder coming from other sources (minor arable enterprise). On average, sheep farms emitted 4.1 tonnes of CO₂ equivalent per hectare. The average sheep farms emitted 0.17 tonnes of energy based CO₂ equivalent per hectare. *Social Sustainability Indicators* On average, 21% of all specialist sheep farms were classified as being at risk of isolation. The proportion of all specialist sheep farms with a high age profile was 37%. Sheep farmers worked an average of 1,541 hours per year on farm in 2021 (or 29.6 hours a week) and 2,085 hours in between on and off-farm work (approximately 40.1 hours per week). On average, 29% of sheep farmers reported experiencing business related stress in 2021 and 45% indicated stress levels had increased over the previous 5 years. Only 52% of sheep farmers indicated having daily human contact outside the farm household. *Trade-offs* Higher GHG emissions per farm and per hectare were associated with the more profitable sheep farms. Whereas, better economic performance was linked with lower GHG and ammonia emissions per kg of live-weight output.

Should animal welfare indicators be integrated into the environmental impact assessment of farms?

L. Lanzoni¹, L. Whatford², K. Waxenberg³, R. Ramsey³, R.M. Rees³, J. Bell³, E. Dalla Costa⁴, S. Throude⁵, A.S. Atzori⁶ and G. Vignola¹

Animal welfare (AW) is fundamental priority for a sustainable transition of the livestock sector. Understanding to what extent AW affects the environmental performances of farms can promote the integration of animal welfare (AW) indicators into environmental assessments (EA). The aims of the present project were to (1) quantify the climatic cost of impaired AW in sheep farms and to (2) summarise existing methods that integrate AW indicators with farm EA. A scenario study was developed using AgreCalc© to test the change in emission intensity (EI, kgCO₂/kg fat and protein-corrected milk) from a baseline dairy sheep farm to six scenarios of impaired welfare, modelled from literature data. Moreover, a scoping review was conducted to summarise the studies that combined AW with Life Cycle Assessment (LCA). Impaired welfare caused an increase in EI for all the scenarios compared to the baseline: overstocking (+10.0%), mastitis (+6.8%), gastrointestinal nematodes (+6.5%), lameness (+2.1%), water deprivation (+1.6%), and thermal discomfort (+1.0%). The scoping review, which included 24 articles, showed that while LCA was performed with a fairly homogeneous approach, AW was assessed rather heterogeneously, mainly due to differences in the number and type of indicators used. Sixteen papers aggregated the AW indicators into a final score. Within these, four proposed to associate the welfare scores to the LCA functional unit, while the others used either an AW scale (n=10) or a traffic light system (n=2). These results show that although the inclusion of AW indicators in the EA of farms can help identify the best mitigation strategies, guidelines are needed to harmonise their systematic integration.

Galway, Ireland, ⁶National R&D Institute for Animal Biology and Nutrition, Calea Bucuresti N1, Balotesti, 077015, Romania; sindy.throude@idele.fr

Climate change is an existential threat to Europe and the world. To overcome this challenge, the Europe commission aims at reducing net greenhouse gas (GHG) emissions by at least 55% by 2030, compared to 1990 levels, and becoming the first climate-neutral continent by 2050. The livestock sector plays an important role in climate change and has to reduce its GHG emissions. In 2013, FAO shows that there was a potential to significantly reduce global GHG emissions by 33%. In line with this, the LIFE GREEN SHEEP project aims to identify, demonstrate and disseminate innovative good practices on sheep farms to reduce GHG emissions by 12% and to increase carbon storage. In Green Sheep, 282 innovative farms are monitored with an environmental and sustainability assessment, and some mitigation actions have been identified and tested to target the objective of the project. These meat and dairy sheep farms are located in 5 EU countries (France, Ireland, Italy, Romania, Spain) and represent different sheep systems, and have implemented mitigation actions dealing with flock, feed, manure and crop management. Impacts of these actions varies according to their contribution to GHG emissions. Indeed, flock management actions enable the reduction of enteric methane emissions which represent on average 55% of farm GHG emissions. Thus, mitigation actions tested enable the reduction of GHG emission by -1% to -10%. Most of the mitigation actions facilitate an improvement in flock technical and economic performance. Furthermore, one of the main mitigation actions is carbon storage, which can compensate for around 50% of emissions of sheep farming. It is a real asset for this sector to reduce its GHG emissions. As sheep farming enhances a large proportion of grasslands and pastoral areas, it has a strong capacity in preserving and increasing absorption of carbon in soil.

The effect of forage type on methane production from hill bred lambs grazing alternative foragesM. Dolan¹, T. Boland², N. Claffey¹, F. McGovern¹ and F. Campion¹¹Teagasc, Animal & Bioscience Department, Animal & Grassland Research & Innovation Centre, Mellows Campus, Athenry, Galway, H65R718, Ireland, ²University College Dublin, School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, D04 V1W8, Ireland; mark.dolan@teagasc.ie

Ruminant diets are an important factor in enteric methane (CH₄) production as changes in CH₄ emissions from ruminants are closely correlated to forage quality and digestibility. The objective of this experiment was to investigate the effect of forage type offered post-weaning on CH₄ production from Scottish Blackface (SB) ram and castrate lambs and Texel cross Scottish Blackface (TXSB) ram lambs offered one of six dietary treatments from October to January; forage rape (*Brassica napus* L.; FR) hybrid brassica (*Brassica napus* L.; HB) kale (*Brassica oleracea* L.; K) perennial ryegrass reseed (*Lolium perenne*; RS) permanent pasture (predominantly *Lolium perenne*; PP) grazed in-situ and *ad libitum* concentrates indoors (ALC). The study was a 6×2×2 factorial design with lambs blocked by weight and balanced for breed and sex. The study was carried out over two separate years with 16 entire males and 8 castrates per treatment per year. Lambs were removed from feed and weighed a minimum of one hour and maximum of three hours prior to entering portable accumulation chambers (PAC). Methane measurements were obtained using individual chambers over a 50 minute time period at three specific time points (0, 25 and 50 minutes) on two separate occasions 14 days apart. Lambs offered ALC had the lowest CH₄ emissions compared to all other dietary treatments (5.13±0.719 g/day; *P*<0.01). Lambs grazing kale had higher CH₄ emissions than lambs offered FR and HB (10.87 g/day, 8.82 g/day and 9.19±0.534 g/day; *P*<0.01) but these were lower than the CH₄ emissions from lambs offered RS and PP (14.34 g/day and 15.80±0.579 g/day; *P*<0.01). Breed had no effect on CH₄ emissions (*P*>0.05). However, lamb weight and time off feed had a significant effect on CH₄ produced (*P*<0.001). Results from this study show that while lambs offered ALC diets had the lowest CH₄ emissions, the inclusion of forage brassica crops has the potential to reduce CH₄ emissions from fattening lambs in the autumn winter period compared to perennial ryegrass swards.

Poster 15

Preliminary results of the LIFE Green Sheep project in ItalyM. Acciaro¹, M. Decandia¹, M.G. Serra¹, S. Picconi¹, V. Giovanetti¹, A. Atzori², D. Usai³ and S. Throude⁴¹AGRIS Sardegna, Loc Bonassai, 07100, Italy, ²University of Sassari, Department of Agricultural Sciences, Sassari, 07100, Italy, ³LAORE Sardegna, Cagliari, 09123, Italy, ⁴Institut de l'Elevage, Paris, 75012, France; macciaro@agrisricerca.it

LIFE Green Sheep project (LIFE19 CCM/FR/001245) aims at reducing the carbon footprint of milk and meat sheep by 12%, while ensuring farms' sustainability, in five European countries (France, Ireland, Italy, Spain, and Romania). One of the project's action is to carry out a large-scale assessment of GHG emissions and carbon storage in 1,355 'demonstrative' sheep farms (885 in France, 185 in Ireland, 100 in Italy, 100 in Romania and 90 in Spain) using a simplified life cycle inventory tool, in order to create a European observatory of the environmental and sustainability performances of this sector. This paper summarizes the first results for 64 dairy sheep farms in Italy (only Sardinia) using CAP'2ER® tool level 1 (C2E; 'Institute de l'Elevage', France) that allows a simplified estimate of farms' environmental impact. The preliminary assessment reported an average GHG emissions from Italian milk sheep of 3.70±1.37 kg CO₂-eq/kg FPCM (fat-protein corrected milk), with 29±36% of GHG emission offset from carbon sequestration. Therefore, the net carbon footprint turns out to be 2.67±1.68 kg CO₂-eq/kg FPCM. The largest contribution to GHG emissions comes from the enteric fermentation (41±9% of GHG emissions). CAP'2ER also enabled to estimate: (1) the contribution of sheep farms to maintain biodiversity, expressed as hectares equivalent (ha-eq) of biodiversity that is on average 0.52±0.47 ha-eq/ha TSA (total sheep area, total surface used by sheep flock); (2) the carbon sequestration, estimated to be 173±201 kg C/ha TSA. The high variability observed is related to the different extensification/intensification level of dairy sheep farms. This is also confirmed by the variability in milk productivity (247±95 kg FPCM/animal) and number of heads per farm (429±296 animals/farm). Finally, the data analysis confirmed the relationship between animal productivity (expressed as kg FPCM/sheep) and total GHG emissions, evidenced by the good Pearson's correlation coefficient (*r*=0.49, *P*-value<0.001).

Carbon footprint assessment of a Pecorino cheese produced in central Italy

L. Lanzoni¹, L. Di Paolo², S. Abbate², M. Giammarco¹, M. Chincarini¹, I. Fusaro¹, A. Atzori³, D. Di Battista², S. Throude⁴ and G. Vignola¹

¹University of Teramo, Dep. of Veterinary Medicine, Località Piano d'Accio, 64100 Teramo, Italy, ²University of L'Aquila, Dep. of Industrial and Information Engineering and Economics, Piazzale Ernesto Pontieri 1, 67100 L'Aquila, Italy, ³University of Sassari, Dep. of Agricultural Sciences, Viale Italia 39, 07100 Sassari, Italy, ⁴Institut de l'Elevage, Rue Jean Baldassini 23, 69007 Lyon, France; llanzoni@unite.it

To mitigate the environmental impact of small ruminant farming it is important to define tailored mitigation solutions, which require a thorough understanding of the different systems. The following study aimed to assess the environmental impact of three different sheep farms located in central Italy, oriented towards the production of local pecorino cheese. The three farms were classified according to the different management strategies adopted as 'extensive' (1 mating group, lambs with the mothers), 'intermediate' (2 mating groups, lambs weaned at 1 month) and 'intensive' (3 mating groups, lambs artificially reared). Inventory data were collected on the farm to perform the Life Cycle Assessment (LCA) and 'CarbonSheep', developed by the University of Sassari, was used to evaluate the climate change impact to produce 1 kg of pecorino cheese with an economic allocation. The carbon footprint of the three farms was 20.04 ('extensive'), 17.4 ('intermediate') and 16.64 ('intensive') kgCO₂eq/kg pecorino, reflecting the farms' differences in productive efficiency. However, farms had a different relative contribution to the farm sectors, associated with their management differences. The extensive farm, which was the less efficient, had a higher relative impact (RI) derived from enteric fermentation and manure management (83 vs 76%-intermediate and 74%-intensive). The 'intensive' farm had a higher RI from the purchased feed (15 vs 9%-extensive and 6%-intermediate) while the 'intermediate' farm from the use of fuel (18 vs 8%-extensive and 11%-intensive) due to a higher farmed land extension. The present results indicate that, even though the same production process and geographical area are involved, mitigation solutions need to be studied on a case-by-case basis as the types of management can change considerably.

Ten groups of goat farmers (4 to 8 farmers per group and their advisor) in western France (Nouvelle-Aquitaine and Pays de la Loire) have been working since 2020 to identify solutions to adapt their forage systems to climate change. Grassland management (choice of species and varieties, sowing techniques, fertilisation strategy) and stocking grass (hay, silage) were identified as the primary levers. It will also be necessary to plan for a greater carryover of fodder stock, which will also secure the system. Diversification of fodder resources and the method of valorisation are also favourable, as is the establishment of grasslands under a cover of sunflower, meslin, oats, barley, etc., alfalfa in the spring or grass/multi-species meadows in the autumn. For non-grazing systems, the first cut will be earlier (wrapping, grass silage, barn drying) to ensure a quality harvest and regrowth before the summer droughts. Grazing and green feeding can also help to make the most of this early spring grass. The spring yield of grassland will be greater in the future, with a reduced period of grass growth. It will be necessary to ensure that there is enough work to harvest the grassland at the best stage, sometimes with a diversity of harvesting methods. For grazing farms, the main issue will be linked to summer droughts (and the capacity of the grassland to grow back in the autumn). The choice of species and varieties will be important. Other forage crops are interesting for summer/autumn, such as sorghum or rape.

Positive effects of grazing mulberry trees in summer on dairy goats' milk and cheeseC. Boyer¹, H. Le Chenadec¹, F. Noël¹, A. Stocchetti¹, J. Jost¹, A. Pommaret², S. Fressinaud² and R. Delagarde³¹Institut de l'élevage, 149 avenue de Bercy, 75012 Paris, France, ²EPLEFPA Olivier de Serres, Ferme du Pradel, 950 chemin du pradel, 07170 Mirabel, France, ³PEGASE, INRAE, Institut Agro, 16, Le Clos, 35590 Saint-Gilles, France; jeremie.jost@idele.fr

With more frequent and intense summer droughts linked to climate change, fodder trees appear to be a solution allowing farmers to offer green fodder to their animals at this period. The objective of this project was to study the effect of grazing white mulberry (*Morus alba* L.) young trees on dairy goats' production and cheese making capacity as Picodon PDO. Grazing of white mulberry trees was tested during 16 days in July 2021 and 12 days in July 2022, at the goat farm of Pradel (Ardèche, France). Each year, 2 homogeneous groups of 24 goats were used. The Experimental group grazed the mulberry trees between 8:00 am to 3:00 pm (7 h /d), while the Control group was fed alfalfa hay *ad libitum* in the barn at that time. After evening milking, both groups were fed alfalfa hay *ad libitum* indoor. Each goat was individually fed 250 g/d of a commercial concentrate and 500 g/d of whole maize grain. After 7 days of grazing, individual milk production and milk fat and protein contents were measured on 4 days. Faeces were sampled from 4 representative subgroups of goats every 4 days to estimate the proportion of mulberry leaves in the diet from n-alkanes profile in faeces and feeds. With only 30% of the daytime spent outdoor, mulberry leaves (140 g of crude protein/kg DM) represented 61±4 and 67±7% of the goats' forage ration in 2021 and 2022, respectively, on a DM basis. Milk production (3.5 kg/d) was similar between groups. Milk fat content was much greater when goats grazed mulberry trees (39 vs 30 g/kg of milk) as was milk protein content (32 vs 30 g/kg of milk), with lower milk urea (300 vs 450 mg/l of milk). Due to the greater milk fat and protein contents, cheese yield increased by 1.5 kg of cheese per 100 kg of milk, without problems in draining. The Picodon cheeses were tasted after 12 or 14 days of ripening and no difference was found between the two groups.

Session 54

Poster 19

Effects of heat stress and forage quality on feed intake and milk production of Sarda dairy ewes

M. Sini, F. Fulghesu, A. Ledda, A.S. Atzori and A. Cannas

Università degli studi di Sassari, Agricultural Science, Viale Italia 39, 07100, Italy; msini1@uniss.it

The persistency of lactation of dairy ewes is positively affected by the utilization of highly degradable fibre sources. At the same time, mid-late lactation often occurs during spring-summer, periods with high temperatures. Thermal stress can markedly affect the performances of dairy ewes, especially when fed fibre rich feeds, which highly thermogenic. Thus, this study evaluated the impact in lactating ewes of three different forage sources, fed *ad libitum*, and of thermal stress (assessed measuring the temperature-humidity index, THI). Sarda dairy ewes (n=21; 150, days in milk) were divided into three groups balanced for dry matter intake (DMI), milk yield (MY), body weight (BW) and BCS (mean ± SD; DMI 2.22±0.05 kg/d MY 2.00±0.03 kg/d; BW 53.9±2.04 kg; BCS 2.98±0.08). Two groups received dehydrated chopped alfalfa hay of medium quality (AMQ: 19.7% CP, 43.5% NDF, 6.48% ADL, DM basis) or high quality (AHQ: 23.5% CP, 39.0% NDF, 5.8% ADL, DM basis) fed *ad libitum* and a supplementation of 528 g of DM/d of whole corn grains. The third group received dehydrated chopped oat hay (OAT: 7.3% CP, 63.9% NDF, 4.78% ADL, DM basis) *ad libitum* and a supplementation, DM basis, of 176 g/d of whole corn grains and 360 g/d of soybean meal. The experimental period lasted 21 d. A factorial design with feeding treatment, THI classes, time and their interactions as fixed factors, animals as random effect was applied. Voluntary DMI was affected by the diet (OAT=1.289 vs AMQ= 2.085 vs AHQ= 2.733 kg/d, $P<0.001$) and its interaction with THI, showing a decrease in DMI with THI>76 (-17% of ingestion compared to THI=70; $P<0.05$) in OAT group, while the AHQ and AMQ were not affected by heat stress. Milk yield was affected by the diets (OAT=1.491 vs AMQ=1.755 vs AHQ=2.028 kg/d, $P<0.001$) and by its interaction with the THI when comparing OAT vs AHM group ($P<0.05$), while no effects was observed when OAT was compared to the AMQ group and also between AHQ and AMQ. This study highlighted the importance of feeding high quality forage during the mid-lactation phase in order to maintain the persistency of lactation, sustain the voluntary dry matter intake and increase the tolerance response to heat stress by the animal.

Seasonal rainfall patterns modify summer energy balance and nutritional condition of grazing sheepY. Yoshihara¹, B. Chojilsuren², T. Kinugasa³ and M. Shinoda⁴¹Mie university, kuirmachoyacho1577, 5148507, Tsu city, Japan, ²Institute of Veterinary Medicine, Zaisan, PO 53/2, Ulanbaatar, Mongolia, ³Tottori university, Koyamacho 4-101, Tottori city, Japan, ⁴Nagoya University, Furocho, Nagoya city, Japan; marmota.sibirica@gmail.com

Recent spring and summer rainfall patterns in Mongolian grasslands have shown high annual fluctuations and are thought to affect sheep energy balance and nutritious condition via plant community changes. To test this, we obtained climatic and vegetation data in Mongolian semi-arid grasslands from spring to summer for 3 years. Sheep energy intake and expenditure were calculated, and the energy balance and nutrition indicators were compared among years with different seasonal rainfall patterns. In 2019 and 2022, rainfall patterns were characterized by the presence or absence of an early summer drought, respectively. Compared to 2019, plants were tall and abundant in 2022, and thus mean bite size, energy intake, and body weights were greater. Estimated energy intake and expenditure were 4.56 and 2.10 Mcal in 2019, and 6.75 and 1.63 in 2022, respectively, demonstrating that rainfall timing and amount affected vegetation assemblage, plant height, herbage nutrition, grazing behaviour, animal energy balance, and nutrition conditions. Insufficient rainfall events before early summer in semi-arid grazing lands resulted in low energy intake and balance, and the delayed body weight gain could not be recovered. The findings can inform management of grazing land to ensure optimal livestock condition.

Session 54

Poster 21

Effect of the inclusion of rumen-protected amino acids in the diet of high production dairy sheepA. Cabezas¹, D. Martinez Del Olmo², J. Mateos², J. Matilla³, M.T. Díaz¹, R. Bermejo-Poza¹, J. De La Fuente¹ and V. Jimeno⁴¹Facultad de Veterinaria. UCM, Av. Puerta de Hierro s/n, 28040 Madrid, Spain, ²Kemin Animal Nutrition and Health, Herentals, 2200 Herentals, Belgium, ³Oceva Sdad.Coop, Mirador del Duero 5, 49017 Zamora, Spain, ⁴E.T.S.I.A.A.B. UPM, Av. Puerta de Hierro 2, 28040 Madrid, Spain; diego.martinez@kemin.com

The aim of the study was to examine the effect of including rumen-protected amino acids in the diet of high-production dairy sheep, on performance and milk composition. A total of 188 Lacaune dairy sheep were divided into two homogeneous groups in lactation number (3) and located in separated sheep sheds. Treatments were a control diet (CON) and a diet with rumen-protected amino acids LysiGEM™ and KESSENT® Me (Kemin Animal Nutrition and Health, Belgium) (APR). Diets were supplied after milking (morning and afternoon) for 60 days. Both diets were isoproteic (17% CP and 11.4% PDI) but with different energy levels (1.02 and 1.00 Milk Forage Units, MFU/kg DM, in CON and APR diets, respectively) LysDI and MetDI (7.4 and 2.0% PDIE in CON vs 7.9 and 2.8% PDIE in APR diets). Twenty-five sheep of each group were daily controlled in milk production and a sample of milk was weekly taken to determine milk composition. Blood samples were collected from venipuncture of the jugular vein at 1, 4, 7, and 9 weeks from the start of the trial and after the morning milking in the selected sheep. Data were analysed using the PROC GLM procedure of SAS with diet as a fixed factor. Milk yield was similar in CON and APR diets (3.95 vs 3.79 l/d respectively; $P=0.47$), however, milk fat content was higher ($P=0.0003$) in CON (5.53%) than in APR (5.23%), while milk protein content was higher ($P=0.0149$) in APR (4.77%) than in CON (4.69%). CON and APR showed significant differences ($P=0.0013$) in plasma D-β-hydroxybutyrate (mmol/l), being lower in APR (0.61) than CON (0.70) while plasma glucose (mg/dl) was higher ($P=0.0001$) in APR (50.78) than CON (46.78), which means that energy metabolism was more efficient in APR than in CON. Using rumen-protected amino acids, it is possible to formulate diets with lower levels of energy density (MFU/kg DM) and achieve greater efficiency in the use of nitrogen from the diet to synthesize protein in milk without affecting daily milk production.

Reaction norm model analysis for heat stress tolerance of growth performance in purebred pigs

Y. Fukuzawa^{1,2}, S. Ogawa², T. Okamura², N. Nishio², K. Ishii², K. Tashima³, K. Akachi³, H. Takahashi³ and M. Satoh¹
¹Tohoku University, Graduate School of Agricultural Science, Sendai, Miyagi, 980-8572, Japan, ²National Agriculture and Food Research Organization, Institute of Livestock and Grassland Science, Tsukuba, Ibaraki, 305-0901, Japan, ³Global Pig Farms, Inc., Shibukawa, Gumma, 377-0052, Japan; fukuzaway282@affrc.go.jp

Heat stress due to global warming has increased the loss of productivity among essential livestock such as pigs. However, genetic improvement may provide a solution. Therefore, reaction norm model analysis was performed, to develop a methodology to evaluate the genetic ability for heat tolerance of purebred Landrace (L), Large White (W), and Duroc (D) pigs in Japan. The number of records of lifetime average daily gain (LADG) from birth to the end of testing collected from five farms was approximately 35,000 per breed. First, accumulated thermal load (TL) as an indicator of heat stress on LADG was developed via evaluation over a suitable period (from 1 to 16 weeks before the day at the end of testing), and a threshold temperature (10-30 °C) that showed best-fit performance was ascertained. Next, reaction norm model analysis was performed using the developed TL as an environmental variable (linear covariate). The threshold temperature and period of study were 15 °C and 6 weeks, 18 °C and 5 weeks, and 20 °C and 9 weeks for L, W, and D, respectively. The maximum TL values were 19, 16, and 13 for L, W, and D respectively and varied according to the threshold. Values of heritability estimated from reaction norm model analysis ranged between 0.50-0.55, 0.46-0.56, and 0.35-0.47 in L, W, and D, respectively. Minimum values of estimated genetic correlation were 0.75, 0.56, and 0.46 for L, W, and D, respectively. These results suggest a genotype-TL interaction effect; therefore, growth performance under different TL conditions could be genetically improved. All breeds showed negative estimated genetic correlations between the intercept and slope terms, specifically, -0.45 for L, -0.56 for W, and -0.64 for D, implying that some pigs could be genetically more sensitive to heat stress. Further studies investigating the approach to ranking selection of candidates are necessary for efficiently improving growth performance while considering the genetic ability of heat tolerance.

Investigating the slick gene and its effects on heat stress in New Zealand grazing dairy cattle

G.M. Worth, E.G. Donkersloot, L.R. McNaughton, S.R. Davis and R.J. Spelman
 Livestock Improvement Corporation, 605 Ruakura Road, Hamilton 3286, New Zealand; gemma.worth@lic.co.nz

In New Zealand pastoral grazing systems, dairy cattle are exposed to increased heat load via environmental temperature and solar radiation combined with the effects of walking to and from the milking parlour. We investigated the use of the slick gene, a naturally occurring deletion in the prolactin receptor gene found in Senepol cattle introgressed into a New Zealand dairy genetic background. This results in a slick, short hair coat and an improved ability to regulate body temperature under heat load. Our objective was to compare thermotolerance of slick and control cattle when observed under heat stress conditions. Data was collected across 3 studies on a commercial dairy herd in (1) non-lactating (slick n=9 and control n=9) heifers (exercise induced heat challenge), (2) first lactation cows (slick n=9 and control n=9) with rumen bolus temperature and vaginal temperature loggers at pasture and (3) first lactation cows (slick n=7 and control n=7) with indoor heat challenge plus sweating rate measurement. The vaginal temperature differential between slicks and control cattle were similar to the temperature differential seen with the rumen bolus. While at pasture and a temperature-humidity index (THI)<70 temperatures were similar between groups. When exposed to heat load (walking) at a THI of >74, differences in temperatures between the two groups were significant (t-test, $P<0.001$) in both non-lactating heifers and lactating cows rising to a 0.8-1.0 °C difference. Additionally, slick animals returned to baseline temperatures more rapidly than control animals. Hair length differed (t-test, $P<0.05$) between slicks and controls when sampled at the neck (4.3 ± 0.46 vs 13.8 ± 1.16 mm, respectively), pin bone (6.9 ± 0.61 vs 15.2 ± 1.42 mm, respectively) and shoulder (6.5 ± 0.69 vs 14.9 ± 1.5 mm, respectively). Previous research has identified a difference in sweating rates, no difference between groups was identified in this study. These findings demonstrate that cattle with the slick genotype are better able to maintain temperature homeostasis under heat load in grazing conditions. A breeding programme is continuing to improve the genetic merit of slick dairy cattle.

Use of sensors for the detection and genetic evaluation of heat stress in dairy cattle*P. Lema¹, M.-N. Tran², M. Schroyen¹ and N. Gengler¹**¹ULiège – GxABT, Passage des Déportés, 2, 5030 Gembloux, Belgium, ²Elevéo, Rue des Champs Elysées, 4, 5590 Ciney, Belgium; pauline.lema¹@uliege.be*

Heat stress (HS) detection and its genetic evaluation is still a challenge. Indeed, the low frequency of milk recording drastically limits the number of records available during hot days. A solution could be to add the information of data from sensors. The objectives of this study were thus to evaluate the usability of sensor data to detect HS and to assess the possible gain of adding sensors data for HS genetic evaluation. SenseHub™ collars daily records were obtained from October 2019 to July 2022 in six herds. A total of 453 Walloon Holstein cows were followed during this period for activity and rumination time. Meteorological data and milk yield records were also obtained from 2015 to 2022 for 1,740 cows from the same herds. The thresholds at which the different traits start to be affected by heat stress were estimated at a temperature-humidity index (THI) of 63, 64 and 66 respectively for milk yield, activity, and rumination time with multi-traits models. Sensor data showed clear thresholds with a good variation along the THI scale. A three-trait random regression reaction norm model was fitted with these different thresholds. Heritability values were 0.19, 0.14 and 0.21 respectively for the three traits at the thresholds and these values were similar at high THI. Regarding reaction norm effects, activity and rumination time showed a positive phenotypic correlation with milk yield (0.37 and 0.50 respectively) and activity time also showed a positive genetic correlation with milk yield (0.51). If confirmed, results seem to validate that daily available sensors data could be a great help to detect HS animals because it allows to follow the cows in real time. Moreover, the drop is important (good variation along the THI scale), sudden (clear thresholds) and the same cows will probably also suffer from milk yield drop (positive phenotypic correlations with milk yield regression on THI). Activity time could also be a valuable tool for genetic evaluation of HS because the daily recording gives information for all events of HS, it is heritable including at high THI and the genetic correlations between the effect on milk yield and activity time is positive.

Session 55

Theatre 4

Evaluation of heat stress effects on production traits and somatic cell score of Dutch Holstein cows*J. Vandenplas¹, M.L. Van Pelt² and H. Mulder¹**¹Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH, the Netherlands, ²CRV, P.O. Box 454, 6800 AL, the Netherlands; jeremie.vandenplas@wur.nl*

Global climate changes are expected to have an impact on livestock production throughout the world. For example, heat waves should increase in frequency and intensity, resulting in temperate regions facing regularly hot periods. During these hot periods, dairy cows will suffer from heat stress, reducing their milk production, reproductive performance and welfare. Therefore, selecting heat-tolerant dairy animals is of interest to cope with future heat waves. Among several indicators for heat stress, one of them is the temperature-humidity index (THI) that combines the effects of temperature and humidity on animals. The first aim of this study is to evaluate heat stress effects on milk production traits and somatic cell score (SCS) of Dutch Holstein cows using a THI indicator. The second aim is to estimate genotype by THI interactions for the same traits to evaluate the magnitude of the individual variability in heat tolerance. Data included more than 1.5 million test-day records for milk, fat, and protein yields, and somatic cell score (SCS). Data were collected from around 500 thousand first and second-parity cows in 1,581 Dutch herds between 2010 and 2022. All test-day records were associated with 3-day average THI values computed from publicly available meteorological records. For both parities, decreases in milk yield are observed from a value of THI around 65 (i.e. between 18 and 23 °C), and decreases in fat and protein yields are observed from a value of THI around 50. For SCS, increasing THI results in increasing SCS for the first parity (especially from a value of THI around 40), but does not impact SCS in the second parity. Individual responses to THI and to days-in-milk were estimated simultaneously using random regression models. Most genetic correlations along the THI gradient were higher than 0.90 at the 150th day-in-milk. Based on these results, genotype by THI interactions are weak for production traits and SCS of Dutch Holstein cows. This project has received funding from the European Union's Horizon 2020 Programme for Research & Innovation under grant agreement n°101000226. This project is part of EuroFAANG.

Multi-omics and multi-tissues data to improve knowledge of heat stress acclimation mechanismsG. Huau^{1,2}, D. Renaudeau², J.L. Gourdière³, J. Fleury⁴, J. Riquet¹ and L. Liaubet¹¹INRAE, GenPhySE, 24, Chemin de Borde-Rouge, 31326 Castanet, France, ²INRAE, UMR PEGASE, 16 Le clos, 35590 Saint Gilles, France, ³INRAE, URZ, Domaine Duclos, 97170 Petit-Bourg, France, ⁴INRAE, PTEA, Domaine Duclos, 97170 Petit-Bourg, France; guilhem.huau@inrae.fr

Elevated temperature is one of the main stressors with a huge impact on performance in the pig industry, and warming climate will enhance these concerns in the future. Long-term stress lead to acclimation of the pigs to cope with the effect of heat stress (HS) but underlying physiological mechanisms remains poorly described. This study aims to use multi-omics and multi-tissues data to understand the physiological pathways involved in heat tolerance in pigs. Transcriptomic data from seven different tissues (muscle, adipose tissue, liver, blood, pituitary, thyroid, adrenal gland), metabolomics data from four tissues (muscle, liver, plasma, urine), and blood parameters were obtained in an experiment involving 36 pigs from 3 genotypes slaughtered before (n=18) or after a 5-d exposure to 32 °C (n=18). Respiratory rate, rectal and skin temperatures significantly increased within the first 24 to 48 h of exposure to 32 °C when compared to the thermoneutral (TN) conditions ($P < 0.01$). The average daily voluntary feed intake was significantly lower in HS conditions than in TN conditions (1,560 vs 1,707 g/d; $P < 0.01$). With the aim to identify differentially expressed genes (DEG) and differentially produced metabolites, data were analysed with a mixed model with the effects of HS conditions, breed and sire origin. We identified 4,248 DEG in all tissues, with differences in the expression pattern between regulatory tissues (pituitary, thyroid, adrenal gland) and the other tissues. With a pathway enrichment analysis querying KEGG database, we have identified tissue-specific and recurrent pathways. Integrating metabolome with transcriptome data from muscle and sub-cutaneous adipose tissue, we have produced correlation networks about oxidative stress and thermogenesis, two important mechanisms related to HS. Integration of transcriptome data between regulatory tissues and an effector tissue allowed identifying hub genes that could have an importance regarding HS acclimation. This research was part of the MP ACCAF project P10157 (PigChange).

Session 55

Theatre 6

Should we consider fertility when improving thermotolerance in dairy cattle?M.J. Carabaño¹, C. Díaz¹ and M. Ramón²¹INIA-CSIC, Mejora Genética Animal, Ctra de La Coruña km 7,5, 28040 Madrid, Spain, ²IRIAF- CERSYRA, Departamento de Investigación-Area de Reproducción y Mejora Genética Animal, Av. del Vino s/n, 13300 Valdepeñas, Spain; mjc@inia.csic.es

Breeding for adaptation to heat stress (HS) has been normally approached by the use of indicators derived from the decline in production traits (quantity and quality) under high temperatures in dairy species. However, indicators of impairment of other functions associated with HS, such as reproductive performance, which have been less studied, may be advantageous because the reproductive function is most affected by stress and because the antagonistic relationship between productive level and productive decline under HS. In this study, different indicators of heat tolerance through the use of artificial insemination (AI) outcome and meteorological data have been analysed and the relationship with traditional productivity indicators quantified. Data for conception rate (CR, measured as 0/1) in first lactation, first insemination from 913,493 Holstein cows in 7,858 herds in Spain were used to select the optimal phenotypic indicator for HT derived from fertility data. Ridge regression considering average temperatures for the 5, 10, 15 and 30 days pre and post AI were used to compare the alternative indicators and decide in which period the AI outcome is more sensitive to the effects of heat. Substantial loss in CR was observed for all indicators beyond 20 °C of average temperature. Post AI indicators showed better goodness of fit than pre AI values. Genetic evaluations under a threshold random reaction norm model on CR using average temperature for 7 days post AI showed relevant variability in the slope of CR decay and an antagonistic relationship fertility level and slope of CR decay under HS. Correlations with heat tolerance derived from productive traits were close to null, indicating that selection for heat tolerance through maintaining productivity will not result in improving reproductive performance under HS and vice versa. This result points at the consideration of including both productive and reproductive declines when aiming at improving adaptation to high temperatures in dairy cattle. This project has received funding from the European Union's Horizon 2020 Programme for Research & Innovation under grant agreement n°101000226.

Trade-off between fertility and production in French dairy cattle in the context of climate changeA. Vinet¹, S. Mattalia², R. Vallee², A. Barbat¹, C. Bertrand³, B.C.D. Cuyabano¹ and D. Boichard¹¹Université Paris Saclay, INRAE, AgroParisTech, GABI, Jouy-en-Josas, 78350, France, ²Idele, UMT eBIS, Paris, 75012, France, ³INRAE, CTIG, Jouy-en-Josas, 78350, France; aurelie.vinet@inrae.fr

Climate change will induce harsher environments for European cattle production. One likely consequence is a growing antagonism between production and functional traits. To address this question, we investigated the evolution of trade-offs between fertility and production in French dairy cattle across a range from 15 to 75 of the temperature-humidity index (THI). Conception rate (CR) at first insemination (AI) and test-day protein yield (PY) from Holstein (HOL) and Montbeliarde (MON) cows were analysed. Only first lactation performances, recorded between 2010 and 2020, were considered. CR and PY were modelled according to the average THI of the 8 days after the AI and of the 3 days before the test-day, respectively. In total, we analysed 3,351,068 and 649,814 CR and 10,245,692 and 1,966,985 PY records from 3,368,605 and 656,164 HOL and MON cows, respectively. The evolution of trade-offs between CR and PY according to THI values was estimated with bivariate random regression models which included the fixed effects of herd $\times$ year, conventional vs sexed semen, weekday, age at AI, days in milk at AI for CR, and herd-test-day, age at calving, and days in milk for PY, and two random effects, the additive genetic effects of the sire for both traits and the permanent environment effect of the cow for PY. A sire model was chosen to allow very large analyses and thus ensure accurate estimates. The random effects were modelled with THI-dependent third-order Legendre polynomials. These models estimate genetic variances all along the THI trajectory as well as genetic correlations between traits across increasing THI conditions. The genetic correlations between PY and CR were moderately negative and evolved only slightly in the range of the observed THI. They increased with THI in HOL (around -0.1 for high THI), whereas they decreased in MON (around -0.15 for high THI). This study received funding from the European Union's Horizon 2020 research and innovation program under grant number 101000226 (Rumigen) and from APIS-GENE (CAICalor). The authors thank Meteo-France for the Safran database.

Genetic analyses of resilience indicator traits in German Holstein, Fleckvieh and Brown Swiss

F. Kessler, R. Wellmann, M. Chagunda and J. Bennewitz

University of Hohenheim, Animal Genetics and Breeding, Garbenstraße 17, 70599 Stuttgart, Germany; franziska.kessler@uni-hohenheim.de

Modern livestock farming faces various challenges such as climate change and new evolving pathogens, associated with new animal stressors. To meet these challenges, high performance and resilient animals are needed that are able to cope with disturbances. Animal breeding has been dealing with the possibilities of breeding for resilience since several years. In this context, the indicator traits variance of performance (Var) and variance (LnVar), autocorrelation (r_{Auto}) and skewness (Skew) of deviation of the observed from the expected performance were introduced in different animal species. With the long-term objective of establishing resilience as a breeding goal, we used in our study daily milk yields to apply these resilience indicators to 9,373 lactations from 4,426 dairy cows of German Holstein, Fleckvieh, and Brown Swiss breeds. A breed comparison and the effect of different degrees of smoothing of the expected lactation curves were investigated. We estimated heritabilities, phenotypic- and genetic correlations between resilience indicators and resilience indicators of different smoothing degrees. We also examined the correlations between resilience indicators and performance traits as well as functional traits. Resilience indicators showed low to moderate heritabilities in all breeds e.g. approximately 0.09 in Var, 0.14 in LnVar, 0.06 in r_{Auto} and 0.02 in Skew. Significant phenotypic and genetic correlations between resilience indicators were found e.g. approximately 0.43 Var/LnVar, -0.21 LnVar/ r_{Auto} and 0.63 LnVar/Skew. The highest correlations between smoothing levels were found for LnVar and the lowest correlations were identified for Skew. The strongest correlations between performance traits and resilience indicators were found for LnVar e.g. 0.23 with milk yield. Estimation of genetic correlations with further functional and health traits are in progress, as well as a detailed investigation of external triggers (e.g. heat waves) that causes the resilience traits to be relevant.

Estimating the heritability of nitrogen and carbon isotopes in the tail hair of beef cattle*M. Moradi, C. Warburton and L.F.P. Silva**Queensland Alliance for Agriculture and Food Innovation, The University of Queensland, Gatton, QLD, 4343, Australia; m.moradi@uq.edu.au*

The natural abundance of nitrogen isotopes ($\delta^{15}\text{N}$) in animal tissues is related to the ability of cattle to lose less nitrogen in the urine and has been used to estimate nitrogen use efficiency and feed efficiency. Carbon isotope enrichment ($\delta^{13}\text{C}$) has also been used to estimate feed conversion ratio and grazing behaviour in beef cattle. There are significant variations between the individual beef cattle in the same environment for $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ of the tail hair. Thus, the objective was to determine the heritability of $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ in the tail hair of tropically adapted beef cattle to further validate their use in genetic breeding programs. A total of 497 *Bos indicus* steers (269 Brahman and 228 Droughtmaster) were used, and the steers had reliable pedigree information for three generations as they were part of the beef cattle genetic evaluation system in Australia. Two single, mixed breed, contemporary groups of steers are used including the steers weaned in 2019 ($n=254$) and steers weaned in 2020 ($n=243$). Samples of tail switch hair representing hair segments growing during the dry season were collected and analysed for $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$. Fixed effects fitted in the linear regression model were age, breed, year (as contemporary groups), and average daily gain during the different seasons. The heritabilities of $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ in the tail hair were estimated at 0.43 ± 0.14 , and 0.41 ± 0.15 , respectively, which indicates both are moderately heritable traits. The genetic correlation between $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ was negative at -0.78 ± 0.16 , and the phenotypic one was -0.40 ± 0.04 . The negative correlation can be explained by the contrasting isotope fractionation in the urine of cattle, as urine has less $\delta^{15}\text{N}$ and more $\delta^{13}\text{C}$ than the diet. The findings of this study have shown for the first time that both $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ in the tail hair of cattle are heritable traits. These results support the feasibility of utilizing tail hair isotopes as a promising approach for identifying cattle with greater nitrogen use efficiency, which is a key trait in low-protein diets. Moreover, genetic selection for nitrogen-efficient cattle can reduce the environmental impact of beef production.

Session 55

Theatre 10

Changes in genetic correlations over generations due to selection and random drift*B.C.D. Cuyabano¹, S. Aguerre² and S. Mattalia²**¹INRAE, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²IDELE, Domaine de Vilvert, 78350 Jouy-en-Josas, France; beatriz.castro-dias-cuyabano@inrae.fr*

The evolution of genetic variance over generations is a topic that has been widely studied in quantitative genetics. In many breeding populations, both selection (resulting in the Bulmer effect) and limited population sizes (which builds up co-ancestry, resulting in random drift and inbreeding) reduce a trait's genetic variance. Until recently most research related to this topic remained theoretical due to limitations of data availability with sufficient generations for many species. Moreover, studies regarding the consequences on genetic correlations between traits under selection (and on their evolution over generations) are limited in the theoretical perspective, and to our knowledge inexistent empirically. It is however, reasonable to expect that both the Bulmer effect and random drift impact genetic correlations between traits under selection. Furthermore, if changes are significant when compared to a base population (typically used for inferences of genetic parameters), they should be accounted for when performing genetic evaluations comprising the most recent generations of a breeding population. A preliminary study on simulated data that mimics a dairy cattle population with respect to production and fertility ($h^2=0.3$ and $h^2=0.01$, respectively, and genetic correlation -0.18) indicated that when the population evolved through ten generations under random mating, although genetic variances decrease due to random drift, the genetic correlation remains unchanged. However, through ten generations under selection for either one of the traits individually, the genetic correlation was significantly attenuated. This attenuation was systematically progressive when selection was performed for production; when selection was performed for fertility, an immediate and relatively large attenuation is attained, then the genetic correlation is partially recovered and its trend follows the same as that of when selection was performed for production. Such attenuations are expected to be observed in real populations, a work that is currently undergoing. This study received funding from the European Union's Horizon 2020 research and innovation program under grant number 101000226 (Rumigen).

Longitudinal study of environmental effects for American Angus beef cattle over 30 yearsG. Rovere¹, B.C.D. Cuyabano², B. Makanjuola¹ and C. Gondro¹¹Michigan State University, Animal Science, East Lansing, 48824-1225, MI, USA, ²INRAE, Domain de Vilvert, 78350 Jouy-en-Josas, France; rovere.gabriel@gmail.com

Beef cattle production in the USA is mostly pasture-based, thus, animals spend most of their life outdoors. In such a vast country, herds are exposed to different degrees of climate variability across location, each potentially influencing animals' performance differently. We analysed the trends of the American Angus population on birth weight (BW; ~6.7Mill records), weaning weight (WW; ~6.6Mill records), and post-weaning gain (PWG; ~3.4Mill records) over 30 years, and used historical records of climate variables to associate those trends with the climate variability in the locations of the herds. A single-step-multi-trait genetic evaluation was performed, with fixed contemporary group (CG) effect, maternal effect for BW and WW, and a permanent effect for WW. Using historical climate records from 1980-2020, we defined 5 classes of locations (LOC) in the USA, according to their frequency of higher than usual temperature-humidity-index (THI) during the breeding season. This classification of LOC was then assigned to the herds in our data through their GPS coordinates. From 1990, phenotypic and genetic trends were both decreasing for BW, and increasing for WW and PWG, with a smaller phenotypic slope observed after 2005 on WW and PWG. As for the effects obtained for CG (comprising climate+management), the trend was of decreasing effects over the years for all traits, while the variance of the CG increased during the same period. Interestingly, when studied per LOC, genetic trends were equivalent irrespective of LOC; phenotypic trends, although in the same direction for all LOC, presented lower values in LOC with more unusual THI events (LOC 4 and 5), and slopes of their trends were significantly different. CG effects were also consistently lower and with higher coefficient of variation in LOC 4 and 5 for all traits. From a population perspective, these results might suggest that, although genetic progress was equally achieved for herds in all LOC, in regions where unusually high THI events are becoming more frequent, management practices might not be sufficient to countervail the depressor effect of the climate on the animals' performance.

Theatre 12

Characterization of environmental impact of 13,000 French dairy farmsR. Vial¹, A. Stocchetti², M. Mevel³ and C. Brocas³¹Institut de l'Elevage, 9 rue de la Vologne, 54520 Laxou, France, ²Institut de l'Elevage, 149 rue de Bercy, 75595 Paris Cedex 12, France, ³Institut de l'Elevage, Monvoisin, 35652 Le Rheu, France; remi.vial@idele.fr

The French dairy sector is committed to the fight against global warming thanks to the low carbon dairy farm initiative. Indeed, several projects have been carried out to build the milk carbon footprint reduction road map. As part of these projects, a national life cycle assessment tool named CAP'2ER® was developed to measure the milk carbon footprint considering GHG emissions and carbon sequestration. Since the creation of the tool, 13,000 audits in dairy farm have been made. These assessments are a significant source of information on environmental impact of French dairy farms. A multicriteria analysis have been carried out to access the contribution of production parameters to the carbon footprint. The results are expressed in kg CO₂ equivalent per litre fat and protein corrected milk and per ha. There is a big variability in the results among farms. The average carbon footprint is 1 kg CO₂eq per litre and the farms which are among the 10% lowest emitters have carbon footprint 20% lower than the average. The production system has a small impact on the milk carbon footprint and practices explain a big part of the variability. Practices with the largest impact are milk yield, age at first calving, quantity of concentrate, N-fertilizer used, and direct energy consumed.

Plateau-linear regression analysis of farrowing records on temperature data for pigs reared in JapanS. Ogawa¹, T. Okamura¹, Y. Fukuzawa^{1,2}, M. Nishio¹, K. Ishii¹, M. Kimata³, M. Tomiyama³ and M. Satoh²¹Institute of Livestock and Grassland Science, NARO, Division of Meat Animal and Poultry Research, 2 Ikenodai, Tsukuba, Ibaraki, 305-0901, Japan, ²Graduate School of Agricultural Science, Tohoku University, Sendai, Miyagi, 980-8572, Japan,³CIMCO Corporation, Koto-ku, Tokyo, 136-0071, Japan; ogawas897@affrc.go.jp

In Japan, national-scale genetic evaluation for female reproductive traits has been conducting with data collected throughout the year at multiple farms distributed around Japan. Farrowing performance of sows is affected by the time of year such as season, and heat stress induced by high temperature would be a contributing factor in shaping the effect of time of year. Here, for robust modelling of heat load, a plateau-linear regression analysis was performed using records of number born alive (NBA) from purebred Landrace, Large White, and Duroc female pigs reared in six farms in Japan obtained during 2007 and 2022 and public weather data. Daily maximum temperature data measured by Automated Meteorological Data Acquisition System (AMeDAS) at Japan Meteorological Agency (JMA) meteorological stations nearest from the farms were downloaded. The number of NBA records analysed was 52,668 for Landrace, 42,668 for Large White, and 5,459 for Duroc pigs. Coefficient of determination of the plateau-linear regression model was obtained with changing the breakpoint value from 10.0 to 25.0 °C at 0.1 °C intervals, and the value showing the greatest model fitting was reported as the threshold temperature. Daily maximum temperature data at mating day was used. For all breeds, values of coefficient of determinations showed trajectories like upward convex parabolas and estimated values of plateau-linear regression coefficient were negative, indicating the adverse effects of heat load by high temperature on sows reared in Japan. Our results show the possibility of utilizing publicly available weather data for considering the effects of heat load on NBA of pigs reared in Japan, which might contribute more flexible statistical modelling for national genetic evaluation of female reproductive performance to cope with ongoing global warming.

Session 55

Poster 14

Genetic parameter of heat tolerance for reproductive traits in Landrace, Large White and Duroc pigsT. Okamura¹, Y. Fukuzawa^{1,2}, M. Nishio¹, S. Ogawa¹, K. Ishii¹, H. Takahashi³, K. Tashima³, K. Akachi³ and M. Satoh²¹Institute of Livestock and Grassland Science, National Agriculture and Food Research Organization, 2 Ikenodai, Tsukuba, Ibaraki, 3050901, Japan, ²Graduate School of Agricultural Science, Tohoku University, 468-1, Aramaki Aza Aoba, Aoba-ku, Sendai, Miyagi, 9808572, Japan, ³Global Pig Farms, Inc., 800, Kamihakoda, Hokkitsu-machi, Shibukawa-shi, Gunma, 3770052, Japan; okamut@affrc.go.jp

This study aimed to estimate the genetic variance components reacting to heat stress in five reproductive traits, i.e. number of born alive; NBA, number of weaning piglets; NW, number of death piglets during suckling; NDW, total weaning weight; WW and average weaning weight; AWW. The data consisted of 26,770, 25,973, and 12,544 litters of Landrace, Large White, and Duroc sows, respectively, from five farms in Japan. The heat loads for each trait and breed as heat stress indicator were defined based on the daily maximum ambient temperature with optimal thresholds and periods for each trait and breed. The reaction norm model was fitted with the heat load for each breed and traits. Although the ratio of variances of heat tolerance to that of performance under comfortable condition were from 18 to 32%, these results indicated heat tolerance of these traits were heritable traits. The genetic correlations between heat tolerance and performance under comfortable condition were almost zero or positive (-0.01 to 0.79) for NW, NDW, WW and AWW, although these correlations were negative (-0.98 to -0.13). This suggested improving the heat tolerance by genetic selection could not interfere with the performance under comfortable condition for except of NBA. These results demonstrated that the heat tolerance was heritable and could be improved by genetic selection, and that can achieve to adapt pork production under global warming.

Breeding soundness evaluation of bulls in extensive systems in interior centre and south of PortugalJ. Várzea Rodrigues¹, L. Pinto De Andrade^{1,2}, S. Dias¹, J. Carvalho¹ and M. Martins^{1,3}¹Instituto Politécnico de Castelo Branco, ESA, Av Pedro Álvares Cabral, no. 12, 6000-084, Portugal, ²CERNAS, Av Pedro Álvares Cabral, no. 12, 6000-084, Portugal, ³QRURAL, Av Pedro Álvares Cabral, no. 12, 6000-084, Portugal; luispa@ipcb.pt

Reproductive efficiency in beef cattle is a fundamental objective for the economic viability of farms and it is known that the bull contributes significantly in defining the profile that the fertility of a herd presents. Between January 2012 and December 2022, 1147 animals aged between 13 and 151 months were evaluated through breeding soundness evaluation (BSE) on 85 beef cattle farms in the interior centre (1) and in the south (2) of Portugal. BSE was carried out throughout the year with a higher prevalence in the months of September to January (71.58%), the time of greatest demand for this service by farmers, to prepare for the subsequent mating season. Considering the hottest months (June to October), the probability of bull failure is almost twice as high as in the rest of the year (OR=1.9867: IC 95%, 1.2841-3.0737). In the coldest months (November-March), the probability of failure is between 1.39-3.36 lower than in the rest of the year (OR=0.4622: IC 95%, 0.2974-0.7183). Of the evaluated animals, 80.21% were satisfactory, 6.28% unsatisfactory, and 13.51% deferred. Among the deferred animals (n=155), only 58 were reassessed and of these, 74.71% were reclassified as satisfactory. Assessing Body Condition Score (BCS) scale 1-9, we found that in the satisfactory animals, 11.62% had BCS≤4, 62.73% had BCS between 5 and 6 and 25.65% had BCS≥7. Considering the regions 1 and 2, 86.99 and 94.71% males were considered satisfactory and within these, the percentage of animals aged ≤24 months satisfactory was 24.28 and 78.57% respectively. The andrological examination should be considered an essential tool for the elimination of males characterized by subfertility or infertility, optimizing reproductive results, however it should be complemented with libido tests. The re-evaluation of animals classified as deferred is pertinent and necessary, recovering many males and avoiding the elimination of bulls that may be necessary for mating and may have a good genetic value.

Session 55

Poster 16

Transcriptome analysis identifies genes affected by heat stress in hen uterovaginal junctionS. Kubota¹, P. Pasri¹, S. Okrathok¹, O. Jantasaeng¹, S. Rakngam¹, P. Mermillod² and S. Khempaka¹¹Suranaree University of Technology, School of Animal Technology and Innovation, 111 University Avenue, Suranaree, Muang, 30000 Nakhon Ratchasima, Thailand, ²National Research Institute for Agronomy, Food and Environment (INRAE), UMR de Physiologie de la Reproduction et des Comportements, INRAE, 37380, Nouzilly, France; skubota@sut.ac.th

Female birds have the potential to modulate the motility of resident sperms. Heat stress decreases the reproductive ability of broiler breeder hens. However, its effects on the sperm storage tubules (SSTs) in the uterovaginal junction (UVJ), the primary site of sperm residence, remain unclear. In this study, we used RNA-sequencing to identify the differentially expressed genes (DEGs) in UVJ tissues containing SSTs of breeder hens affected by heat stress (36 °C for 6 h). A total of 561 genes, including 181 upregulated and 380 downregulated DEGs, were found to be differentially expressed compared to those in chickens raised under thermoneutral conditions (23 °C). Gene Ontology analysis revealed 209 significantly enriched terms involving heat shock proteins (HSPs). Kyoto Encyclopaedia of Genes and Genomes analysis identified nine significant pathways, including the protein processing in endoplasmic reticulum, neuroactive ligand-receptor interaction, biosynthesis of amino acids, ferroptosis, and nitrogen metabolism pathways. Protein-protein interaction network analysis of DEGs revealed two large networks. Our findings indicate that heat stress inhibits innate immunity in UVJ tissues of broiler chickens and that heat-stressed chickens protect their cells by increasing the expression levels of HSPs. Our results suggest that DEGs, including *HSP25*, *HSPA5*, *HSPA8*, *GKN2*, *IL4I1*, *PDK4*, *TAT*, *CA*, *LHCGR*, *GPX*, and interferon-stimulating genes may be used to further investigate SSTs in UVJ tissues of heat-stressed hens.

Establishing and scaling up breeding programs: a challenging, but not impossible task*M. Wurzinger**BOKU-University of Natural Resources and Life Sciences, Vienna, Department of Sustainable Agricultural Systems, Gregor-Mendel-Str. 33, 1180 Vienna, Austria; maria.wurzinger@boku.ac.at*

Establishing breeding programs is challenging, especially in extensive systems and developing regions. Breeding programs are complex and require good planning, but they also require constant monitoring during implementation. Many logistical problems, complex communication, and the coordination of different actors (farmers, agricultural extension service, research organizations, ministries) must be overcome. In recent years, a new approach to implementing breeding programs has been developed. So-called community-based breeding programs (CBBP), which focus on the needs and objectives of livestock farmers, have been successfully established. These programs usually start in pilot regions with fewer farmers with a common interest in improving their animals. Once the program is established, the next critical step is up-scaling. Expansion with new members also requires rethinking and reorganization, as existing decision-making structures often no longer meet the requirements. All stakeholders must be aware of and play their role in successful implementation. Scientists must work in an inter- and transdisciplinary approach and have a good understanding of the livestock production system, a profound technical understanding of animal breeding, and organizational management and development knowledge. Programs must be institutionally based and not dependent on individuals. Local and national governments must fulfil their mandate, create an enabling environment and ensure long-term support for farmers. Different examples of breeding programs are presented, and the specific challenges and possible solutions are discussed. Breeding programs are complex, very dynamic and must constantly adapt to new conditions (e.g. market requirements, and policies). But at the same time, this dynamic makes them so appealing and makes the work so exciting for animal breeders.

Session 56

Theatre 2

Development of a breeding programme for oysters*P. Haffray, R. Morvezen, F. Enez, L. Dégremont and P. Boudry**INRAE/SYSAF, Campus de Baulieu, 35042 Rennes, France; romain.morvezen@inrae.fr*

In this presentation, we report how the French hatcheries invested since 1990 in polyploidization and selective breeding of the Pacific oyster *Crassostrea gigas*. After its massive introduction in 1971 to replace previous oyster species hit by a virus and two parasites, the production was hit again mid 80's by two new pathogens: OSHV-1 herpes virus and *Vibrio aestuarianus*. A collective initiative to increase genetic resistance to OSHV-1 virus by sib-selection was not supported as this innovation could compete with the production of wild spats. Commercial hatcheries invested then in breeding program with SYSAF expertise initially based on mass selection of surviving candidates to OSHV-1. Research works, developed in partnership with Ifremer and INRAE research organizations, improved practices by the development and application of reproductive and genomic tools to ease family productions (reproductive extenders), to manage inbreeding (DNA-parentage assignment) and since the last ten years by sib and genomic selection of the diploid lines (high-through put phenotyping, genomic indexation). The hatchery production of nearly 3 billion of mostly triploid spats (>50% of the national production) is making the application of breeding technologies and genomic selection as a case study for low trophic and extensive productions.

Status of implementation of EU animal breeding legislation for endangered breedsH. Göderz¹, L. Balzar¹, J. Wider¹, C. Danchin², M. Spoelstra³, M. Schoon³ and S. Hiemstra³¹BLE, Deichmanns Aue 29, 53179 Bonn, Germany, ²IDELE, 149 rue de Bercy, 75595 Paris Cedex 12, France, ³WUR, P.O. Box 338, 6700 AH Wageningen, the Netherlands; holger.goederz@ble.de

With the Implementing Regulation (EU) 2022/2077 the European Commission designated the European Union Reference Centre for Endangered Animal Breeds (EURC-EAB). The EURC-EAB is led by Wageningen University & Research (WUR). Partners in the consortium are the Institut de l'Élevage (IDELE) and the Federal Office for Agriculture and Food (BLE). The EURC-EAB shall work with breed societies and third parties designated by them, competent authorities and other authorities of EU Member States to facilitate the preservation of endangered breeds and genetic diversity existing within those breeds. Within its Work Programme, EURC-EAB initiated a European wide survey and mapping process to show the status of the implementation of Regulation (EU) 2016/1012 concerning breeding programmes for endangered breeds. The mapping process will identify challenges and obstacles in the development and implementation of breeding and conservation programmes for endangered breeds. The regulation gives the opportunity to implement special derogations for endangered breeds in the design and implementation of their breeding programmes. The survey will show to what extent these derogations are used by breed societies. Breed societies will also be asked about the status of implementation of relevant elements of their breed specific breeding programmes, including performance recording, genetic evaluation, monitoring of genetic diversity and their collaboration with national gene banks. The survey will give insight in differences between countries, in particular their respective policies and procedures at national level, such as definitions and endangerment classification systems. Through this survey both breed societies and competent authorities will also be able to indicate specific challenges and obstacles in relation to the implementation of the breeding legislation and the development of sustainable breeding programs. The results of the study will be presented to the Standing Committee on Zootechnics for discussion among the Member States.

Box 3000, Chuo Kikuu, Morogoro, Tanzania, ⁷University of Ljubljana, Biotechnical Faculty, Kongresni trg 12, 1000 Ljubljana, Slovenia; ihouaga@ed.ac.uk

African smallholder dairy production systems are characterized by small and scattered herds with low genetic connectedness between them. Coupled with the lack of an appropriate recording system, genetic evaluations are challenged to deliver meaningful accuracy, and hence typical genetic progress is low. One key underlying mechanism of genetic selection is an accurate separation of environmental and genetic effects. Thus, this study aimed to assess the impact of accounting for spatial distance/relationships on variance components estimation and the accuracy of genetic evaluation for daily milk yield in Tanzanian smallholder crossbred dairy cattle. To this end, we applied GBLUP-based model on 19,494 test-day milk yield records of 1,906 genotyped crossbred dairy cows from 1,394 herds. Genomic information consisted of 664,822 SNP markers after quality control. We modelled herds either as a random independent effect, a random spatially-correlated effect between the wards, or a random spatially-correlated (distance-based) effect between the herd locations. The results show large amount of spatial variation as well as of genomic estimated breeding values. We conclude that spatial modelling of herd effect more accurately separates genetic and environmental effects than independent herd effect and thus increases the accuracy of genomic evaluations. Further studies that integrate the genotype-by-environment interactions are needed to further modelling of the staggering variation in African smallholder crossbred dairy production systems.

Genetic parameters for grazing behaviour traits of Boutsko sheep

S. Vouraki¹, V. Papanikolopoulou¹, A. Argyriadou¹, V. Fotiadou¹, V. Tsartsianidou^{1,2}, A. Triantafyllidis^{1,2}, G. Banos³ and G. Arsenos¹

¹Aristotle University, University Campus, 54124 Thessaloniki, Greece, ²Epigenomics Translational Research, Center for Interdisciplinary Research and Innovation, Balkan Center, 57001 Thessaloniki, Greece, ³Scotland's Rural College, Easter Bush, EH25 9RG Midlothian, United Kingdom; svouraki@vet.auth.gr

The objective was to estimate genetic parameters for grazing behaviour traits of Boutsko sheep reared semi-extensively in mountainous regions. A total of 296 ewes were randomly selected from three flocks (n=198, n=49 and n=49, respectively) in Epirus, Greece. Rotational monitoring of animal grazing behaviour was performed from June to September 2021, using global positioning system devices (GPS, n=50) attached on designated collars. GPS tracking of each animal was performed for 4-10 days at 2-60 minutes intervals. Traits measured included duration of daily grazing, distance, speed, altitude difference and elevation gain. Blood samples of the ewes were obtained from the jugular vein and DNA was extracted; samples were genotyped with the OvineSNP50 Genotyping Bead Chip v2. (Co) variance components and genetic parameters of grazing behaviour traits were estimated with mixed model analyses. Statistically significant ($P < 0.05$) heritability estimates were reported for duration of grazing and speed (0.75 and 0.78, respectively). The latter traits and elevation gain were significantly repeatable (0.85, 0.86, and 0.14, respectively). Significant ($P < 0.05$) negative genetic and phenotypic correlations were found between grazing duration and speed (-0.99 and -0.96, respectively) and positive ones between duration and distance (0.28 and 0.24, respectively). Such correlations indicate that practices for higher grazing duration are expected to decrease speed and favourably increase distance. Overall, results suggest that genomic selection practices could be implemented to improve grazing behaviour in the context of a multi-trait breeding programme. Moreover, there is significant between-animal variation for most grazing behaviour traits studied to support management practices aiming to improve adaptation to extensive rearing conditions. This work was funded by the SMARTER Horizon 2020 project (Grant No: 772787), <https://www.smarterproject.eu/>

Research and development innovations for climate-smart beef production in subtropical countries

M.M. Scholtz^{1,2}, G.M. Pyoos^{1,2}, M.L. Makgahlela^{1,2}, M.C. Chadyiwa², M.D. MacNeil^{1,2}, M.M. Seshoka^{1,3} and F.W.C. Naser¹

¹University of the Free State, Department of Animal Science, P.O. Box 339, 9301 Bloemfontein, South Africa, ²Agricultural Research Council, Animal Production, Private Bag X2, 0062, Irene, South Africa, ³Northern Cape Department of Agriculture, Environment, Land Reform and Rural Development, Vaalharts Research Station, Private Bag X9, 8550 Jan Kempdorp, South Africa; naserfw@ufs.ac.za

The impact of climate change and the release of greenhouse gases influence the ruminant livestock industry in two ways. Firstly, the continuous increase in temperature will have both direct and indirect effects on the animal. The direct effects are mostly associated with heat and the indirect effects with feed sources, ecosystem changes and diseases. Secondly, ruminant production has the responsibility to limit the release of greenhouse gases to ensure future sustainability. The focus should be on adaptation, mitigation and resilience. Some research and innovations to achieve this in beef cattle in subtropical developing countries, will be discussed. The utilization of adapted and indigenous genotypes and the development of early warning systems should get attention. This could result in maintained levels of production in spite of adverse weather conditions. Any mitigation strategy should be aimed at improving efficiency of production, which will have positive effects on sustainability, while reducing the carbon footprint. The focus should thus be to improve cow-calf efficiency, selection for alternative measures of efficiency as well as the effective use of crossbreeding. It is recommended that, when selecting for cow-calf efficiency the use of the calf/cow weight ratio should be replaced by an index that includes both weights and reproductive performance. Residual traits such as residual feed intake, residual daily gain or a combination of both should be used when selecting for efficiency. Effective crossbreeding can have a small to medium effect on the reduction of the carbon footprint, while increasing the efficiency of production. Lastly resilience can be achieved through the breeding of less plastic or more climate resilient genotypes (identify genes for function / adaptation that make them more resilient).

Genetic and environmental factors influencing skin traits of South African farmed ostrichesK.R. Nemutandani¹, A. Engelbrecht², S.W.P. Cloete³, K. Dzama³ and O. Tada¹¹University of Limpopo, Agricultural economics and animal production, Private Bag X1106, Sovenga, 0727 Polokwane, South Africa, ²Western Cape Government, Directorate Animal Sciences, Department of Agriculture, P.O. Box 351, 6620 Oudtshoorn, South Africa, ³Stellenbosch University, Department of Animal Sciences, Private Bag X1, 7602 Matieland, South Africa; khetho.nemutandani@ul.ac.za

Genetic and environmental parameters for ostrich skin traits were estimated in this study. Slaughter records of 2,660 South African Black ostriches were used, with an age range of 210 to 596 days. Fixed effects included were contemporary group, sex, dam age and their interactions. ASReml program was used for analysis. Age influenced all traits, except for neckline traits. Sex was significant for crown length, hair follicle score, skin weight, skin thickness, nodule size score and nodule shape score, with males producing thicker skins than females. Males had significantly higher scores for nodule size (4.6 vs 4.3), nodule shape (4.4 vs 4.1) and hair follicles (3.9 vs 3.5) than females. Direct single-trait heritability for skin size, slaughter weight, skin weight, skin thickness, hair follicle score and pitting score were 0.41 ± 0.06 , 0.37 ± 0.06 , 0.27 ± 0.06 , 0.20 ± 0.05 , 0.42 ± 0.06 and 0.08 ± 0.04 , respectively. The significant genetic correlations of slaughter weight with crown width, crown length and crown shape were moderate to high at 0.58, 0.81 and 0.79, respectively. The genetic correlation of slaughter weight with skin size was high (0.92), moderate with skin weight (0.48), and low with skin thickness (0.15). Slaughter weight was also positively and significantly correlated to nodule size on the genetic level. High genetic correlation (0.71) was observed between nodule shape and nodule size scores. It was concluded that appreciable levels of genetic variation existed in most quantitative skin characteristics and genetic progress appears to be feasible through indirect selection as all traits are genetically favourably correlated to slaughter weight.

Session 56

Theatre 8

Genomic signatures of adaptive response driven by transhumant pastoralism in native Boutsko sheepV. Tsatsianidou^{1,2}, S. Vouraki³, P. Papanikolopoulou³, G. Arsenos³ and A. Triantafyllidis^{1,2}¹Center for Interdisciplinary Research and Innovation, Genomics and Epigenomics Translational Research, Balkan Center, 57001 Thessaloniki, Greece, ²Aristotle University of Thessaloniki, School of Biology, University Campus, 54124 Thessaloniki, Greece, ³Aristotle University of Thessaloniki, School of Veterinary Medicine, University Campus, 54124 Thessaloniki, Greece; tsarvale@bio.auth.gr

Current and future climate fluctuations combined with selected livestock populations for production purposes raise major concerns about the preservation of animal genetic resources and food security. This study aimed to identify signatures of adaptive selection related to the impact of environmental heterogeneity on the genome of Boutsko, a Greek native transhumant sheep. Global positioning system (GPS) devices were used to monitor a total of 296 purebred Boutsko sheep reared semi-extensively during summer in three flocks located in Northwestern Greece. These populations were georeferenced based on the farm coordinates for lowland winter locations and genotyped with the Ovine SNP50K Bead Chip v2. A genotype-environment association (GEA) analysis was conducted with high and low-altitude grazing locations implementing logistic regressions. Fifteen SNPs were significantly associated with the bioclimatic variable of precipitation seasonality (bio15) representing the variation of monthly precipitation totals over the course of the year. Five candidate SNPs located on chromosomes 6, 15 and 22 were positioned within annotated genomic regions and their spatial genotype distribution coincided with geographic variation of precipitation seasonality. Functional enrichment analyses detected gene sets related to climate response, such as hypoxia response, energy metabolism, cell proliferation and differentiation and body conformation traits. The association between specific genomic loci and precipitation variation in the contrasting eco-climatic regions could be attributed to water and relevant pasture availability and composition within grazing areas seasonally and altitudinally. These results can enhance the incorporation of adaptive-related SNPs in selective breeding programs to face projected climate change. This work was funded by the SMARTER H2020 project (Grant No: 772787).

An Australian sheep genomic reference to meet the evolving breeding objectives of industryS.F. Walkom¹, D.J. Brown¹ and J.H.J. Van Der Werf²¹Animal Genetics and Breeding Unit, University of New England, Armidale, 2351, Australia, ²School of Environmental and Rural Science, University of New England, Armidale, 2351, Australia; swalkom@une.edu.au

The Australian sheep industry has used genomically enhanced breeding values since 2012. The ability to incorporate genomic information was only made possible by industry investment in a national genomic reference. Initiated in 2007, the Sheep CRC Information Nucleus Flock and its later incarnation the MLA Resource Flock has provided growth, carcase, and wool phenotypes on ~40k genotyped individuals across Merino, Terminal and Maternal breed types. Australian Wool Innovation's Merino Lifetime Productivity project and the Australian Merino Sire Evaluation sites also provided valuable data for the Merino breed. By maintaining a successful genomic reference that directly contributes to the national genetic evaluation producers were shown the direct value of genotyping. Currently, across the core national Sheep Genetic analyses, there are over 500k genotyped animals from industry and research contributing to the evaluation. As a result, the genomic reference is expanding beyond the research population and the role of industry levies to fund the reference population is declining. Future funding will depend on co-investment by breeders beyond levy contributions, with investment dependent on breeders perceiving value in a genomic reference. New and hard to measure traits continue to require recording in research flocks. Consequently, the next iteration of the resource flock will focus on underrepresented and future traits of importance. Providing the core population for the recording of methane and feed intake as well as resilience and maternal behaviour traits. The role of the reference population can be further enhanced by creating stronger linkages between different maternal and Merino ram sources, needed for prediction of breeding values across breed types and of crossbred animals. This would achieve more reliable genomic prediction reliability for key traits such as reproduction and meat eating quality across the commercial breeding flocks.

Session 56

Poster 10

Evaluation of the perceptions of the functions of local breeds of domestic ruminants in MayotteJ. Vuattoux¹, A. Lauvie², A. Giraud³, E. Ozarak³, J. Janelle⁴, A. Rozier³, T.T.S. Siqueira¹, M. Naves⁵ and E. Tillard⁶¹CIRAD, 7 chemin de l'IRAT, ligne paradis, 97410 Saint Pierre, France, ²INRAE, 2 place Viala, 34060 Montpellier Cedex 01, France, ³CIRAD, 69 Rue Moussa Oili, 97660 Tsararano, Dombéni, Mayotte, ⁴CIRAD, Chem. de Baillarguet, 34980 Montferrier-sur-Lez, France, ⁵INRAE, Centre de Recherche Antilles-Guyane, Domaine Duclos – Prise d'eau, 97170 Petit-Bourg, Guadeloupe, ⁶CIRAD, Campus agronomique de KOUROU, Avenue de France, BP 701, 97387 Kourou cedex, French Guiana; anne.lauvie@inrae.fr

In Mayotte, local populations of ruminants are well adapted to the difficult breeding conditions of the island. The importation of animals and artificial insemination with European breeds, has led to a policy of crossbreeding and a decrease of the size of the local breeds herds. The work carried out by CIRAD, INRAE and the Chamber of Agriculture enabled the characterization of local bovine, ovine and caprine breeds. These three populations are a reservoir of adaptive genes. The conservation of domestic breeds is often considered from a genetic and zootechnical perspective. However, the choice of breeds follows along socio-economic dimensions. Two studies questioned the perception that breeders have of local breeds. The first study aimed at understanding the factors that influence the preservation or abandon of the Mahoran zebu breed. Sixty farmers were surveyed through semi-structured interviews. The data collected made it possible to describe the diversity of cattle farms in five types: (T1) small traditional farms; (T2) small precarious farms; (T3) farms specialized in dairy production; (T4) intermediate farms between tradition and intensification; (T5) farms in transition. The zebu is used for its ease of breeding and its resistance, in addition to its heritage and cultural value (T1, T2). It is of economic interest for crossbreeding (T3, T4) and ¾ of the breeders note the superior quality of its meat. The second study which is based on comprehensive interviews carried out on 19 farms on the island, explore the link between the functions assigned by the farmer to his small ruminant herd and the choice of its genetic composition. Both of these studies help to define the design of the conservation programs of the ruminant breeds in Mayotte, based on farmers perspectives.

Signature of selection in South African Dexter cattle reveal resistance genes and genetic variationsE.D. Cason¹, J.B. Van Wyk¹, P.D. Vermeulen² and F.W.C. Naser¹¹University of the Free State, Department of Animal Sciences, 205 Nelson Mandela Drive, Bloemfontein, 9301, South Africa, ²University of the Free State, Office of the Dean, 205 Nelson Mandela Drive, Bloemfontein, 9301, South Africa; CasonED@ufs.ac.za

The environment shapes the genome of animals and drives them to carry sufficient genetic variations to adapt to changes in temperature. The Dexter breed is a small, dual purpose, breed of cattle that originated in the Southwestern region of Ireland and was imported to South Africa in 1917. These animals are farmed intensively and were under artificial and natural selection for adaptation to the semi-arid South African climate. Due to the small initial population, these animals were also crossbred with other local breeds. Selection should thus have left detectable signatures on the genome of these Africanised cattle. However, the selection response for production and adaptation traits in the Dexter genome is not explored. In this study, we provide the first overview of the selection signatures in the Dexter genome. The cattle were genotyped using the BovineSNP50 BeadChip and the SNP genotype data of its European contemporaries and constituent breeds were obtained from affiliates. Signatures of selection revealed genomic regions subject to natural and artificial selection that may provide background knowledge to understand the mechanisms that are involved in economic traits and adaptation to the South African environment. Principal component analysis (PCA) and genetic clustering emphasised the genetic distinctiveness of Dexter cattle relative to other South African cattle breeds. HapFLK results identified selection sweep regions distributed across 3 chromosomes, 1, 14 and 27. The identified regions overlapped with regions previously associated with quantitative trait loci (QTL) which included tick resistance, *Mycobacterium paratuberculosis* susceptibility, bovine tuberculosis susceptibility and bovine respiratory disease susceptibility. Selection for production traits were also present, such as carcass weight, milk yield, calving ease, fertility index as well as marbling and tenderness score.

Breed environment interaction and suitability of Dutch cattle breeds for low input systemsJ.J. Windig^{1,2}, G. Bonekamp², M.A. Schoon^{1,2}, A.H. Hoving² and S.J. Hiemstra¹¹Wageningen UR, Centre for Genetic Resources the Netherlands, P.O. Box 338, 6700 AH, the Netherlands, ²Wageningen UR, Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; jack.windig@wur.nl

Dutch dual-purpose cattle breeds have been replaced for 98% by international transboundary high input/high output breeds, mostly the Holstein Friesian cattle breed. However, there is renewed interest in native dual purpose cattle breeds and their potential suitability for more 'nature-inclusive' production systems that require less external inputs. We performed a national inventory of dairy herds with Dutch dual purpose cattle breeds using data on production, health and fertility, combined with farming system characteristics and input and output parameters across production environments and regions in the Netherlands. Results were contrasted with performance of Holstein Friesian herds neighbouring the Dutch dual purpose cattle herds. Milk production varied considerably within breeds but was on average of a higher level in Holstein compared to the Dutch dual purpose breeds. Across the range of farming systems and environments milk, fat and protein levels were lower in grass based systems, on smaller farms and in more 'nature-inclusive' low input systems within the Holstein breed. For the dual purpose breeds changes across environments and systems were less clear, mainly because these breeds were more confined to specific regions and farm systems. Fat and protein and reproduction traits of Dutch dual purpose breeds were comparable and in some cases higher than levels in Holstein. For example, the Groningen White Headed had higher protein levels in grass based systems and the MRY in systems where more maize and concentrates were fed compared to the Holstein. These results help to identify future opportunities for the Dutch native dual purpose breeds in the context of transitions in Dutch livestock farming systems.

Identification of candidate gene variants for the alpaca Suri phenotype by WGS analysisS. Pallotti¹, D. Pediconi², M. Picciolini³, M. Antonini⁴, V. Napolioni¹ and C. Renieri²

¹School of Biosciences and Veterinary Medicine, University of Camerino, Via Gentile III Da Varano, 62032 Camerino (MC), Italy, ²School of Pharmacy, University of Camerino, Via Gentile III Da Varano, 62032 Camerino (MC), Italy, ³SYNBIOTEC Laboratori s.r.l., Località Torre del Parco, 62032 Camerino, Italy, ⁴Italian National Agency for New Technologies, Energy and Sustainable Development (ENEA), Casaccia, Via Anguillarese, 301, 00123 Galeria (RM), Italy; stefano.pallotti@unicam.it

Alpaca is a South American camelid bred for meat and fibre production. Two different phenotypes are described for this species: the short and crimped hair phenotype, known as Huacaya, and the long, straight and luster hair phenotype, known as Suri. To date, the genetic background behind the two phenotype is still unknown, however, segregation analysis suggest the Suri phenotype as dominant trait. In this research, whole-genome sequencing (WGS) analysis was used to uncover the genetics variant behind the Suri phenotype. Sample consisted of 19 WGS from Huacaya alpacas retrieved from public available repository (NCBI-SRA), 3 new WGS of Huacaya alpacas and 4 new WGS of Suri alpacas. Single reads were aligned to the most updated alpaca reference genome (VicPac3.1) and the genomic joint variant calling was performed. 37,421,914 variant were called, classified as single nucleotide polymorphism (30,749,986), insertions (3,547,803) and deletions (3,124,125). The called variants were then annotated in order to predict the phenotypic effects. 81,859,906 phenotypic effects were predicted, of which 61,094 were of 'high impact', 312,519 were of 'moderate impact', 545,541 were of 'low impact' and lastly, 80,940,752 were classified as 'modifier impact' influencing genomic untranslated regions. Finally, a case-control filtering were performed assuming the Suri phenotype as dominant mutation. 258 out of 35.371.788 variants remains. Five variants located on four loci were missense mutations while the remaining 253 were annotated to untranslated genomic regions. The five missense variants identified are promising candidate for the alpaca Suri phenotype.

Session 57**Theatre 1****Extensive permanent grasslands in Europe: multifaceted functions, threats and prospects**

M. Bassignana

Institut Agricole Régional, Reg. La Rochère, 1/A, 11100 Aosta, Italy; m.bassignana@iaraosta.it

Permanent grasslands represented in 2020 more than 30% of the 157 million hectares of land used for agricultural production in the EU, but they were incurring a declining trend, with a reduction of 2.0 million hectares in a decade. The EU Biodiversity Strategy for 2030 explicitly highlights the preservation of low-intensive permanent grasslands as one of the sustainable practices to be implemented, in accordance with the Farm to Fork Strategy, in the framework of the new Common Agricultural Policy. The first and evident function of extensive permanent grasslands, with particular reference to mountain ones, is to support sustainable animal productions, given that the breeding of domestic ruminants is the only way to obtain food for humans in vast areas where, at the present time, no other type of food crops would be possible. At the same time, their aptitude to deliver multiple ecosystem services, in addition to provisioning ones, is unique and peculiar, ranging from biodiversity and supporting services, to regulating and cultural ones. Mountain grasslands, in fact, are essential elements of centuries-old breeding systems which have been maintaining over time local breeds – often on the verge of extinction – as well as the continuity of mountain civilization, whose distinctive characteristics are absolutely original and peculiar. The durability of these systems is increasingly jeopardized by the combination of various factors, such as low economic benefits, workload and scarcity of manpower, climate change and drought, leading to the abandonment of marginal areas. In order to promote the proper preservation of these resources and of the farming systems associated with them, multidisciplinary research is essential to highlight their significance – for animal production but more generally for the environment and for people, be aware of the risks they are facing and, finally, discern what prospects can be expected for their future.

The effect of establishment and grazing management on clover and herb establishment and persistenceL. McGrane^{1,2}, N. McHugh², T.M. Boland¹ and P. Creighton²¹University College Dublin, School of Agriculture and Food Science, Belfield, Dublin 4, D04V1W8, Ireland, ²Teagasc, Animal and Grassland Research and Innovation Centre, Mellows Campus, Athenry, Co. Galway, H65R718, Ireland; Lisa.McGrane@teagasc.ie

The addition of clovers and herbs to grazed swards has shown many benefits including increased performance of grazing ruminants, increased herbage production and reduced dependence on chemical nitrogen inputs. Poor plant persistency under grazing is one of the main challenges associated with these diverse sward types. Although there has been an increase in the use of diverse sward types in recent years, there is a lack of grassland management advice available for their use. Two adjacent sheep grazed plot studies were established using a complete randomised block design in 2019 and measured in the years 2019 to 2022 inclusive, investigating the effect of: (1) establishment method (n=60 plots); and (2) post-grazing sward height (n=36 plots), on binary sward mixtures of perennial ryegrass plus one companion forage (white clover, red clover, plantain or chicory). Post removal of the pre-existing sward the four establishment methods implemented were: (1) conventional (plough, till, sow); (2) Disc (disc harrow cultivation, power harrow cultivation, sow); (3) Power Harrow (Power harrow cultivation, sow); and (4) Direct Drill (direct drill with no cultivation of the soil). The three post-grazing sward heights implemented were: (1) 4.0 cm; (2) 4.75 cm; (3) 5.5 cm. Results show that establishment method had no effect on white clover, red clover or chicory content in the sward, however there was a higher plantain content in swards sown using the Direct Drill method compared to the Conventional method ($P<0.05$). In the third full production year, white clover content was similar across all post-grazing sward heights, however there was a higher red clover content in swards grazed to 4.75 cm than both the 4.0 and 5.5 cm treatments ($P<0.05$). There were higher chicory and plantain contents in swards grazed to 4.0 cm than those grazed to 5.5 cm ($P<0.05$). In conclusion, establishment method had an impact on plantain content in the sward and appropriate grazing management is vital to maximise forage persistency in diverse sward types.

Session 57

Theatre 3

Strategic concentrate supplementation in reducing slaughter age in pasture-based dairy-beef systemsJ. O'Driscoll^{1,2}, D. Purfield¹, N. McHugh² and N. Byrne²¹Munster Technological University, School of Biological Sciences, Bishopstown, Cork, T12 P594, Ireland, ²Teagasc, Animal & Grassland Research and Innovation Centre, Grange, Dunsany, Co. Meath, C15 PW93, Ireland; jamie.odriscoll@teagasc.ie

Increased efficiency within livestock production systems is critical to reducing greenhouse gas emissions, with reduced age at slaughter cited as a key mitigation policy. Beef systems of reduced slaughter age must maximise the use of grazed grass over the animal's lifetime due to its lower cost of production and lessened environmental impact compared to other feeds. The objective of this study was to investigate the strategic use of concentrate within a pasture-based dairy-beef steer production system, to establish its effectiveness in reducing slaughter age, using Holstein Friesian (HF; n= 80 animals) and Angus × Holstein Friesian (AAX; n= 160 animals) genotypes. Contrasting supplementation strategies were analysed: (1) grass only (GO), pasture only diet in the first and second grazing season; (2) intermediate (INTER), concentrate supplementation throughout the first grazing season, pasture only thereafter; and (3) high concentrate supplementation (HIGH), concentrate supplementation throughout the first grazing season, and from July until slaughter/housing of the second grazing season. Drafting for slaughter across each strategy occurred at a body condition score ≥ 3.75 , on a 5-point scale. The age at slaughter of AAX steers was 80 days earlier than HF (631 vs 712 $\pm$ 2 days: $P<0.001$) across concentrate treatments. HIGH treatment AAX steers were slaughtered 43 ($\pm$ 3.8) days earlier ($P<0.001$), and produced a lighter carcass (294 vs 307 $\pm$ 4.8 kg, $P<0.05$) than both GO and INTER AAX steers. However, HIGH AAX steers consumed more concentrates (+122 $\pm$ 21.75 kg, $P<0.001$) over the finishing period than the GO and INTER steers (278 $\pm$ 21.75 kg), which did not differ. Irrespective of concentrate treatment, slaughter age did not differ for HF steers ($P>0.05$). HIGH HF steers produced a heavier carcass (326.2 vs 308.2 $\pm$ 6.3 kg, $P<0.05$), and consumed more concentrate (+334 $\pm$ 32.2 kg, $P<0.001$) than GO and INTER HF steers, which did not differ. Age at slaughter of AAX steers, can be reduced by strategic concentrate use during the second grazing season, allowing earlier finish at pasture.

Morphology and body composition of beef-on-dairy heifers along compensatory growth itineraryI. Morel¹, A. Dieudonné¹, R. Siegenthaler¹, C. Xavier^{1,2} and S. Lerch¹¹Ruminant Nutrition and Emissions, Research Contracts Animals, Agroscope, 1725 Posieux, Switzerland, ²INRAE-Institut Agro, PEGASE, 35590 St-Gilles, France; isabelle.morel@agroscope.admin.ch

The aim was to evaluate if finishing heifers fed a grass-based diet during a compensatory growth period (CG) would recover the effects of a previous restrictive feeding (RF). Sixty-six crossbred heifers (♀ Swiss Brown × ♂ Angus, Limousin or Simmental) were used from 271 to 527 kg BW. Thirty-three grew discontinuously (DI), 111 d on mountain pasture, followed by 80 d CG at barn (65:20:8:7 grass silage/hay/maize silage and concentrates, DM basis). The remaining 33 were fed continuously (CO) the barn-diet during 191 d. Body morphological measurements were performed on 12 heifers per treatment by full body 3D imaging, dorsal and rump ultrasounds, and trained operator grading (CHTAX), at the beginning and the end of RF, at the end of CG and before slaughter. At the same dates (except end of CG), direct *post mortem* measurements of empty body (EB) chemical composition were performed on 6 additional heifers per treatment and date. The RF induced lower average daily gain (ADG, 0.45 vs 1.06 kg/d), leading to a weight difference of 84.4 kg at the start of CG ($P < 0.001$), lower fat cover score (1.34 vs 3.27) and skin and adipose tissue thickness ($P < 0.05$) for DI vs CO heifers. Accordingly, lipid content in EB (9.0 vs 17.3%) was lower and protein content higher at the end of RF ($P < 0.001$). Morphologically, the DI heifers were significantly lower in body length, area, and volume, but not in height. Over 80 days of CG, the DI heifers ingested more (8.7 vs 7.8 kg DM/d), had a higher ADG (1.46 vs 1.02 kg/d) and valorised the ration more efficiently (0.17 vs 0.13 kg ADG/kg DMI; $P < 0.01$) than CO heifers, achieving a BW compensation index of 43%. Increase in body height was however strongly slowed down during CG, thus prioritizing width gain. At slaughter after 160 d of refeeding, full compensation of the gap due to RF between DI and CO heifers was observed, in carcass grading, morphological measurements, as well as for EB lipid and protein contents ($P > 0.10$). This trial highlights wide adaptive processes in body morphological and composition traits when growing cattle had to cope with nutritive challenges along CG itinerary.

Session 57

Theatre 5

In France, a new beef × dairy calf to steer production for the out-of-home consumersM.A. Brasseur^{1,2}, C. Fossaert^{1,2}, F. Guy^{1,2}, J.J. Bertron², T. Dechaux² and S. Brouard²¹CIRBEEF, 4 La Touche Es Bouvier, 56430 Mauron, France, ²Institut de l'élevage, 149 rue de Bercy, 75595 Paris, France; marc-antoine.brasseur@idele.fr

Following the decline in veal and young bull productions, French dairy calves are increasingly oriented towards export, resulting in long distance transport for young calves and rising questions from consumers. However, these calves could produce carcasses adapted to the out-of-home market, which is mainly supplied by imported meats from dairy herd. In this context, trials have been realized on the CIRBEEF farm in Mauron (56), with the aim of developing beef × dairy steer production (16-17 months) with light carcass weight (280-300 kg carcass), well fattened and maximizing grazed or conserved grass. Four groups of 56 beef × dairy calves have been studied with two modalities depending on finishing mode (indoor/pasture) linked to the birth period (fall/winter). Weaned 56 days after their arrival, then fed a maize silage-based ration, the four groups showed an average daily gain (ADG) of 736 g/day on the arrival-weaning period and 1,011 g/day on the weaning-120 days of presence period. The two very contrasting climatic years had a strong impact on the growth of grass and therefore on the feeding practices (housing in summer, supplementation, etc.). However, the global growths are 1,070 g/day for the group finished indoor and 973 g/day for the group finished on pasture. With 5.4 and 7.4 months of pasture, respectively for the groups finished indoor and on pasture, the grass account for 54 and 61% of the lifetime feed consumption. This main grass part in the diet explains the protein self-sufficiency level of 81% which is better than 51% for our full indoor production based on maize silage. Of the 222 animals slaughtered, the average age at slaughter and the average carcass weight were 17.2 months and 304 kg. Slaughterhouses are looking for conformations O+ or better which is the case of 71% of carcasses. Moreover, the carcass yields were relatively high for dairy origin animals (on average 54%) and reflect well the diversity of the potentialities of the meat breeds used for the crossbreeding. The meat produced with these systems have gross emissions of 6.4 kg eq. CO₂/kg LW and a net carbon footprint of 6.2 kg eq. CO₂/kg LW (Calculated using the CAP'2ER® method).

Behavioural and welfare responses of dairy cows learning a virtual fencing systemP. Fuchs^{1,2}, J. Stachowicz², M. Schneider², M. Probo², R. Bruckmaier³ and C. Umstätter⁴¹GCB, University of Bern, Mittelstr. 43, 3012 Bern, Switzerland, ²Agroscope, Rte de la Tioleyre 4, 1725 Posieux, Switzerland,³University of Bern, Veterinary Physiology, Bremgartenstr. 109a, 3001 Bern, Switzerland, ⁴Thünen-Institute of Agricultural Technology, Bundesallee 47, 38116 Braunschweig, Germany; patricia.fuchs@agroscope.admin.ch

Virtual fencing (VF) offers the possibility of replacing physical fences with a virtual system. A proper use of VF aims to condition animals to an audio tone (AT, 82 dB for 5-20 s) to avoid a light electric pulse (EP, 0.2 J for 1 s). The present study investigated the learning behaviour of 10 lactating cows under VF and its effects on cow behaviour and welfare compared to 10 cows managed with electric fences (EF). Both treatments were split into groups of 5 ($2 \times \text{VF}$, $2 \times \text{EF}$) balanced by age and lactation stage. Each group grazed half-day in a separate, EF paddock during a 3 d lead-in period (P0) with inactive VF, followed by 4 periods (P1-4) with active VF. All cows were equipped with a VF collar (Nofence AS, Batnfjordsøra, Norway) and an IceQube pedometer (Peacock Technology Ltd., Stirling, UK). We continuously monitored cow activity and daily milk yield, body weight, and feed intake. Further, we recorded milk cortisol and the frequency of agonistic interaction, vocalization and excretion at the start, middle, and end of P0-P4. During 59 d, the cows received a mean of 108 ± 54 AT and 7 ± 3 EP. At Day 1, the number of EP was highest (18) but decreased to 5 at Day 3 (-72%) and remained below that threshold for the rest of the trial. With each paddock change, cows were successively conditioned to the AT, which was reflected in a decreasing ratio of EP/AT from Week 1 (22%) to Week 4 (2%), 6 (1%), and 8 (0%). Milk yield, milk cortisol, feed intake, body weight, and activity were similar in VF and EF groups. Throughout the trial, we observed a mean of 11.2 vocalizations and 5.9 displacements more per cow in the VF groups compared to the EF groups ($P < 0.05$). However, their frequency did not differ between P0-P4. Our results indicate that all cows learned to cope with the VF system without lasting behavioural changes or negative effects on animal welfare. The conditioning of the cows to the AT of the VF system succeeded at herd level after 3 repetitions on a new virtual fence.

Session 57

Theatre 7

Age does not affect the learning capacity of virtually fenced cowsA. Confessore¹, C. Aquilani¹, P. Fuchs², C. Pugliese¹, C.M. Pauler², M. Schneider², G. Argenti¹ and M. Probo²¹University of Florence, Department of Agriculture, Food, Environment and Forestry (DAGRI), Piazzale delle Cascine, 18, 50144 Firenze (FI), Italy, ²Agroscope, Rte de la Tioleyre, 4, 1725 Posieux, Switzerland; andrea.confessore@unifi.it

Virtual Fencing (VF) can be a helpful technology in managing herds in pasture-based systems. In VF systems, paddock boundaries are set in GIS only. Animals wear a GPS collar, which emits a sound signal of increasing pitch as soon as an animal crosses the virtual fence, followed by a weak electrical impulse if the animal does not return. The stimuli sequence is repeated up to 3 times if the animal continues to walk forward. It is well known that animals can learn a VF system, but it is unknown if learning capacity decreases with animal age. The study aimed to investigate whether old learn the system worse than young ones and whether VF impacts grazing activities and milk production. The study was conducted in the Swiss lowlands on 4 strip-grazing paddocks, comparable in forage biomass and botanical composition. 20 lactating Holstein-Friesian cows were divided into 4 groups of 5 animals, with each group grazing a separate paddock. Groups differed in terms of age: 2 old age groups (average of 5.2 and 4.8 lactations) and 2 young age groups (first lactation). After a 7-d training period, each paddock was gradually increased in size by VF during 5 consecutive grazing periods, based on forage biomass availability. Each cow was equipped with VF collars (Nofence AS, Batnfjordsøra, Norway) and leg pedometers (Peacock Technology Ltd., Stirling, UK) to record the daily number of sounds and electrical pulses as well as step count respectively. Data were analysed by generalized mixed-effect models demonstrating that age had no significant impact on animals' overall response to the VF system. However, there was a clear effect of time: independent of age, both electrical pulses and sounds significantly decreased within days of each period. Moreover, there were no significant differences in daily step count between ages. Finally, no changes in milk production were detected, comparing before, during, and post-VF treatment. In conclusion, results suggest that age does not affect animals' learning capacity, grazing activities, and milk production as well.

Integrating multiple data streams and models to inform precision grazing management in the U.S

J.R. Brennan, H. Menendez and K. Ehlert

South Dakota State University, 711 N Creek Dr., Rapid City, SD 57703, USA; jameson.brennan@sdstate.edu

Precision livestock management (PLM) technology has the potential to increase efficiency and sustainability of animal agriculture. Although any specific piece of technology requires unique steps for processing and turning data into insights, key to the advancement of PLM will likely be the integration of multiple technologies and data streams into animal nutrition models to better inform management decisions. Stocking rate (the number of animal units on an area of land per unit of time) is an essential component for setting forage utilization targets, minimizing overgrazing, and meeting land management objectives. However, setting appropriate stocking rates requires information on current forage production (kg/ha), and animal body weight (kg), variables which are often unknown to livestock managers at relevant time scales. The objectives of our study were to: (1) develop machine learning models to predict forage quantity and quality using open source climate and satellite imagery datasets; (2) develop data pipelines to process real-time information on individual animal and herd weight; and (3) develop a precision grazing model that integrates forage predictions and animal weights to dynamically adjust grazing rotations using virtual fence technology. Random forest regression trees were used to predict forage quality and quantity across the two sites in South Dakota, U.S. based on climate and imagery metrics derived from Google earth engine. R² values for predicted vs measured data in 2020-2021 were 0.91 for forage production, 0.78 for CP, 0.55 for NDF, and 0.77 for ADF. SmartScalesTM were deployed in grazing areas, and an automatic program interface was developed to estimate daily average herd weight. Weight and forage predictions were incorporated into a decision grazing model to estimate when to rotate animals based on forage utilization targets under three stocking rate scenarios (heavy, moderate, and light). The decision grazing model was then used in conjunction with virtual fencing technology to inform grazing area rotations and is a critical next step to maximizing precision technologies and mathematical animal nutrition modelling.

Session 57

Theatre 9

Yearly monitoring of soil ingestion by dairy cows in a grassland system with feed supplyC. Collas¹, A. Laflotte², C. Feidt¹ and S. Jurjanz¹¹Université de Lorraine, INRAE, URAFPA, 54000 Nancy, France, ²ENSAIA, Université de Lorraine, Centre R&D La Bouzule, 54280 Laneuvelotte, France; claire.collas@univ-lorraine.fr

Soil may be a vector of contaminants, such as trace metals or organic pollutants, from the environment to the animal. This can result in exceeding regulatory thresholds in food of animal origin and questioning the livestock farming sustainability in contaminated areas. Quantifying soil ingestion and determining its variation factors allow to characterise and adapt farming practices to reduce the free-range animal exposure to contaminants. Soil ingestion has been few studied in dairy cows, once in different barns in the USA and once with strip grazing in France. The present study monitored the soil ingestion in a dairy herd in East France from July 2019 to June 2020. During the winter period from December to March, the cows were housed without outside access and fed with a total mixed ration based on corn silage. Otherwise, cows had access to permanent grassland with the same ration in lower proportions depending on grass availability. Soil ingestion was estimated collectively every fortnight when the cows had access to pasture and every month when they were housed. A composite faecal sample was taken at each time point from a pool of 12 cows. Individual estimates of soil ingestion were made on 30 cows on four dates. Grass, feed, soil and faeces samples were analysed using titanium as a soil marker. Data were analysed by mixed models. Daily soil ingestion averaged 0.5% of total intake (125 g dry soil). The highest level (1.5% of total intake, 300 g dry soil) was obtained in late autumn when the soil was very wet which could amplify grass soiling. Low or not-detectable soil ingestions were observed in winter (housing conditions) and in summer when the soil was dry. Animal characteristics (age, lactation stage, milk yield) affected poorly soil ingestion. Compared to the literature, this farm management resulted in relatively low soil ingestions compared to cattle on exclusive grazing, but consistent for grazing with supplementation. Feed supply during difficult pasture conditions has shown to be an efficient practice to maintain low levels of soil ingestion and ensure animal health and food safety.

Pre-grazing sward height affects enteric methane emission during grazing

L. Koning, G. Holshof, A. Klop and C.W. Klootwijk

Wageningen University and Research, Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, the Netherlands; cindy.klootwijk@wur.nl

In order to reduce national greenhouse gas emissions, the Dutch dairy sector aims to reduce the enteric methane (CH₄) emission of dairy cattle. Grazing strategies could facilitate in achieving this goal as recent research showed that enteric CH₄ might be lower during grazing compared to grass silage diets. One of the strategies expected to influence CH₄ emission during grazing is the height of the sward prior to grazing. The pre-grazing sward height is related to the number of growing days thereby impacting the quality of the grass. The objective of this study was to compare enteric CH₄ emission based on a grazing system with a low and a high pre-grazing sward height. An experiment was conducted in 2020 and 2021 in Leeuwarden, The Netherlands. Two groups of fifteen dairy cows were randomly assigned to two treatment groups: a low pre-grazing sward height (8 cm; LS) and a high pre-grazing sward height (15 cm; HS). The experiment was divided into two weeks of adaptation and two weeks of measurement period and was repeated three times during the season: Apr-May (period 1; P1), Jun-Jul (period 2; P2), and Aug-Sept (period 3; P3). Cows had outdoor access to a pasture during the day and received grass silage indoors during the night in a 50:50 ration. In addition, they were fed 5.5 kg concentrates per cow per day. Enteric CH₄ emission was measured using GreenFeed® stations. Per period no significant differences were found in CH₄ emission, with exception of the CH₄ intensity (per kg FPCM) in P1 of 2020 and P3 of 2021, which was lower for LS compared to HS. The meta-analysis of the CH₄ emission across periods and years showed a significantly ($P < 0.001$) lower CH₄ yield, intensity and production for LS (resp. 20.0 g CH₄/kg DM, 15.2 g CH₄/kg FPCM and 378 g CH₄/cow/day) compared to HS (resp. 20.9 g CH₄/kg DM, 16.2 g CH₄/kg FPCM and 397 g CH₄/cow/day). Based on these results we can conclude that the pre-grazing sward height, which is related to the number of growing days, can influence enteric CH₄ emission. This study highlights that grazing strategies can contribute to mitigate enteric CH₄ emission in dairy farming systems.

Session 57

Theatre 11

Forage shortage affects performances, CH₄ emissions and cheese quality in grass- or corn-fed cowsM. Bouchon¹, I. Verdier-Metz², M. Eugene³, C. Bord², B. Martin³, J. Bloor⁴, M.C. Michalski⁵, B. Graulet³ and C. Delbès²

¹INRAE, UE Herbipole, 63122 Saint-Genes-Champanelle, France, ²UCA, VAS, INRAE, UMR Fromages, 15000 Aurillac, France, ³UCA, INRAE, VAS, UMR Herbivores, 63122 Saint-Genes-Champanelle, France, ⁴UCA, INRAE, VAS, UMR UREP, 63000 Clermont-Ferrand, France, ⁵INRAE, Inserm, Univ-Lyon, UMR CarMeN, 69310 Pierre-Bénite, France; matthieu.bouchon@inrae.fr

Grass-based dairy systems are considered to contribute to the agroecological transition and resilience of farming compared with more intensive corn silage-based systems, but the impacts of drought-induced forage shortages on services provided by these different systems are unclear. This study aims at evaluating the impact of a reduction of grass availability of -25% of the total intake during two months, as might be expected in case of a summer drought, for groups of cows fed either a pasture-based diet (AE) or a corn silage-based diet (IN). In each group, only half of the cows were subjected to the reduction in grass allowance (75 to 50% in AE, replaced by a hay-based diet; 25 to 0% in IN, replaced by corn-silage based TMR). Milk yield (MY) was higher for IN cows but the reduction in grass allowance did not affect MY nor milk fat content. MY decreased more over time for AE cows, in line with seasonal decreases in grass nutritional value. Milk protein content was the highest for IN cows with no more access to pasture. Dry matter intake was higher for IN cows and increased by the reduction in grass allowance. Raw CH₄ emissions were estimated using INRAE 2018 equations and were higher for IN cows, particularly for those with no grass in the diet. However, CH₄ emissions calculated on a MY basis were similar for all cows but expressed on a DMI basis, they were lower for IN groups and decreased in response to forage shortage for both AE and IN cows. Cheeses made with raw milk from AE groups were more yellow and softer while cheeses from IN groups had a lesser intense global odour. Within each group, cheeses were less yellow and firmer for cows subjected to a forage shortage. This study suggests that reducing access to pasture in a grazing system has less effect than removing pasture in a corn-silage based system on the services provided by the farming system.

Variability of economic and GHG performance in dairy-beef systems at different stocking ratesM. Kearney^{1,2}, E. O'Riordan¹, J. Breen², R. Dunne³, P. French⁴ and P. Crosson¹¹Teagasc, Animal & Grassland Research and Innovation Centre, Teagasc, Grange, Dunsany, Co. Meath, Ireland, C15PW93, Ireland, ²University College Dublin, School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, D04V1W8, Ireland, ³Teagasc, Johnstown Castle, Co Wexford, Y35Y521, Ireland, ⁴Teagasc, Livestock Systems Department, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy Co. Cork, Ireland., P61C997, Ireland; mark.kearney@teagasc.ie

The capacity of dairy-beef systems to run at high stocking rates (SR) has been identified as a key driver in increasing farm profitability and reducing GHG emissions. However, excessive SR may restrict animal performance with potential implications for GHG emissions and farm profitability. Therefore the objectives of this study was to parameterize a farm-level model using data from an experimental field study to model the effects of contrasting stocking rates on the economic and GHG emission performance of dairy-beef production systems. A total of 216 spring-born early and late-maturing dairy-beef steer and heifer calves were purchased and blocked by breed, birth date and weight on arrival and assigned to one of three treatments. The three treatments were based on SR and classified as low SR (LSR; 2.6 Livestock Units (LU)/ha), medium SR (MSR; 2.9 LU/ha) and high SR (HSR; 3.2 LU/ha). Each treatment consisted of 36 steers and 36 heifers. Slaughter weight and carcass weight were heavier and better conformed for LSR than MSR and HSR. Steers and heifers finished in HSR had greater live weight and carcass output per hectare and subsequent net profit per ha than LSR and MSR. GHG emissions per kg of product were lower for HSR. Increases in stocking rate maximise profit per hectare and reduce GHG emissions per kg of product provided it is undertaken via improvements in pasture productivity and utilisation.

Session 57

Poster 13

Feeding behaviour, methane emission and digestibility of crossbred heifers along compensatory growth

B. Hayoz, I. Morel, A. Dieudonné, M. Rothacher, R. Siegenthaler, F. Dohme-Meier and S. Lerch

Research Contracts Animals; Ruminant Nutrition and Emissions, Agroscope, 1725 Posieux, Switzerland; bastien.hayoz@agroscope.admin.ch

Compensatory growth (CG) occurs along refeeding after a period of feed restriction, and is characterized by high feed intake. Aim was to study feeding behaviour, enteric methane (CH₄) emission and digestibility during CG in beef-on-dairy crossbreeds. Heifers [♀ Brown Swiss × ♂ Angus (AN), Limousin (LI) or Simmental (SI), n=66] were used from 271 to 527 kg body weight (BW). Thirty-three grew discontinuously (DI), 111 d on mountain pasture, followed by refeeding 80 d at barn (65:20:8:7 grass silage/hay/maize silage and concentrates, DM basis). The remaining 33 were fed continuously the barn-diet (CO). Individual intake and feeding behaviour were obtained using automatic weighing troughs. Enteric CH₄ emission was measured with greenfeed system and digestibility over 5 d using insoluble ashes as indigestible marker. Individual means were computed over refeeding for ANOVA analysis (package GLM, RStudio 4.1.3) with fixed effects of dietary treatment, crossbreed and their interaction, and pen as random effect. Correlations between variables were explored (package RCORR). During CG, DI had higher DM intake (DMI) than CO heifers (9.2 vs 8.2 kg/d, P<0.01) with concomitant increases in meal duration and DMI per meal (P≤0.05). Nevertheless, DI had a lower organic matter digestibility (dMO) than CO (79.8 vs 81.9%, P<0.01), and tended to have lower CH₄ yield (28.4 vs 29.8 g/kg DMI, P=0.09). Compared to LI and SI, AN heifers had higher DMI but lower dMO (P≤0.01), whereas none difference was observed on CH₄ yield (g/kg DMI) between crossbreeds (P=0.34). Methane (g/d) was positively correlated with DMI and DMI per meal (r=+0.60, +0.39, respectively; P≤0.05) and negatively with dMO (r=-0.42, P<0.01). The dMO was also negatively correlated with DMI (r=-0.50, P<0.001). Only correlation between DMI and CH₄ remained significant when DI and CO groups are considered separately (r≥+0.48, P≤0.01). This trial highlights broad adaptive processes in feeding behaviour, concomitant with increase in feed intake along CG, with further consequences on CH₄ emission and digestibility.

Involving farmers in the development of a grassland monitoring tool: sunshine's co-design approachD.M. Mathy¹, C.L. Lucau-Danila¹, Y.C. Curnel¹, E.R. Reding², K.D. Dichou³ and S.L. Lagneaux¹¹Walloon Agricultural Research Center, Rue du Serpont, 100, 6800 Libramont, Belgium, ²Walloon Breeders Association (Elevéo), Rue des Champs Elysées, 4, 5590, Ciney, Belgium, ³Gembloux Agro-Bio Tech (ULG), Passage des Déportés, 2, 5030, Gembloux, Belgium; d.mathy@cra.wallonie.be

To help farmers managing their grasslands more efficiently, researchers around the world have been working on the development of new technologies such as biomass assessment out of satellite imaging and grass growth modelling. The Sunshine project aims at adapting these technologies for Wallonia (Belgium) and making them available in a dedicated decision support tool (DST). However, latest research revealed a low utilization rate of other existing grassland-related DSTs by Walloon farmers. To understand the reasons of this low adoption rate and to overcome it, a participatory approach including farmers in a co-design process has been set-up. In the first stage, we led semi-directive interviews with dairy and beef farmers spread across Wallonia, which allowed us to collect their design ideas, unveil their practical constraints and build a list of the ideal features for the software. In the second stage, we submitted this list to evaluation by a group of technicians and a group of farmers in order to identify the most relevant features. In the third stage, we developed a prototype with a core selection of basic features. Then, we engaged the farmers actively in the design process by organizing focus groups where they could try the prototype and exchange in an advanced co-design session. Using this approach allowed us to refine a typology of grassland management practices. Subsequently, this made possible to identify a core of features that would match to a greatest range of farmers and at the same time to avoid overspecific features that would inevitably lead to poor utilization rate of the software. This approach also generated novel ideas coming from the farmers, such as the way information should be addressed (e.g. eating-days left on a given paddock) or by reversing the purpose of a given feature. Lastly, our case study allowed us to discuss the critical points that raised our attention when it comes to involving farmers in the development of new DSTs.

Effects of increasing portion of grass-silage in dairy cow diet on carbon footprint of raw milkS. Hietala¹, A. Vanhatalo², K. Kuoppala³, T. Kokkonen², A. Reinikainen¹, K. Timonen¹ and A.-L. Vålmaa³¹Natural Resources Institute Finland, Bioeconomy and environment, Paavo Havaksen tie 3, 90570 Oulu, Finland,²University of Helsinki, Department of Agricultural sciences, Koetilantie 5, 00014 Helsinki, Finland, ³Natural Resources Institute Finland, Production systems, Paavo Havaksen tie 3, 90570 Oulu, Finland; sanna.hietala@luke.fi

Finnish dairy cows' diet consists of 55-60% of the grass silage (GS). Aim of this study was to find the impact of increasing GS content of dairy cows' diet to the carbon footprint (CF) of milk. We conducted a simulation study using experimental data from lactating dairy cows. Different diets were based on GS or equal mixture of red clover / GS and supplemented with barley and oats. Current results are for different proportions of forages on GS based diets, GS 55 or 65%. The CF of milk was assessed with life cycle assessment (LCA). IPCC approach was used as described in Hietala *et al.* and it was adjusted for the diet composition, as well as milk yield and composition according to the simulation results. Milk yield was converted to fat and protein corrected milk (FPCM). Average number of calvings per cow was assumed to be 3.3 and slaughter age was 1,825 d. Equal slaughter weight was assumed for both diets. The '55% GS' diet included 4,000 kg dry matter (DM) GS/year, cereals 1,800 kg DM/year (1:1 barley and oat) and rapeseed meal 650 kg DM/year. The milk yield was 10,735 kg FPCM/year. The '65% GS' diet included 4,413 kg DM GS/year, cereals 1,298 kg DM/year (1:1 barley and oat) and rapeseed meal 469 kg DM/year. The predicted milk yield was 10,092 kg FPCM/year. Increasing the GS proportion in the diet led to lowered milk yield (-1,769 kg FPCM). The demand for arable land was reduced (-2,353 m²), when GS portion was increased. The total emissions of the dairy cow were lowered by 1,819 kgCO₂eq with the increased GS content of the diet. Yet, when the emissions were allocated to the products, the higher FPCM yield of the 55% GS diet levelled out the difference at product level and carbon footprint of FPCM was 2% higher with 65% GS diet. Acknowledgments This study was conducted in Leg4Life project (2019-2025) funded by the Strategic Research Council at the Academy of Finland (grant numbers 327700 and 327698).

Blood metabolite, hormone and $\delta^{13}\text{C}$ turnover kinetic during compensatory growth of crossbred heifers

S. Lerch¹, P. Silacci¹, G. Cantalapiedra-Hijar², R. Siegenthaler¹, S. Dubois¹, A. Delavaud², M. Bonnet² and I. Morel¹
¹Ruminant Nutrition and Emissions, Animal Biology, Research Contracts Animals, Feed Chemistry, Agroscope, 1725 Posieux, Switzerland, ²INRAE, Université Clermont Auvergne, Vetagro Sup, UMRH, 63122 Saint-Genès-Champanelle, France; sylvain.lerch@agroscope.admin.ch

Compensatory growth occurs when cattle are refed after feed restriction and is characterized by changes in metabolic and hormonal profiles. Aim was to explore relationships between feed efficiency or compensation intensity, and blood metabolites, hormones and ^{13}C natural abundance ($\delta^{13}\text{C}$). Sixty-six beef-on-dairy heifers (♀ Swiss Brown × ♂ Angus, Limousin or Simmental) were used from 270 to 527 kg body weight (BW). Thirty-three grew discontinuously (DI), 111 d on mountain pasture, followed by 80 d refeeding at barn (65:20:8:7 grass silage/hay/maize silage and concentrates, DM basis). The remaining 33 were fed continuously the barn-diet (CO). Blood serum non-esterified fatty acids (NEFA), glucose, creatinine, τ -methyl-histidine (τMH , CAS:332-80-9), and plasma insulin, IGF-1 and $\delta^{13}\text{C}$ were determined at d 0, 2, 4, 8, 16, 35 and 70 of refeeding. Relationships (Proc CORR, SAS 9.4.) were explored with feed conversion efficiency [FCE=average daily gain (ADG)/DM intake] and compensatory index (CI; reduction of BW differences between DI and CO treatments over 80 d refeeding). When compared to CO, ADG of DI heifers was lower at pasture (0.45 vs 1.06 kg/d), but higher during compensation (1.46 vs 1.02 kg/d), as for FCE (0.17 vs 0.13; $P<0.001$). CI was 43% whatever the crossbreed ($P=0.52$). Plasma $\delta^{13}\text{C}$ at d 0 was negatively correlated with ADG at pasture ($r=-0.77$), but positively over compensation ($r=+0.76$), as for FCE ($r=+0.63$); the reverse being observed for d 0 IGF1 ($r=+0.46$, -0.76 , -0.51) and d 70 τMH ($r=+0.34$, -0.65 , -0.59 ; $P\leq 0.10$). The FCE was positively correlated with increases (by difference) in glucose from d 0 to 70 and creatinine from d 0 to 4 ($r=+0.59$, 0.56 , respectively; $P\leq 0.06$), but negatively with d 2 to 16 τMH and d 16 to 70 insulin increases ($r=-0.62$, -0.58 ; $P\leq 0.05$). The CI was positively correlated with d 0 to 4 creatinine increase ($r=+0.60$) and $\delta^{13}\text{C}$ turnover ($r=+0.57$; $P\leq 0.06$). Feed efficiency and CI were associated with blood metabolites, hormones and $\delta^{13}\text{C}$ kinetic following a refeeding in beef-on-dairy heifers.

Metabolic assessment of parasite dilution and forage niche sharing in sheep/cattle mixed-grazing

F. Joly¹, P. Nozière¹, P. Jacquet², S. Prache¹ and B. Dumont¹

¹Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, 63122 St Genes Champanelle, France, ²IHAP, INRAE, ENVT, Université de Toulouse, 31076 Toulouse, France; frederic.joly@inrae.fr

Mixed-grazing by sheep and cattle is the simultaneous or sequential grazing of a pasture by both species. It can improve lamb liveweight gain through parasite dilution (PD) and/or forage niche sharing (FNS). Here, we assessed the relative strengths of the two mechanisms through a novel metabolic approach. We used recently published equations to model the infection cost of gastrointestinal nematodes in metabolizable energy (ME) and crude protein (CP). By comparing infection levels in mixed and monospecific grazing, we quantified the gains of PD in ME and CP. We also used feed value tables to assess the gains in ME and CP, resulting from sheep diet improvement through FNS. We applied this approach to the dataset of an experiment, comparing sheep monospecific grazing to simultaneous mixed sheep-cattle grazing. We also applied it to a generic situation where we studied the relative gains in ME and CP, along gradients of increasing strength of PD and FNS. The approach applied to ewe lamb in our experimental data revealed that: (1) infection by gastrointestinal nematodes can represent 100% of ME and 75% of CP requirements in monospecific grazing; (2) mixed-grazing can reduce these costs to 25 and 15% of requirements, respectively; and (3) PD was more important than FNS in terms of ME gains, whereas it was the opposite for CP. However, meeting CP requirements was less constraining than meeting ME requirements in our experimental conditions, which puts into perspective the importance of CP gains. With the generic approach, most of the situations modelled also identified PD as the main mechanisms of ME gain (79%), whereas it was FNS for CP (70%), with the same observation that CP requirements were less difficult to meet. Both our experiment and generic approach thus suggest that PD matters more than FNS in mixed-grazing, owing to the greater difficulty in meeting ME requirements. We proposed a novel approach to assess the roles of two contrasting mechanisms through common metrics. It can help improve the comprehension of the biological processes involved in agroecological practices, such as mixed-grazing.

Effects of different additives on the correlation between fermentation characteristics of wilted ryeY.F. Li¹, L.L. Wang¹, Y.S. Yu¹, H.J. Kim² and J.G. Kim^{1,2}¹Seoul National University, Graduate School of International Agricultural Technology, 1447 Pyeongvhang-Ro, Daehwa, Pyeongchang, Gangwon, Korea, 25354, Korea, South, ²Seoul National University, Institute of GreenBio Science and Technology, Seoul National University, 1447 Pyeongvhang-Ro, Daehwa, Pyeongchang, Gangwon, Korea, 25354, Korea, South; 2019-20640@snu.ac.kr

The primary objective was to explore whether chemical or biological additives have effective effects on the correlation between the fermentation characteristics of wilted rye. The whole rye was harvested at the early heading stage and wilted in the field for 24 h. Wilted rye was divided into 6 treatments: no additive (C), 3 g/kg sodium diacetate (SDA3), 6 g/kg sodium diacetate (SDA6), *Lactobacillus plantarum* (Lp), *L. buchneri* (Lb), or their equal mixture (Lbp) at 1×10^6 cfu/g fresh matter. After 60 days ensiling, it showed that lactic acid (LA) was negatively correlated with acetic acid (AA) except for the C, where the negative correlation of Lp was the highest (-0.994 , $P < 0.05$). There was a negative correlation between LA and $\text{NH}_3\text{-N}$ in all groups with Lp (-0.990) having the highest negative correlation and S3 (-0.198) the lowest ($P < 0.05$). LA in C and S6 showed a positive but extremely low correlation with its pH while the other groups showed a negative correlation. LA in C, Lp and Lbp was negatively correlated with WSC while the other three groups were positively correlated and Lbp was the highest (0.997 , $P < 0.05$). Interestingly, the correlation between AA and WSC was just the opposite. $\text{NH}_3\text{-N}$ increased with AA in all silages except the C. AA in all silage showed a positive correlation with pH but a negative correlation with CP. WSC concentration of C, Lp and Lbp was negatively correlated with $\text{NH}_3\text{-N}$ and pH. There was a positive correlation between $\text{NH}_3\text{-N}$ and LAB counts only in Lp and Lbp and Lp (0.927) > Lbp (0.144). The $\text{NH}_3\text{-N}$ concentration was low, the pH was high except for the C. AA and pH were higher, CP was lower. CP content was positively correlated with LA but negatively correlated with NH_3 apart from C. Additives significantly altered the correlation between fermentation characteristics and LP was optimal.

Bite item selection by grazing suckler cows in multi-species grasslandsC. Siede¹, W. Pohlmann¹, A. Juch¹, D. Hamidi¹, J. Isselstein^{1,2} and M. Komainda¹¹University of Goettingen, Department of Crop Science, Von-Siebold-Str. 8, 37075 Göttingen, Germany, ²University of Goettingen, Centre for Biodiversity and Sustainable Land Use, Büsgenweg 1, 37077 Göttingen, Germany; caroline.siede@uni-goettingen.de

Bite item (BI) choice of grazing cattle depend on various interacting factors including BI diversity and availability in the grass sward. Multi-species grasslands provide a spatio-temporally varying availability of potential BI. It remains an open question if cattle utilize the available BI diversity by choice or not and if that depends on the grazing intensity (GI). The BI availability and choice of suckler cows was studied in a long-term replicated cattle grazing experiment under two GI (moderate, M; lenient, L) (in total six 1 ha paddocks). The GI paddocks were stocked with three or two non-lactating Fleckvieh cows. During two grazing periods in 2022 (spring, autumn) the actual available BI were assessed pre grazing along two transects (200 points per paddock) using a modified sward stick (10×10 cm steel frame) to simulate the bite size area of adult cattle. At each point, the height as well as the botanical composition (functional groups, colour and the phenological stage) were measured. The diversity of unique BI per pasture and period was calculated subsequently. The realised BI choice was assessed by video recording and observation of each cow in the morning and afternoon (4×2 minute intervals; in total 16 min/cow and period) using a mobile phone app for recording and subsequent video analysis. The diversity of chosen BI was calculated. In total 51 unique BI were found. Available BI diversity in the grass sward was significantly higher in spring (M: 22.8 ± 2.15 vs 13.5 ± 2.15 ; L: 22.3 ± 2.15 vs 17.0 ± 2.15). Chosen BI diversity increased with greater available BI diversity in the grass sward and was affected by the interaction of GI×period. Generally, it was greater under lenient grazing (spring: 12.1 ± 0.08 vs 14.9 ± 0.09 ; autumn: 1.4 ± 0.03 vs 4.5 ± 0.05). More BI are selected in pastures with greater available BI diversity.

Nutritional value of intramuscular fat of the muscle of Arouquesa weaners from different systems

L. Sacarrão-Birrento¹, C.A. Venâncio^{2,3}, A.M. De Almeida¹, L.M. Ferreira^{3,4}, M.J. Gomes^{2,3}, J.C. Almeida^{2,3}, J.A. Silva² and S.P. Alves⁵

¹LEAF, ISA, Lisboa, Portugal, ²CECAV, UTAD, Vila Real, Portugal, ³ECV, UTAD, Vila Real, Portugal, ⁴CITAB, UTAD, Vila Real, Portugal, ⁵CIISA and Associate Laboratory for Animal and Veterinary Sciences, FMV, Lisboa, Portugal; laurasvbirrento@isa.ulisboa.pt

The awareness about the fatty acids (FA) content in beef is increasing due to the relation of some FA with several diseases. Autochthonous breeds like the Arouquesa from Northern Portugal, are associated with healthier beef due to a more extensive way of production. This work aimed to compare the lipid nutritional value of Longissimus thoracis from Arouquesa weaners produced under different systems: TF, traditional system with weaning and slaughtering at 9 months; TFS1, the addition of an initiation supplement (S1); S1S2, animals fed with S1 until weaning at 5 months and then a growing supplement (S2); TFS3, addition of a rearing period until 12 months with a finishing supplement (S3); and S3, animals produced like the S1S2 but with the rearing period. Total lipids were extracted from freeze-dried muscle with dichloromethane and methanol (2:1), and intramuscular fat (IMF) was quantified gravimetrically by weighting the final lipid residue. FA methyl esters were prepared and quantified through gas chromatography with flame ionization detection. The IMF differed between the 5 groups being highest in the TFS1 group and lowest in TFS3 group. The omega-6/omega-3 ratio in meat was lowest in the TF and TFS1 groups (3.53 and 4.52), as expected since the omega-3 FA were higher, and highest in the TFS3 and S1S2 groups (11.37, and 10.0). About the ratio PUFA/SFA, it was lowest in TF, TFS1 and S3 groups (0.35, 0.30 and 0.36) and highest in TFS3 (0.56). The h/H index (hypocholesterolemic/hypercholesterolaemic fatty acids) was higher in groups S1S2 and TFS3 (2.24 and 2.35). In conclusion, Arouquesa meat produced under the traditional system seems to be healthier for human consumption when considering the omega-3 FA. Regarding the h/H ratio and PUFA/SFA, that are associated with lowest proportions of hypercholesterolaemic fatty acids, the group TFS3 produced the meat nutritionally more favourably, however, this effect could be associated with the lowest IMF content.

Prediction of nutritional parameters of naturalized grassland in the dry zone of Chile using NIRS

P.M. Toro-Mujica

Instituto de Ciencias Agroalimentarias, Animales y Ambientales. Universidad de O'Higgins, Ruta I-90 km 1, 3070000, Chile; paula.toro@uoh.cl

The naturalized grassland in the dry central zone of Chile presents a wide variety of species whose presence is conditioned by climatic, edaphic, and management factors. The nutritional quality of the pasture, in addition to the species present, depends on its phenological state. In this way, the nutritional quality varies widely between farms and throughout the year. The objective of the work was to develop calibration curves based on near infrared (NIR) spectra of parameters related to the nutritional quality of the naturalized grassland in the dry central zone of Chile. One hundred thirty eight grass samples were obtained from 32 exclusion plots on four farms from August to December 2021 and 2022. The spectra of the samples were obtained through a FOSS NIRS™ DS2500 to later determine dry matter (DM), crude protein (CP), acid detergent fibre (ADF), and neutral detergent fibre (NDF) by chemical analysis. Modified partial least squares calibration equations were developed in different spectral regions, applying several mathematical treatments. The values (mean ± standard deviation) obtained for the parameters were 60.9±28.6, 8.4±4.7, 40.2±5.7, and 57.4±10.7% for DM, CP, ADF, and NDF, respectively. Models showed good predictive values for the prediction. Coefficients of determination of cross validation (1-VR) of the selected equations presented values between 0.8 and 0.9 and standard error of cross validation (SECV) between 1.47 and 4.39. These results support the viability of NIRS technology to predict the composition parameters of naturalized grassland in the dry central zone of Chile.

Effect of cutting length on fermentation dynamics of wilted Italian ryegrass silageJ. Kim^{1,2}, Y. Li², L. Waang², Y. Yu² and H. Kim¹¹Seoul National University, Institute of GreenBio Science and Technology, #1447, Pyeongchang-ro, Pyeongchang, Kangwon, 25354, Korea, South, ²Seoul National University, Graduate School of International Agricultural Technology, #1447, Pyeongchang-ro, Pyeongchang, Kangwon, 25354, Korea, South; forage@snu.ac.kr

Italian ryegrass silage is currently quite popular in Korea and the cutting length plays an important role in the success of the fermentation in making silage. The harvested Italian ryegrass was wilted in the field for 2 days and divided into 3 parts, which were chopped into 10 (CL10), 20 (CL20) and 30 (CL30) mm respectively. The ensiled IRG was sampled at 1, 2, 3, 5, 10, 20, 30, and 45 days indicated that different cutting length had significant effect on CP content for 2-days wilted IRG silage. CL30 had the highest CP from 5 to 45 days ($P < 0.05$), and showing an upward and downward trend in the first 10 days, and then an upward trend. CP changes in CL20 was more stable than CL10 and CL30 and CL10 was the greatest ($P < 0.05$). NDF and ADF content of CL10, CL20 and CL30 had similar trends during ensiling but different cutting length had no significant effect on the NDF content changes ($P > 0.05$). For ADF, CL20 was significantly lower than CL10 and CL30 ($P < 0.05$). IVDMD was negatively correlated with NDF in all treatments. WSC as a whole was declining during ensiling. After 45-days ensiling, CL10 was the lowest (11.44 g/kg DM) but at day 10 CL20 and CL30 showed the opposite change from CL10 ($P < 0.05$). Cut length significantly affected lactic acid production and CL10 was the highest, followed by CL20, and CL30 was the lowest ($P < 0.05$). pH value and lactic acid have the opposite trend of change, and CL10 was lower than CL20 and CL30 ($P > 0.05$). pH value had an overall slow decline trend.

Grazing behaviour of energy-limited dairy cows and development of detection method by deep learning

Y. Shinoda, S. Asakuma, Y. Ueda, S. Tada and K. Sudo

Hokkaido Agricultural Research Center, NARO, Sapporo, Hokkaido, 062-8555, Japan; shinoday080@affrc.go.jp

Understanding the exact energy status of grazing dairy cows is important for health management. However, it is difficult to accurately estimate the amount of dry matter intake in pasture. Recent advances in sensors have enabled long-term and high-density monitoring of animal behaviour. The purpose of this research is to clarify the behavioural characteristics caused by energy deficient by analysing behavioural data from sensors and to develop a method to automatically detect the energy-deficient of cows. From 2019 to 2021, a total of 24 lactating Holstein-Friesian cows, eight each year, were grazed in Hokkaido region for one month during the summer. Two treatment groups were established according to the amount of supplementary feed supplied at the barn: a control group ($n=12$) with a TDN sufficiency of 110% and a limited group ($n=12$) with a TDN sufficiency of 80%. The behaviour of individual was monitored using a global navigation satellite system (GNSS) logger and an accelerometer attached to the cow's collar. To assess the impact of energy deficient on behaviour, a generalized linear mixed model was used with collected behavioural data as the explanatory variable, treatment group and grazing duration as fixed effects and individual and day and year as mixed effects. Total eating time, eating bout duration, distance travelled during eating bout and total moving distance were significantly longer in the limited group than in the control group. We developed an energy deficient detection model using a convolutional neural network (CNN) using all 441 movement trajectory images. Of all movement trajectory images, 70% were divided into data for model creation and 30% were divided into data for testing. Moreover, of the former, we randomly split 70% of the data as training data and 30% as validation data to develop a detection model. As a result, the highest accuracy of energy deficient detection model using movement trajectory images was about 65.1%. Although there is a need for improvement, it was suggested that the movement trajectory could be used to detect the energy deficient of grazing dairy cows.

Evaluation of 3 equations based on grass height measurement for estimating grass stocks in pastures

F. Lessire, J.-L. Hornick and I. Dufrasne

Faculty of Veterinary Medicine, FARA, Avenue de Cureghem, 6 B43, 4000 Liège, Belgium; flessire@uliege.be

Despite its benefits, grazing is decreasing, in southern Belgium because of its difficult management. In fact, farmers lack confidence in the amount of fodder available on the grasslands. The herbage mass (HM – kg DM/ha) is an essential data to estimate grass stocks. To obtain it, the reference method is to clip grass from delimited quadrats in the paddocks. The weight of the sample (kg DM/quadrat) allows an estimate of the stocks (kg DM/ha) on the paddock. However, this method needs labour to get a valuable overview of the grassland stocks. Another method is based on measuring the sward height (H-cm) using rising plate meters (RPM) and then to convert it into HM. Using the RPM is easy but needs a calibration equation to convert the compressed height (CSH, cm) to HM. Yet, the rising plate meters available on the market are calibrated by manufacturers under conditions somewhat different from those where they will be used. This study aims thus to evaluate the accuracy of different calibration equations from commercial RPM. Measurements of CSH and HM were carried out in 5 Walloon farms on permanent grasslands from 2013 to 2015. In total, 299 data were collected. We compared three calibration equations. Equation 1 developed in New-Zealand is proposed at use of Jenquip EC20®. Equation 2 developed in Ireland is proposed at use of GrassHopper® and the Equation 3 is developed in France. Calculated HM was faced to the collected field data. The coefficient of determination (R^2), the mean square error (MSE) and the relative prediction error (RPE) were determined. The HM and CSH of field data were $1,599 \pm 674$ kg DM/ha and 9.73 ± 2.86 cm (mean $\pm$ SD). The values of HM obtained from Equ.1 to 3 were: $1,862 \pm 400$ kg DM/ha (Equ. 1), $1,489 \pm 339$ kg DM/ha (Equ. 2) and $2,315 \pm 680$ kg DM/ha (Equ. 3). The R^2 values ranged from 0.41 (Equ.2) to 0.42 for Equ.1-3. The Equ.1 and 3 led to a recurrent over-evaluation of stocks (74% in Equ.1 and 90% in Equ. 3). This over-estimation reached 503 kg DM/ha. Conversely, the RPE of Equ. 2 was the lowest (33.6%) and the errors were more equally balanced (55% under vs 45% over-estimation). It seems thus that the Irish equation could be fairly used.

Session 57

Breeding of native breeds as a chance for the development of livestock households in ecological sys

P. Radomski and P. Moskala

National Research Institute of Animal Production, Sarego 2, 31-047 Krakow, Poland; pawel.radomski@iz.edu.pl

Modern methods of breeding and production of meat and other products have, on the one hand, reduced prices for consumers, but on the other hand, they have made the food market less diversified. The increasingly widespread ecological awareness of consumers reinforces the ever-growing tendency to eat products derived from animals traditionally kept, i.e. in natural conditions, with free access to open space and grasslands. The growing demand for traditional (without enhancers) food products should contribute to an increase in the consumption of meat, cheese and other products derived from farm animals fed and reared on traditional (self-sufficient) farms. It is therefore necessary to draw the farmer's/producer's attention to the development of agricultural production using environmentally friendly methods and ensuring food safety. This is a great opportunity for the development of breeding and the use of the potential of native breeds kept in low-input production systems of family farms. Of great importance is the fact that global sales of organic food and drinks are growing every year and in 2019 reached over EUR 106 billion. The leading country is the United States with €44.7 billion, followed by Germany (€12 billion) and France (€11.3 billion). With regard to spending on organic products per capita, Denmark (EUR 344) and Switzerland (EUR 318) are in the lead, while in Poland the average is EUR 8. In terms of the area of ecological agricultural land, Australia is invariably the world leader (35.7 million ha). Argentina comes second (3.6 million ha) and Spain comes third (2.4 million ha). In Europe, organic production covered almost 16.5 million hectares (as at the end of 2019), which is almost 1 million hectares more compared to 2018. Spain boasts the largest area of organic farming in Europe (2.4 million hectares), France (2.2 million ha) and Italy (2 million ha). Poland ranks 9th in this ranking – 0.5 million ha. Currently, Poland ranks in the second ten in organic animal production compared to other European countries in each of the basic groups of animals: cattle breeding – 20th place, pig breeding – 14th place, sheep breeding – 20th place, and the highest place is only in poultry farming – 11th.

Conceptual model for the analysis of energy allocation of cow-calf farms native grassland-based

V. Figueroa, I. Paparamborda, S. Scarlato and P. Soca

Universidad de la República, Departament of Animal Production and Pastures, EEER., Ruta 26, Km. 408, Bañados de Medina, Cerro Largo, 37000, Uruguay; vfigueroa@fagro.edu.uy

Reproductive and productive outcome of cow-calf farms on native grassland is controlled by the energy nutritional management in breeding herds. Farmers' techniques are necessary to manage energy nutrition of livestock. The index of bovine breeding techniques (ITB) condenses in a hierarchical manner the techniques recommended by research and their mode of application in beef cows systems. We hypothesize that an increase in the value of ITB is positively related to the beef cows pregnancy rate and calf weight at weaning. The 12 cases were analysed, participants of the 'Livestock and Climate' Project (L&C). Distributed in the East and North of Uruguay, from March 2020 to March 2023. L&C is a project with approach the Co-innovación, developed cycles of analysis and design in 60 farms to achieve a systemic rethinking of the farm through ecological intensification. The sum of the value of each technique is the final result of the ITB, therefore farms with a higher value of the ITB correspond to a greater and better way of applying strategic and tactical management. The variables production of bovine meat per animal unit (PBMAU), calf weight at weaning (CWW), weight of weaning calf per mating cow (kgWC/MC) and bovine pregnancy rate (%BP) were analysed using a linear model. PBMAU was calculated as total kilos of bovine meat referred to the animal stock in the year (kg) and %BP is the ratio between pregnant cows and matching cows. Statistical model included (ITB) and project phases (beginning and end) as fixed effects. The results showed that ITB increased from 57,0 to 73,3 between project phases ($P<0.0001$). The PBMAU improved from 127.2 to 135.0 kg between project phases ($P<0.0001$), finding a positive relationship between ITB and %BP, CWW, so contribute to explain the improve of PBMAU and kgWC/MC. The results suggesting, ITB constitute robust conceptual model for the analysis and comprehens of energy allocation and use of cow-calf farms. The co-innovation was favourable to encourage the ITB, a necessary condition to the ecological intensification of cow-calf farms on native grassland.

Session 57

Poster 27

Do botanically diverse pastures effect the meat eating quality of lamb?S. Woodmartin¹, P. Creighton¹, T.M. Boland², E. Crofton³, A. Monaghan¹ and F. McGovern¹¹Teagasc, Animal and Grassland Research and Innovation Centre, Mellows Campus, Athenry, Galway, H65R718, Ireland,²School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, D04FX62, Ireland, ³Teagasc,

Ashtown Food Research Centre, Food Quality and Sensory Science Department, Ashtown, Dublin, D15 DY05, Ireland;

sarah.woodmartin@teagasc.ie

Efficient utilization of pasture is Ireland's competitive advantage in sheep meat production. The aim of this study was to assess the effect of binary swards on slaughter data and meat quality. Five treatments were investigated, perennial ryegrass (*Lolium perenne* L.; PRG), PRG plus white clover (*Trifolium repens* L.; PRG+WC), PRG plus red clover (*Trifolium pratense* L.; PRG+RC), PRG plus chicory (*Chicorium intybus* L.; PRG+Chic) and PRG plus plantain (*Plantago lanceolata* L.; PRG+Plan). Sixty lambs (n=12 per treatment) were selected from the main cohort of lambs born. Males were castrated within 24 hours of birth. Groups were balanced for sex and weight. Post-weaning, weight was recorded from all lambs fortnightly. Lambs were drafted for slaughter once they reached the desired weight of 45 kg. Meat samples were obtained from the longissimus dorsi muscle. Sensory analysis was carried out by a descriptive panel. Quality attributes were scored on a scale of one (low) to ten (high) under red filtered light in isolated booths. There was no difference in pre-slaughter live-weight, carcass weight or kill out percentage with mean values of 45.4 kg, 21.1 kg and 46.3%, respectively. Average values of pH5.6 and 12.0°C were recorded for ultimate pH and temperature of the *longissimus dorsi* with no difference between treatments. Sensory results show meat from lambs finished on PRG+Plan scored lower for tenderness and higher for chewiness when compared to meat from lambs finished on PRG+WC or PRG+Chic ($P<0.05$). Diets with herb inclusion, PRG+Chic or PRG+Plan, produced lambs with lower meat juiciness scores than the legume treatments, PRG+WC and PRG+RC ($P<0.05$). Diverse pastures did effect meat eating quality. Meat from lambs grazing PRG+WC swards was deemed more tender and juicy than meat from lambs grazing PRG+Plan. This gives scope for future work to further explore the relationship between diverse pastures and red meat eating quality.

Altering milking frequency from 14 to ten milking's per week: effects on milk production of pasture*E. Kennedy, K. McCarthy, J.P. Murphy and M. O'Donovan**Teagasc, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy, Co. Cork, Ireland; emer.kennedy@teagasc.ie*

One of the biggest factors in attracting and retaining people to work on dairy farms is that they must be desirable places to work. Milking is the most labour demanding task on Irish dairy farms and one, which necessitates farmers being present on the farm twice daily, if milking twice-a-day (TAD). The objective of this study was to alter weekly milking frequency by milking ten times per week and compare their milk production to cows milked 14 times per week, the industry standard. Pre-calving, cows were balanced based on calving date, breed, PD for milk, fat and protein and assigned to one of three treatments: (1) milked ten times per week for the full lactation (F107); (2) milked TAD for the first half of lactation and ten times per week for the second half of lactation (P107); and (3) milked TAD for the full lactation (TAD; control). When cows were milked ten times per week the milking schedule was TAD milking on a Monday, Wednesday and Friday and once-a-day milking on Tuesday, Thursday, Saturday and Sunday. The TAD cows were milked at 7am and 4pm daily; when the F107 and P107 were milked once-a-day milking time was approximately 10am, it was 7am and 4pm on TAD days. Milk yield was recorded at each milking and milk composition and quality were determined across four days each week. Data were analysed using mixed models in SAS. Completing ten milkings per week for the full lactation reduced milk yield ($P<0.01$) by 10% in comparison to TAD cows (5,210 kg) while milk solids yield (kg fat + kg protein) was reduced by 11% when milking ten times per week in comparison to TAD (463 kg; $P<0.001$). Interestingly, switching to ten milkings per week half way through lactation (approx. 20 weeks) resulted in no difference in total lactation milk or milk solids yield compared to cows milked TAD for the entire lactation (5,204 and 458 kg, respectively). There was no difference in somatic cell score between any of the three treatments across the entire lactation (1.99). The results from this study suggest there are options to reduce the labour associated with milking, particularly for the second half of lactation, without reducing production.

Robustness of suckling cows at herd level is associated with cows' productive longevity*L. Barreto-Mendes, A. De La Torre, S. Ingrand and F. Blanc**Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, 63122 Saint-Genès-Champanelle, France; luciano.mendes@inrae.fr*

Reproductive failure is one of the main reasons for involuntary culling in beef cattle herds. Consequently, individual cows' productive longevity (PL, 1st calving to culling interval), a proxy of their robustness, is highly determined by their ability to conceive and recalve within the time window defined by the farmer. One indicator to measure this ability is the calving-to-calving interval (CCI). At the herd level, robustness can be defined as the ability to maintain performance stable across time. The objective was to verify whether the herds' robustness was associated to cows' robustness. We used time-series from 89 herds (min. size of 20 cows) of Charolais suckling cows with individual dates of birth, calving and culling for at least 10 years (max. 36 years). Primiparous and multiparous cows that did not manage to complete pregnancy were attributed a theoretical CCI calculated as the max. herd CCI at a given year plus 1.5 times inter-quartile range. For each herd, robustness was assessed by the standard error of mean PL (SE_PL) and mean CCI (SE_CCI) across time. Links between herd and cows' robustnesses were studied via the correlations between SE_PL and the average PL of cows present in a farm across the studied period and between SE_CCI and the average CCI. Between herds time averaged PL and CCI were negatively correlated (-0.28 , $P=0.008$). Correlations between $\log(\text{SE\_CCI})$ and $\log(\text{SE\_PL})$ with PL and CCI were negative and positive (-0.18 , $P=0.09$; 0.35 , $P=0.0009$), respectively. PL stability ($\log(\text{SE\_PL})$) was positively associated with CCI stability ($\log(\text{SE\_CCI})$) as well (0.40 , $P=0.0001$). When herds were grouped based on these four variables, two clusters (CL1 and CL2) emerged that presented distinct properties as follows: CL1 had significantly higher PL than CL2 ($\text{PL}_{\text{CL1}}=2,213\pm35$ d; $\text{PL}_{\text{CL2}}=2,004\pm47$ d; $P=0.0005$), associated with significantly lower SE_CCI and higher SE_PL ($P<0.0001$), respectively. On the other hand, CL2 presented significantly higher CCI than CL1 ($\text{CCI}_{\text{CL1}}=389\pm1$ d; $\text{CCI}_{\text{CL2}}=401\pm1$ d; $P<0.0001$) and presented significantly higher and shorter SE_CCI ($P<0.0001$), respectively. In conclusion, robustness traits observed at the individual scale seem to have been transmitted to the herd scale.

Variability in consumer perception of meat and meat substitutes

E. Hocquette¹, J. Liu², S. Chriki^{1,2}, M.P. Ellies-Oury^{2,3}, M. Kombolo², J.H. Rezende-De-Souza⁴, S.B. Pflanzner⁴ and J.F. Hocquette²

¹ISARA, 23 rue Jean Baldassini, 69364 Lyon Cedex 07, France, ²INRAE, VetAgro Sup, UMR1213, 63122 Theix, France,

³Bordeaux Sciences Agro, 1 cours du Général de Gaulle, 33175 Gradignan, France, ⁴University of Campinas, Rua Monteiro Lobato, 80, Campinas 13083-862, SP, Brazil; ehocquette@etu.isara.fr

This study, conducted with more than 16,000 respondents in 5 countries (Brazil, Cameroon, China, France, South Africa) was aimed at analysing the consumption of meat and meat substitutes according to sociodemographic factors. For this, we asked for the criteria to choose food products at purchase time and for the proportion of people consuming meat substitutes and willing to consume 'cultured meat'. The most important criteria when purchasing food products are the following: sensory quality (67%), price (56%), food safety (47%), origin/traceability (45%), ethics (42%), nutritional value (35%), environmental impact (33%), and then appearance (24%) and presence of a label (22%). Men place less importance on food safety (44 vs 50% for women, $P < 0.01$). There is also an age effect ($P < 0.01$), people over 51 years of age putting less importance on price (40 vs 52-69% than younger respondents). Respondents who rarely consume meat place price first, vegans/vegetarians place ethical and environmental concerns first, unlike meat consumers who consider sensory quality to be the most important ($P < 0.01$). These results also depend on countries ($P < 0.01$): sensory quality, food safety, origin/traceability and price are more important in Brazil, China, France and then two African countries respectively. On average, 45% of respondents eat meat substitutes. This result depends on gender (50% for women vs 39% for men), country (70% in China vs 29% in Brazil) and dietary habits, with flexitarians and vegetarians being 59-60% to consume meat substitutes. Thirty nine percent of the respondents would be regularly willing to eat cultured meat (43% of women and 36% of men; 46% among 18-30 year-old respondents vs 33-36% for the oldest). This proportion is higher for flexitarians and vegetarians (47-49%). The French are the least ready to consume 'cultured meat' (17%) vs 54% in Brazil. To conclude, perception of meat and meat substitutes depends on sociodemographic factors, mainly countries and dietary habits.

Theatre 2

Bibliometric analysis of scientific articles related to 'cultured meat'

J.F. Hocquette¹, D. Fournier², M.P. Ellies-Oury^{1,3} and S. Chriki^{1,4}

¹INRAE, VetAgro Sup, UMRH 1213, 63122 Theix, France, ²INRAE, SDAR, 34000 Montpellier, France, ³Bordeaux Sciences Agro, 1 cours du Général de Gaulle, CS 40201, 33175 Gradignan, France, ⁴ISARA, 23 rue Jean Baldassini, Cedex 07, 69364 Lyon, France; jean-francois.hocquette@inrae.fr

'Cultured meat' aims to produce large quantities of 'meat' from muscle cell culture to feed humanity while slaughtering fewer animals. It is a hot topic, but which is much less present in academic research. Indeed, a first study found a total of 327 scientific publications only on this topic though the first cultured meat was approved in 2020 for commercialisation in Singapore. The purpose of this work was therefore to analyse the recent evolution of the scientific literature as of February 13, 2023. Thus, 826 scientific publications are present on the Web of Science (108 in 2020, 180 in 2021 and 242 in 2022) including 159 reviews. Although the number of scientific papers on this topic has increased over the last three years, the total number of scientific articles remains modest and mainly on technological aspects. While a bibliometric search was carried out with more than 20 keywords, it appears that 'cultured meat' is present in the title in about 30% of the articles from 2020. More than a third of scientific articles concern the 'Food Science and Technology' section. The top three journals publishing articles on this subject are Foods (39 articles), Frontiers in Sustainable Food Systems (two recent publishers) and Fleischwirtschaft (a technical international magazine for the meat industry) (24 articles each). Authors originate mainly from the USA (197 articles), UK (93 articles), China (73 articles), Germany (59 articles) and The Netherlands (55 articles). The two authors who published the most are Prof. Mark Post from The Netherlands (16 articles), who trusts the technology, and JF Hocquette (15 articles) from France who has a more critical view. More generally, the network of authors is very fragmented with more than 15 groups of authors who do not publish together, which may reflect various approaches on this topic. In conclusion, the scientific literature on cultured meat is limited but originates mainly from countries with an Anglo-Saxon or Germanic culture, and from China, which tend to support this innovation.

Addressing the challenges of animal-free meat using plant-based tissue engineering*M.O.R. Yahav**Redefine Meat, Technology and innovation, Openheimer 10 rehovot, 7670110, Israel; morya@redefinemeat.com*

Addressing the Challenges of Animal-Free Meat using Plant-Based Tissue Engineering By Mor Yahav, Redefine Meat Ltd. Today the necessity of replacing animal meat with animal-free alternatives is commonly accepted in our society. This concept has matured along with the growing awareness among the public of the extent of the ecological damage that animal farming and industrial meat production are causing to our habitat and to the biodiversity of our planet. While it is clear that today's society is not ready to give up the meat-eating experience, the food industry and food science are facing the challenge and the opportunity of making meat without animals. The degree to which this alternative meat should imitate its animal twin varies according to the market segments. While vegans and vegetarians can be content with even a rough approximation of meatiness, the flexitarians, who replace only part of their diet with meat alternatives, set a much higher bar. Indeed, the introduction of new generation of meat replacements in the last decade seemed to drive penetration to new market segments and expand the total market size. However, over the last year, this market has shown stagnation, possibly caused by the lack of progress in culinary and organoleptic performance of alternative meat. There is much work done to further disrupt the alternative meat industry and new ways are proposed for bringing the performance of new meat a significant leap forward. In this work, we disclose some novel ways for reconstructing meat using plant-based ingredients, while acknowledging for its anatomical origins and its composite tissue structure. We show that most of the organoleptically-relevant meat features can be mimicked by first modelling the composite structure of meat and its biochemical building blocks and reconstructing them separately via plant-based formulations. Then, an automatized process is employed for assembling these blocks and recreating the meat tissue elements and its dynamical and thermal behaviour.

Session 58**Theatre 4****Comparing the potential of meat alternatives for a more sustainable food system***T. Bry-Chevalier**Université de Lorraine, BETA, 23 rue Baron Louis, 54000 Nancy, France; tom.bry-chevalier@chaireeconomieduclimat.org*

A growing body of scientific works document how high meat consumption is incompatible with a sustainable food system through a disproportionate use of resources. The negative externalities of livestock farming are not limited to its impact on the environment but extend to health, antibiotic use and the risk of epidemics. In this paper, I investigate how alternative proteins perform regarding the positive and negative externalities of the current food system. Most studies on alternative proteins focus solely on one environmental dimension when they discuss their relative benefits compared to livestock farming. In this paper, I stress the importance of having a multi-dimensional approach to fully assess the relevance of meat alternatives in mitigating the externalities of the food system. Moreover, alternative proteins are rarely compared with each other. In this paper, I compare the relative merits of different meat alternatives not only on environmental dimensions but also on their overall public health, scalability and acceptability potentials. Although some alternative proteins may be complementary it is not impossible that they also compete with each other for funding or purchases in shops. For example Slade finds that preferences for plant-based burgers and cultivated meat are broadly, though not perfectly, correlated. Overall, I find that the most promising category of alternative proteins for achieving a sustainable food system is plant-based meats and proteins produced by fermentation. Cultivated meat may be an interesting addition if it appeals to a different category of consumers (people with a strong attachment to meat), but it cannot be considered a solution for the immediate climate issues given the remaining challenges it has to face to achieve mass production at an affordable price. Insects probably have the lowest potential because of the difficulties in maintaining their environmental benefits on a large scale as well as their very low acceptability compared to other alternative proteins.

IMR3G Foundation, DATAbank software to facilitate collaborative data collection for mutual benefitR. Polkinghorne¹, H. Cuthbertson¹, A. Neveu² and J. Wierzbicki³¹Birkenwood Pty Ltd, Blandford, 2338, Australia, ²Birkenwood Europe, Lanon, 03240, France, ³IMR3GF, Warsaw, 00-389, Poland; rod.polkinghorne@gmail.com

Development of consumer prediction models requires extensive high-quality research data. The International Meat Research 3G Foundation has developed a collaborative software system to facilitate integrated project design and delivery across multiple international partners who maintain ownership of their individual data with underlying protocols to ensure data compatibility. The DATAbank software supports experimental design through sequential processes that assist statistical balance. After specifying the number and type of livestock to be acquired for an experiment these are allocated to primary treatment-based groups and with further treatments progressively assigned through to sensory samples. While developed for specific cattle and sheep use the base design is adaptable to other species of any size with the principal being that the live animal is progressively converted to component portions to final sensory samples. For bovine and ovine use, the carcass can be assigned sides with allocation of side-based treatments to achieve parsimonious allocation to the smallest number of animals needed to achieve treatment balance. UNECE Bovine language codes define the carcass portions collected from each side and which individual muscles are available from each portion and, from carcass weight, the expected muscle mass, designated within-muscle positions and feasible sample numbers for evaluation by 10 consumers. Parsimonious allocation of multiple treatments including cooking methods, ageing periods, further treatments, packaging and sample destinations can be overlaid on the base sample plan. The final design is then supported by automated production of labelling and control files to facilitate data collection, with the completed samples and their related information stored in the DATAbank. Further routines assist in assignment of samples to consumer sensory test sessions and associated production of cooking, serving and data collection protocols. It is intended that the software be made widely available at minimal cost and hoped that it will prove valuable in facilitating highly compatible data across research projects thereby increasing the value of data through extensive linkage.

Session 58

Theatre 6

Beef processors experience large variation in yield and quality traits on a daily basis

W. Pitchford and S. Miller

University of Adelaide, Davies Livestock Research Centre, Roseworthy Campus, 5371, Australia; wayne.pitchford@adelaide.edu.au

Increasingly beef processors are able to extract more value from higher quality carcasses which will increase demand for quality and be reflected in price. Pitchford *et al.* examined various pricing strategies based on yield and quality and concluded that the majority of variation was associated with yield even when high premiums were placed on quality. However, concerns were raised by processors that the data set used had less variation in quality than they commonly experienced. This work was conducted using a subset of the Meat Standards Australia (MSA) database, covering a period of 4 years from start of 2010 to end of 2013, totalling 1,159 days. This subset covers a range of different lots from across Australia, processed at nine different plants that slaughter a total of approximately 1.7 million carcasses with data from 35 variables. The carcass weight and traits associated with yield and eating quality variables utilised for this section of work were Hot Standard Carcass Weight (HSCW, kg), Eye Muscle Area (EMA, cm²), Ossification Score (OSS, score out of 590), MSA Marbling Score (MARB, score out of 1,190), MSA Index Score (MSA, index), P8 fat depth (P8, mm), and Rib fat depth (RIB, mm). Variance was partitioned by differences and presented graphically. The variance for each trait was HSCW 2,506 kg², EMA 101 cm⁴, OSS 3,416 scores², MARB 8,945 scores², MSA 11.1 index², P8 18.3 mm² and RIB 12.7 mm². The largest proportion (49-73%) of the variation was between and within lots so processors experience the bulk of the variation in carcass quality on a daily basis. Processors experience much greater variation in ossification and marbling than that observed within genetics trials where animal age and growth path are more consistent. The result of this is that genetics type trials will underestimate the importance of quality relative to yield when modelling price effects.

Introduction to plant-based, cultivated, and fermentation-made meat, eggs, and dairy

S. Kell

GFI Europe, ASBL Drève du Pressoir 38, 1190 Forest Belgium, Belgium; serenka@gfi.org

Animal agriculture causes 20% of global greenhouse gas emissions – equivalent to all the planes, trucks, cars, trains and ships on Earth. And research cited by the Intergovernmental Panel on Climate Change shows it will be impossible to meet the Paris Agreement targets without a reduction in conventional meat production. Additionally, intensive animal agriculture is a leading driver of antimicrobial resistance, environmental and habitat destruction and – to feed a population of 10 billion by 2050 – we need a system less sensitive to climate shocks and global supply chain vulnerabilities. Yet global demand for meat will have grown by 52% by 2050. People from all walks of life want our food system to be sustainable, secure and just. But most people's day-to-day food choices are based on taste, price and convenience, and alternative sources of protein can not yet compete on these terms: people are unlikely to move away from animal products unless they're presented with sustainable food that looks and tastes as good as the conventional products they love. This talk will cover the growing need for transforming our global food system in order to sustainably feed the world by 2050, introducing the role that plant-based, fermentation-made, and cultivated meat can play in this transition. It will also overview the present commercial and investment landscape across these sectors, as well as the scientific and industrial challenges presently preventing these solutions from achieving large-scale market uptake. Finally, it will outline the opportunities for researchers and scientists from multiple disciplines (including agricultural and animal sciences) to help to tackle these challenges, and how they can contribute towards this flourishing global research community.

Session 58

Theatre 8

Environmental impact of dairy alternatives: a case study of Hemp milk and other products

B. Queiroz Silva, J. Ferdouse and S. Smetana

DIL Deutsches Institut für Lebensmitteltechnik e.V., Food Data Group, Professor-von-Klitzing-Straße 7, 49610 Quakenbrück, Germany; b.silva@dil-ev.de

Milk consumption in humans lasts longer than in other mammal species. Today consumers' awareness of the environmental burden that some products carry keeps growing. Thus, they look for alternatives that are more environmentally friendly and nutritionally similar. One example of growing demand can be found in plant-based beverages, as these have a lower environmental impact, though not nutritionally comparable to bovine milk. Though these beverages bring benefits (e.g. overall lower environmental impact), there are also disadvantages (e.g. high water consumption in almond beverages). One promising plant is industrial hemp, as all parts of the plant can be used in different ways (e.g. fibres for paper production, seeds for animal feed or milk production). This type of plant does not require many inputs and is capable of mitigating soil desertification. Though some studies show the potential of hemp milk as a more sustainable alternate plant-based beverage, there are no LCA studies. This research aims to explore the lack of data using fat and protein-corrected beverages (1 kg of FPC beverage). The boundaries are from farm to industry gate, leaving out transportation, retail and consumer-related impacts, and data was collected from licensed agricultural farmers, databases and literature. The methods used were ReCiPe 2016 Midpoint (H)(V1.06) and Cumulative Energy Demand (V1.01). It was found that hemp milk has a high impact on human carcinogenic (7.61E02 kg 1,4-DCB) and non-carcinogenic (3.04E05 kg 1,4-DCB) toxicity, marine (7.90E02 kg 1,4-DCB) and freshwater (6.67E02 kg 1,4-DCB) ecotoxicity when compared to bovine milk (5.44E-1, 4.39E-2, 4.02E-2 and 3.23E-2 kg 1,4-DCB respectively). On the other hand, bovine milk had higher values for global warming potential (1.54E00 kg CO₂ eq.), land use (7.69E00m²a) and water consumption (3.86E-2 m³). In conclusion, overall, the environmental impacts associated with this plant-based beverage are lower than animal milk, as reported for other similar beverages in literature.

The tools of prediction of the sensory quality, the opinion of the French professionals*T. Fayet**Ecole supérieure d'agriculture, 55 Rue Rabelais, 49000 Angers, France; thomas-fayet@outlook.fr*

The French beef industry is structured by two types of consumption: everyday purchases oriented towards economical products in tender portions, often processed (such as chopped steak) and pleasure purchases oriented towards a search for gustatory pleasure and the satisfaction of societal and environmental criteria. However, it is difficult for the industry to guarantee regular and homogeneous products to satisfy consumers. These inadequacies stem from the current carcass grading systems. Thus, the professionals we met appear to be in favour of a change in the grading system based on a sensory quality prediction system that could be inspired by foreign systems such as 'Meat Standards Australia' for butchered cuts. Such a system, through its segmentation, could meet the expectations of both types of consumption, daily and pleasure, allowing to generate an added value for the whole sector as it is the case in Australia. However, the diversity of organizations with sometimes divergent interests makes it very unlikely, in the short term, to set up a prediction system on a sector-wide scale. Thus, the implementation of a carcass prediction system would more likely be the result of an individual initiative. The links where an individual initiative is most likely are, on the one hand, mass distribution for which the triggering lever lies in the dissemination of knowledge and, on the other hand, meat companies independent of livestock farming that wish to ensure a regular and qualitative supply. In addition, economic, operational, political and knowledge barriers make it unlikely that a sensory quality prediction system for beef will be developed collectively or by the upstream sector. However, a low probability exists, depending on the perception of a possible socio-economic opportunity by an innovative organization or on the evolution of European regulations.

Session 58

Theatre 10

Limitations and challenges for the successful launch to market of cultured animal protein products*J.F. Fuentes-Pila**Technical University of Madrid (UPM), Agricultural Economics, Statistics, and Business Management, Av. Puerta de Hierro, 2-4, 28040 Madrid, Spain; joaquin.fuentespila@upm.es*

Sustainable development goals 2 (zero hunger), 3 (good health and well-being), and 13 (climate action) require healthier, safer, and more sustainable diets. High-quality protein diets are essential for reaching goals 2 and 3, but meat products alone will not be able to assure food security, safety, and sustainability at a global scale in the medium term. In this scenario, cultured animal protein products are becoming a key alternative protein to meat. I will provide, in this presentation, an analysis of the major limitations and challenges for the successful launch to market of cultured animal protein products in a way that allows to reach the SDGs 2, 3, and 13 globally. The main limitations and challenges identified are: (1) immortalized cell lines vs non-immortalized cells lines; (2) tridimensional growth with scaffolds vs growth in suspension without scaffolds; (3) serum-free cell culture media and growth factors; (4) development of cultured animal protein and fat products; (5) bioreactors design and size; (6) cultured meat vs hybrids of plant-based protein and cultured animal protein and fat; (7) financial limitations and business model; (8) sustainability and transparency in the value chain; (9) consumers' acceptance and willingness to pay. Possible solutions to these limitations and challenges will be discussed.

Implementing advanced characterization methods and building a new reference for alt-meat development

M.O.R. Yahav

Redefine meat, technology and innovation, Openhier 10 Rehovot, 7670110, Israel; morya@redefinemeat.com

Implementing Advanced Characterization Methods and Building a New Reference For Alt-Meat Development By Mor Yahav, Redefine Meat Ltd. Recently, with the increasing demand for meat analogues, we have become acutely aware of the gap between the performance of plant-based meats vs livestock meat products. The alt-meat industry is making a substantial effort to close this gap by introducing new ingredients, processes, and manufacturing technologies. However, to make a tangible impact, the various academic and industry players must develop an in-depth understanding of the product that they strive to mimic, optimally in a quantitative form. Like to other players, Redefine Meat is facing this challenge, while implementing additive manufacturing technology for recreating beef whole- muscle cuts. and is addressing this task with a major investment in meat science, combining the collection and organization of existing literature data with its own studies aimed to populate the white spaces in this data gamut. In this talk we will review the Redefine Meat's custom-made Meat Knowledge Center and two unique studies that were recently conducted for understanding specific aspects of beef whole-muscle cuts. In one study, synchrotron radiation was employed for micro-CT scanning of bovine muscle and understanding the effect of cooking process on its morphology and structure. In the second study, a robotic tool was built for automatic measurement of multiple areas of a steak and creating 2D maps of characteristics that illustrate the sophisticated, heterogeneous structure of livestock meat.

Whey proteins as alternative supplement to FBS in C2C12 muscle cells for cultured meat production

T.S. Sundaram, D. Lanzoni, R. Rebucci, F. Cheli, A. Baldi and C. Giromini

Università degli studi di Milano, Veterinary Medicine and Animal Science, via dell'università 6, 29600 Lodi, Italy; carlotta.giromini@unimi.it

Lab-cultured meat has gained worldwide attention as a potential sustainable alternative for conventionally farmed meat. Unlike traditional meat, it doesn't involve animal cruelty, emits less greenhouse gas, and importantly reduces human diseases associated with antibiotic resistance. The complex structure of livestock muscle is recreated in lab-cultured meat by cultivating cells in artificial medium consisting foetal bovine serum (FBS), and other essential nutrients. However, since cultured meat's goal is to decrease animal slaughter, the primary challenge lies in the acquisition of FBS from calves' blood. Whey is a by-product of the dairy industry, which has become an interest of research due to its bioactive and nutritional properties. Presently, we accessed the suitability of high-hydrolysed whey (HW), beta-lactalbumin, and lactoferrin as an alternative to FBS in the mouse C2C12 muscle cells during its proliferative stage. To this aim, the colorimetric assays such as MTT cell viability and lactate dehydrogenase (LDH) cytotoxicity were performed after 24, 48, and 72 h of treatment with 0.03-1% HW and beta-lactalbumin while, 3.125-200 µg lactoferrin in DMEM medium. Statistical analysis was performed in GraphPad Prism 9.3.1 for repeated measures one-way ANOVA with Tukey's post-hoc test. We observed that HW did not significantly affect the cell viability and LDH activity until 72 h compared to the control (0%) ($P < 0.05$). Conversely, only 1% of beta-lactalbumin significantly ($P < 0.05$) enhanced the cell viability until 72 h, while it did not affect the LDH activity. Further, 6.25-200 µg of lactoferrin after 48 h and 200 µg after 72 h significantly improved the cell viability compared to the control (0 µg) ($P < 0.05$). This study shows beta-lactalbumin and lactoferrin could be a promising alternative to FBS as a growth supplement for utilization in cell culture systems. The data need to be confirmed in further studies, considering not only the proliferation stage but also the full differentiation process. (Project funded under the National Recovery and Resilience Plan (NRRP), 'ON Foods – Research and innovation network on food and nutrition Sustainability, Safety and Security–Working ON Foods').

German consumers' attitudes towards cultured meatA.-K. Jacobs¹, M.-P. Ellies-Oury^{2,3}, H.-W. Windhorst¹, J. Gickel¹, S. Chriki^{2,4} and J.-F. Hocquette²*¹University of Veterinary Medicine Hannover, WING, Heinestraße 1, 49377 Vechta, Germany, ²INRAE, Université d'Auvergne, Vetagro Sup, UMR Herbivores, Theix, 63122 Saint Genès Champanelle, France, ³Bordeaux Sciences Agro, 1 cours du Gal De Gaulle, 33175 Gradignan, France, ⁴Isara, 23 rue Jean Baldassini, 69364 Lyon, France; jean-francois.hocquette@inrae.fr*

Meat plays an important role in German nutrition, but recent surveys reveal a growing interest in plant based meat alternatives. The aim of this study was to document similarities and differences regarding the attitudes of potential German consumers towards other meat alternatives such as cultured meat. For this purpose, the responses of 3,558 German participants of an online survey were evaluated. More than 94% of the respondents were familiar with cultured meat technology. Nearly 63% of them thought that this novel food is promising/acceptable and 22% indicated that it is absurd/disgusting. Most respondents believed that cultured meat is both a more ethical (67%) and environmentally friendly (58%) solution than conventional meat. In terms of future, almost 75% of respondents believed that cultured meat production and consumption will be commercialised in more than 5 years. The vast majority (70%) would be willing to try this new product, while around 57% only would be willing to eat it regularly. Among them, respondents could imagine a regular consumption especially at home (47%), and in equal shares in restaurants and ready-to-eat meals (37%). Around 40% would prefer to pay the same price as for conventional meat. Only 27% would be willing to pay more or much more whereas 33% want to pay less or much less. There were significant impacts of demographic factors on the willingness to try, regularly eat, or pay for cultured meat. For example, a high willingness to try and to eat this new product was found among male respondents who were young (18-30 years), rarely meat's consumers or with a low income (<1,500€). This also applies to the female respondents, who, however, belonged to higher income classes. Males with the highest income were only willing to pay much less/less for cultured meat. But females with a low income would like to pay the same/more. These results are important for the discussion of a paradigm change in global meat production.

Session 58

Poster 14

Development of the beef eating quality management system in PolandG. Pogorzelski¹, J. Wierzbicki², E. Pogorzelska-Nowicka³, A. Jasieniak⁴ and A. Wierzbicka¹*¹Institute of Genetics and Animal Biotechnology of the Polish Academy of Sciences, Department of Biotechnology and Nutrigenomics, Postępu 36A, Jastrzębiec, 05-552 Magdalenka, Poland, ²Polish Beef Association, Smulikowskiego 4, 00-389 Warsaw, Poland, ³Warsaw University of Life Sciences, Department of Technique and Food Development, Faculty of Human Nutrition and Consumer Sciences, Nowoursynowska 159C, 02-776 Warsaw, Poland, ⁴Food and product law centre, Wiejska 17 street, suite 6, 00-480 Warsaw, Poland; grzegorz.t.pogorzelski@gmail.com*

Since 2010, work has been started in Poland on the assessment of beef quality other than only commercial quality assessment according to the EUROP system. During the ProOptiBeef project, various beef cuts were subjected to four cooking methods and tested by almost 10,000 consumers. This made it possible to build a prototype of eating quality predicting model for Polish beef. The construction of the model was based on the Australian approach to eating quality management. For this purpose, a significant amount of beef carcasses was chiller assessed and then samples were collected from selected carcasses for consumer evaluation. Meat Standards Australia (MSA), an eating quality system based on consumer evaluation, uses an interactive prediction model to provide objective descriptions of beef meal outcomes for 33 carcass muscles by multiple cooking methods. The Australian beef eating quality prediction system is proving to be a useful tool for quality management. It not only supports quality management but is also responsible for the creation of new beef brands and maintains their stability. Therefore, it was decided to continue work on the development of the Polish model. The next step in the construction of the Polish quality management system will be the identification of gaps in the existing data to obtain the accuracy of the tool sufficient for use in the production plant and the development of a research plan on this basis. The following step will be to conduct a chiller assessment, select the appropriate beef carcasses, collect samples and conduct consumer tests. It is planned to use approximately 6,000 consumers to evaluate the eating quality of various beef cuts.

Degradation of Amazonian grasslands by weeds, how to managing this situation?V. Blanfort¹, C. Favale¹, S. Bazan¹, V. Petiot², D. Bastianelli¹ and T. Le Bourgeois¹¹CIRAD, Mediterranean and Tropical Livestock Systems Unit, University of Montpellier, France, Campus international de Baillarguet – TA C-112/ A, 34398 Montpellier Cedex 5, France, ²Chamber of Agriculture of French Guiana, 1 avenue des Jardins de Sainte-Agathe, 97355 Macouria-Tonate, French Guiana; vincent.blanfort@cirad.fr

Tropical grasslands face two major challenges: maintaining food security in the face of growing needs and coping with global change. In French Guyana, pastures are not very profitable for farmers in a constrained climatic context and are criticized for their potential contribution to Amazon deforestation. This work aims to study the sustainability of pasture cover in French Guiana and to characterize the weed flora. On the other hand, this work seeks to determine the relationship between agronomic practices and pasture degradation, mainly with the evolution of pasture flora 4 years after the implementation of dynamic rotational grazing. Flora surveys of 83 stations in 21 exploitations, distributed from Regina to Saint-Laurent-du-Maroni, have been done. 132 species were referenced as weeds. 27% of the stations are characterized by a degradation index greater than or equal to 25%, and 23% by a degradation index greater than or equal to 50%. The weed flora mainly is composed of *Cyperaceae*, *Mimosa pudica* and *Spermacoce verticillata* are the two most frequent and abundant weeds. *Cyperus aromaticus*, a recently recorded alien species, is of concern. No environmental factors seem to be linked to the level of degradation, but agronomic practices are the most likely to explaining it. This work contributed to the collaborative portal on weeds in tropical agrosystems, WIKTROP, on Guianese pastures.

Session 59

Theatre 2

Analysing strategies adopted to cope the climate variability in pastoral zone of Burkina Faso

H.P. Yarga, A. Kiema, L. Ouedraogo and S. Ouedraogo

INERA, Gestion des ressources naturelles, 01 BP 910 Bobo Dioulasso, 910, Burkina Faso; yargapaul@yahoo.fr

The objective of this study is to identify the strategies implemented by agro-pastoralists to cope with the effects of climate variability in two representative pastoral zones in Burkina Faso (Gadeghin in the Sudanian zone and Sideradougou in the northern Sudanian zone). The study methodology consisted of a one-pass survey using a questionnaire with 290 agropastoralists in the two pastoral zones. The questionnaire focused on livestock and pastoral resource management practices in relation to climate variability. The data collected were analysed with SPSS 22 software. The results show that producers have adaptive practices to climate change ranging from pastoral resource management to herd management. A total of 10 pastoral resource management methods were identified. In order of importance, these are: digging deep wells (31%), using organic manure (20%), planting trees (18%) and applying water and soil conservation methods (14%). In terms of herd management, 9 techniques were identified. The most important are, in order of importance: reducing the number of animals by destocking (27%), dividing the herd into sub-groups for management (20%), purchasing animal species that are resistant to climatic hazards (17%) and purchasing animal feed (13%). Climate variability is a global phenomenon. Therefore, for these strategies to be more efficient, the government and development actors must support these endogenous initiatives developed by producers through capacity building and by providing adequate resources.

How do changes in crop-livestock integration and specialisation affect farm performance in Vietnam?A. Le Trouher¹, H. Le Thi Thanh², T. Dinh Khanh², T. Han Anh², C.-H. Moulin³ and M. Blanchard¹¹CIRAD – UMR SELMET, Campus de Baillarguet, 34398 Montpellier Cedex 5, France, ²NIAS, 9 P. Tân Phong, Thuy Phuong, Từ Liêm, Hà Nội, Viet Nam, ³L'institut Agro Montpellier, INRAE – UMR SELMET, 2 Place Pierre Viala, 34060 Montpellier, France; alice.le_trouher@cirad.fr

In Northwest Vietnam, mixed farms integrating crop and livestock are undergoing major changes driven by a multitude of factors: lack of labour force, reforestation law, limited land resources, and fluctuating markets. The changes in farming systems and practices raise questions about the future performance of farms and their role in the sustainability of the territory. This study aimed to assess the effects on farm performance of changing crop-livestock integration practices and farming systems at the farm level. A participatory workshop with local stakeholders was held to define prospective scenarios based on available knowledge of farming systems and their past evolution. The participants identified the drivers of change in practices and their impacts. A modelling tool has been used to simulate the effects of the scenarios on a diversity of mixed farms. The model used considers all biomass flows on the farm and between the farm and the other farms, the market and the environment (livestock and crop products, crop residues, forage and manure). Based on a set of indicators, the model assesses the effect of each scenario on the productivity, economic, environmental and social performances of farms. The five scenarios simulated were: the continuity of current practices (scenario A), the development of local feed self-sufficiency (scenario B), the implementation of environmental protection measures (scenario C), the development of intensive livestock farming (scenario D) and the development of quality livestock and crop products (scenario E). As expected, the simulation results show contrasting differences between farms. The results show which scenarios have the most positive effects on farm performances and highlight which farms are most affected by resource access limitations. These results could be used to support dialogue with local stakeholders on the expected development of crop and livestock systems and the sustainability of the agricultural sector.

Session 59

Theatre 4

Problem of water supply in a context of climate variability in the pastoral zones of Burkina Faso

H.P. Yarga H Paul, S. Ouedraogo, A. Kiema and L. Ouedraogo

INERA, Gestion des Ressources Naturelles, 01 BP 910 Bobo Dioulasso, 910, Burkina Faso; yargapaul@yahoo.fr

This study aims to analyse the modalities of water supply under the effect of land pressure and climate variability in two representative pastoral areas in Burkina Faso, Gadeghin in the northern Sudanian zone and Sidéradougou in the southern Sudanian zone. The methodology consisted of processing geospatial data (Landsat 8 OLI-TIRS images) and a cross-sectional survey conducted with a questionnaire in 2022 among 290 herders in 10 villages in the two pastoral zones studied. Cartographic processing was done using Qgis 3.22.6 software to produce thematic maps. Data analysis was done using SPSS 22 software to produce descriptive statistics. The results showed an unequal distribution of hydraulic infrastructures in the pastoral zones. Thus, around 70% of the livestock move more than 2.5 km to have access to a water point. Furthermore, 80% of the tracks leading to a water source are occupied by crops during the rainy season. In the dry season, water sources are limited to water drillings, 38% of which are frequently out of service during this period. In response to these difficulties, producers rationalize the water requirements of livestock (37%) and use deep wells (25%). However, these strategies are not very efficient because they partly affect the animal's regular need for water. The solution for better access to water in these areas relies in the implementation of a development plan that will enable a good distribution of water points, the protection of pastoral paths by planting trees and a good management of hydraulic facilities by well qualified committees in this matter.

Local feeding strategies allow to reduce enteric methane emission from cattle in Sahel

G.X. Gbenou^{1,2,3}, M.H. Assouma^{2,4}, C. Martin⁵, D. Bastianelli⁶, L. Bonnal⁶, T. Kiendrebeogo³, O. Sib^{2,4}, B. Bois⁶, S. Sanogo⁴ and L.H. Dossa¹

¹FSA-UAC, Cotonou, BP 526, Benin, ²SELMET, Univ Montpellier, CIRAD, INRAE, Institut Agro, Montpellier, 34398, France, ³CNRST, INERA, Bobo-Dioulasso, 01 BP 910, Burkina Faso, ⁴CIRDES, Bobo-Dioulasso, 01 BP 454, Burkina Faso, ⁵INRAE, UMRH, Clermont-Ferrand, 63122, France, ⁶CIRAD, UMR SELMET, 34398, Montpellier, France; gerard_xavier_djidjo.gbenou@cirad.fr

In Africa, a large diversity of diets (forage + staple food crop residues or other agricultural byproducts) is used by cattle herders in different production systems. It is reported that feeding strategies could help to reduce enteric methane (eCH₄) in ruminants by up to 55%. In order to test different feeding strategies, a trial was carried out (CIRDES, Burkina Faso) on 10 Sudanese peulh zebu steers (32 months of age) with live weight (LW) 147±5.8 kg (i.e. 0.59 Tropical Livestock Unit). Animals were kept in individual box and were fed at 3.5% LW with natural pasture and crop byproducts (75:25, DM basis). Individual eCH₄ (GreenFeed system) and total tract digestibility were measured. The 6 main crop byproducts used in cattle diet were identified with a survey from farmers: legume haulm-based diets (cowpea and peanut haulms), and cereal straw-based diets (maize, sorghum, millet and rice straws). For each crop byproduct, the experiment consisted in 3 weeks, including 2 weeks of feed adaptation and 1 week of data collection. Basal diets consisted in natural forage hay (CTL hay) to test cereal crops, and Panicum maximum hay (CTL Pm) to test legume crops. Dry matter intake (DMI, g/kg LW) were on average 18.0±1.92 in cereal straw diets vs 16.4±2.06 in CTL hay; and 25.5±1.69 in legume haulm diets vs 21.7±2.29 in CTL Pm. The DM digestibility (%) were 48.1±3.01 in cereal straw diets vs 46.0±3.05 in CTL hay; and in legume haulm diets 49.8±1.4 vs 48.7±6.1 in CTL Pm. Intake content was lower in fibre for cereal straw and legume haulm diets compared to their control (NDF, g/kg DMI, 664±26.7 and 611±8.5 vs 734±13.6 and 712±14.0, respectively). Amounts of eCH₄ (g/kg DMI) emitted were 26.5±6.85 in cereal straw diets vs 30.6±7.17 in CTL hay; and 24.0±4.26 in legume haulm diets vs 27.9±4.66 CTL Pm. Complementation with cereal and legume crops reduced by 13 and 21% eCH₄ yield.

Session 59**Theatre 6****Development of a decision support tool to secure cattle production in chlordecone-contaminated areas**

A. Fournier¹, C. Feidt¹, A. Fourcot², M. Saint-Hilaire³, Y. Le Roux¹ and G. Rychen¹

¹Université de Lorraine, INRAE, UR AFPA, 2 avenue de la Forêt de Haye, 54000 Nancy, France, ²GIP-FCIP, 4 rue du Père Delawarde Desrochers, 97200 Fort-de-France, France, ³Institut Pasteur de Guadeloupe, Morne Jolivière, 97139 Les Abymes, France; agnes.fournier@univ-lorraine.fr

Soil historical contamination by chlordecone (CLD) is weakening the Caribbean livestock production in contaminated areas. The first impact is concerning farmers who are threatened by providing non-compliant carcasses. Indeed, some breeders have decided to stop their activity without any new facilities taking over, reducing, thus, the volume of local production. Furthermore, the existence of contaminated carcasses affects consumer confidence in local animal products. Such elements impair societal objectives of maintaining ecosystem services provided by livestock farming and producing healthy local food. Animal contamination depends on environment contamination and on farming practices. Its determinism remains therefore complex. However, it is essential for farmers to know the contamination status of their animals before deciding whether or not to send them to the slaughterhouse. These elements of context made it necessary to develop a decision support tool (DST) to guarantee the conformity of animal products. Thus a DST, based on a PBPK model, was created and developed on the fate of CLD in adult cattle. This DST is based on two main elements: (1) the ability of the adult bovine to eliminate CLD; (2) the predictability of edible tissue concentrations from serum levels. Thus, from an initial blood sample, the decontamination period required to respect the Maximum Residue Limit in perirenal fat (regulated target tissue) can now be estimated. This DST has recently been validated *in situ*. This validation process was possible due to a close collaboration between stakeholders: volunteer farmers recruited, local livestock organizations (GDSM, Sanigwa), administrative authorities taking charge of CLD analyses (DAFFs), and analytical laboratories (IPG, LDA). A steering committee including the DGAL and the two Prefectures was also set up. In the next step, local actors will be trained to implement the DST on a larger scale.

Can tropical legume grass forage reduce enteric methane yield from suckler cows in the Sahel?M.H. Assouma^{1,2,3}, A. Baro³, G.X. Gbenou^{2,3}, O. Sib^{1,2,3}, S. Sanogo¹, H. Marichatou⁴ and E. Vall^{2,3}¹CIRDES, Bobo-Dioulasso, 01 BP 454, Burkina Faso, ²SELMET, Univ Montpellier, CIRAD, INRAE, Institut Agro, Montpellier, 34398, France, ³CIRAD, Bobo-Dioulasso, 01 BP 454, Burkina Faso, ⁴AGRHYMET, Niamey, BP 11011, Niger; habibou.assouma@cirad.fr

Enteric methane emissions (eCH_4) from ruminants are the main source of greenhouse gas from the livestock sector in sub-Saharan Africa. In this region, very few references with *in vivo* measurements are available on local breeds, particularly on suckler cows. With the development of the dairy sector in Africa, it is important to integrate the evaluation of enteric methane emissions into the various feeding strategies. The aim of this study was to evaluate the impact of protein supplementation with a legume grass fodder (*Stylosanthes hamata*) on enteric methane emissions in Sudanese Zebu suckler cows. The study was conducted with Greenfeed in stall at CIRDES (Burkina Faso). The experiment was carried out on 10 animals: 5 steers (38 months old with liveweight (LW) of 179 ± 20.3 kg, i.e. 0.72 Tropical Livestock Unit (TLU), and 5 suckler cows (75 months old with LW of 204 ± 13.3 kg, i.e. 0.82 TLU). Animals were kept in individual boxes. The measurements of eCH_4 and milk production were made on the cows, and *in vivo* digestibility test was made simultaneously on the steers. Two trials of 4 week including 2 rounds of one-week data collection were successively conducted. The animals were fed respectively with *Bracharia ruziziensis* (100) (R1) and *Bracharia ruziziensis* + *S. hamata* (75:25) (R2). The results showed that the daily dry matter intake (DMI) is 15.67 ± 2.70 g/kg LW for R1 and 20.33 ± 4.28 g/kg LW for R2. *In vivo* DM digestibility (%) was 52.72 ± 1.4 for R1 and 58.25 ± 1.43 for R2 when milk production was 3.0 ± 1.2 kg/d for R1 and 3.46 ± 0.98 kg/d for R2. Amounts of eCH_4 (g/kg DMI) emitted were 25.05 ± 8.27 for R1 and 20.99 ± 7.30 for R2. Our results show that protein supplementation with *S. hamata* L. increases the DM intake (g/kg LW) for 30%, the digestibility (%) for 11%, and reduces eCH_4 yield (g/kg DMI) for 16%.

Session 59

Theatre 8

Agroforestry: an opportunity to improve the sustainability of livestock systems in Vietnam?M. Blanchard^{1,2}, P. Tos², A. Le Trouher^{1,2}, A. Lurette³ and H. Le Thi Thanh¹¹NIAS, Hanoi, 01, Viet Nam, ²CIRAD, UMR SELMET, Univ Montpellier, CIRAD, INRAE, Institut Agro, Montpellier, France, 34000, France, ³INRAE, UMR SELMET, SELMET, Univ Montpellier, CIRAD, INRAE, Institut Agro, Montpellier, France, 34000, France; melanie.blanchard@cirad.fr

In the mountainous areas of Vietnam, agroforestry is being developed in response to new market opportunities, the need to improve forest cover, and to reduce soil erosion. These resulted in changes in land use and affect the animal mobility and feeding patterns of ruminants, which represents an economic opportunity and contributes to the trade balance on meat. Using the example of the Dien Bien district in northwestern Vietnam, and based on a modelling of crop livestock integration and biomass flows in the area, this study assesses the effect of these changes on livestock systems, helping to define strategies for the sustainable development of livestock systems. The development of agroforestry contributes to the intensification of feeding systems, or leads to a cessation of livestock activities. Agroforestry systems intercropping forage within tree plantations increase the areas dedicated to forage production and the quantities and quality produced. Depending on their objectives, farmers maintain livestock activities to maintain soil fertility from avoiding over grazing and have access to manure as an organic fertilizer source for crops, trees and forage. They adapt their livestock systems, by stalling the animals, recycling grasses produced elsewhere and ensure feed supply in the whole year, thanks to silage. Animal housing, harvesting, transport and forage conservation technics can also represent a significant workload for farmers who then abandon livestock farming. The increase in forage production with agroforestry offers opportunities to develop local forage and silage markets and to participate in local livestock development, while providing opportunities to improve the livelihoods of farms without livestock. Agroforestry with forage production, combined with forage conservation, offers opportunities for sustainable intensification of livestock systems in the Mountainous area of Vietnam.

Selection signatures of the indigenous Sanga cattle of Namibia

D.A. Januarie, E.D. Cason and F.W.C. Naser

University of Free State, Animal Sciences, P. O. Box 339, 9300, Bloemfontein, South Africa; deidre.januarie@gmail.com

The majority of the indigenous Sanga cattle in Namibia are found in the Northern Communal Areas (NCA) of Namibia. Tradition, culture and environment play an important role in the selection of the animals. The indigenous Sanga cattle are well adapted to the harsh environment of Namibia resulting in identifying possible candidate genes that could explain performance and adaptability of these animals. Hair samples from the Kavango- (n=124), Caprivi- (n=135), Ovambo- (n=269), Kunene- (n=118), Herero (n=17) Sanga ecotypes as well as Nguni (n=148) cattle were collected and analysed using a 150K Single Nucleotide Polymorphism (SNP) chip. HapFLK results identified selection sweep regions over chromosomes 6, 4, 14 and 5. Selection sweep regions used Quantitative Trait Loci (QTL) to determine the possible candidate genes under selection. QTL for hair pigmentation, reproduction traits (gestation length, calving ease, age at first calving, heifer pregnancy and stayability), tick resistance, milk traits (yield, fat and protein percentage, somatic cell score), structural soundness traits (foot angle, rump width & length, teat placement), growth traits (average daily gain & residual feed intake) body weight and carcass traits (tenderness, eye muscle area, dressing percentage, marbling, weight) were identified. These results underline traditional selection habits for traits such as milk production, walking ability, coat colour, tick resistance, ease and age of calving were being applied.

Session 59

Theatre 10

***Diodelle sarmentosa*, an invasive plant in the rangelands of the sylvopastoral zone of Senegal**

E.H. Traore and F. Sow

Institut Sénégalais de Recherches Agricoles (ISRA), Laboratoire National de l'Élevage et de Recherches Vétérinaires, ISRA, PRH, Hann, 3120, Senegal; elhadji.traore@isra.sn

Livestock occupies an important place in Africa and particularly in Senegal where, the ruminant size is about 3,541 millions cattle, 6,678 millions sheep, 5,704 millions goats and 5 thousand camels. This livestock essentially conducted on extensive mode, has as a feed resources the natural pasture which is becoming rare due to a strong agrarian and urban pressure, but also, a negative influence of global changes, which affect the rainfall, on which depends the development of fodder. The effects of climate change can sometimes lead to the invasion of pastures by new plant species, especially herbaceous species that are more or less consumed. Thus, since some years, the pastoral space of the sylvopastoral zone of Senegal, has been colonized by an invasive species: *Diodelle sarmentosa*, (diodia) which has caused indigestion problems especially in straw state in ruminants, especially cattle and sheep. Then, the species although fleeting, begins to be palatable. The present work was devoted to study the bromatology of diodia, completed by *in vivo* ingestion and digestibility tests. The trials took place at the Centre de recherches zootechniques (ISRA-CRZ) of Dahra Djollof and involved 16 sheep male (08 *Peul-peul* and 08 *Touabir* breeds), aged about 22 months, divided into two batches (4 *Touabir* and 4 *Peul-peul* per batch) and kept in digestibility cages. Daily rations consisted of 1,500 g of *D. sarmentosa* straw alone for batch 1 and 1,500 g of a mixture of 50% *D. sarmentosa* and 50% other natural forages for batch 2. Refusal and faeces were assessed each morning. The bromatological analysis shows that the ration 2 was richer in MAT than the one made of diodia straw alone. Also, the negative values of the MAT digestibility coefficients of both rations, show their low nitrogen content. However, a significant difference in the digestibility of MAT, NDF and ADF in favour of ration 2 (diodia and other forages) is noted. It appears that the feed value of *D. sarmentosa* is low. However, this is a preliminary work that should be continued to better determine the best methods to valorise this invasive plant if not to eliminate it.

Environmental challenges in dry tropical livestock systems: GHG emissions and carbon storage balance

M.H. Assouma, D. Bastianelli and P. Salgado

CIRAD, TA C-112/A, Campus International de Baillarguet, 34398 Montpellier, France; habibou.assouma@cirad.fr

The effects of livestock on global warming and more generally on the environment are widely reported. It is estimated that the livestock sector accounts for 14.5% of global anthropogenic greenhouse gas (GHG) emissions of which 39% is due enteric methane (CH_4). Sub-Sahara African (SSA) livestock (pastoral and agropastoral) systems suffer from a criticism because their environmental impact appears high when GHG emissions are expressed per kg of product (milk, meat), due to their limited productive efficiency. Enteric emission rates are also high because of the low overall quality of forage resources and their seasonal variability. But these assessments do not account for the animal's role in organic matter recycling and carbon, nitrogen, and phosphorus cycling in grazed ecosystems. Moreover, most calculations are based on default emission factors which are not adapted to local conditions, and to approximative regional livestock populations. One of the major challenges of SSA pastoral and agropastoral livestock systems is to modify this negative perception of their impact, by working to recognize these systems as a mode of production and lifestyle and acknowledging their environmental contribution. Through research work and production of reference data, CaSSECS project is promoting an original approach to assess the environmental impact of livestock systems in SSA. This original approach, called an ecosystem approach of the carbon balance, aims to evaluate over a complete annual cycle all the GHG emission (animals, soil and water surfaces) and carbon storage (trees and soil) by using local references. To calculate the carbon balance at the national level, FAO's GLEAM tool will be updated with novel GHG emission references and an additional module for carbon storage of land management related to the livestock sector assessment in soil and trees.

Resilience analysis based on heifer productive and reproductive aspectsV.T. Rezende¹, G.R.D. Rodrigues², A.H. Gameiro¹, M.E.Z. Mercadante³, R.C. Canesin³ and J.N.G.S. Cyrillo.³

¹University of São Paulo, Faculty of Veterinary and Animal Science, 13635-900, Pirassununga, SP, Brazil, ²Uberlândia Federal University, BR-050, 38410-337, Uberlândia, MG, Brazil, ³Institute of Animal Science, Beef Cattle Research Center, 14174-000, Sertãozinho, SP, Brazil; jgcyrillo@sp.gov.br

Extensive beef cattle production on tropical areas has the dry seasons as a challenge in all phases of breeding because of low forage availability. This study aimed to assess the influence of heifer resilience at dry season on pregnancy rates. Data from Nelore heifers born between 2008 and 2017 belonging to a selection experiment started in 1980 were analysed. Heifers from selection line (NeS, n=283) and Control line (NeC, n=129) selected for higher and mean yearling weight (YW), respectively, were submitted to the breeding season at two years of age. Resilient animals were those with higher values of the difference (DFW770) between observed weight at 770 days old (W770, 347±54 kg), measured at the beginning of the breeding season, and the standardized weight at the same age (W770E, 296±43 kg), obtained using the ADG of the rainy season (391 to 550 days of age) as a growth pattern for the studied period. Animals were classified as susceptible (S, 300.07±4.40 kg, n=82), average (A, 291.34±3.11 kg, n= 214), or resilient (R, 301.66±3.73 kg, n= 107) based on the first, second, and third quartiles of DFW770, respectively. A logistic model included the fixed effects: RES, breeding season year, selection lines, and body condition score, using R 4.2.2 software. The significance of the odds ratio was given by the confidence interval of 95% (CI). All factors showed significant effects on pregnancy rates, except the selection lines ($P<0.05$). Heifers with the highest body score (7) had a 74.16% (CI: 70.45-77.87%) chance of becoming pregnant than heifers with a low body score (4) ($P=0.0048$). R animals had a 32.41% (CI: 30.78-34.02%) higher chance of becoming pregnant than S animals ($P=0.0201$). There were no significant differences between animals S and A ($P=0.4708$) regarding the chance of becoming pregnant. Resilient animals have a greater chance of pregnancy compared to non-resilient ones, regardless of selection for yearling weight and the body weight on breeding season.

Impact of GreenFeed protocols on cattle visitation and methane data collection

M.C. Parra¹, M.H. Dekkers², S.A. Cullen² and S.J. Meale¹

¹The university of Queensland, School of Agriculture and Food Science., 5391 Warrego Highway, 4343, Australia, ²The university of Queensland, Queensland Animal Science Precinct., 5391 Warrego Highway, 4343, Australia; m.parramunoz@uq.edu.au

Reliable methane emission data from a GreenFeed emission measuring (GEM) unit depends on cattle visitation. Six drought-master steers (411.83±48.29 kg BW) housed in a 3-ha paddock with *ad libitum* pasture were offered 2 kg/d of alfalfa pellets for 20 d, followed by grain-based pellets for 25 d to test attractiveness and subsequent number of visits to the unit. Two GEM protocols were used with Alfalfa pellets: (1) six daily visits (240 g/ea) with 8 drops/visit; (2) six daily visits (180 g/ea) with 6 drops/visit. While four protocols were used with energy-based pellets, (3) six daily visits (180 g/ea) with 6 drops/visit; (4) five daily visits (300 g/ea) with 10 drops/visit; (5) Five daily visits (390 g/ea) with 13 drops/visit and; (6) four daily visits (510 g/ea) with 17 drops/visit. All drops released 30 g of pellet at intervals of 30 sec, except protocol 2 which dropped pellets at 45 sec intervals. Daily average visits per head and pellet intake were measured. Visits >3 mins in length were considered to provide reliable methane (CH₄) data. Protocol 1 resulted in more visits to the GEM and a greater pellet consumption (3.2× daily and 0.7 kg/d/h), compared to protocol 2 (2.4× daily and 0.4 kg/d/h). Protocol 2 aimed to increase the time spent at the feeder, but steers left the GEM unit prior to consuming all available drops and increased the number of visits unable to capture reliable CH₄ data to 32.06%, compared to 10.43% for protocol 1. Grain-based pellets increased steers visits, where protocol 3 and 5 showed the highest daily visits per head (4.8 and 4.8 times, respectively), compared to protocol 4 and 6 (4.2 and 3.8 times, respectively). Pellet intake was greater with protocol 5 and 6 (2.2 and 1.8 kg/d/h, respectively), compared to protocol 3 or 4 (0.8 and 1.3 kg/d/h, respectively). Protocol 6 had more visits providing reliable CH₄ data (98.1%), followed by protocol 5 or 6 (~96.1%) and protocol 4 (94.9%). Therefore, to maximise emissions data collection we recommend the use of grain-based pellets with protocol 5 or 6 for future grazing trials using a GEM unit.

Effect of production system and season on composition of retail cow milk in Greece

G. Papatzimos¹, R.A. Stergioudi², V. Papadopoulos¹, Z. Basdagianni³, M.A. Karatzia⁴, P. Mitlianga² and E. Kasapidou¹

¹University of Western Macedonia, Department of Agriculture, Florina, 53100, Greece, ²University of Western Macedonia, Department of Chemical Engineering, Kozani, 50100, Greece, ³Aristotle University of Thessaloniki, School of Agriculture, Department of Animal Production, Thessaloniki, 54124, Greece, ⁴Research Institute of Animal Science, HAO-Demeter, Paralimni, 58100, Greece; papatzimos@hotmail.com

Information on cow milk nutritional quality at retail level is limited even though the effect of breed, diet, production system and season on milk composition has been well documented. Regarding Greece, there are no studies on the nutritional value of retail fluid milk. This study investigated the effect of the production system and season on the composition of cow milk produced in Greece. Milk samples (n=108) were collected monthly from four major supermarket retailers between November 2019 and October 2020. All samples were full-fat homogenized milk, either conventionally (n=7 brands) or organically produced (n=2 brands). Milk composition (fat, protein, lactose and solids non-fat content) was determined with a milk analyser, and fatty acid profiles were analysed by GC flame ionisation detection. General linear models were used to investigate differences in milk composition due to production system and season. Production system did not affect ($P>0.05$) milk chemical composition, whereas a highly significant ($P<0.001$) season effect was observed in protein content. Lactose and solids non-fat contents were also affected ($P<0.05$) by season. Higher protein levels of protein, lactose and solids non-fat were observed in autumn and winter. The lower protein content observed in summer months is related to the impact of high temperatures on lactating cows. Season did not affect ($P<0.05$) milk lipid classes, i.e. saturated, monounsaturated and polyunsaturated fatty acids, while a significantly higher content ($P<0.01$) of polyunsaturated fatty acids was found in organically produced milk. Differences in fatty acid composition in relation to the production system are attributed to diet-related parameters such as differences in the forage to concentrates ratio, type of flora in the grazing site and type of grass (fresh or silage).

Influence of heifer resilience on the productive performance of calvesG.R.D. Rodrigues¹, V.T. Rezende², C. Raineri¹, M.E.Z. Mercadante³, S.F.M. Bonilha³ and J.N.S.G. Cyrillo³¹Uberlândia Federal University, BR-050, 38410-337, Brazil, ²University of São Paulo, Faculty of Veterinary and Animal Science, 13635-900, Brazil, ³Institute of Animal Science, Beef Cattle Research Center, 14174-000, Brazil; jgcyrrillo@sp.gov.br

This study aimed to assess the relationship between heifer's resilience to the dry season challenge on calves' weights at birth and weaning. Data from Nellore heifers born between 2008 and 2017, belonging to a selection experiment started in 1980 were used. Heifers from selection line (NeS, n=283) and control line (NeC, n=129), selected for higher and mean yearling weight, respectively, were submitted to the breeding season at two years of age. Resilient animals (DFW770) were those with higher observed weights at 770 days old (W770, 347±54 kg), measured at the beginning of the breeding season, when compared to the standardized weight at the same age, obtained using the ADG of the rainy season as a growth pattern (W770E, 296±43 kg). Heifers were classified as susceptible (S) (n=82), average (A) (n=214), or resilient (R) (n=107) based on the first, second, and third quartiles of DFW770. Calves data corresponded to birth weight (BW) and adjusted weight at 210 days of age (WW) from NeS (n=183) and NeC (n=89). Analyses were carried out in R 4.2.2. The model of analysis included the effects of heifer resilience (RES), month of birth (M), calf gender, selection line (SL), and interaction RES×SL. Differences between factors were evaluated by SNK test at 5% significance. NeS calves were born and weaned heavier (32.08±0.32 kg, 198.17±2.87 kg) than NeC calves (26.00±0.38 kg, 161.58±2.77 kg) ($P<0.001$). Calves from R heifers had higher BW (31.31±0.49 kg) than calves from A and S animals (30.01±0.44 kg × 28.69±0.65 kg) ($P<0.001$). Calves from R heifers had higher WW (191.26±2.83 kg) than calves from A and S animals (180.26±2.33 kg × 161.35±3.44 kg) ($P<0.001$). Calves from R NeS (198.17±2.87 kg) and R NeC (161.58±2.77 kg) heifers had higher WW than calves from S NeS (166.94±4.97 kg) and S NeC (156.06±4.65 kg) heifers ($P=0.013$). Results suggest that the dry season challenge on heifers impacts calves' birth and weaning weight; R heifers wean heavier calves than S heifers in both selection lines.

Session 59

Poster 16

Feed autonomy and manure's recycling of dairy sheep farming systems in Roquefort (France)W. Nasri^{1,2}, F. Stark¹, N. Amposta³, M. Lamarque³, C. Allain³, D. Portes³, S. Arles³, S. Parisot³, C. Corniaux^{1,2}, P. Salgado^{1,2} and E. González-García¹¹UMR SELMET, Univ Montpellier, CIRAD, INRAE, L'Institut Agro, 34060 Montpellier, France, ²CIRAD, UMR SELMET, 34398 Montpellier, France, ³INRAE, UE0321 La Fage, 12250 Roquefort-sur-Soulzon, France; waad.nasri@cirad.fr

The aim of this work was to identify the main gaps and opportunities for increasing the efficiency and autonomy in the use of resources (i.e. natural, farm- or locally-produced, external or imported), as well as the resilience to climate change in dairy sheep farming systems (DSFS). The DSFS from the INRAE Experimental Farm La Fage (43°54'54.52"N; 3°05'38.11"E) was chosen as a typical case study, representative from the Roquefort region, the main production basin for sheep milk in France. Firstly, a deep characterization was carried out with the aim of diagnosing the global functioning of the DSFS; then its nutrient flows were analysed using Ecological Network Analysis. A second step was looking to identify the main opportunities for building future DSFS through a multi-stakeholder platform. A historical dataset for the period 2015-2019 was collected, organized, processed, analysed and interpreted. Detailed features of each DSFS component and interactions between them were detailed in the deep characterization phase. The main components of the DSFS are: the flock (n=608 females; 70% ewes and 30% hoggets), feeding resources, infrastructures (buildings, sheds, etc.) and manure stockpile. The feeding system is based on improved (96%) and native (4%) grasslands both used for direct grazing and producing roughage. The grazing rate is 12% while the indoors feeding covers 88% of the yearly flock consumption. Main gaps are related to the feeding system and manure use. In fact, the quantity of purchased feed keeps increasing (from 7 to 30% during 2015-2019), contrarily to the quantity of on-farm produced feedstuffs (from 92 to 70%). There are considerable nitrogen losses mainly by leaching and by volatilization during manure's storage and spreading. There are opportunities for increasing feed and forage autonomy of the farm as well as for optimising processes for organic matter recycling, conservation and use. Acknowledgements: This work is part of the TRUSTFARM project carried out under the ERA-Net Cofund FOSC (Grant N° 862555).

Metabarcoding study of the microbial dynamics in cheeses as a function of milk tank temperatureL. Giagnoni^{1,2}, C. Spanu², A. Tondello¹, S. Deb¹, A. Cecchinato¹, P. Stevanato¹, M. De Noni³ and A. Squartini¹¹University of Padova, DAFNAE, Viale dell'Università 16, 35020, Italy, ²University of Sassari, Department of Veterinary Medicine, Via Vienna 2, 07100, Italy, ³Latteria Montello S.p.A., Via Fante d'Italia 26, 31040, Italy; l.giagnoni@studenti.uniss.it

Milk tank temperature variations and fresh cheese seasoning timing can affect the shelf-life and the sensory properties of cheese as final product. Milk refrigeration temperature before pasteurization plays a crucial role as it can affect especially the proportions of psychrotrophic taxa abundance over the total milk bacterial population. Generally, 4 °C is the standard choice, due to its general growth control effect. However, some cold-tolerant genera featuring a proteolytic attitude, upon proliferation, could negatively affect curd clotting and regular cheese maturation at 4 °C, becoming an inconvenience. The present study was commissioned by a major fresh cheese producing company with an in-factory trial. The aim of this study was to evaluate the microbial communities of cheese preparations derived from raw milk stored at different temperatures, before pasteurization and cheese making, by DNA extraction and 16S-metabarcoding sequencing. Working at actual dairy facility level, raw milk was stored at 4, 7 and 9 °C, performing a gradual shift of the same tank across the above values. Milk was then pasteurized and used to prepare a caciotta-style fresh cheese. The temporal dynamics of the microbial communities at different times of maturation, from time zero up to two months, were evaluated. The taxa alpha and beta diversity across the different communities and their relative shifts in abundance, with particular emphasis on the complementary dynamics of psychrotrophic groups vs temperature-favoured enteric ones, will be discussed. Relevant clues for a better anticipation of the effects of thermal abuse and overall process parameters variation, have been gathered, to the benefit of an improved handling of the technical conditions by the cheese manufacturing industry.

Adaptive integumentary traits of cattle raised in a silvopastoral system in tropical regionA.R. Garcia^{1,2}, A.N. Barreto¹, M.A.C. Jacintho², W. Barioni Junior², L.N. Costa³, F. Luzi⁴, J.R.M. Pezzopane², A.C.C. Bernardi² and A.M.F. Pereira⁵¹UFPA, Rod BR 316, 68740, Castanhal, Brazil, ²Embrapa Pecuária Sudeste, P.O. Box 339, 13560, São Carlos, Brazil, ³Università di Bologna, Viale Fanin, 46, 40127, Bologna, Italy, ⁴Università degli Studi di Milano, Via Celoria, 10, 20133, Milan, Italy, ⁵Universidade de Évora, R Cardeal Rei, s/n, 7000, Évora, Portugal; alexandre.garcia@embrapa.br

This work aimed to investigate whether the environment of afforested pastures or in a silvopastoral system (SPS) determines adaptive differences in the morphophysiological characteristics of the integument of beef cattle. The experiment was conducted for 12 months in a tropical climate (São Carlos, Brazil, 21°57'42"S 47°50'28"W). Steers previously raised together in conventional pastures (n=64 Nelore and Canchim; 31.4±1.6 mo; 482.6±47.7 kg) were placed in rotational grazing systems with *Urochloa brizantha* in full sun (FS, n=32) or in shaded area with *Eucalyptus urograndis* (SPS, n=32). Animals were evaluated monthly, during periods of thermal challenge (11:00am-2:00pm). Skin microbiopsies were performed in winter and summer for histomorphometric evaluation (Bioethical Prot. CPPSE 07/17). No significant interaction (treat×seas) was found. Overall means were compared using Tukey's test ($P \leq 0.05$). Rectal temperature (FS=39.45±0.05 vs SPS=39.29±0.05 °C; $P < 0.05$) and the coating thickness differed (FS=1.60±0.04 vs SPS=1.42±0.04 mm; $P < 0.05$), suggesting that steers raised in SPS had an external adaptive feature that favoured heat loss. Histological analysis revealed greater epidermal epithelial thickness in animals raised in FS (FS=76.4±42.2 vs SPS=64.4±42.2 µm; $P < 0.05$), which may be attributed to greater outer cell proliferation in the integumentary layer of the animals most exposed to ultraviolet radiation. The distance between the epidermis and sweat glands was smaller in SPS animals (FS=805.9±25.1 vs SPS=727.1±25.1 µm; $P < 0.05$), indicating their greater glandular activity and lumen filling, which increases the sweating efficiency. Integrated production systems have been pointed out as a strategy to mitigate and adapt to the effects of climate change. Indeed, animals raised in SPS showed greater plasticity and adaptability of skin tissue, favouring cutaneous convective and evaporative thermolysis.

Impact of fodder quality seasonality on enteric methane emission from cattle in Sub-Saharan Africa

¹FSA-UAC, Cotonou, BP 526, Benin, ²SELMET, Univ Montpellier, CIRAD, INRAE, Institut Agro, Montpellier, 34398, France, ³CNRST, INERA, Bobo-Dioulasso, 01 BP 910, Burkina Faso, ⁴CIRDES, Bobo-Dioulasso, 01 BP 454, Burkina Faso, ⁵INRAE, UMRH, Clermont-Ferrand, 63122, France, ⁶CIRAD, UMR SELMET, Montpellier, 34398, France; gerard_xavier_djidjo.gbenou@cirad.fr

In Sahel, pastures feed resources drastically decline both in quantity and quality from rainy to dry season. Several models to estimate enteric methane (eCH_4) emission were developed but have low accuracy in Sahelian production systems. In order to improve these models, direct reference measurements are necessary. We aimed to measure *in vivo* eCH_4 emission in Sudanese peulh zebu during each season (rainy: RN, cold dry: CD, and hot dry: HD) of the year. The experiment was carried out (CIRDES, Burkina Faso) on 10 steers of 32 months old with liveweight (LW) of 147 ± 5.8 kg (i.e. 0.59 Tropical Livestock Unit-TLU). Animals were kept in individual boxes. Individual eCH_4 (GreenFeed system) and total tract digestibility were measured. The animals were fed with natural forage harvested from rangelands in each season. Different levels of forage were offered by mimicking the gradient of forage availability on pastures during a year: 7% LW during the rainy season; 3.5% LW during the cold dry season; and 3.5, 2.5 and 1.5% LW during the hot dry season. Each trial lasted 3 weeks including 2 weeks of feed adaptation and 1 week of data collection. In RN, CD and HD, the average content of intake in crude protein (CP, g/kg DMI) was 65 ± 1.6 , 48 ± 1.6 , and 28 ± 1.1 , respectively. Average content of intake in fibre (NDF, g/kg DMI) was respectively 619 ± 29.0 , 660 ± 17.4 , and 712 ± 17.8 . Dry matter intake (DMI, g/kg LW) was respectively 22 ± 1.4 , 23 ± 1.5 , and 16 ± 1.8 in RN, CD, and HD. The average DM digestibility (%) was respectively 56.9 ± 3.04 , 49.9 ± 2.12 , and 46.2 ± 3.08 . Amounts of eCH_4 (g/kg DMI) emitted was different with HD compared to others seasons: (33 ± 7.9 vs 21 ± 4.4 in RN and 25 ± 4.7 in CD). A global calculation over a year revealed that in extensive systems of Sub-Saharan Africa, local zebus cattle fed on natural pastures emitted 44.9 ± 3.34 kg of eCH_4 /TLU/year.

Session 60**Theatre 1****Variation in mineral content of feeds for dairy cows and how that can affect ration formulation**

W.P. Weiss

Ohio State University, 2145 Riverside Drive, Cincinnati, OH 45202, USA; weiss.6@osu.edu

Sources of variation in the mineral concentrations of feedstuffs include those produced by the observer (sampling and analytical variation) and the true variation caused by soil, climate, manufacturing method, etc. Partitioning variation correctly requires large amounts of data with multiple points of replication. From a previous experiment, observer variation for macrominerals (Ca, P, Mg, and K) and trace minerals (Cu, Fe, Mn, Zn) was about 10% and 60-80% of total variation, respectively. Data on observed variation in mineral composition can be obtained from various databases, but this observed variation will include both sampling and analytical variation. For this abstract, the database from NASEM (2021) Dairy Requirements was used. That database was derived from $>10^6$ records obtained from commercial testing labs that used approved methods. The data were screened using a robust statistical method to remove mislabelled feeds and partition feeds into subpopulations when appropriate. Several exceptions exist but some general conclusions can be reached. Concentrations of minerals were more variable (based on CV) than the concentration of total ash. For most feeds, concentrations of ash, P, Mg, and S approximated a normal distribution but for all TM and Ca, distributions were skewed with long tails at higher concentrations. Within feeds, concentrations of P were least variable (CV averaged 15%) and Fe was most variable (CV $>50\%$). As a comparison crude protein had CV generally <10 . Within a feed, variation in Cu and Zn concentrations were similar. Variation in mineral concentrations was generally greater for forages than concentrates, but differences between those feed classes were less for macrominerals than for TM. However, sampling variation may have caused much of these differences. Although variation for many minerals is quite high in feeds, well-made mixed diets will vary less because the composition of feeds vary independently. Using a simple 5 ingredient diet with no supplemental minerals, means and SD from NASEM, and Monte Carlo simulations, diet CV for crude protein was 2.9. For P, Mg, S, Cu, and Zn the CV were 4.7, 9.5, 9.1, 15.9, and 10.9. Variation in basal concentrations of minerals is greater than for macronutrients, but sampling error is likely a major contributor to that variation.

Evolution of nutritional explorations in herds of dairy and beef cattle between 2013 and 2021*L. Reisdorffer**OBIONE, 71, 239 Rue Fernand Leger, 71000 Macon, France; lr@obione.fr*

Nutritional explorations are helpful in understanding the problems encountered in farming. For several years the company Obione in partnership with the Labeo laboratory have been offering Nutritional Explorations (NE) to French breeders and veterinarians. Based on their data between 2013 and 2021, the results of the NE are analysed by elements, by year and by month. The analysis of these data shows variations which are explained both by the analysis technique but also by season and therefore at the same time the fodder availability, by the type of housing which conditions the intake of minerals in the ration of animals and by drought which can limit the availability of vitamins for animals. Prevalences are still quite high since about 50% of the samples that are processed show by deficiencies. The hierarchy within the deficient elements shows a fairly marked evolution with for the Trace elements, Copper is the leading deficient element and for Vitamins, it is Vitamin A. These data should lead veterinarians and breeders to not forget these two elements significant and often loss-making.

Session 60

Theatre 3

Selenium supply in animal feeds, a powerful nutritional tool against cancer*M. López-Alonso¹, I. Rivas¹ and M. Miranda²**¹University of Santiago de Compostela, Animal Pathology, Veterinary Faculty, 27002 Lugo, Spain, ²University of Santiago de Compostela, Anatomy, Animal Production and Veterinary Clinical Sciences, Veterinary Faculty, 27002 Lugo, Spain; marta.lopez.alonso@usc.es*

Selenium (Se) is an essential trace element for the proper functioning of all organisms. It is a cofactor of many essential enzymes, as glutathione peroxidase, selenoprotein P, with a well-known role on the protection against oxidative stress as a free radical scavenger. Selenium deficient areas are very frequent around the world, including Europe, and given the low concentrations of Se in the feed ingredients, animal diets are regularly supplemented with Se to maintain health and production. In this areas, human food ingredients also contain inadequate levels of Se, and Se deficiency is associated with a compromised immune system and increased susceptibility to many diseases, including arthritis, cardiovascular disease, cataracts, cholestasis, cystic fibrosis, diabetes, immunodeficiency, lymphoblastic anaemia, macular degeneration, muscular dystrophy, stroke and some others, even though the most compelling evidence exists in relation to the cancer-protective effects of Se. In epidemiological observations and prospective studies, an inverse correlation between Se levels in food and blood and the risk of cancer and cancer mortality was observed. Particular interest in Se has been generated as a result of clinical studies showing that dietary supplementation with organic Se decreased cancer mortality two-fold. As a result, finding solutions to this problem is now on the agenda of many government health bodies. Results derived from various research studies conducted over the last few years have indicated that the enrichment of animal-derived foods with Se via supplementation of animal feeds can be an effective way of increasing human Se status in countries where Se consumption falls below the recommended daily allowances. This paper reviews how Se concentrations of animal products (meat, eggs and milk) can be manipulated to give increased levels, especially when organic Se is included in diet, which offers the opportunity to produce tailored Se-enriched animals products well adapted to the needs of the population.

Effect of mineral source on 48-h *in vitro* fermentationG.M. Boerboom¹, C.B. Peterson², L. Jansen¹, M.M. McCarthy², J.S. Heldt² and J. Johnston³¹Selko, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands, ²Selko USA, 3905 Vincennes Rd, Indianapolis, 46268, USA, ³Fermentrics Technologies Inc, 961 Campbell Drive, Arnprior K7S0E1, Canada; carlyn.peterson@selko.com

A total of 4 trials were completed to evaluate the effect of trace minerals (TM) sources on *in vitro* fermentation. In the 1st trial the inclusion of copper (Cu), zinc (Zn) and manganese (Mn) was evaluated when comparing sulphate (SU) to IntelliBond (IB). In the 2nd trial, the inclusion of Mn from Mn oxide (MO), Mn sulphate (SM), organic Mn (OM) and IntelliBond M (IBM) was compared. Targeted supplemental TM were 222 mg/d and 555 mg/d for Mn and 1,035 mg/d for Zn, for a dairy cow consuming 25 kg DM with 120 l rumen volume. In the 3rd trial, 7 different sources of Mn were tested at 500 mg/d: Control (CM, no TM), MO, SM, IBM, Vistore Mn (VM), Availa Mn (AM), and Maintrex Mn (MM). In the 4th trial, 7 different sources of Zn were tested at 750 mg/d: Control (CZ, no TM), Zn oxide (OZ), Zn sulphate (SZ), IntelliBond Z (IBZ), Vistore Zn (VZ), Availa Zn (AZ), and Mintrex Zn (MZ). Fermentation vessels contained a mix of KSU buffer (80%) and rumen fluid (20%) with 6 mm ground dairy TMR, as fermentation substrate, in 5×10 cm bags. Vessels were incubated for 48-h in a 39.5 °C water bath. Data were analysed using PROC MIXED (SAS institute Inc, Cary, NC). A *P*-value ≤0.05 was considered significant. The 1st trial indicated reduced apparent organic matter disappearance (aOMD) with SU compared with the control (*P*<0.01), whereas IB did not differ from control. The 2nd trial indicated that MO and SM reduced aOMD relative to the control (*P*<0.001), whereas IBM and OM were similar to the control. IBM and OM had higher apparent microbial biomass production (aMBP) than the control, SM and MO treatments (*P*<0.01). In the 3rd trial, IBM increased aMBP compared to MM, SM and AM (*P*<0.05) but was no different from VM or the control. Compared to MO a trend for an improved aMBP was observed for IBM (*P*<0.10). In the 4th trial, IBZ resulted in greater aMBP compared to the control, MZ, VZ and SZ (*P*<0.05). A trend was observed for an improved aMBP compared to AZ (*P*<0.10). IBZ also increased aOMD compared to all other treatments (*P*<0.05). Overall, results indicated that trace minerals can affect *in vitro* fermentation, with IntelliBond reducing the negative effects.

Session 60

Theatre 5

Feed phosphates market dynamics: does price influence demand?

G. Milochau

Praxed, 1 rue Napoléon Ancelin, 78400 Chatou, France; guillaume.milochau@praxed.fr

For people new to the inorganic feed phosphate (IFP) market, it's hard to find any logic! This market is highly volatile, and it is hard to find a good proxy or benchmark to determine when it's the right time to close a deal. For example, when it comes to Polish imports, the price range of monocalcium phosphate (MCP) is wide: from below €200/tonne up to €1,400/tonne! Of course, if we compare feed phosphate prices with prices for phosphate fertilizers such as diammonium phosphate (DAP), we can see they follow the same basic trend, but there is no clear correlation between fertilizer and feed phosphates. These markets have different dynamics, although they share the same fundamentals. Access to phosphorous is limited to a few regions in the world, with most of the reserves in North Africa. Many key agricultural regions depend on the import of phosphorous in one form or another (phosphate rock, phosphoric acid, DAP, TSP, etc). Production of phosphates is increasingly concentrated within vertically-integrated producers that are not only expanding their production capacities but also investing in their own distribution systems. This is what we mean when we talk about mine-to-market strategies. We hear from the field that consumption has been heavily reduced, and soon feed phosphates may become niche products in pig feed, for instance. Are feed phosphates going to become niche products with the introduction of last phytase generation? Does the recent price of IFP will have destroyed demand for good?

Reduction of trace mineral supplementation on performance and mineral status of fattening pigsE. Gourlez^{1,2,3}, J.Y. Dourmad³, F. Beline², A. Monteiro¹, A. Boudon³, A. Narcy⁴, P. Schlegel⁵ and F. De Quelen³¹Animine, rue Léon Rey Grange, 74960 Annecy, France, ²INRAE, OPALE, Av. de Cucillé, 35000 Rennes, France, ³INRAE, PEGASE, Le Clos, 35590 Saint-Gilles, France, ⁴INRAE, BOA, Centre INRAE Val de Loire, 37380 Nouzilly, France, ⁵Agroscope, Rte de la Tioleyre 4, 1725 Posieux, Switzerland; emma.gourlez@inrae.fr

Excreted Cu and Zn can accumulate in the upper soil layer and harm its fertility. Thus, managing dietary contents in pig diets should reduce such risk. However, a limited supply of these essential trace elements to pig requires a better knowledge. This study aimed to evaluate the effect of three levels and two sources of Cu and Zn on performance and mineral status of fattening pigs. Four dietary treatments were compared including a negative control (NC) corresponding to the basal growing and finishing diets, without Zn and Cu supplementation (5 and 29 mg/kg Cu and Zn respectively); an intermediate level (O1) supplemented with Cu and Zn oxides (Cu₂O and ZnO; CoRouge® and Hizox®, Animine, France), which provided on average 7.4 mg/kg Cu and 47.5 mg/kg Zn; two diets were supplemented with oxides (O₂) or sulphates (PC, positive control) at maximal EU regulation levels (25 and 120 mg/kg for total Cu and Zn, respectively). Ninety-six pigs (24.3±3.3 kg BW) were allocated to one of the four experimental treatments and raised in individual pens during 14 weeks (up to 110.3±8.9 kg). Animal performance were measured and samples of plasma (at d1, d41 and d90), bones and liver (at slaughter) were collected. Every third week, samples of faeces were obtained to determine the dynamic of Cu and Zn excretion. Over the whole experimental period feed intake, body weight and feed conversion ratio were not affected by the level nor the source of Cu and Zn. Plasma Cu was not affected neither by treatment nor period, whereas plasma Zn increased with period but did not differ between treatments. Hepatic Cu increased ($P<0.05$) with dietary content, and a tendency for increase of bone Zn with dietary content ($P<0.10$) was observed. Faecal Cu and Zn decreased significantly ($P<0.01$) with dietary content. Although it seems possible to reduce dietary Cu and Zn without affecting performance, these results require to be validated in commercial farms with more challenging health constraints.

Session 60**Theatre 7****Optimal level of dietary zinc for pigs between 10 and 30 kg**

T.S. Nielsen, S.V. Hansen, J.V. Nørgaard and T.A. Wøyteng

Aarhus University, Animal and Veterinary Sciences, Blichers Allé 20, Box 50, 8830 Tjele, Denmark; tinas.nielsen@anivet.au.dk

Zinc (Zn) is an essential nutrient but excessive dietary Zn is excreted via faeces by pigs and spread to the environment. To establish the optimal level of dietary Zn from 10-30 kg, we conducted a Zn dose-response experiment (80, 92, 117, 189 and 318 ppm total Zn) in 150 pigs, 2 to 6 weeks post-weaning (PW). The basal diet (including 1000 phytase units/kg feed) without added Zn contained 80 ppm Zn, and added Zn was high purity zinc oxide. From weaning at 28 days of age to 2 weeks PW, pigs were supplied 1,500 ppm total Zn, which we previously showed was the optimal level of dietary Zn in this period. From 2 to 6 weeks PW, pigs were housed individually and feed intake, BW and faecal scores were recorded. Zinc status was evaluated in blood (weekly), and in liver, small intestinal mucosa and bone by the end of the trial. Average daily feed intake (ADFI) and average daily gain (ADG) was unaffected by dietary Zn content ($P=0.99$ and $P=0.60$, respectively) but there was a tendency for feed conversion ratio (FCR) to be better ($P=0.07$) for pigs fed 80 ppm Zn (1.34) compared to 318 ppm Zn (1.39), with the other dietary Zn levels being in between. The probability of a diarrheic faecal score was lowest (0.35-0.36) at 80, 189 and 318 ppm Zn and highest (0.45) at 92 ppm Zn ($P<0.001$). Serum Zn status was on average 873 µg/l at the beginning of the experimental period, but decreased ($P<0.001$) by 13-24% after one week, depending on dietary Zn level. After 3 and 4 weeks, 80 and 92 ppm Zn still resulted in serum Zn levels lower ($P<0.001$) than at the beginning of the experimental period. Zinc status in liver, bone and intestinal mucosa was affected ($P<0.001$) by dietary Zn level but for liver, there was no difference between dietary Zn levels. Intestinal mucosa Zn increased from the lowest to the highest dietary Zn level ($P<0.05$), whereas there was a quadratic effect of dietary Zn level on bone Zn content. Based on ADFI, ADG, FCR and probability of diarrhoea, we conclude that 10-30 kg pigs can do without added Zn in the diet when a high level of phytase is included and pigs are initially supplemented with 1,500 ppm Zn. However, serum Zn status decline gradually when Zn is not added to the diet and other Zn status parameters may also be lower at 30 kg.

Administration of potentiated Zn and monovalent Cu in weanling piglets dietL. Marchetti¹, R. Rebucci¹, P. Cremonesi², B. Castiglioni², F. Biscarini², A. Romeo³ and V. Bontempo¹¹Università degli Studi di Milano, Department of Veterinary Medicine and Animal Science, Via dell'Università, 6, 26900, Lodi, Italy, ²Institute of Agricultural Biology and Biotechnology, Via Einstein, 26900, Lodi, Italy, ³Animine, 10 rue Léon Rey Grange, Annecy 74960, France; luca.marchetti1@unimi.it

The aim of this study was to determine the suitability of potentiated Zn combined with a monovalent Cu as a replacement for pharmacological ZnO supplementation in piglets after weaning. A total of 120 piglets (7.143 ± 0.924 kg) were weaned at 27 d and divided into 4 experimental treatments. A positive control (PC, 2,500 ppm of Zinc through standard ZnO) was compared to 3 treatments in which Cu and Zn were supplemented through potentiated Zn (HiZox®) and monovalent Cu (CoRouge®) at European and non-European levels of inclusion: EU (120 ppm of Zn; 140 ppm of Cu), non-EU⁺ (300 ppm of Zn; 200 ppm of Cu) and non-EU⁻ (300 ppm of Zn; 140 ppm of Cu). Performance data were analysed using the MIXED procedure of SAS. Serum diamine oxidase (DAO) and D-lactate were analysed through a MIXED procedure of SAS at 0 d and 14 d. SIgA was evaluated with a GLM procedure of SAS (28 d). Faecal samples (14 d and 28 d) and intestinal content (28 d) were collected and the V3-V4 hypervariable regions of the bacterial 16S gene were sequenced in one MiSeq (Illumina) run. Performances were not affected by different Zn and Cu dosages. Plasma DAO was negatively ($P < 0.05$) affected in non-EU⁻ treatment. The level of sIgA was increased in PC group (157.73 ± 19.58 ng/ml) compared to EU (143.81 ± 12.96 ng/ml; $P < 0.05$) and non-EU⁻ group (138.01 ± 16.88 ng/ml; $P < 0.01$). non-EU⁻ contributed to a significant decrease in biodiversity in faecal microbiota as shown by the Shannon diversity and Simpson evenness indexes ($P < 0.05$). A total of 18 differentially abundant genera ($P < 0.05$) were identified in the caecal content with the presence of genera linked to the disruption of the gut barrier (*Campylobacter*) with non-EU⁻. These results suggest that a more balanced supplementation of the two trace elements, through more bioavailable sources, could represent a valid tool to enhance gut health of weaning piglets and reduce environmental impact.

Session 60

Theatre 9

Unexpected Cu and Zn speciation patterns in the feed-animal-excreta systemS. Legros¹, M. Tella¹, A.N.T.R. Monteiro², A. Forouzandeh³, F. Penen², S. Durosoy² and E. Doelsch⁴¹CIRAD, Avenue Agropolis, 34398 Montpellier, France, ²Animine, 10 rue Léon Rey Grange, 74960 Annecy, France, ³Universitat Autònoma de Barcelona, Department of Animal and Food Science, Edifici V, 08193 Bellaterra, Spain, ⁴CIRAD, Recycling and risk research unit, CEREGE Europole de l'Arbois, 13545 Aix-en-Provence Cedex 4, France; doelsch@cirad.fr

Trace minerals such as copper (Cu) and zinc (Zn) are animal nutrition supplements necessary for livestock health and breeding performance, yet they also have environmental impacts via animal excretion. Here we investigated changes in Cu and Zn speciation from the feed additive to the animal excreta stages. The aim of this study was to assess whether different Cu and Zn feed additives induce different Cu and Zn speciation patterns, and to determine the extent to which this speciation is preserved throughout the feed-animal-excreta system. Two types of animals were considered, broilers and pigs. Synchrotron-based X-ray absorption spectroscopy (XAS) was used for this investigation. The principal findings were: (1) In feed, Cu and Zn speciation changed rapidly from the feed additive signature (Cu and Zn oxides or Cu and Zn sulphates) to Cu and Zn organic complexes (Cu phytate and Zn phytate). (2) In the digestive tract, the results depend on the animal studied. In broilers, we showed that Cu and Zn phytate were major Cu and Zn species while Cu sulphide and Zn amorphous phosphate species were detected but remained minor species. In pigs, we showed that the Cu and Zn dominant species were Zn phytate and Cu sulphide. (3) In fresh excreta, the results depend on the element studied. For Cu, Cu sulphide is always the major species regardless of the animal studied. For Zn, Zn amorphous phosphate is the major species for broilers while Zn sulphide is the major species for pigs. These results should help to: (1) enhance the design of future research studies comparing different feed additive performances; (2) assess Cu and Zn bioavailability in the digestive tract; (3) gain further insight into the fate of Cu and Zn in cultivated soils when poultry manure is used as fertilizer.

Coarse limestone particles limit the formation of Ca-phytate complexes in laying hensF. Hervo^{1,2}, M.-P. Létourneau-Montminy², B. Méda¹, M.J. Duclos¹ and A. Narcy¹¹INRAE, Université de Tours, BOA, 37380, Nouzilly, France, ²Sciences Animales, Université Laval, G1V 0A6, Québec city, Québec, Canada; fabie.hervo@inrae.fr

Reducing phosphorus (P) excretion in laying hen production is a challenge. In the digestive tract, calcium (Ca) can form de novo unavailable complexes with phytate, impairing phytase efficiency to release non-phytic P (NPP) from phytate. In broilers, it has been shown that coarse limestone particles (CL) limit the formation of Ca-phytate complexes. Thus, the effect of CL and microbial phytase was investigated in laying hens between 31 and 35 wk of age to study the potential beneficial effect of CL incorporation on P utilization. Seventy-two Lohmann Tradition laying hens were randomly assigned to one of the four experimental diets. A 2×2 factorial arrangement was used with two levels of phytase and basal available P (aP); 0 FTU/kg with 0.30% aP or 300 FTU/kg with 0.15% aP and two limestone particle sizes (LmPS); fine particles (FL, <0.5 mm) or a mix (MIX) of 75% CL (2-4 mm) and 25% FL. Diets contained equivalent levels of Ca (3.5%), phytic P (PP, 0.18%) and, considering the phytase P equivalency, equivalent levels of aP (0.30%). Egg production and average daily feed intake (ADFI) were measured weekly throughout the experimentation. Tibia ash (%), apparent pre-caecal digestibility (APCD) of P and Ca (%) and PP disappearance at the ileal level (%) were measured. No differences were observed between treatments in ADFI, FCR and tibia ash. Phytase and CL together increased the APCD of Ca by 7.3 percentage points (Phytase × LmPS, $P < 0.001$). Hens fed with FL and phytase exhibited a lower APCD of P compared with hens fed FL without phytase, while no differences were observed in hens fed with CL (Phytase × LmPS, $P < 0.001$). Additionally, hens fed with FL and phytase showed a lower PP disappearance at the ileal level than hens fed with CL and phytase (Phytase × LmPS, $P = 0.005$). These results may be explained by a lower formation of Ca-phytate complexes when limestone was provided as CL, and thus a higher availability of minerals for the animal. This strategy may therefore help improving the utilization of P and Ca and reducing P excretion in laying hens.

Poster 11

The duration of efficacy of a single oral dose of selenium in sheepS.E. Gallimore¹, E.J. Hall¹ and N.R. Kendall²¹Rumenco Ltd, T/A Nettex, Stretton House, Derby Road, Burton-on-Trent, DE13 0DW, United Kingdom, ²University of Nottingham, School of Veterinary Medicine and Science, Sutton Bonington campus, Loughborough, LE12 5RD, United Kingdom; sgallimore@rumenco.co.uk

Selenium is commonly deficient in the diets of grazing sheep and can limit immune responses, growth, fertility and flock profitability. Oral drenches are widely used to supplement Se and research on duration of efficacy of these products is required to inform best-practise mineral supplementation. This study aimed to determine the response and duration of efficacy of a single dose of oral Se in grazing lambs. Two groups of weaned lambs (ewe n=339, wether n=347) were randomly allocated to 3 treatments; 1.55 or 3.5 mg of Se administered on 0 d via a sodium selenite drench, or a control group which received no drench. Lambs were weighed on 0 and 54 d; between these days they were run as a single group and then separated into 2 groups (ewes/wethers) rotating around the same block of pasture. From each treatment group, 6 ewes and 6 wethers were sampled by jugular venepuncture on 0 d prior to drench administration and subsequently sampled on days 12, 26, 33, 40, 47, 54, 68, 89 and 108. Samples were analysed for plasma Se and Co by ICP-MS, for erythrocyte glutathione peroxidase (GSHPx) by colorimetric assay and for plasma vitamin B₁₂ by immunoassay. Lambs across all treatments began the trial with adequate Se status. Results showed both drench treatments elevated plasma Se for 6-7 weeks. The 3.5 mg dose had a slightly longer duration with significance ($P < 0.05$) compared to controls on 40 d present for this dose only. The 3.5 mg dose also displayed a higher peak in plasma Se compared to 1.55 mg on 12 d ($P < 0.05$). No other plasma Se differences between doses were found. GSHPx activity declined over the duration of the study in both treatment and control groups, which could be attributed to diminishing effects of maternal Se transfer. However, both Se drenches partially mitigated this with elevated activity ($P < 0.05$) present from 33 to 108 d compared to unsupplemented controls. There were no treatment effects for weight, plasma Co or vitamin B₁₂. In lambs with adequate Se status, a single dose of oral Se elevated plasma Se for 6-7 weeks and subsequently enhanced GSHPx activity for 108 days post treatment.

Dietary manganese impacts on growth, carcass and reproductive traits in angus bulls

J.R. Russell¹, E.L. Lundy-Woolfolk², A.S. Cornelison¹, W.P. Schweer¹, T.M. Dohleman² and D.D. Loy²
¹Zinpro Corporation, Eden Prairie, MN, USA, ²Iowa State University, Ames, IA, USA; jrussell@zinpro.com

Although minerals like zinc and copper have been substantially researched in beef cattle diets, manganese (Mn) remains poorly understood. A pooled analysis revealed improved growth and carcass traits when zinc amino acid complex was provided in diets at twice the NASEM (2016) requirement. Therefore, the current objective was to evaluate dietary Mn sources at twice the NASEM requirement. Sixty weaned angus bulls received a common starting ration containing Mn sulphate while acclimating to feed bunks capable of measuring individual feed intake. Bulls then transitioned to a finishing diet in which a pellet was included to provide one of two dietary treatments (TRT) for 182 d. The TRT provided 40 ppm supplemental Mn on a total dietary basis, consisting of either inorganic Mn hydroxychloride (INORG; Intellibond M, Micronutrients LLC, US) or Mn amino acid complex (AVMN; Zinpro Availa Mn, Zinpro Corporation, US). Starting on d 60, bulls were electro-ejaculated (EJAC) monthly to collect semen for puberty determination. Following harvest (d 183), carcass traits were measured, and one testicle was collected to measure testicular degradation (TD) and other traits. Utilizing PROC Mixed of SAS for all continuous variables, bull was experimental unit (n=30/TRT) and TRT was a fixed effect. Initial BW (267 kg) served as a covariate for final bodyweight and carcass weight. PROC Glimmix was utilized to evaluate the pubertal data (binomial) and TD data (multinomial). Growth and carcass traits did not differ ($P>0.39$) due to TRT. Though TRT did not affect ($P>0.3$) puberty across timepoints, more AVMN bulls met or exceeded puberty prerequisites than INORG (20 vs 16, respectively) on the final EJAC day (d 171). Pubertal headcount for INORG regressed and it is unclear why, though TD score was greater ($P=0.01$) in post-harvest testicles from INORG vs AVMN bulls. No other differences ($P>0.15$) were detected for testicular measurements post-harvest. Although Mn source had no measurable impact on growth and carcass traits in developing bulls, Mn source effects on reproductive outcomes should be further explored.

Session 60

Micronutrient supplementation for suckling calves

M.S.V. Salles¹, F.J.F. Figueiroa², A. Saran Netto², C.M. Bittar³, F.F. Simili¹ and H.N. Rios¹

¹Animal Science Institute, A. Bandeirantes, 2419, 14030-670, Brazil, ²FZEA/USP, R. Duque de Caxias, 225, 13635-900, Brazil, ³ESALQ/USP, Av. Pádua Dias, 11, 13418-900, Brazil; marcia.saladini@gmail.com

Micronutrient supplementation for suckling calves is important to support metabolism and the immune system, thus reducing the incidence of diseases and improving performance in this early stage of life. The objective of this research was to evaluate the supplementation of selenium, iron, and vitamin E on metabolism, the incidence of diarrhoea, and the performance of calves in an immunological challenge. Holstein male newborn calves (n=42) up to 60 days old, in a randomized block design, were allocated in three treatments: C (control milk substitute); SeVitE (milk substitute supplemented with 0.6 mg organic selenium/kg + 100 IU vitamin E); SeVitEFe (milk substitute supplemented with 0.6 mg organic selenium/kg + 100 IU vitamin E + 200 mg Fe chelate/kg). The calves received 6 litres of milk substitute daily until 30 days of age and then 4 litres until weaning at 60 days, and received concentrate *ad libitum*. The animals were inoculated with *Anaplasma marginale* at 40 days of age. Food intake was monitored daily. Blood was collected for nutrient analysis and the weight and growth of the animals were monitored. The daily faecal score was used to monitor the incidence of diarrhoea. The results were analysed using the SAS PROC MIXED. Intakes of the nutrient selenium, vitamin E, and iron were higher in the supplemented animals compared to the control treatment. There was an increase in selenium in the serum of supplemented calves, with no change in vitamin E and iron. Animals with SeVitEFe tended to have lower diarrhoea scores and a lower frequency of diarrhoea. The performance of the animals did not differ between treatments. Supplementation with the micronutrient selenium, vitamin E, and iron in the diet helped to control the incidence of diarrhoea without altering the performance of the calves during the suckling phase. Financial support: FAPESP 2017/04165-5 CNPQ: 301990/2022-0.

Impacts of trace mineral source and ancillary drench on steer performance during backgroundingK. Harvey¹, L. Rahmel¹, J. Cordero¹, B. Karisch¹, R. Cooke² and J. Russell³¹Mississippi State University, Starkville, MS, USA, ²Texas A&M University, College Station, TX, USA, ³Zinpro Corporation, Eden Prairie, MN, USA; ks3114@msstate.edu

Crossbred steers (120 hd) were purchased at auction and transported to the experimental facility. Steer BW was recorded at arrival (d -1; initial shrunk BW=227.7±1.3 kg). On d 0, steers were ranked by BW and allocated to 1 of 8 groups (8 steers/group) and housed in dry lot pens (6×12 m) equipped with GrowSafe automated feeding systems (Model 8000; 2 bunks/pen; d 0 to 60). Groups were randomly assigned to receive a total mixed ration (TMR; 47% corn) containing: (1) sulphate sources of Cu, Co, Mn, and Zn (INR; n=40); (2) organic complexed sources of Cu, Mn, Co, and Zn (AAC; Availa 4; Zinpro Corp., Eden Prairie, MN; n=40); or (3) AAC and an organic trace mineral drench (30 ml/hd; ProFusion, Zinpro Corp.) on d 0 and ancillary to any morbidity treatment (APF; n=40). Diets were formulated to provide the same daily amount of energy, protein, macro minerals and trace minerals based on 7 g/steer daily of Availa4. Steers were assessed for bovine respiratory disease (BRD) signs daily and vaccinated for BRD pathogens on d 0 and 21. Individual feed intake was evaluated daily (d 0 to 60) using GrowSafe 8000 software. Liver biopsy was performed on d 0 (used as covariate), 28, and 60. Final BW was recorded on d 60 and 61. Blood samples were collected on d 0, 2, 6, 10, 13, 21, 28, and 45. No treatment differences were detected ($P \geq 0.59$) for TMR intake, final BW, ADG, feed efficiency, or BRD incidence. Mean liver Co concentrations were greater ($P=0.02$) in AAC and APF compared to INR steers. Mean liver Cu was greater ($P=0.02$) in APF compared to AAC steers. Liver Zn tended to be greater ($P=0.10$) on d 28 but less ($P=0.05$) on d 60 for INR compared to AAC and APF steers. Plasma haptoglobin was lowest ($P=0.05$) for steers supplemented with AAC on d 6, whereas AAC steers tended to have greater ($P=0.09$) plasma haptoglobin on d 13 compared with APF. Plasma cortisol tended to be greater ($P \leq 0.10$) for INR steers on d 28 and 45 compared to AAC and APF. While supplementing cattle with AAC or INR resulted in similar animal performance and clinical disease, AAC and APF improved stress and acute phase protein responses.

Session 60

Poster 15

Impact of trace minerals and water/feed deprivation on performance and metabolism of grass-fed beefM.J.I. Abreu¹, I.A. Cidrin¹, D. Brito De Araujo², F.D. Resende³ and G.R. Siqueira³¹Sao Paulo State University, School of Veterinary & Agricultural Sciences, Via de acesso Professor Paulo Donato Castellane s/n, 14884-900, Jaboticabal, Brazil, ²Nutreco Nederland, Selko Feed Additives, Stationstraat 77, 3811 MH, Amersfoort, the Netherlands, ³Sao Paulo State Agency of Technology & Agribusiness, Department of Research & Innovation, Avenida Rui Barbosa s/n, 14470-000, Brazil; davi.araujo@selko.com

Two studies investigating how sources of Cu/Zn and 48-hours water/feed deprivation affect performance and metabolism of grass-fed beef cattle. Study 1: 20 castrated-canulated Nellore steers (350±132 kg) were blocked and randomly distributed in individual pens, in 2×2 factorial: supplemental Cu/Zn sources from inorganic (ITM; sulphate) vs hydroxy (HTM, Selko® IntelliBond®); and 48-hours deprivation (WFD) vs unrestricted (WFU) access to water/feed. The study was divided in adaptation (-21 to -1 d) and evaluation (0 to 36 d) periods. Deprivation did not affect ($P > 0.10$) DMI but deprivation × period interaction was detected ($P < 0.05$) for digestibility of DM, OM, NDF and ADF. HTM increased DMI ($P=0.075$) and NDFD in 1.6%. VFA concentration decreased from 62.3 to 20.1 mMol/dl, while rumen pH increased from 7.3 to 8.2 ($P < 0.05$). After the deprivation, butyrate increased ($P=0.065$) and VFA ($P=0.004$) decreased in WFU. Study 2: 84 intact Nellore males (260±35 kg) were blocked and randomly assigned to *Urochloa brizantha* cv. Marandu paddocks for 131 d. Animals were randomly distributed among same treatments as describe in study 1. WFD animals increased urea and NEFA ($P < 0.05$) and increased AST and total protein on 2 d ($P=0.080$). HTM lowered urea peak on 2 d and remained lower on 12 and 105 d ($P < 0.05$). Liver Cu was higher in WFU/HTM animals ($P < 0.05$). Interaction between deprivation × period ($P < 0.05$) was detected for BW and ADG. WFD lost 34.5 kg, resulting in lower BW on 2 d, but increased ADG after 12 d, recovering BW lost. In conclusion, water/feed deprivation were able to impact nutrient digestibility and ruminal fermentation parameters. After deprivation, animals were able to compensate, recovering BW faster, resulting in no performance differences between WFD and WFU. Additionally, HTM increased liver Cu and increased DMI and NDFD, although no changes in performance observed when compared to ITM.

The impact of trace mineral sources of copper and zinc on performance and ruminal bacteria diversityI.A. Cidrini¹, I.M. Ferreira¹, D. Brito De Araujo², G.R. Siqueira³ and F.D. Resende³¹Sao Paulo State University, School of Veterinary & Agricultural Sciences, Via de Acesso Professor Paulo Donato Castellane s/n, 14884-900, Jaboticabal, Brazil, ²Nutreco Nederland, Selko Feed Additives, Stationsstraat 77, 3811 MH, Amersfoort, the Netherlands, ³Sao Paulo State Agency of Technology & Agribusiness, Department of Research & Innovation, Avenida Rui Barbosa s/n, 14470-000, Colina, Brazil; davi.araujo@selko.com

Research indicates the solubility of trace mineral (TM) can vary between sources and impact rumen function, bioavailability and performance. Two studies were carried out to evaluate the effect of TM source on performance and rumen microbial diversity of grazing beef cattle. In the first study, 120 intact Nelore males (BW=349.72±24 kg; 24 m) were blocked by BW and randomly assigned to 12 paddocks (06 paddocks/treatment; 10 animals/paddock). Animals were grazing *Urochloa brizantha* cv. Marandu and offered 01 of 02 supplements (0.5% BW; 25% CP; 65% TDN). Supplements were formulated for 40 mg Cu and 148 mg Zn/kg DM from either inorganic (ITM; Cu-sulphate and Zn-oxide) or hydroxy (HTM; Selko® IntelliBond®) during 90 d. BW were collected every 30 d. Data were analysed by ANOVA using PROC MIXED. Each 30 d period was used as REPEATED measurement. HTM-fed animals increased ADG (0.469 vs 0.506 kg/day, $P=0.01$) and increased final BW (391.97 vs 397.11 kg $P=0.03$) compared to ITM. In the second study, 08 cannulated Nelore steers (541±18 kg) were blocked by BW and randomly distributed in individual paddocks and supplemented during 101 days with the same diet supplements from study 1. Ruminal content samples were collected on d97 for total DNA extraction using commercial kit. The V3/V4 regions of 16SrRNA gene was sequencing using Illumina MiSeq and QIIME (v.1.9.1) to filter reads, determining OTUs. A total of 293 OTUs were identified at genus level. HTM supplementation resulted in a higher ruminal abundance of several groups such as *Prevotella* 1 ($P=0.01$), *Ruminococcaceae* ($P=0.01$) and lower abundance of *Fibrobacter* ($P=0.04$) and others. These results suggests that HTM source of Cu and Zn improves animal performance and ruminal abundance of bacteria, i.e. *Firmicutes* phylum with important structural/non-structural carbohydrates degradation functions.

Are inorganic Mn sources soluble and improve rumen fermentation?

A. Vigh, C. Gerard and C. Panzuti

ADM Animal Nutrition, Talhouet, 56250, France; clemence.panzuti@adm.com

The aim of this study was to compare the ruminal solubility and bioavailability of two inorganic sources of manganese (Mn) and their effect on ruminal activity. *In vitro* fermentations, using a low-Mn substrate, a Mn-free buffer and a rumen juice-based inoculum were conducted for 70 h. The substrate was tested solely (CON), or with an addition of 0.06% DM of Mn oxide (MnO) or Mn sulphate (MnS), introduced at the start (Mn_0h), after 24 h (Mn_24h) or 48 h (Mn_48h) of incubation. Fermentation activity was measured through total gas production and substrate dry-matter degradability (dDM%). Mn ruminal bioavailability and solubility were assessed by measuring the Mn concentration in fractions obtained after successive centrifugations of the final fermentation juice, allowing to separate the remaining big particles, containing feed particles, insolubilized minerals, protozoa, a bacteria concentrated fraction, containing bioavailable minerals and a final supernatant, containing the solubilized minerals. Concerning the fermentation activity, the Mn_0h (regardless of source) tended ($P<0.10$) to decrease the total gas production compared to the CON (224±3.9 and 234±5.4 ml/gDM, respectively). dDM% was significantly lower ($P<0.01$) with MnO_24h compared to CON (86.5±2.3 and 88.6±2.4 dMD% respectively), while all the other treatments tended ($P<0.10$) to decrease dDM%. Analysis of the Mn content of the centrifugation fractions showed that 84-93% of the additional Mn was found solubilized in the supernatant, 4-11% in the big particles, and only 2-4% in the bacteria concentrated fraction. Mn concentration of the supernatant was significantly increased ($P<0.05$) in all treatments compared CON, with no differences between MnO and MnS source. Mn concentration of the bacteria concentrated fraction was significantly higher ($P<0.001$) in all treatments compared to CON (+238%, +358%, +354%, +307%, +353% and +338% for MnO_0h, MnO_24h, MnO_48h, MnS_0h, MnS_24h and MnS_48h, respectively). These results indicate that both inorganic sources of Mn are soluble in the rumen and can be assimilated by the rumen bacteria. However, as the addition of these soluble Mn forms had no positive effects on the gas production or dry matter fermentability, it seems that the rumen microbiota does not require Mn for its fermentative activity.

Effect of diet type, Cu source and antagonists on rumen *in vitro* fermentation and Cu distributionI. Bannister¹, J.A. Huntington², L.A. Sinclair², J.H. McCaughern² and A.M. McKenzie²¹SRUC Aberdeen, Department of Veterinary and Animal Sciences, Craibstone Estate, AB21 9YA, United Kingdom, ²Harper Adams University, Harper Adams University, Edgmond, TF10 8NB, United Kingdom; jhuntington@harper-adams.ac.uk

Effects of molybdenum and sulphur on copper status in dairy cattle have recently been shown to be influenced by diet type. Diets high in maize silage or high in starch resulted in an increased copper status compared with a high grass silage or a diet low in starch. A 2×3 factorial rumen *in vitro* study was designed to further investigate the interaction between copper, molybdenum and sulphur and diet type. The diets had either a Barley : Hay ratio of 80:20 or 20:80 on a DM basis. All cultures were supplemented with 7.5 mg/kg DM Mo and 4.0 g/kg S. Copper was supplemented at 10.0 mg/kg DM either as CuSO₄ or Cu₂O (CoRouge, Anime) or received no supplemental copper. Diet (2.0 g DM) was incubated in 200 ml buffered (Mould's buffer) rumen fluid (20%) at 39 °C for 48 h. Cumulative increase in headspace gas pressure was recorded and gas profile was measured for 48 h. After 48 h, culture pH was recorded and the cultures were split into solid, liquid and microbial pellet samples. These were then analysed by ICP-MS for mineral levels. There was a significant increase in cumulative gas pressure in the high barley diet ($P<0.001$) but there was no effect of copper source. Final rumen pH was 5.84 for the high barley diets compared with 6.26 for the hay diets (sed=0.016; $P<0.001$). H₂S gas levels were significantly greater in the high barley diet compared with the hay diet (3,400 vs 2,182 ppm; sed=171.6; $P<0.001$). Diets supplemented with copper had significantly higher levels on copper in the solid fraction but there were no effects of Cu source on the liquid or microbial fractions. It was concluded that the effect of diet type on rumen pH and H₂S gas levels were a major influence on the interaction between copper, molybdenum and sulphur in the rumen.

Session 60

Meta-analysis on zinc oxide's mode of action in reducing weaning stress in healthy pigletsC. Negrini¹, D. Luise¹, F. Correa¹, P. Bosi¹, A. Roméo² and P. Trevisi¹¹University of Bologna, DISTAL, Viale fanin 46, Bologna, 40127, Italy, ²Animine, 10 rue Léon Rey Grange, Annecy, 74960, France; federico.correa2@unibo.it

Pharmacological concentrations of zinc oxide (ZnO) are known to improve growth performance and reduce diarrhoea incidence in piglets. However, to address environmental concerns, the EU banned the use of ZnO at pharmacological dosage (2,500-3,000 ppm). This meta-analysis aims to examine the effect of different doses of ZnO on post-weaning pig productivity and gut health. Forty-one peer-reviewed articles from 2001 to 2021 were selected and assigned to four ZnO levels: LZn (0-200 ppm), M1Zn (201-630 ppm), M2Zn (631-1,600 ppm), and HZn (1,601-3,000 ppm). Statistical analyses were based on ANOVA mixed models in Minitab. Results showed that the M2Zn and HZn groups had significantly higher average daily gain (ADG) values than the LZn group ($P<0.05$). HZn also had the highest gain-to-feed (G:F) values compared to M1Zn and LZn ($P<0.05$). Higher liver Zn concentrations were observed in the HZn group ($P=0.01$), consistent with increased dietary Zn levels. However, blood Zn concentration was higher in M2Zn ($P=0.003$). Villus height and width increased with increasing Zn level ($P<0.05$). HZn increased the expression of ZO-1 ($P<0.05$) and decreased the expression of IFN- γ ($P<0.05$), while also tending to increase occludin and TNF- α expression ($P=0.06$ and $P=0.09$, respectively). The presence of *Escherichia coli* was higher in the HZn group ($P<0.05$), while the highest presence of *Lactobacillus* content was found in the LZn group ($P=0.05$). In summary, the positive effects of HZn were confirmed, but medium dosages (M1Zn and M2Zn) yielded comparable results. Our findings suggest a mode of action for HZn and can aid in the development of alternative feeding strategies.

Marine mineral complex reduces nutrient interactions and allows efficient use of Ca and P in broilerM.A. Bouwhuis¹, R. Casserly², A. Craig³, D. Currie³ and S. O'Connell^{1,4}¹Celtic Sea Minerals, Strand Farm, Carrigaline, Co. Cork, Ireland, ²Ernevation Ltd, Clonfower, Lanesboro, Co. Longford, Ireland, ³Roslin Nutrition, Gosford Estate, Longniddry, East Lothian, United Kingdom, ⁴Munster Technological University, Plant Biostimulant Group, Shannon ABC, Clash Road, Tralee, co. Kerry, Ireland; m.bouwhuis@celticseaminerals.com

Enhancing performance through reducing calcium (Ca) levels in broilers has been well investigated. Lowering Ca will reduce interactions with phosphorus (P) and phytate. However, bone issues have been reported which impact implementation. Novel strategies are required to allow this. A Ca rich marine mineral complex (MMC) derived from red seaweed *Lithothamnion* sp. is assembled on a scaffold of polysaccharide hydrogel, reducing the interaction between Ca, available P (avP) and phytate and making them more bioavailable. In this study, the potential to reduce Ca and avP levels in broiler diets was evaluated with MMC inclusion. The study was set up as a central composite design with 3 avP levels and 3 Ca levels, resulting in 9 treatments. The avP levels were 0.17-0.22, 0.34 and 0.45% and Ca levels were 0.5, 0.7, 0.90-0.98% in the starter period (day 0-20) and were reduced in the grower phase (day 21-35). All diets contained 0.2% MMC. The Ca and avP levels were obtained by differing levels of monocalcium phosphate, limestone and phytase. At day 0, 1,260 Broilers were divided over 9 treatments, resulting in 7 replicates containing 20 birds per treatment. Bird performance was measured by weight gain (ADG), feed intake (ADFI) and feed conversion (FCR). The data was analysed as a complete randomised design by JMP® PRO 14.2.0. An effect of dietary treatments was observed for all parameters ($P < 0.05$). The observed trends were similar for ADG, ADFI and FCR. The highest performance was observed at high avP levels, with the lowest performance observed at the low avP levels ($P < 0.001$). A high Ca:avP ratio reduced performance ($P < 0.001$). Hence, absolute avP level had the highest influence on performance, while Ca:avP ratio had a smaller influence. This study concludes that inclusion of MMC enhances bird performance by allowing a reduced Ca level, while maintaining a high avP level, thereby reducing the optimal Ca:avP ratio to 1.6:1.

Seaweeds in animal nutrition, a valuable source of minerals but in need of fine-tuningS. Al-Soufi¹, J. García², E. Cegarra³, A. Muñíos⁴, V. Pereira¹ and M. López-Alonso¹¹University of Santiago de Compostela, Animal Pathology, Veterinary Faculty, 27002 Lugo, Spain, ²Polytechnic University of Madrid, Dept Producción Agraria, 28040 Madrid, Spain, ³DeHeus España, Plaza de Mina 1, 15004 A Coruña, Spain,⁴Porto Muñíos SL, Cereda, 15185 A Coruña, Spain; sabelalalsoufi.novo@usc.es

Seaweeds are a rich source of biologically active compounds such as polysaccharides, proteins and essential amino acids, minerals, polyunsaturated fatty acids, antioxidants, vitamins and pigments, among others, with beneficial antioxidative, anti-inflammatory, antibacterial or antiviral properties. These properties give them a great potential as innovative and eco-friendly feed ingredients/additives to provide animals with high nutritive value, promote their health and productivity, and obtain high-quality products. Although very variable depending on the species, seaweeds contained higher amounts of both macrominerals and trace elements than those reported for edible land plant, making them, particularly brown and red spp., an interesting source of minerals that are oftentimes deficient in European populations. In turn, high concentrations of some elements, such as iodine, need to be carefully addressed when evaluating seaweed consumption, since excessive intake of this element was proven to have negative impacts on health, and could limit the amount of seaweed used in animal feeds. Another weakness of seaweed consumption is their capacity to accumulate several toxic elements, particularly arsenic, which can pose some health risks. This study evaluates the macro and micro element profile of 17 seaweed species and seaweed extracts with the potential to be used in rabbit farming as an alternative to antibiotics. Overall, iodine concentration can be as high as 6,850 mg/kg DM in *Saccarina Lattissima*, which limit the amount of algae used in the complete feed. Moreover, although the arsenic concentration is higher than in most other feedstuffs (up to 35 mg/kg DM) their low level of inclusion (generally 1-2%) make not a limitation when used in animal feed. The project TIRAC was co-financed by the European Agricultural Fund for Rural Development (EAFRD) of the European Union (80%) and the Ministry of Agriculture, Fisheries and Food (20%), within the framework of the National Rural Development Program 2014-2020.

Online mislabelling of mineral and complementary feeds available in France*F. Toutiou¹, C. Marin¹, T. Blanchard¹, A. Meynadier¹ and N. Priymenko²**¹INRAE, ENVT, GenPhySE, 23 Chemin de Borde Rouge, 31326 Castanet-Tolosan, France, ²INRAE, ENVT, Toxalim, 180 Chemin de Tournefeuille, 31027 Toulouse, France; florian.toutiou@envt.fr*

Many complementary feedstuffs for horses are currently available on the market in order to balance diets and meet horses' mineral requirements. Producers' websites are the main source of information available. A database of feed producers selling in France was obtained using veterinary product catalogues as well as listing members of the French national association of equine feed producers (CNEF) and producers appearing on the main online shopping sites. Only complementary feed that are supplemented to the diet daily and in a quantifiable form were retained resulting in 83 brands and 1,164 complementary feeds. Among these, mineral feeds (i.e. complementary feeds containing at least 40% crude ash, Regulation (EC) 767/2009), complementary feeds that were presented as 'mineral feeds' and complementary feeds containing at least 10% crude ash and 5% calcium were retained since they are all likely to be used to balance horses base diets. It resulted in a database containing 235 complementary feeds from 71 brands: 132 were mineral feeds, 81 were complementary feeds containing less than 40% of crude ash and 22 were presented as complementary feeds but did not mention their crude ash content as mandatory. Systematic analysis of the data available for each of these products on the internet highlighted mistakes in the composition (e.g. a percentage of calcium higher than the advertised content of crude ash) and translation mistakes (e.g. feeds identified as feed material in French that were actually compound feeds). Furthermore, many claims, that should legally be objective, verifiable by the competent authorities and understandable by the user, were found to be quite abusive and sometimes dealt with particular nutritional purposes when feeds were not labelled as feed intended for particular nutritional purposes. In conclusion, a large choice of mineral and other complementary feed enriched in minerals is available on the market but quasi-systematic mislabelling and inaccuracies on producers' websites impair the capacity for the veterinarian or the owner to choose an adequate mineral supplementation.

Session 60

Poster 23

Diversity of practices and advisors in mineral and vitamin supplementation of dairy farms*C. Manoli¹, G. Springer¹, L. Barbier¹, C. Chassaing², C. Sibra², G. Maxin², A. Boudon³ and B. Graulet²**¹ESA, USC URSE, 55 rue Rabelais, 49007 ANGERS, France, ²Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Rte de Theix, 63122 St-Genès-Champanelle, France, ³INRAE, UMR PEGASE, 16 Le Clos Domaine de, La Prise, 35590, Saint Gilles, France; c.manoli@groupe-esa.com*

In a context of agroecological transition, reducing inputs and maintaining animal health are important issues for livestock activities. In French dairy farms, addition of minerals and vitamins to rations is a common practice to prevent health disorders or production losses, but knowing and covering cows' requirements is a complex process and the farmers' practices are poorly described. Moreover, scientific recommendations adapted to feeding systems with a large part of fodder are scarce and it is difficult to know how do farmers take decisions on mineral and vitamin supplementation. Our objective was to decipher the way practices and recommendations are performed for mineral and vitamin supplementation in the context of herb-based livestock, such as largely encountered in Auvergne-Rhône-Alpes region (France). A study based on semi-structured interviews was conducted with 24 dairy farmers and 13 of their advisors. A qualitative and thematic analysis of discourses was conducted and led to identify 5 main variables characterizing the diversity of practices. A multiple correspondence analysis and ascending hierarchical classification allowed to classify the farmers into 3 types according to their mineral and vitamin supplementation practices: (1) farmers expressing indifference toward mineral and vitaminic supplementation; (2) farmers expressing a high need to be advised; (3) farmers looking for autonomy. The first type gathered more simplified practices than the other 2 types. Interviews with advisors revealed 3 types of advisors: feed sales representatives; nutritionists of performance monitoring associations, and veterinarians. Each advisor is characterized by a particular message. Our results are consistent with sociological studies on the relationship between farmers and their advisors and confirm the extreme complexity and diversity of minerals and vitamins supplementation practices, in a context of lack of scientific knowledge on this subject.

How to improve resilience, from animal to system level*A. Mottet, R. Baumung, G. Velasco Gil, G. Leroy and B. Besbes**FAO, Viale delle Terme di Caracalla, 00153, Italy; anne.mottet@fao.org*

Climate change impacts, such as droughts and floods, market crisis and disease outbreaks are the main shocks affecting the global livestock sector and regularly threatening the livelihoods of the most vulnerable populations in the world. Building resilience means not only reducing vulnerability but also increasing adaptive capacity, at all levels, animal, farm, system and community. We provide examples from a diversity of contexts and countries. The presence of livestock can be in itself a climate change adaptation strategy, as a way to buffer climate or market variability through the management of animal mobility, herd structure and feed resources. The management of animal genetic resources, but also of feed and fodder species, are among the most efficient ways to support the necessary adaptation of livestock to climate change, for example through breeding strategies for better resilience or the choice of adapted and robust livestock populations. However, at farm and household level, resilience can and should be built differently depending on the type of systems considered. Examples are available from recent work on the economics of pastoralism in Argentina, Chad and Mongolia, as well as from a cross-country analysis of the results from the FAO Tool for Agroecology Performance Evaluation. Changes to production systems to increase resilience can be both incremental (e.g. growing drought resistant fodder, improving water management, breeding towards resilience animals) or transformational (e.g. areas where extensive grazing replaces partially mixed crop-livestock farming, diversification in terms of species and breeds). Social protection mechanisms, such as cash transfers and school meals, or insurances are also key to reduce vulnerability. Policies for increasing resilience also include disaster risk reduction and management (DRRM), which can take the form of disease prevention and outbreak containment plans or early warning systems (for example drought monitoring).

Session 61

On the link between climate change mitigation and adaptation in dairy cow farming in West of France*B. Godoc, E. Castellan, A. Madrid and C. Karam**Institut de l'Élevage, French Livestock Institute, Monvoisin, 35650 Le Rheu, France; brendan.godoc@idele.fr*

The dairy cow sector faces two intertwined challenges at the same time: while there is a growing necessity to lower the greenhouse gas emissions from dairy farming, farmers need to adapt their systems and practices to harsher climate conditions. Our work studied the relationship between the concepts of adaptation and mitigation through the design of future dairy systems using a participatory approach. First, four groups of dairy farmers in the French Loire region co-constructed resilient dairy systems using a serious board-game called 'forage rummy'. Farmers started with four representative dairy systems with contrasting share of maize silage in their total forage area. Choices upon forages, grassland and herd management were made to ensure the balance between year-round forage production and animal feeding requirements with the support of the computerized model of the serious game. The four resulting systems manage to maintain production performances in a projected 2050 climate implying new crop yields and grass yield repartition. Climate data of the regionalised model were used to predict grass growth through the STICS crop model under the RCP8.5 business-as-usual scenario. Secondly, the life cycle assessment model CAP'2ER Level-1 allowed us to estimate the greenhouse gas emissions of the four co-constructed systems. The four simulated dairy farms all reduced their net carbon footprint when comparing past and future greenhouse gas emissions and soil organic carbon sequestration. Results show that strategies to adapt dairy farming systems to climate change can lead to mitigate the contributions of these systems to climate change.

Resilience of ruminant organic systems to climatic hazards: a study model in a French grassland area*C. Boivent and P. Veyssset**INRAE, UMR Herbivores, 63122 Saint-Genès-Champanelle, France; patrick.veysset@inrae.fr*

Climate change and the increase of frequency of climatic perturbations could have a severe impact on organic farms in grassland areas. Years of severe drought such as 2003 or more recently 2022 prove the need to study the adaptations of ruminant farms to climate perturbations. Resilience provides a framework for analysing livestock systems in this context. Based on structural, technical, and economic data from thirty-six specialized ruminants (beef and dairy cattle, dairy sheep and sheep for meat) organic farms in the Massif Central (a mountain area) monitored between 2014 and 2020, and meteorological data enabling to calculate agro-climatic indicators for each farm and each year, we studied the determinants of the resilience of the systems. Resilience was measured by the stability or increase in the gross value added (gross output without subsidies minus intermediate consumption) of the farm. We used a Partial Least Square (PLS) path modelling and then a hierarchical ascending classification (HAC). In the farms studied, the management of the forage system is primarily based on maximizing grazing at the expense of the constitution of fodder stocks. Maintaining herd production, even at the expense of fodder autonomy, is essential for the resilience of the farms. Good management of the fodder system with fodder stocks also seem to be decisive for the sustainability of farms. Finally, the climatic variation of the seven years of observations did not impact the structures of the farms. Farmers managed the climatic perturbations by maximizing grazing and by purchasing fodder to compensate forage deficits. However, more concentrates were not used to compensate climatic perturbations. More intense hazards could, however, call into question the capacity of the systems to manage climatic variability, mainly if organic fodder become scarce on the market.

Session 61

Theatre 4

Resilgame: a game to experiment farm adaptation to climate change*G. Martel¹ and S. Colombie²**¹INRAE, UMR BAGAP, 55 rue Rabelais, 49100 Angers, France, ²Chambre d'Agriculture des Pays de la Loire, 9 rue André-Brouard, 49000 Angers, France; gilles.martel@inrae.fr*

The issue of climate change is particularly important for the agricultural sector, whose production is directly linked to the climate and where the effects are already observed. Although farmers are aware of this, they only make marginal adjustments to mitigate these effects. Adaptation levers to improve the resilience of farming systems have already been identified within the different compartments of the farm. But all this knowledge is fragmented and difficult to integrate at the same time by both farmers and their advisors. This is why we have designed a serious game to confront farmers and student, with future climates and put them in a decision-making situation. To build the game, we brought together people involved in projects related to adaptation to climate change, i.e. teachers, trainers, advisors, and researchers in various disciplines: agronomy, meteorology, animal science, economics, and sociology. The game is made up of two parts: a common board where players choose adaptation levers (for crops, pastures and animals), react to hazards and observe environmental performances; and an individual board where they decide on the cropping plan and animal numbers. The goal of the game is to reach objectives (income, reduction of phytosanitary treatments or work time) according to the character played. Crops can be sold or used to feed the animals. Crops, animals, but also technical choices and responses to hazards affect greenhouse gases, crop protection treatments, net margin and labour time. The game includes climatic and economic hazards that affect the characteristics of the crops and animals. Their effects can sometimes be countered by an adaptation lever. Some of these levers can be activated in reaction to the hazard, while others must be anticipated for the effect to be active. The first tests of the game have confirmed its ability to simulate the consequences of climate changes that force players to change their practices. It must be combined with knowledge inputs to help players understand the mechanisms and the effects of global changes and the levers of adaptation. The next step is to evaluate the players' ability to implement the adapted practices on their farms.

Evolution of agroecology and associate indicators – looking for balance in farming systemsE. Benedetti Del Rio¹, A. Michaud² and E. Sturaro¹¹University of Padova, DAFNAE, Viale dell'Università 16, 35020 Legnaro, Italy, ²VetAgro Sup, UMR-1213-Herbivores, 89 Avenue de l'Europe, 63370 Lempdes, France; elena.benedettidelrio@phd.unipd.it

Agroecology can be defined as an integrated approach that applies ecology and sociology to agricultural production systems. The agroecological transition has to be accounted through multi-disciplinary approaches, in fact in the last 20 years it has been studied coupling agricultural or animal sciences with social and economic approaches. Since 2014, the growth of case studies was exponential and produced several indicators to measure its applicability. This study aims to identify a set of indicators for monitoring agroecological transition in grassland-based farming systems with a systematic literature review approach, through Scopus search engine. Selection criteria are the following: (1) published since 2000; (2) concerning agroecology as a discipline. The database consists of 74 papers, 35 of them related to our objective. Through article's aim we sorted indicators, based on the principles from Dumont *et al.* and Wezel and Peeters. The results showed that for Dumont at least 20 articles cover 3 principles out of 5: 'decreasing input', 'decreasing pollution' and 'preserving biodiversity in agroecosystems'. Only 5 articles relate to 'increasing animal health' and 9 to 'enhancing diversity in animal production'. Based on Wezel and Peeters at least 21 articles reach out 4 principles out of 6: 'resources' and 'system management', 'biodiversity conservation' and 'knowledge, culture and socio-economics of farmers'. The principles of the authors overlap on biodiversity and resources management. Both indicators and principles suggest that most of the articles still relate to the agricultural sector more than livestock. Moreover, it appears that the two sectors are still taken into consideration in a separate way. The results of this research evidenced that the indicators can be used to highlight threats and opportunities of different contexts, to enhance the resilience of grassland-based farming systems, both from an economical and practical point of view, and favour the agroecological transition. The outputs of this study will be used to define a multicriteria approach for grassland-based case studies in Italy and France.

Session 61

Theatre 6

Small ruminants farming systems of Spain: challenges and attributes for their resilienceJ. Lizarralde¹, B. Soriano², A. Benhamou-Prat³, P. Gaspar-García⁴, Y. Mena-Guerrero⁵, J.M. Mancilla-Leyton⁵, A. Horrillo⁴, R. Ruiz¹, D. Martín-Collado³ and N. Mandaluniz¹¹Basque Institute for Agricultural Research and Development, Campus Agroalimentario de Arkaute, 01192 Arcaute, Álava, Spain, ²Research Centre for the Management of Agricultural and Environmental Risks of the Polytechnic Univer, Pº de la Senda del Rey, 13, 28040 Madrid, Spain, ³Agrifood Research and Technology Centre of Aragon, Av. de Montañana, 930, 50059 Zaragoza, Spain, ⁴University of Extremadura, Av. de la Universidad, 10003 Cáceres, Spain, ⁵University of Sevilla, C. San Fernando, 4, 41004 Sevilla, Spain; jlizarralde@neiker.eus

Small ruminants farming systems (SRFS) is facing an important crisis (linked to high input prices, low meat and milk prices, social issues, etc) which ends up in a significant lack of generational turnover. The aim of this paper is to analyse the current challenges with different origin (economic, environmental, institutional or social) and temporality (short-term, ST; long-term, LT) faced by SRFS in Spain and to identify the attributes that promote or limit their resilience. To collect data, 24 depth interviews with farmers have been conducted in 4 case studies of SRFS in Spain: 8 in dairy goats in Andalucía, 6 in meat sheep in Aragón, 4 in dairy sheep in Extremadura and 6 in the Basque Country and Navarra. The interviews were analysed using deductive content analysis coding them according to the bibliographic compilation of challenges and attributes. Results have shown that the SRFS have common challenges referred to institutional ST bureaucracy and administrative workload. However, particularities between the systems have been observed: for example, Andalusian system highlights economic difficulties; Aragon and Extremadura systems highlight LT and ST institutional aspects; and Basque Country and Navarra system highlights ST social challenges. In terms of the attributes that strengthen their resilience, farmers differ according to the specificities of each system, but they agree that resilience is strengthened by aspects such as the autonomy, functional diversity and human capital, and it is weakened by the lack of economic capital. The knowledge about the attributes that promote the resilience will help to define the political measures to support the SRFS to deal with current and future challenges.

Building resilience in drylands' extensive livestock systems under climate uncertaintyA. Tenza-Peral¹, I. Pérez-Ibarra¹, A. Breceda², J. Martínez-Fernández³ and A. Giménez⁴¹University of Zaragoza, Department of Agricultural Sciences and the Natural Environment, Calle de Miguel Servet 177, 50013 Zaragoza, Spain, ²Center for Biological Research of the Northwest, Instituto Politécnico Nacional s/n, 23096 La Paz, Mexico, ³New Water Culture Foundation, Pedro Cerbuna 12, 50009 Zaragoza, Spain, ⁴Miguel Hernández University, Avenida de la Universidad s/n, 03202, Spain; atenza@unizar.es

Extensive livestock farming systems in drylands ensure food security, support social well-being and provide vital ecosystem services. They have evolved to cope with the spatiotemporal variability of natural resources and frequent disturbances. However, climate change poses significant challenges to the adaptive capacity of these social-ecological systems. Here, using the dynamic simulation model SESSMO about a case study (the oasis of Comondú in the Sonoran Desert, Mexico), we assessed the contribution of management strategies proposed by local stakeholders to the resilience and long-term sustainability of these social-ecological systems under the uncertainty of climate change. Management strategies were classified according to their contribution to: (1) strengthening robustness (e.g. improving veterinary technical assistance); (2) improving adaptive capacity (e.g. changes in marketing channels); and (3) fostering transformation (e.g. local tourism development). We explored outcomes under various climate scenarios (i.e. favourable and unfavourable). Our simulation results showed the great sensitivity of these social-ecological systems to climate variability. Contrary to what was expected, fostering transformation showed limited effects. Tourism development is not a panacea. Strengthening robustness showed a very similar impact on systems dynamics, and the effect was reinforced when the robustness and the adaptive capacity were enhanced together, even under unfavourable climate conditions. Here we identified a clear synergy between these strategies that do not imply structural changes. Nevertheless, to cope with climate uncertainty, the best strategy was to act simultaneously on robustness, adaptive capacity, and transformation.

Session 61

Theatre 8

A thirty-year assessment of interactions between weather conditions and sheep milk yield and qualityA. Mantino¹, M. Milanesi², M. Finocchi¹, G. Conte¹, G. Vignali², G. Chillemi², L. Turini¹ and M. Mele¹¹University of Pisa, Department of Agriculture, Food, and Environment, via del Borghetto 80, 56124, Pisa, Italy, ²University of Tuscia, Department for Innovation in Biological, Agro-Food and Forest Systems, via San Camillo de Lellis snc, 01100, Viterbo, Italy; alberto.mantino@unipi.it

The Mediterranean area is a climate change hot spot. Locally, up to 40% of winter precipitation could be lost and, generally, summer will be warmer and drier. Semi-extensive mixed farming systems are threatened by the reduction and the variation of rainfall distribution rather than intensive systems because the increase of frequency of dry spells negatively affects pasture mass and quality. Moreover, elevated temperatures combined with intense solar radiation lead to the decrease of intake and animal welfare due to heat stress. A study focusing on the interaction of climate and animal production was performed in the Maremma region (central Italy) on milk sheep farms. Firstly, a thirty-year (1993-2022) assessment of the spatial and temporal patterns of dry spells and thermal comfort indexes was conducted on a daily dataset. Secondly, the collection of milk yield and quality daily data was carried out on more than 200 farms on the same time span. Lastly, the analysis of interactions between weather conditions and sheep milk production was performed. In the Mediterranean, climate changes seem to negatively affect milk production in semi-extensive farms and, moreover, dairy sheep productivity is being threatened by several factors such as the predation by wild carnivores and the volatility of diet supplement costs. The outcomes of the analysis will be presented. This study was carried out within the Agritech National Research Center and received funding from the European Union Next-GenerationEU (Piano Nazionale di Ripresa e Resilienza (Pnrr) – Missione 4 Componente 2, Investimento 1.4 – D.D. 1032 17/06/2022, CN000000022). This manuscript reflects only the authors' views and opinions, neither the European Union nor the European Commission can be considered responsible for them.

Indicators for animal health on agro-ecological dairy farmsA. Ceppatelli¹, M. Crémilleux², A. Michaud² and E. Sturaro¹¹UNIPD, DAFNAE, Viale dell'Università 16, 35020 Legnaro, Italy, ²Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Saint-Genès-Champagnelle, 63122, France; andrea.ceppatelli@phd.unipd.it

The agroecological transition, supported by European policies and strategies, can strengthen the sustainability and resilience of farming systems in the face of climate and socio-economic change challenges. This approach considers the farm as a key part of the ecosystem in which it is embedded. Thus, the farm contributes to regulate the health of the system, which is influenced by all the actors involved: environment, farm, productions. Making the most of these interactions and improving their level of health contributes to achieving the highest possible level of sustainability. The present research aims to identify a set of indicators to assess animal health on agroecological dairy farms, adopting a Global Health approach. 18 farms located in the Auvergne-Rhone-Alpes Region (France) rearing dairy cows, goats, and sheep, were monitored over two years. Four rounds of on-site visits were conducted to carry out measurements on the animals (behaviour, nutritional and health status, milk parameters, parasitism). Two lists of animal health indicators were selected by combining statistical analysis on the collected data (Principal Component Analysis) with expert knowledge. For dairy cows, a list with 16 indicators related to animal health, housing, behaviour, feeding, production and reproduction was performed. For sheep and goats, another list with 16 indicators referring to animal health, housing, feeding and production was performed. These indicators were then evaluated on the 18 farms, to assess their level of health. On average, veterinary interventions were low (0.18/animal/year for cows and 0.07 for small ruminants), as was the incidence of lesions (8%), lameness (5%) and dirty animals (7%). However, small ruminants had higher levels of parasitism (*Eimeria* and *Strongles*) than dairy cows (*Paramphistome*). Based on the results obtained, the selected indicators can contribute to the definition of agroecological practices within the farms and to the global assessment of their sustainability and resilience. Other farms located in similar territorial contexts (Italian Eastern Alps) will be involved in the network to validate the results.

Exploring climate change adaptation strategies from the perspective of Mediterranean sheep farmersD. Martín-Collado¹, S. Lobón¹, M. Joy¹, I. Casasús¹, A. Mohamed-Brahmi², Y. Yagoubi², F. Stark³, A. Lurette³, A. Abuoul Naga⁴, E. Salah⁴ and A. Tenza-Peral⁵¹CITA-IA2, Avda. Montañana 930, Avda. de Montañana 930. CIF: Q5000823D, 50059, Spain, ²ESAK-INRAT, Rue Hédi Karray, 1004 Menzah 1 Tunisie, Tunisia, ³INRAE-UMR SELMET, Campus International de Baillarguet, 34398 Montpellier, France, ⁴APRI, Nadi El Said, Dokki, Giza, Egypt, ⁵UNIZAR, Calle Miguel Servet, 177, 50013 Zaragoza, Spain; dmartin@cita-aragon.es

Sheep production systems in the Mediterranean region are particularly vulnerable to the impact of climate change (CC) due to their relatively high use of local food resources. Most studies analysing farm adaptation strategies tend to follow top-down approaches without considering the feasibility of their implementation on farms. In this work, which is part of the PRIMA project Adapt-Herd, we investigated farmer perceived CC impact on-farm and their view about the best adaptation strategies to future CC scenarios in representative farming systems in Egypt, France, Spain, and Tunisia. Scenarios of CC were developed for each region based on IPCC projections. Two hundred-five farmers were surveyed face-to-face and asked to point out the actions they would take to adapt to the CC scenarios. Possible actions covered feed, grazing, reproduction and flock management, breeding, and machinery and facilities. Strategies were identified using K-modes cluster analysis. Discriminant analysis was used to determine their preferred strategies across countries, farming systems, farm features, and farmer profiles and perceptions. Five general strategies were identified: (1) farm machinery and facilities (high preference in Egypt, France, and Spain); (2) feed intensification (Egypt and Spain); (3) flock management and feed extensification (France); (4) feed optimization (Tunisia); and (5) general farm adaptation. Besides differences among countries, farmers with irrigation systems perceive the impact of feed shortage, and heat stress on farms to be lower than other farmers and tend to prefer strategies focus on machinery and facilities and feed intensification. Our results show that both farm profile and CC impact perception factors influence farmer's views on adaptation strategies.

Combining serious games in a process to support sustainable livestock farming systemsR. Etienne¹, S. Darnat¹, C. Rigolot¹ and S. Ingrand²¹INRAE, ACT, UMR Territoires, campus des Cezeaux, 63000 Aubiere, France, ²INRAE, PHASE, Theix, 63000 Saint Genès Champanelle, France; rebecca.etienne@inrae.fr

Farmers have to articulate individual and collective objectives, to face global challenges but need support to address these issues. The objective of this study is to propose a methodological approach to support this process, based on a combination of serious games. This method was proposed to a group of farmers involved in a French cheese PDO area ('Fourme de Montbrison'), in order to improve their fodder autonomy in the context of climate change. Three serious games were combined at different scales in order to (1) choose levers of adaptation (Lauracle); (2) simulate and design their effects on the farm systems (Forage Rummy); (3) enhance collective decision at territorial scale (Dynamix). These serious games were chosen because they address forage system adaptation and help to collaboratively apprehend the trade-offs between individual and collective scales. Other forms of interventions are also set up (farmers lead on-farm experiments, trainings, farm visits). The support method is evaluated along the way and *a posteriori* with an evaluation model adapted for the case study. It allows to follow four levels of evaluation (reactions, learning, behaviours and results) which are detailed in the presentation. Different tools are combined before, during and after game sessions such as participant observation; in-game observations and debriefings of game sessions; interviews and technical diagnosis. The results highlight contributions of the serious games on future changes of practices, at individual and collective level, either technical or organizational innovations. We could observe that farmers decide the levers of adaptation, then simulate some of them and finally, set up on-farm experiments (long-lasting multi-species grasslands adapted to drought) but also impulse the creation of a machine to brush grassland seeds. These learnings and changes on behaviours consider the articulation of individual and collective objectives. Those results will ensure the development of an operational method for agricultural extension services to articulate both farm and territorial scales towards sustainable livestock farming systems.

Under current global change situation, strengthening farming systems' resilience is an aim of agricultural policy institutions. Resilience is defined as 'the ability to ensure the provision of the system functions in the face of increasingly complex and accumulating shocks and stresses, through capacities of robustness, adaptability and transformability'. In this sense, we test the hypothesis that farms' features (farm attributes) and farmers' profile (personal attributes) influence the resilience capacities in different manner. Based on this hypothesis, we used farmer's resilience self-assessments to evaluate resilience drivers. We conducted face-to-face surveys to farmers of 4 different small ruminant farming systems in Spain, that resulted in 160 questionnaires. Data analyses were based on multiple regression models. Results showed that farmer's optimism and the availability of different management options enhance the three resilience capacities. However, most attributes influenced differently to each capacity. Farmers' who are proud of their achievements and bounded to local traditions, lead more robust farms, farms with a higher autonomy and better farm infrastructures are more adaptable, and proactiveness and cooperation with other economic sectors are positive for transformability. Finally, some attributes showed trade-offs for the resilience capacities. We found the use of natural resources influenced positively farm robustness but negatively adaptability due to the complexity of natural processes. In conclusion, we argue that both farm features and farmer personal attributes are key for the understanding of farm resilience and should be considered in resilience assessments.

The difference between abnormal climate and extreme climate that cause yield damage to silage corn*M. Kim¹ and K. Sung²**¹Institute of Animal Life Science, Gwangwondaehak gil 1, 24341, Korea, South, ²Kangwon National University, Gwangwondaehak gil 1, 24341, Korea, South; lunardevil@kangwon.ac.kr*

This study aimed to compare the characteristics by estimating the impacts of abnormal climate and extreme climate on silage corn. The silage corn metadata (n=3,232) were collected from cultivation experiments that conducted by the Rural Development Administration of Korea. To define abnormal climate and extreme climate, climate data including daily weather information were collected from the weather information system of the Korean Meteorological Administration. The variables were dry matter yield (DMY, kg/ha), mean temperature (MT, °C), lowest temperature (LT, °C), highest temperature (HT, °C), maximum precipitation (MP, mm/hr), accumulated precipitation (AP, mm), maximum wind speed (MW, m/s), mean wind speed (WS, m/s), sunshine duration (SD, hr). Firstly, to define the extreme climate, the median-interquartile method was used instead of the mean-standard deviation method. Secondly, the abnormal climate was defined by comparing the characteristics of favourable and poor conditions for the growth and development of silage corn. For doing this, principal component analysis and discriminant analysis were used. Finally, the t-test and ANOVA with the 5% significance level were carried out to confirm the difference in DMY. For the extreme climate in mid-June, the low-extreme LT, high-extreme AP, and high-extreme MW were detected in the trends. However, the year records were different for each point. Thus, the damage in DMY was estimated based on high-extreme AP, as a representative scenario. As a result, the damage in DMY caused by the extreme climate in mid-June was estimated to be 927.2 kg/ha. Meanwhile, for the abnormal climate in mid-June, the characteristics of early monsoons without typhoons were confirmed as poor. In particular, MP in abnormal climate (20.54 mm/hr) was three times greater than that in normal climate (6.61 mm/hr). The damage in DMY caused by the abnormal climate in mid-June was estimated to be 1,155.9 kg/ha. Hence, the magnitude of yield damage to silage corn caused by extreme climate and abnormal climate, as well as characteristics of high precipitation, were similar.

Causality in climate-soil-yield network for silage corn*M. Kim¹ and K. Sung²**¹Institute of Animal Life Science, Gwangwondaehak gil 1, 24341, Korea, South, ²Kangwon National University, Gwangwondaehak gil 1, 24341, Korea, South; lunardevil@kangwon.ac.kr*

This study aimed to confirm causality of climatic and soil physical factors on yield of silage corn based on climate-soil-yield network in Korea. The climatic variables were GDD, high temperature, low temperature, surface temperature, rainfall, relative humidity, wind speed, sunshine duration in the before and after silking stages. The soil physical variables were effective soil depth, slope and drainage classes. The yield variables were total digestible nutrients, dry and fresh matter yields. The network was constructed by structure equation modelling and neural network modelling. In the result of networking, three causalities were remarkable. First, all longitudinal climatic causality between before and after silking stages was significant. It implies that the effect of climates in vegetative stage reaches to yield through themselves in reproductive stage. Second, there was the causality between climatic and soil physical factors based on indirect effects. Thus, it is likely to lead to offset between the direct and indirect effects of soil physical factors. Finally, the effects of drought and heavy rainfall were clear in before and after silking stages, respectively. It indicates the stress can damage yield of silage corn. Here, the damage caused by the drought could be recovered due to various indirect effects, while the damage caused by heavy rainfall was fatal because there was a lack of an indirect path to recover from. This study contributed to identifying how various climatic and soil physical factors can affect production in the network. Furthermore, the climate-soil-yield network for silage corn of this study will be helpful to extend the structure with various factors in the future study. This study was supported by the National Research Foundation of Korea funded by the Ministry of Science and ICT (NRF-2023R1C1C1004618).

Can studying the health of livestock systems be a way to improve their resilience?*M. Cremilleux, B. Martin and A. Michaud**Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Theix, 63122 Saint Genès Champanelle, France; maeva.cremilleux@vetagro-sup.fr*

Livestock systems are facing multiple challenges, particularly economical, zoonosis and climatic hazards. These crises, caused by human activities and population growth, remind humanity that human, animal and ecosystem health are interdependent (developing notions of One Health, Eco Health, planetary health, etc.). The farm scale seems particularly suited to a comprehensive approach to health in agriculture. A farm constitutes a system as such and it is on this scale that farmers make decisions, experiment and establish interactions between humans and non-humans (animals, plants, environment, etc.), which have an impact on health. The aim of this study is to characterize farm health (definition and indicators) and to show to what extent this approach can be used to reason about the resilience and sustainability of livestock systems. We first built a framework for analysing the health of a farm, which was then tested in the field. For this purpose, 18 sheep, cow and goat dairy farms – claiming to be agroecological- were monitored in the Massif Central (France), for 2 years (2021-2022). We assessed the soil health (physical, chemical, and biological indicators), grassland health (biodiversity, yield, resilience, products quality, etc.), animal health (production, reproduction, feeding, behaviour, buildings, and health) and farmer health (survey on psychological health) on each farm. We proposed an assessment of the health status of the monitored farms and highlighted their good health. We also discussed the value of health approaches in promoting the sustainability and resilience of farming systems. Moreover, the analysis of the management practices implemented by the farmers and the functioning of the system indicates that it is the coherence of the system that promotes health. This work also highlighted the interest of the notion of health for studying farms. Health, thanks to its holistic vision, allows the study of the decision-making system, the integration of the farmers' relationship with nature and to show the coherence of the systems.

Effect of heat stress on extensive beef cattle's calving percentage in the Central Bushveld Bioregio*S.M. Grobler¹, M.M. Scholtz^{1,2}, F.W.C. Nester², J.P.C. Greyling² and L. Morey³**¹Agricultural Research Council, Animal Production, Irene, Pretoria, 0062, South Africa, ²University of the Free State, Department of Animal, Wildlife and Grassland Sciences, Bloemfontein, 9300, South Africa, ³Agricultural Research Council, Biometry department, Hatfield, Pretoria, 0028, South Africa; mgrobler@arc.agric.za*

Little research has been done locally, on the effect of heat stress in the sub-tropical summer rainfall area of the Central Bushveld Bioregion, even though the mating season coincides with the warmest months of the year. A study was conducted over a six-year period to investigate the effect of heat stress just before and during the mating season on the subsequent calving percentage of extensively managed beef cattle. Average monthly minimum- and maximum-temperature (°C) and average monthly minimum- and maximum relative humidity (%) were used to calculate a monthly discomfort index. An index value above 90 was considered very uncomfortable, relating to heat stress. The highest calving percentage of 89.6% was obtained when the discomfort index never rose above 89 before, during, or after the mating season. The lowest calving percentage of 60.0% was obtained with an average monthly discomfort index above 90 within the month just before mating and during the first two months of the mating season. Average monthly minimum- and maximum- temperature (°C), average monthly minimum- and maximum relative humidity (%), total monthly precipitation (mm), and discomfort index were taken into account performing forward stepwise regression procedures for the dependent variable calving percentage. Maximum relative humidity one month prior to the mating season had a high negative Pearson's correlation coefficient of -0.95. Results suggest that heat stress before and during the mating season has a negative impact on the calving percentage of extensively managed beef cattle in the sub-tropical summer rainfall area of the Central Bushveld Bioregion.

Contrasting rearing and finishing regimens on performance and methane emissions of Angus steersJ. Clariget^{1,2,3}, V. Ciganda³, G. Banchero³, D. Santander³, K. Keogh², D.A. Kenny² and A.K. Kelly¹¹UCD, School of Agriculture and Food Science, Belfield, Dublin 4, Ireland, ²Teagasc, Animal & Bioscience Research Department, Dunsany, Co. Meath, Ireland, ³INIA, Colonia, 70000, Uruguay; jclariget@inia.org.uy

Beef cattle production contributes to global warming mainly through the emission of methane (CH₄) generated during the normal process of feed digestion. Compensatory growth could provide a means to reduce CH₄ emissions, since feed efficiency improves during refeeding and an increase in feed digestibility could explain this improvement. Steers are commonly fattened on pasture or feedlot, so the aim of the experiment was to evaluate the effect of dietary restriction in Angus steers on DM digestibility (DMD) and CH₄ emission under two contrasting refeeding diets. Eighty steers with an average live weight (LW) of 444±39 kg and age of 18±1 months, were blocked, and randomly assigned to 1 of 4 treatments, in a 2×2 factorial arrangement: severity of dietary restriction (moderate vs mild) and fattening system (pasture vs feedlot). During the 97 days period of dietary restriction target growth rates were 0.3 and 0.6 kg/d, for moderate and mild groups, respectively. The dietary restriction period was followed by a subsequent fattening period of 84 days. Methane emissions and DMD were measured at the end of fattening period in 36 and 80 steers, using SF₆ and acid insoluble ash technique, respectively. During fattening, previous moderate restricted steers had higher LW gain compared to mild steers (1.2 vs 1.0 kg/d; $P<0.01$). Feedlot steers had higher LW gain (1.3 vs 0.9 kg/d; $P<0.01$) than pasture steers. Irrespective of previous dietary restriction treatment, methane emission and methane yield were lower for feedlot steers ($P<0.05$; 230 vs 313 g CH₄/d, and 22.2 vs 25.8 g CH₄/kg DMI, respectively). No difference in DMD was evident between previously restricted steers, whereas feedlot steers achieved higher DMD than pasture steers (82.1 vs 69.2%; $P<0.01$). Moderate steers had lower methane intensity than mild steers (246 vs 321 g CH₄/LW gain; $P<0.01$). In conclusion, for both finishing systems, the lower methane intensity of steers initially subjected to a moderate dietary restriction is due to their relatively higher performance during fattening, rather than lower methane emissions or yield *per se*.

Energy and greenhouse gas emissions: tools to discuss sustainability of livestock systems in AmazonD.C.C. Corrêa^{1,2}, R.J.M. Pocard-Chapuis², M. Lenoir², V. Blanfort², J.L. Bochu³ and P. Lescoat¹¹AgroParisTech, INRAE, Université Paris-Saclay, UMR Sadapt, 91120, Palaiseau, France, ²CIRAD, UMR Selmet, 34980, Montpellier-sur-Lez, France, ³SOLAGRO, CS27608, 75 voie du Toec, 31076 Toulouse, France; caroline.da_cruz_correa@cirad.fr

Greenhouse gas (GHG) emissions and energy efficiency are key parameters to consider more sustainable farming systems. Management practices on farms can either improve or deteriorate energy efficiency and GHG emissions. It is therefore essential to identify relevant agricultural practices. This study determined the energy and GHG 'eco'-efficiency of cattle breeding, using energy balance and GHG emissions of 31 farms in two breeding area in the Brazilian Amazon, using a diagnostic tool (AgriClimateChange Tool) adapted to the region. The analysed dairy and meat farms are representative of the diversity of livestock systems in the region: suckling herd, fattener and suckling-fattener and of their degree of intensification. The energy efficiency is on average 16.27 GJ/t produced live weight/year (min= 2.35 GJ/t, max= 45.45 GJ/t) which is 47% lower than studies conducted in mainland France for similar systems. This increased efficiency could be linked to pasture feeding which makes better use of natural resources (highly productive grasses and edaphoclimatic factors) compared to other systems in the world which use more inputs and infrastructure. Results showed that fertilisers/amendments and the purchase of young animals accounted for high percentages of total energy consumption and that fuel constituted the majority of the direct energy used on farms. GHG emissions are on average 24.47 teqCO₂/t produced live weight/year (min= 3.78 teqCO₂/t, max= 65.59 teqCO₂/t) more important than in mainland France (14.20 teqCO₂/t produced LW/year) and similar to French Guiana (30.00 teqCO₂/t produced LW/year). These farms can be also considered as a carbon sink when the forests on their surface are included in the balance, with a production cost in terms of emissions close to neutral. This study shows the interest of this diagnostic tool, which has been calibrated for the tropics, and opens up prospects for the adoption of this tool as an indicator of 'eco'-efficiency of livestock farming systems.

Microclimate and production of a tropical forage intercropped with pigeon pea

J.R.M. Pezzopane¹, P.P.A. Oliveira¹, A.F. Pedroso¹, W. Bonani¹, V.M. Gomes², C. Bosi³, H.B. Brunetti¹, R. Pasquini Neto¹ and A.J. Furtado¹

¹Embrapa Pecuária Sudeste, Rod. Washington Luis, Km 334, 1356-3970, São Carlos, Brazil, ²UNICEP, Rua Miguel Petroni, 5111, 13563-470, São Carlos, Brazil, ³UFPR, Rua Getúlio Vargas, 1642, 87704-010, Paranaíba, Brazil; jose.pezzopane@embrapa.br

Pasture degradation is the main problem in Brazilian livestock systems. Several strategies can be used for pasture recovery, including the use of shrub legumes, which can change the environment (microclimate and soil water content) and pasture productive potential. This research aimed to evaluate the microclimate, soil water dynamics, and production of a tropical pasture intercropped with pigeon pea. The study was carried out in pasture areas of *Urochloa decumbens* (syn. *Brachiaria decumbens*) Stapf cv. Basilisk in São Carlos, SP, Brazil, from 2020 to 2022. Different pasture production systems were evaluated: Degraded pasture (DP); Pasture recovered with application of nitrogen fertilizer (200 kg of N/ha/year) (RP); and pasture intercropped with pigeon pea (*Cajanus cajan*) cv. Mandarin (INT). The microclimate (photosynthetically active radiation and wind speed) and soil moisture characterization were assessed. The effect of the presence of pigeon pea on the vegetative and productive characteristics of the pastures was also evaluated. The results showed that the pigeon pea plants intercropped with the pasture did not promote significant changes in the soil water content in the layer 0-60 cm deep but reduced the transmission of photosynthetically active radiation to the pasture (from 0 to 65%), in addition to decreasing the incidence of winds (from 0 to 60% of reduction). During two experimental years, pigeon pea showed a high potential for biomass production (average of 12,615 Mg/ha/year), serving as forage supply to the animals during the dry season of the year. The recovery of the pasture through the input of nutrients conventionally in the recovered pasture (RP) or by intercropping with pigeon pea (INT) had an impact on forage accumulation compared to degraded pasture (PD). Additionally, the pasture intercropped with pigeon pea showed higher crude protein content compared to the other systems. Acknowledgment: Fapesp 2017/20084-5 and CNPq 421788/2018-6.

Reducing energy consumption to dry alfalfa using organic acids – a field trial

T. Fumagalli and L.L.C. Jansen

Selko, Feed Additives, Stationsstraat 77, 3811 MH, the Netherlands; tancredi.fumagalli@trouwnutrition.com

Italian hay's exporter harvest alfalfa on the field and then dry it in an industrial dryer. The dryer temperature is manually adjusted aiming to achieve the desired humidity. Targeting for a higher moisture level to reduce energy consumption for drying while maintaining shelf life can be a challenge but can lower the costs. The aim of this study was to reduce dryer's energy consumption (source: methane gas) while preserving the product's shelf life by proper moisture management in a challenging condition like during a foggy day. The harvested alfalfa had an average moisture content of 40% (NIR analysis). During a processing period of about 2 hours, 14 bales (700 kg each) of untreated alfalfa (avg moisture 10.0%) and 14 bales of treated alfalfa (avg moisture 12.1%) were produced. The dryer temperature was decreased by 10 °C of the treatment group to reach a higher final moisture content. The treatment consisted of 2 kg of a liquid organic acid-based blend (Fylax® Forte-HC, Selko®, Tilburg, The Netherlands) per ton of alfalfa. At the end of the test, 4 samples of treated and untreated alfalfa each were collected at day 0 and after 36 days. A qualitative mould and yeast analysis was performed with a rapid test (Hygicult® Y&F) 4 days after sample collection. After 36 days of storage samples were recollected to perform a quantitative yeast and mould analysis in order to obtain an accurate count of fungal present. The average difference in final moisture was +2.2% at day 0 ($P=0.0019$) of the treated alfalfa. On day 4, untreated alfalfa showed on average high mould levels while treated alfalfa showed moderate to low mould levels. Yeasts counts were low for both treatments (<1000 cfu/ml). These findings were partially confirmed on day 36 by the quantitative analysis, where on average equal low levels of moulds ($<10,000$ cfu/g) and yeasts ($<50,000$ cfu/g) were detected in both treatments. The study showed that with the use of the organic acid-based blend it is possible to preserve the hay's shelf life even with higher moisture. This benefits in term of potential increase in volumes produced, and of consumption of energy and relative cost, due to a lower need for methane gas to support a drying temperature of -10 °C, which can correspond to up to 23 kg/h less of methane gas consumption.

Carbon and energy footprint of dehydrated alfalfa production, from planting to factory outputD. Coulmier¹, P. Thiebeau², S. Recous² and H. Labanca³¹DESIALIS, Mont Bernard, 51000 Chalons en Champagne, France, ²INRAE, UMR FARE, Esplanade R. Garros, 51100 Reims, France, ³La Coopération Agricole, 43 rue Sedaine, 75011 Paris, France; didier.coulmier@desialis.fr

Agriculture accounts for a significant part of the factors of global warming through the consumption of non-renewable energy (NRE). Dehydration as a means of preservation of the harvested fodder is a great energy-consuming process. Reducing the use of NRE in this area is an important lever for mitigating the impacts of agricultural activity on the climate and can be complemented by the carbon storage achieved by crops. This study updates the energy and carbon balance of the French dehydrated alfalfa (DA) production sector with respect to the efforts made in recent years. The inventory is built with elements carried in the liabilities for both the carbon and energy part: fuel consumption required to the cultivation operations until the entrance of the factory, energy consumption (primary energy renewable or not, electricity) related to the dehydration in factory. The carbon asset consists of the atmospheric carbon fixed by the crop (harvested aerial biomass and root biomass). The energy asset consists of the energy valorisation of dehydrated alfalfa (LD) by the dairy cow. Over the period under consideration (2016-2019 – P2), the energy balance becomes positive with +1.2 GJ/t DM compared to the previous study period (2006-2009 – P1). The carbon balance also improves, reaching +390 kg C/t DM of DA. When entered into the Agribalyse/Ecoalim v8 reference database, these data show a 57% reduction in the impact of DA on the 'climate change (CC)' criterion compared to the pre-existing data (1.150 kg eq. CO₂ in P1 vs 0.494 kg eq. CO₂/kg DM of DA in P2). The environmental footprint of the sector therefore improved between the two periods studied. This improvement results from the generalisation of the flat wilting of alfalfa in the field to all the production sites, reducing the quantities of water to be evaporated, and from the implementation of less energy-consuming furnaces (250 vs 750 °C) able of incorporating biomass as an energy source.

Impact of heat waves on the quality of milk and lactic farmhouse goat cheeses in the Aura regionS. Raynaud¹, E. Lemée¹, H. Le Chenadec¹, C. Laithier¹, P. Thorey¹, C. Boyer¹, M. Legris¹, S. Morge², S. Anselmet³, V. Béroutte⁴, S. Fressinaud⁵, C. Delbès⁶, M. Brocart⁷, N. Morardet⁸, J. Birkner⁹ and Y. Gaüzere⁹¹French Livestock Institute, 149 rue de Bercy, 75595 Paris Cedex 12, France, ²Chambre d'Agriculture de l'Ardèche, Le Pradel, 07170 Mirabel, France, ³Chambre d'Agriculture de l'Isère, ZA Centr'Alp 34 Rue du Rocher de Lorzier, 38430 Moirans, France, ⁴Syndicat caprin de la Drôme, 70 route de Choméane Est, 26400 Divajeu, France, ⁵Ferme caprine expérimentale du Pradel Eplefa, Le Pradel, 07170 Mirabel, France, ⁶INRAE UMRF, 20, côte de Reyne, 15000 Aurillac, France, ⁷Association Nationale Interprofessionnelle Caprine (ANICAP), 42 rue de Châteaudun, 75314 Paris cedex 09, France, ⁸Auvergne-Rhône-Alpes Elevage, Agrapole, 23 rue Jean Baldassini, 69364 Lyon Cedex 07, France, ⁹ENILBIO, Rue de Versailles, 39800 Poligny, France; cecile.laithier@idele.fr

In France, heat waves are becoming increasingly frequent, intense and long. Effects of these heat waves on the forage system and animal feeding are explored in different project but less is known on the effects on milk and milk products quality. The aim of this study was to characterise the consequences of these heat waves on milk and farmhouse lactic cheese quality and technology. Nine farms in the Auvergne-Rhône-Alpes region were monitored over 3 periods: before, during and after a high heat episode. The period has an effect on milk yield and composition (fat and protein rate, fatty acid percentage) and on cheese yields and acidification. These effects can be linked to the decrease of animal intake during periods of heat stress, especially concerning forage, and also to the temperature differences. The importance of these performance losses is nevertheless variable on the different farms in the study. This initial exploratory study on commercial farms allowed to identify issues and methodologies for future experimental or larger-scale studies.

Climate-smart practices can reduce GHG emissions intensity on smallholder dairy farms in KenyaL. McNicol¹, M. Graham², M. Caulfield², J. Kagai², J. Gibbons¹, A.P. Williams¹, D. Chadwick¹ and C. Arndt²¹*School of Natural Sciences, Bangor University, Bangor, LL57 2UW, United Kingdom*, ²*International Livestock Research Institute (ILRI), Nairobi, 00100, Kenya; lsm20fj@bangor.ac.uk*

Milk consumption in Kenya is projected to rise. To meet projected demand in a sustainable manner, Kenya must focus on upscaling climate-smart agricultural (CSA) practices to increase productivity. The Kenya Climate-Smart Agriculture Project has been supporting smallholder farmers to adopt integrated climate-smart Technology, Innovation and Management Practices (TIMPs). The aims of this study were to investigate the effects of these TIMPs on milk production and GHG emission intensity (EI; farm gate GHG emissions per unit of product). Survey data were collected from four counties in Kenya: Baringo, Bomet, Kericho and Laikipia. Emissions estimates were calculated for 566 farms using Agrecalc and data were analysed using multiple linear regressions accounting for variability in geographical context and production system (no graze, semi-intensive, and extensive). Mean daily milk yields ranged from 0.5 to 15.7 l/cow/day. EIs ranged from 0.6 to 12.0 kg CO₂e/kg fat and protein corrected milk (FPCM), highlighting the opportunity for efficiency gains. The lowest EIs were found in Laikipia (2.4 kg CO₂e/kg FPCM) and the highest in Bomet (3.1 kg CO₂e/kg FPCM). This could be due to the difference in milk yields between counties and the prevalence of more extensive systems in Bomet. Dairy production system was the most important explanatory variable for the variability in milk production and EI ($P < 0.001$). County also had a significant effect on milk production ($P < 0.001$) and EI ($P = 0.017$). Increasing adoption of TIMPs led to increased milk production ($P = 0.068$) and reduced EI ($P = 0.117$). The largest gains in milk yield and reductions in EI were seen in extensive systems. While this was not significant, there was a strong visual trend in extensive systems, but not in intensive or semi-intensive systems. Our results show that adoption of TIMPs generally increased milk yields and decreased GHG EIs. Therefore, adoption of CSA practices could allow Kenya to increase milk production to meet projected demand, whilst keeping associated GHG emission increases below business as-usual predictions.

Welfare barriers and levers for improvement in organic and low-input outdoor pig and poultry farmsC. Leterrier¹, C. Bonnefous², J. Niemi³, PPILOW Consortium⁴ and A. Collin²¹*CNRS, IFCE, INRAE, Université de Tours, PRC, 37380 Nouzilly, France*, ²*INRAE, Université de Tours, BOA, 37380 Nouzilly, France*, ³*Natural Resources Institute Finland, Luke, Kampusranta 9, 60320 Seinäjoki, Finland*, ⁴*PPILOW, www.ppilow.eu, https://www.ppilow.eu/wp-content/uploads/2023/03/List-authors.pdf, France; christine.leterrier@inrae.fr*

The PPILOW project aims to co-construct innovations to improve Poultry and Pig Welfare in Low-input outdoor and Organic farming systems through a multi-actor approach. Its first step was to sum up animal welfare challenges observed in these systems and levers of improvement, from a review of literature data and research projects. Data were completed with information from key informants of the supply chains of poultry meat, eggs and pork in Italy, France, the United Kingdom and Finland. The interviews indicated that the main issues in poultry were: feeding, biosecurity, lack of range use and range management, feather pecking, weather, regulation, flock size or density, predation, bone fractures, lack of robustness, parasitism, pododermatitis, arthrosis, nervousness, water quality, catching and time spent by farmers. The main issues in pig were: feeding, tail biting, mortality, weather, predation, lack of robustness, lack of range use, castration, animal aggressiveness and competition, water quality, range management, human welfare, biosecurity issues, flock size or density, parasitism, insulation burns, joint abnormalities, parturition in freedom and pollution. This information has implemented a participatory approach for proposing welfare-improvement levers. Some issues and potential solutions were included in PPILOW experiments (phytotherapy against parasitism, involvement of animal personality in range use, rearing of entire pig males, genetic selection for reduced piglet mortality, improved farrowing huts for sows and piglets reared on range, avoiding feather pecking in laying hens with intact beaks, avoiding the killing of day-old male chicks, etc.), and solution costs evaluated. The results will provide a combination of practical solutions for welfare improvement in Europe. The PPILOW project has received funding from the European Union's Horizon 2020 Research and Innovation Programme under grant agreement N°816172.

Range use relationship with welfare and performance indicators in four organic broilers strains

Free range allows chickens to express more behaviours such as foraging and locomotion in a different environment from the poultry house. To understand how range use is related to welfare and performances of chickens, we studied four intermediate- to slow-growing strains with outdoor access until slaughter at 71 to 106 days of age depending on the strain. Males from JA757, S757N, White Bresse and a dual-purpose crossbreed were classified according to their range use and divided in two extreme groups of 25 high- and low-rangers. We did not observe any significant relationship between range use and welfare indicators collected at the slaughterhouse (hock burn, pododermatitis scores and struggling activity on the slaughter line) in the four studied strains. Leg health of JA757 chickens improved significantly with range use, with tibia being 4% shorter and 2% stronger in high-rangers compared to low-rangers. In both JA757 and S757N strains, range use also reduced the immune and inflammatory responses of birds. However, greater range use was negatively related to performances in all strains, including a 12, 8 and 7% reduction in carcass weight in JA757, S757N and the White Bresse strains, respectively, and a significant 2% reduction in thigh yield in the dual-purpose strain. Overall, greater range use in slow-growing birds did not affect welfare, health and meat quality indicators, but we confirmed a negative relationship with performance. The project PPILOW has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N°816172.

Theatre 3

Case study of a newly-developed genotype for dual-purpose rearing of male chicks

H. Pluschke¹, S. Lombard², B. Desaint², M. Reverchon³, A. Roinsard², O. Tavares², A. Collin-Chenot⁴, M. Ferriz⁵, S. Seelig⁶ and L. Baldinger¹

¹Thünen-Institute of Organic Farming, Trenthorst 32, 23847 Westerau, Germany, ²ITAB, 9 rue André Brouard, 49100 Angers, France, ³SYSAF, Centre INRAE, Val de Loire, 37380 Nouzilly, France, ⁴INRAE, Université de Tours, 37380 Nouzilly, France, ⁵La Bassecour Bio, 41 Chem. de Chaponnay, 69970 Chaponnay, France, ⁶Wendland Geflügel, Diahren 3, 29496 Waddeweitz, Germany; h.pluschke@thuenen.de

The culling of male layer chicks has been subject to widespread disapproval and led to its ban in Germany and France. One approach to divert from this practice is the use of dual-purpose genotypes (DPG) with a balanced performance in egg and meat production. Practitioners and stakeholders selected males of a DGP with a focus on laying (C) for on-farm evaluation under organic conditions in France and Germany. In Germany, the medium-growing JA757 (D) while in France the naked neck strain S757N (F) were reared as control groups. Data collection included mortality, feed consumption, live weight, welfare indicators, behaviour observations and carcass characteristics. In Germany, C cockerels were slaughtered at 16 while D at 13 weeks (wks) of age. In France there were two slaughter dates for C and F: 13 and 15 wks of age. In Germany, the carcass weight of C was 1.8 kg and that of D 2.4 kg. Carcass weights (incl. necks) at 13 and 15 wks of age were 2.9 and 3.3 kg for F while C weighed 2.0 and 2.5 kg in France. The FCR of DPG C until wk 13 was 3.7 for both countries, and 2.6 for F and 2.7 for D. In Germany, D showed dirtier breasts and more footpad lesions than C; on behavioural aspects, D spent more time resting than C while C spent more time foraging. DPGs could be an alternative to end the practice of chick culling, and thus fulfil the societal demand for a shift towards welfare-oriented production. A longer fattening period with higher FCR of DPG cockerels may be economically feasible if their meat is sold at higher price than that of usual genotypes. A perspective is to decipher whether they could valorise side products of the food industry to decrease feeding cost. Furthermore, the productivity of the females should be considered for a complete economical analysis of DPG. This project received funding from EU's Horizon 2020 research & innovation program under grant agreement N°816172.

Poultry production: using dual-purpose genotypes to reduce the culling of day-old male chicks?

J. Niemi¹, M. Väre¹, A. Collin², M. Almadani³, M. Quentin⁴, L. Baldinger³, S. Steinfeldt⁵, T.B. Rodenburg⁶, F. Tuytens⁷ and P. Thobe³

¹LUKE, Kampusranta, Seinäjoki, Finland, ²INRAE, Université de Tours, Nouzilly, France, ³Thünen-Institute, Farm Economics and Organic Farming, Bundesallee, BS, Germany, ⁴ITAVI, Cunicle, Nouzilly, France, ⁵Aarhus University, Tjele, 88333, Denmark, ⁶Utrecht University, Yalelaan, the Netherlands, ⁷EVILVO, Animal and Veterinary Sciences, Scheldeweg, Melle, Belgium; jarkko.niemi@luke.fi

Existing studies show that consumers consider methods that avoid the killing of male day-old chicks (DOC) from layer genotypes as desirable practices. However, only 24% of producers argue that these measures are currently being applied. The use of dual-purpose breeds or *in ovo* sexing are two methods that can be used to address the ethical issues associated with the killing of male DOC. In this context, our study aims to develop a business case that would provide incentives to farmers to adopt these methods. More specifically, using the CANVAS method and insights from expert workshops, a business model outline was developed through reviewing the features, advantages and disadvantages of *in ovo* sexing and dual-purpose breeds. The results show that the promise of more ethical production is the key value proposition of these two methods. The key target groups were found to be consumers who are aware of current practices or are ethically conscious and/or better-informed. The results reveal that the use of dual-purpose breeds is considered a good option to avoid killing of male DOC. However, this option is considered to adversely affect broiler production, as male birds are slow-growing, have low feed efficiency and meat yields, and thus higher production costs, compared with conventional broilers. Hence, the business case of dual-purpose birds was based on addressing both animal welfare and ethical concerns, which in turn, could widen consumer group and promote demand toward compensating production costs. Raising consumers' awareness of culling one-day-old male chicks gives growing potential for keeping dual-purpose birds. The PPILOW project has received funding from the European Union's Horizon 2020 Research and Innovation Programme under grant agreement N°816172. www.ppilow.eu.

Session 62

Theatre 5

Longitudinal assessment of health indicators in four organically kept laying hen flocks

L. Jung¹, M. Krieger², L. Matoni² and D. Hinrichs¹

¹University of Kassel, Animal Breeding, Nordbahnhofstr. 1a, 37213 Witzenhausen, Germany, ²University of Kassel, Farm Animal Behavior and Husbandry, Nordbahnhofstr. 1a, 37213 Witzenhausen, Germany; lisa.jung@uni-kassel.de

Good health is an important precondition for good welfare. Health disorders like feather damage, skin lesions, keel bone damage or footpad lesions are known to be present in most laying hen flocks regardless of the housing system. The aim of this study was to find out whether there is: (1) a difference between genetics in terms of disease prevalence; (2) a specific lifetime for disease occurrence; (3) a temporal relationship between disease occurrences; and (4) a cumulation and subsequence of diseases in individual animals. Health indicators were assessed in four successive organically kept laying hen flocks of Lohmann Brown (flock 1 and 2) and the dual-purpose breed Coffee&Cream (flock 3 and 4) in the years 2018 to 2022. In the first flock 60 hens and in the three following flocks 150 hens were individually marked and assessed at 4-week intervals from housing (17-18 weeks) to depopulation (61-78 weeks). First results show that the prevalence of all indicators was comparable to those found in conventional laying hen flocks. There was no marked difference in terms of general health status between Lohmann Brown and Coffee&Cream chickens. Keel bone damage was the most prominent welfare problem in all flocks. Descriptive statistics showed that all flocks were affected by comb lesions from housing until depopulation and by footpad ulcerations from peak of lay until depopulation. Differences between flocks were found in relation to feather and skin condition. Contrary to the hypothesis, that hens with feather damage are disabled in navigation, this leading to more collisions and thus more keel bone damages, the latter generally occurred prior to plumage damage. Likewise, no general order with respect to the occurrence of plumage damage and skin lesions could be determined from individual animal data.

Alternative pig housing systems with high welfare standards – status quo and perspectives*M. Holinger**Research Institute of Organic Agriculture (FiBL), Livestock Sciences, Ackerstrasse 113, 5070 Frick, Switzerland; mirjam.holinger@fibl.org*

The term ‘alternative housing system’ is an umbrella term for systems that encompass welfare and/or sustainability while also ensuring productivity. ‘Conventional housing’ usually describes a barren indoor system that strongly limits animals’ behavioural freedoms. Alternative systems such as organic, free-range, pasture-based, agroforestry or regenerative generally meet the social, exploratory and locomotory needs of the pigs. Organic production is an absolute niche, with a market share in pigs of less than 1% in Europe. Legislation and private standards for organic livestock production differ between countries. In some countries organic pigs are kept predominantly free-range, in other countries they have access to a concrete outdoor run but not to soil. These differences influence pig health and welfare. Free-range pig husbandry (organic or non-organic) is associated with less (e.g.) respiratory and gastrointestinal problems. As bedding material is provided, organic pigs in general have a lower prevalence of auxiliary bursae. The risk for parasite infestation, however, is increased because of restrictions on preventive deworming. Newer, innovative approaches aim at integrating various essential resources within the housing system. Provision of a rooting area filled with earth-like materials and a pool enable display of rooting and wallowing behaviour, both of which are impeded in most housing environments. While both resources are intensively used by pigs, the soiling of these areas is a management challenge. Targeted temporary restriction on the use of these resources or distribution of feed are measures that have been tested in on-farm settings to reduce soiling. Future developments will aim at further increasing the variability of environments and providing pigs with more choice. More variability could for example be implemented in feeding (location, type, and accessibility) or installations for cognitive enrichment. The ideas for such new approaches originate either from farmers or from researchers. The implementation needs to be accompanied by research to analyse the desired effects on health and welfare, but also to optimize practicability.

Session 62

Theatre 7

Characterising outdoor pig systems in Ireland*O. Menant¹, S. Mullan², F. Butler³, L. Boyle¹ and K. O’Driscoll¹**¹Teagasc, Pig Development Department, Moorepark, P61P302, Ireland, ²School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland, ³School of Biological, Earth and Environmental Sciences, University College Cork, T12 K8AF, Ireland; ophelie.menant@teagasc.ie*

OneWelPig is a project to develop a roadmap for expansion of outdoor pig systems in Ireland not only to meet societal and policy demands, but also through the agro-ecological role that pigs can play in farming systems. As little is known about outdoor pig systems in Ireland, the objective of this study was to characterize current husbandry and management practices. Between Dec 2022 and Feb 2023, 57 owners of outdoor pigs (in 21 out of the 32 Irish counties) completed an anonymous online survey. They had 8±6 years of experience (range: 1-30) and mainly kept pigs for personal meat consumption (62.3%), followed by ‘meat for sale’ (56.6%), breeding pigs for sale (45.3%), conservation of traditional Irish and/or rare breeds (32.1%), hobby (30.2%) and land management (28.3%). Pigs were kept in a variety of land types: pasture (74.5%), scrubland (33.3%) and woodland (37.3%), with additional straw (23.6%); and up to 18.5 animals/ha. Meat was mostly sold directly at the farm (66.6%), farmers markets (45%), in online shops (41%) and in supermarkets (23.3%). Pigs were mainly bred on farm (60.4%) or came from other outdoor farms (41.5%) with fewest from conventional farms (13.2%). Breeds were mainly Duroc (35.8%), Oxford Sandy and Black (32.1%), Tamworth (22.6%), Gloucester old spot (20.8%) and few conventional Large White (7.5%). Participants were all operating at a small-scale (average 7 sows/gilts, 1 boar, 18 grower pigs, 17 piglets at any one time in the year and managed by 2 people) and had a communication network separate from the conventional pig industry. At least 51% of the participants were members of the Irish Pig Society (and 7.5% from others) which promotes ‘non-intensive’ pig farming. When they are facing pigs health issues, 61.7% of the owners consult veterinarians (34.5% with strong experience in outdoor animals, 44.8% generalist large animals, and 10.3% conventional pig specialist), but also farmers that raise pigs outdoors (31.9%). The preliminary survey results demonstrate that a diverse range of outdoor pig keeping systems emerged in Ireland in recent years.

Animal welfare and pork quality of intact male pigs in organic farming according to genotypeB. Lebre¹, S. Ferchaud², A. Poissonnet³ and A. Prunier¹¹PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France, ²INRAE, GenESI, 86480 Rouillé, France, ³IFIP, Institut du Porc, 35650 Le Rheu, France; benedict.lebret@inrae.fr

In organic pig farming, genotype was tested as a lever to improve welfare and pork quality traits (tenderness, processing ability) of intact males while controlling the risk for boar taint. A total of 81 organic intact males from two genotypes: Large White × Duroc (D, n=47) or Large White × Piétrain NN (P, non-carrier of the n allele, n=34) were involved in two batches, each including one group of pigs per genotype. Each group was reared in a pen from the same building on deep straw bedding (1.3 m²/pig) with free outdoor access (1.0 m²/pig) from 27 to 125 kg live weight. All pigs received *ad libitum* the same organic growing and finishing diets and had free access to hay (rack). Overall, health and welfare indicators in live pigs (mortality, lameness, skin scratches and tail lesions) showed few problems, but mortality, severe lameness or number of skin scratches were lower in D than P pigs. On carcasses, the number of skin scratches was lower in D than P pigs ($P<0.05$). Average growth rate, feed intake and feed efficiency (per pen) were similar in both genotypes. Carcass weight was similar but lean meat content was lower ($P<0.001$) in D than P pigs. Compared to P, loin (Longissimus) meat from D pigs had lower drip loss and lightness ($P<0.05$), higher lipid content ($P<0.001$) and tended to have lower shear force ($P<0.10$). Backfat androstenone was higher in D than P pigs ($P<0.01$) but skatole did not differ. Even if not significant, the risk of rejection by consumers of tainted carcasses was higher for D (17.4%) than P (8.8%) pigs. Androstenone content increased with slaughter weight ($P<0.02$) but not skatole. Altogether, raising D instead of P intact males in organic farming seemed favourable for welfare and some pork quality traits (technological, colour, texture) but impaired carcass value. The higher boar taint risk could be reduced by decreasing slaughter weight. Solutions can thus be proposed to better satisfy the needs of farmers and stakeholders according to their priorities for organic pork. The project PPILOW has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N°816172.

Session 62

Theatre 9

Large White genetics in organic system: breeding for piglet survivalL. Canario¹, S. Ferchaud², S. Moreau², C. Larzul¹ and A. Prunier³¹INRAE, Animal Genetics, GenPhySE, 31326 Castanet-Tolosan, France, ²INRAE, UE GenESI, 86480 Rouillé, France,³INRAE, PEGASE, Agrocampus Ouest, 35590 Saint Gilles, France; laurianne.canario@inrae.fr

A multi-generation selection to improve the survival of piglets in organic condition was initiated with the POWER project and is ongoing with the PPILOW project (Horizon 2020 EU's Research and Innovation programmes No. 727495 and No. 816172). The experiment is carried out using Large White animals. In 2019, daughters of sows (G0) with good performance from the national scheme (kept in farrowing crate during lactation) were recruited as G1 for the organic farm. All sows are inseminated with semen from Large White boars with higher genetic merit for litter survival rate and a not too high genetic merit for litter size. Sow performance and behaviour are used to select future breeders. In G1 sows, we studied the effect of temporary crating around farrowing on performance, with comparison of two groups genetically similar. In one batch (n=4 per parity), pairs of sisters were inseminated with the same boar. One sister was 100% free to move in an individual pen (L), while the other was restricted to a crate around farrowing (B). The 24 pairs of sisters were evaluated over their first 3 parities. Causes of piglet death, piglet growth and sow behaviour were analysed. Prolificacy tended to increase between the 1st and 3rd litter in B sows. Piglet survival rate was 75-88% in the 48 h after farrowing and 64-75% until weaning; it varied greatly between sows and sisters. The number of piglets weaned in parity 1 was higher in L sows than in B sows. In parity 2, prolificacy was higher in B sows than in L sows (16.8 vs 14.4 live born piglets, $P=0.01$), but survival rate tended to differ (60.2 vs 69.7%) which led to equivalent litter sizes at weaning (9.9 vs 9.6). Mortality seemed to be slightly delayed in crated compared to loose-housed sows. Sows that were more maternal (at return of their piglets on day 1) had higher litter survival, especially those temporarily crated. First results indicate that G2 sows produced slightly fewer piglets in their two first litters as compared to G1 sows. Survival rate until 48h after farrowing was slightly higher in G2 sows than G1 sows (88.1 vs 83.7%). Response to selection will be further investigated.

Comparing animal welfare assessments by researchers and free-range pig farmers with the PIGLOW appE.A.M. Graat^{1,2}, C. Vanden Hole², S. Nauta³, M.F. Giersberg³, T.B. Rodenburg³ and F.A.M. Tuytens^{1,2}¹Ghent University, Salisburylaan 133, Merelbeke, Belgium, ²ILVO, Scheldeweg 68, Melle, Belgium, ³Utrecht University, Yalelaan 2, Utrecht, the Netherlands; evelien.graat@ilvo.vlaanderen.be

The PIGLOW app was developed for free-range and organic farmers to conduct welfare assessments of their own pigs. The goal of the app is to stimulate farmers to take a closer look at their animals and perhaps gain a different view of certain welfare aspects. A study is being conducted in which 12 free-range pig farmers use the PIGLOW app regularly for two years. While the main goal is to see if this leads to improved animal welfare on the farms, another aim is to compare welfare assessments with the app by researchers and by farmers. For this purpose, one of two researchers visits each farm at the start and end of the study to conduct the first and last welfare assessment simultaneously with the farmer. For all first welfare assessments, the group means for farmers ($\bar{x}_F$) and researchers ($\bar{x}_R$) and the average absolute differences in the percentages of animals/groups that they scored as 'positive' for a welfare indicator were calculated for 18 animal-based indicators. For group indicators, the largest differences were for 'coughing/sneezing' ($|\bar{x}_F - \bar{x}_R| = 14.6$, $\bar{x}_F = 12.5$, $\bar{x}_R = 27.1$) and 'difficulty accessing water' ($|\bar{x}_F - \bar{x}_R| = 37.5$, $\bar{x}_F = 8.3$, $\bar{x}_R = 45.8$). For individual indicators, the most striking differences were for 'scratches' ($|\bar{x}_F - \bar{x}_R| = 6.5$, $\bar{x}_F = 0.5$, $\bar{x}_R = 6.8$) and 'too small' ($|\bar{x}_F - \bar{x}_R| = 2.4$, $\bar{x}_F = 3.7$, $\bar{x}_R = 2.1$). Both 'coughing/sneezing' and 'scratches' require close and focused observation, which perhaps the researchers were more skilled at. The difference for 'difficulty accessing water' suggests a difference in judgement of the water facilities, where researchers consistently judged more severely. 'Too small' was one of few indicators scored more severely by farmers, possibly because body size is an important performance parameter. These results show that farmers score the welfare of their pigs differently and often more positively than researchers. These results will be complemented by those of the final welfare assessments, which will be completed by early August 2023. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N°816172.

Session 63

Theatre 1

Growth performance and digestive tract parameters in weaned piglets fed *Nannochloropsis limnetica*A.A.M. Chaves¹, C.F. Martins^{1,2}, D.F. Carvalho¹, A.R.J. Cabrita³, M.R.G. Maia³, A.J.M. Fonseca³, R.J.B. Bessa², A.M. Almeida¹ and J.P.B. Freire¹¹Instituto Superior de Agronomia, Universidade de Lisboa, LEAF Linking Landscape, Environment, Agriculture and Food, Associated Laboratory TERRA, Tapada da Ajuda, 1349-017 Lisboa, Portugal, ²Faculdade de Medicina Veterinária, Universidade de Lisboa, CIISA – Centre for Interdisciplinary Research in Animal Health, AL4Animals, Av. da Universidade Técnica, 1300-477 Lisboa, Portugal, ³Instituto de Ciências Biomédicas de Abel Salazar, Universidade do Porto, REQUIMTE, LAQV, R. Jorge Viterbo Ferreira 228, 4050-313 Porto, Portugal; andrea_ac_22@hotmail.com

Presently, it is necessary to find novel and more sustainable alternatives to complement conventional feedstuffs, such as corn or soybean meal. Due to their rich nutritional profile, microalgae such as *Nannochloropsis limnetica* (NCH) can be an interesting solution for monogastric feeding. The aim of this study was to evaluate the effect of dietary NCH on growth performances and digestive tract development of weaned piglets. Animals were individually housed in metabolic cages and randomly allocated to 4 dietary treatments (n=6): control, 5, 10 and 15% dietary incorporation of NCH as a replacement of the basal diet. Water was always available. The experiment lasted 14 days (with a previous adaptation period of 4 days) and feed intake was monitored daily and equalized between experimental diets. Piglets were weighed weekly. At the end of the experiment, animals were slaughtered and stomach, pancreas, vesicle, small and large intestine weighed and measured. Polynomial contrasts were performed to test the effect of NCH incorporation levels in the diet. No differences were observed in average daily intake, average daily gain and feed conversion ratio among dietary treatments ($P > 0.05$). The weight of full ($P < 0.05$) and empty ($P < 0.001$) small intestine and liver ($P < 0.05$) linearly increased with dietary NCH inclusion. The group fed with 10% incorporation of NCH had the heaviest pancreas ($P < 0.05$, quadratic). Diet did not affect weight of stomach, vesicle and large intestine and length of large intestine. Further information, to be provided by digestibility coefficients analysis, will complement the results herein described, allowing further knowledge of the nutritional value of NCH for the weaned piglet.

Synbiotic administration to suckling piglets on health parameters at weaning and postweaning period

E.A. Sureda¹, M. Schroyen², J. Uerlings², F. Fannes³, J. Liénart³, A. Sabri⁴, P. Thonart⁴, V. Delcenserie², J. Wavreille⁵ and N. Everaert¹

¹KU Leuven, Kasteelpark Arenberg 30, 3001 Leuven, Belgium, ²Liège University, Av. Cureghem 7, 4000 Liège, Belgium,

³Vésale Pharma SA, Rue L. Allaert 9, 5310 Eghezée, Belgium, ⁴Artechno SA, Rue H. Meganck 21, 5032 Isnes, Belgium,

⁵Walloon Agricultural Research Centre, Rue Liroux 9, 5030 Gembloux, Belgium; ester.arevalosureda@kuleuven.be

In pig production, probiotics, prebiotics and their combination are being widely explored to improve intestinal health. This study investigated if synbiotic (Syn) supplementation to suckling piglets could have health benefits up to the post-weaning (PW) period. From birth to 25 days of age (d25), piglets received Syn1 (*Clostridium butyricum*, oligosaccharides), Syn2 (*Bifidobacterium animalis lactis Intellicaps*®, 2' fucosyllactose) or water [n=6/7]. Growth performance parameters were evaluated weekly. Diarrhoea incidence and behaviour were evaluated for the suckling and the PW period. Faeces (d25) were analysed for detection of the probiotics, beneficial microbial groups and gene expression of butyrylCoA:acetylCoA transferase (BCO). At day 25, 1- and 5-weeks after weaning, a piglet per litter/pen was selected for sampling. Colon content and faeces were analysed for lactate and short-chain fatty acids. Colon tissue was analysed for changes in gene expression. Syn-supplemented piglets had lower weight at the end of the PW period compared with the control group. Yet, syn-supplementation significantly reduced diarrhoea prevalence during suckling (Syn1) and PW periods (Syn2), which was accompanied by an increase of piglets' active behaviour. Microbial communities and metabolites showed no major differences, and BCO expression was reduced in Syn2 piglets' faeces. However, syn-supplemented piglets showed lower expression of MUC2, which could lead to reduced mucus production at d25, and lower expression of inflammation related genes (CXCL10, IFN α , IL1 β , IL6, IL8, ILRN1) at all times. Syn-supplementation to piglets had health and well-being benefits even if not resulting in improved piglet's performance. Observed differences in weight of piglets could be caused by higher energy expenditures on syn-supplemented piglets due to increased active behaviour. Synbiotics had anti-inflammatory effects on gene expression in colonic tissue.

Session 63

Theatre 3

Fine characterisation of a standardized citrus extract and its effect on weaned piglet performances

S. Cisse^{1,2}, J. Laurain¹ and M.E.A. Benarbia^{1,2}

¹Nor-Feed SAS, R&D, 3 rue Amédéo Avogadro, 49070, France, ²FeedInTech, R&D, 42 rue Georges Morel, 49070, France; sekhou.cisse@norfeed.net

Plant extracts such as Citrus extract have more and more interest in animal nutrition, as growth performances enhancer. However, their effects on animals' growth performances vary, depending on the used product. A possible explanation of these variation may be the composition. The lack of composition data of plant extracts makes the understanding of their mechanisms of action unclear. This study aimed to evaluate the composition of a standardized natural citrus extract (SNCE). The effect of SNCE dietary supplementation has also been assessed on weaned piglet growth performances. Apolar and polar compounds of SNCE were characterized by GC-MS and LC-MS (dereplication) respectively. In parallel, 864 piglets weaned at day 28 (Duroc $\times$ Large-White $\times$ Landrace) were divided into two groups. Each group consisted of 12 replicates of 36 piglets: A control (CTL) group fed with a standard diet and a SNCE group fed with a standard diet supplemented with 250 ppm of SNCE. All diets had been formulated without antibiotics, organic acids or enzymes, or probiotics. The trial duration was in two steps, post-weaning phase during 42 days and growing-finishing phase from day 70 until slaughtering at day 168. Growth performances were recorded and statistical analysis (T-test) was performed using GraphPad prism V7. SNCE characterization allowed to identify pectic oligosaccharides as major compounds as well as 30 secondary metabolites, including hesperidin, naringenin, and eriocitrin. Moreover, no variation has been observed in the composition and the concentration of SNCE active compounds from 5 different SNCE batches manufactured over 2 years. Regarding piglets' performances, supplementation with SNCE increased ADG between day 28 and day 70 compared to CTL group (333.9 vs 322.4, $P=0.0426$). A positive effect of SNCE was also observed on the FCR (2.179 vs 2.051, $P=0.0016$). Supplementation with SNCE also improved FCR (2.83 Vs 2.70, $P=0.0003$) during the growing and fattening period. Data evidenced that Citrus extract could be effective solution as growth performances enhancer for weaned piglets. SNCE characterisation revealed its standardization and the trial on weaned piglets confirm its interest for pig industry.

Essential oils and butyric acid effects on growth performance, blood metabolites and health in pigs*U. Marume and R.B. Nhara**North-West University, Animal Science, P. Bag X2046, Mmabatho, 2735, South Africa; upenyu.marume@nwu.ac.za*

The study was conducted to determine the effect of Kalahari melon essential oil (EO), butyric acid (OA) and their blend on performance, blood metabolites and faecal health in growing pigs. Forty growing pigs were weighed, stratified, and randomly allocated to five dietary treatments, NC-Negative control (no antibiotic), PC-Positive Control (zinc bacitracin), EO (0.4%), OA- (0.6%) and EOOA- EO (0.4%) + OA (0.6%). Each dietary treatment had eight replicate pigs regarded as the experimental units. Treatment significantly affected growth performance. Pigs fed the OA and EOOA diet had higher ADFI (1.07 kg and 1.10±0.01 kg) and ADG (0.60 and 0.62±0.01 kg/d) compared with the control. Those fed the NC diet had the lowest values for all growth parameters. The pigs fed the EOOA diet also had lower FCR value compared with the control diet. With regards to the protein efficient ratio which measures the food values of different proteins, the EO and butyric acid inclusion in diets appeared to improve the protein utilisation in the diets with pigs fed the EO, OA and EOOA having the highest values for protein consumed (PC) protein efficient ratio (PER), specific growth rate (SGR) and growth efficiency (GE) compared with the control. Although there were no significant effects on haematology, EO and OA inclusion in diets appeared to slightly improve the haematological parameter. With regards to non-cellular metabolites, the inclusion of OA and EO in diets significantly reduced liver enzyme activity as reflected by lower values for alanine aminotransferase, aspartate transferase and alkaline phosphatase. Nevertheless, the inclusion of OA and EO appeared to deplete the levels of total serum protein probably due to its effect use by the animals. Throughout the study, the pigs fed the EOOA diet consistently had the lowest faecal score with no incidences of diarrhoea. A decline in faecal scores was observed in all other treatment as the trial progressed apart from the NC fed pigs. The findings indicate that essential oils, butyric acid and their blend can positively influence growth performance and blood metabolites and reduce diarrhoea incidence in growing pigs. They can therefore be used as alternatives to the conventional antibiotics.

The impacts of a spectrum of varied lifestyle factors on the porcine gut microbiota*L. Comer, E. Arévalo Sureda and N. Everaert**KU Leuven, Biosystems Department, Kasteelpark Arenberg 30, 3001 Leuven, Belgium; luke.comer@kuleuven.be*

Given piglets' vulnerability to gastrointestinal disease during the weaning period, it is vital that we better understand how varied factors influence the gut microbiota, so as to be able to promote the establishment of a healthy microbiota. Studies hitherto have highlighted the importance of a plethora of different factors in shaping the microbiota. Yet, these studies tend not to deviate from small-scale experimental setups, and neglect the interplay of varied lifestyle factors (diet, environment, breed) seen in the real world. We hypothesised that a study analysing the microbiota across a range of varied lifestyles would show more variation in microbial composition, and highlight the dominance of a few factors such as diet and environment-type. To address this, we have established a microbiota repository for which we are obtaining faecal samples from >300 pigs and other members of the Suidae family. Subjects have very varied lifestyle factors including diet, environment-type and age. As an ongoing project, we are continuing to gather more samples. After sample collection, V1-V9 16S rRNA gene sequencing is performed and data is processed using QIIME2 with DADA2. Early analysis indicates a particularly strong influence of several factors (PERMANOVA $P < 0.05$) including inside/outside environment and age which drive marked clustering on a PCoA. A number of genera were also significantly different by location, with *Treponema* and *Cellulosilyticum* among the many taxa enriched in pigs with outdoors environments or access to straw. *Lactobacillus* on the other hand was associated with animals fed a more commercial diet. These initial results provide trends to explore and target through further sample collection in the immediate future, as well as providing an insight into the microbiota responses to many lifestyle factors.

In vitro inhibition of avian pathogenic *Enterococcus cecorum* isolates by probiotic *Bacillus* strainsM. Bernardeau^{1,2}, S. Medina-Fernandez¹ and M. Cretenet¹¹Normandy University, UNICAEN, ABTE, Campus 1, Bât M, Esplanade de la Paix, 14032 Caen, France, ²IFF, Danisco Animal Nutrition and Health, Innovation, Willem Einthovenstraat 4, 2342 BH Oegstgeest, P.O. Box 2300 AE, Leiden, the Netherlands; marion.bernardeau@iff.com

Enterococcus cecorum is a commensal bacteria and opportunistic pathogen that can cause outbreaks of Enterococcal spondylitis in poultry, with a growing concern worldwide. Numerous *Bacillus*-based probiotic strains are commercially available with proven effects in supporting gut health and growth performance, but efficacy against pathogenic *E. cecorum* is unknown. This study compared the *in vitro* inhibitory potential of Cell-Free Supernatants (CFSs) of 18 *Bacillus* strains (14 being commercial probiotic strains) on the growth of 9 clinical *E. cecorum* isolates. Standardized biomass cultures of live *Bacillus* were harvested and filtered to obtain CFSs. Inhibitory potential against *E. cecorum* isolates was assessed via a microdilution assay in which the final pathogen concentration was $\approx 10^4$ cfu/ml. Absorbance (OD) was measured every 15 min for 15 h and used to calculate percentage growth inhibition at an OD equivalent to 0.4 in the positive control (PC) (pathogen but no CFS), and growth delay vs PC. Growth kinetic responses of pathogen isolate-*Bacillus* strain combinations ranged from total pathogen inhibition to partial inhibition, lag in growth, no effect, or increased growth vs PC. Percentage inhibition of individual isolates varied markedly among *Bacillus* strains, from 100% (*B. amyloliquefaciens* CFSs BS8, 15AP4, 2084, #10B/4 and CFS #1/1) to -100% (growth promotion) (*B. amyloliquefaciens* DSM7T). Five *B. amyloliquefaciens* CFSs (3AP4, 2084, ABP278, #1/1 and #10B/1) produced higher average inhibition rates (>75%) than 2 out of 3 *B. licheniformis* CFSs (#12/1 and #10/4, -2.5% and -8.39% vs PC, respectively) and 1 out of 2 *B. subtilis* CFSs (#11/1, 7.3% vs PC) ($P < 0.05$). Commercial strain 3AP4 exhibited the highest average percentage inhibition vs PC (85.0%, 7.862SD) and the most consistent inhibitory effect across pathogen isolates. The findings indicate that some commercially available poultry probiotic *Bacillus* strains are effective at inhibiting pathogenic *E. cecorum* *in vitro*, but effects are highly strain- and pathogen-isolate- dependent.

Session 63

Theatre 7

Effects of breed and early feeding on intestinal microbiota, gene expression and welfare indicatorsF. Marcato¹, D. Schokker², S.K. Kar¹, J.M.J. Rebel² and I.C. De Jong¹¹Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ²Wageningen Bioveterinary Research, P.O. Box 65, 8200 AB Lelystad, the Netherlands; francesca.marcato@wur.nl

Recently the Netherlands has shifted towards more welfare-friendly broiler production systems using slower-growing broiler strains. Early post-hatch feeding is a dietary strategy that is currently used in commercial broiler production to modulate the gut microbiota, increase performance and improve broiler welfare. However, there is a knowledge gap on the effect of both breed and early feeding strategies and their interplay on microbiota composition and diversity, which in turn can affect the release of endotoxins in the excreta of broilers. Endotoxins are a major concern as these can be harmful for both animal and human health. The main aim of this study was to investigate the effects of breed and early feeding on gut microbiome with the ultimate goal to reduce endotoxin concentration in faeces of broilers. The study also investigated the impact on these factors on relative gene expression and welfare indicators of broilers. A total of 624 Ross 308 and 624 Hubbard JA757 day-old male broiler chickens were included until day 37 and day 51 of age, respectively. Within each breed, one half of the chickens received early post-hatch feeding and the other half not. A total of 2 chickens per pen were euthanized at two time points, i.e. target body weight (TBW) of 200 g and 2.5 kg, and gut samples were collected. Jejunum content samples (n=96) were analysed for the microbiome, whereas the jejunum tissue (n=96) was used for gene expression (data not yet analysed). Welfare assessment was conducted on 10 chickens/pen at TBW of 2.5 kg. Results showed that breed affected the microbiome at a TBW of 2.5 kg ($P=0.04$), with Hubbard chickens having a higher mean alpha-diversity compared to Ross chickens, respectively 209 vs 157. Early feeding did not affect the microbiome at both TBW's. Breed and early feeding impaired the cleanliness score and the gait score of Hubbard JA757 at TBW of 2.5 kg ($P < 0.01$). These results indicate that breed modulates the intestinal microbiota and affects welfare of chickens, whereas early feeding only affected the welfare at a late TBW.

Yogurt Acid Whey addition affects broiler caecal microbiota composition and metabolic activity

I. Palamidi, V.V. Paraskeuas, I. Politis and K.C. Mountzouris

Agricultural University of Athens, Department of Animal Science, Iera odos 75, 118 55 Athens, Greece; inpalamidi@aau.gr

In Greece strained yoghurt is a high nutritional and consumer-desirable product. The production process yields Yoghurt Acid Whey (70% v/v of the milk used) as a byproduct that can pose an environmental problem if left untreated. In this respect and given the composition of the Yoghurt Acid Whey its utilization in animal nutrition merits investigation. The aim of this study was to investigate the addition of yogurt acid whey powder (YAWP) in four dietary levels on broiler performance, caecal microflora composition and metabolic activity. A total of 300 male one-day-old male Ross broiler chickens were randomly assigned into 4 treatments of 5 replicates each. Broilers were fed maize-soybean meal basal diets following a 2- phase feeding program. Depending on YAWP inclusion level, treatments were no YAWP addition (W0), YAWP at 25 g/kg (W25), YAWP at 50 g/kg (W50) and YAWP at 100 g/kg (W100). Overall body weight gain, feed intake and feed conversion ratio were not affected by YAWP addition. In the ceca, a linear decrease in total bacteria counts and a linear increase in *Lactobacillus* spp. was noted with increasing YAWP dietary level. A linear reduction of *Clostridium* cluster I and *E. coli* species were noted with increasing YAWP dietary level. A linear increase in total volatile fatty acids concentration, acetic acid and butyric acid molar ratios were shown with increasing YAWP level. In conclusion, the addition of YAWP did not affect overall performance, and positively modulated caecal microbiota and metabolic activity of 35-day-old broiler chickens. This research has been co-financed by the European Regional Development Fund of the European Union and Greek national funds through the Operational Program Competitiveness, Entrepreneurship and Innovation, under the call RESEARCH – CREATE – INNOVATE (project code:T2EDK-00783).

Session 63

Theatre 9

A richer gut microbiota is related to better feed efficiency and diet adaptability in laying hensM. Bernard¹, A. Lecoœur¹, J.L. Coville¹, N. Bruneau¹, D. Jardet¹, S. Lagarrigue², F. Calenge¹, G. Pascal³ and T. Zerjal¹¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²INRAE, Institut Agro, UMR PEGASE, 16, le clos, 35590 Saint-Gilles, France, ³GenPhySE, Université de Toulouse, INRAE, ENVT, 24, chemin de Borde-Rouge, Auzerville Tolosane, 31326 Castanet Tolosan, France; maria.bernard@inrae.fr

In the egg industry, feed cost represents the majority of total production costs and breeding efforts are ongoing to improve feed efficiency of laying hens. The gut microbiota is known to play an important role in energy harvest and is likely to affect feed efficiency. In this study, we analysed the composition of caecal microbiota of 31 week old hens by 16S metabarcoding sequencing to characterise its composition, interactions with the host and influence on phenotypes of interest. As an animal model, we used hens of the R+ and R- lines divergently selected for high (low feed efficiency) and low (high feed efficiency) residual feed intake values respectively, that were fed either a commercial wheat-soybean diet (CTR) or a low-energy corn-sunflower diet (LE). Our results show a significant line effect on the microbiota richness and composition with the CTR diet, whereas with the LE diet, the microbiota was primarily affected by the diet change. A line × diet interaction was observed: the high efficient R- line presented a greater microbial richness and a reduced impact of the diet change compared to the low efficient R+ line. Interestingly, common taxonomies and/or predicted functions were highlighted between R+ and CTR diet, and between R- and LE diet, which could suggest that common microbiota mechanisms between feed efficiency and adaptation to nontraditional feedstuffs exist. OTUs of *Actinobacteriota* were more abundant in R+ birds and in the CTR diet, whereas OTUs of *Bacteroidota* were preferentially abundant in R- birds and/or LE diet. At functional level, carbohydrates and fatty acid metabolisms on the one hand, and short-chain fatty acids and amino acids metabolisms, on the other hand, were enriched in birds with low or high feed efficiency, respectively. These results provide insight into the role of the microbiota in laying hen feed efficiency and the impact of diet composition on microbiota.

Gut microbiome variations during the productive lifespan of two high-yielding laying hen strains*C. Roth, J. Seifert, M. Rodehutschord and A. Camarinha-Silva**Hohenheim Center for Livestock Microbiome Research, University of Hohenheim, Emil-Wolff-Str. 10, 70599 Stuttgart, Germany; amelia.silva@uni-hohenheim.de*

Gut microbiota affects nutrient digestion, pathogen inhibition, endocrine activity, and interaction with the gut-associated immune system. In laying hens, previous studies focused on excreta and specific gastrointestinal sections, and analysed single time points in the hen's life and their response to specific conditions. This study aimed to characterize the active gut microbiota of a large cohort of two laying hen strains: Lohmann Brown-classic and Lohmann LSL-classic, during their productive life span. All 100 birds were fed the same diet and offered identical raising conditions within each age period. Digesta from the crop, gizzard, duodenum, ileum, and caeca were collected after 10, 16, 24, 30, and 60 weeks of life to represent the complete productive period. RNA from 500 samples was extracted and analysed by target amplicon sequencing. Phylogenetic analysis of the bacterial sequences was assessed using Mothur, followed by multivariate statistical analysis. A statistical significance was obtained for the breed, gastrointestinal section, age, and the combination of all factors ($P < 0.05$). Depending on the strain, the detected genera differed in abundance within gut sections or productive periods. A significant shift in the active microbiota of both strains was observed with the laying onset transition between weeks 16 and 24. Metagenomic shotgun sequencing was further used to reveal the functional shifts between these weeks. Functional profiling showed differences between the strains besides up- and downregulated functions with the onset of the laying phase. The inositol phosphate metabolism: 5-keto-L-gluconate epimerase (iolO) (K22233) was significantly downregulated in the ileum of LSL hens at week 16 compared to 24. Functions K22231-22233 and the inositol-phosphate transport system substrate-binding protein (inoE) (K17237) were downregulated in the caeca of LB vs LSL hens of week 24. The strain and age impacted gut microbiome dynamics. Even though birds have been offered the same diet and were housed under standardized conditions, it remains unclear if the organism's needs caused microbiome variations during the lifespan or if the microbiome adapted to the host alterations.

Session 63

Theatre 11

A rabbit nutrition hypothesis to prevent digestive problems: 'Feed the fusus coli'*K.H. De Greef and M. Van Der Sluis**Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; karel.degreef@wur.nl*

Rabbits are vegetarian feed-to-food converters, equipped to digest fibrous diets at a high passage rate. As hind gut digesters, their prime nutrient utilisation is dependent on fibre digestion in the caecum. Modern breeding, feeding and production methods have practically treated the rabbit as a semi-monogastric animal: high levels of easily digestible nutrients are fed to enhance growth. Existing work (especially in France) has illustrated the need for adequate levels of fibre (especially ADF, acid detergent fibre) alongside this to prevent diarrhoea. However, nowadays, this appears inadequate to prevent digestive problems. High productive animals may suffer from diarrhoea, subsequent obstipation and related problems. This aberration is seen as a production disease, and is the main reason for antibiotics use for growing rabbits in the meat production sector. We have reviewed, analysed and combined existing views on the mechanism of derailment of the digestive system of the rabbit, focusing on the onset of the problems. This has led to a more integrated view on the cause and onset of the problem. In short, a rabbit-specific selection mechanism (the *fusus coli*) in the colon decides to send digesta from the colon back to the caecum, or to send the digesta further down the gastrointestinal tract for excretion. This selection mechanism is, among other factors such as stress, influenced by particle size (generally non-digested fibre). The hypothesis is that especially the lack of large particles hinders the signal to pass on digesta. This results in a too high rate of sending back digesta to the caecum, derailing the digestive processes as illustrated by overloaded caeca seen in affected rabbits (diseased or dead). Studies are currently being performed to validate this hypothesis: low digestible particles (of any kind) should prevent the 'traffic jam' in the gastrointestinal tract. If this hypothesis is indeed confirmed in practice, it opens up opportunities to better compose feeds that combine high productivity (addressing the rabbit as a monogastric animal) with good digestive health (respecting the rabbit as a fibre converter).

Gut microbiota of growing rabbits fed diets with different fibre and lipid contentsG. Zardinoni¹, P. Stevanato¹, A. Trocino^{1,2}, M. Birolo¹, F. Bordignon¹ and G. Xiccato¹¹University of Padova, Department of Agronomy, Food, Natural resources, Animals and Environment (DAFNAE), Viale dell'Università' 16, 35020 Legnaro, Italy, ²University of Padova, Department of Comparative Biomedicine and Food Science (BCA), Viale dell'Università' 16, 35020 Legnaro, Italy; giulia.zardinoni@phd.unipd.it

Fibre with its different fractions, both insoluble and soluble, is the main dietary component guaranteeing the normal functioning of the rabbit digestive physiology and gut health. Thus, the present study aimed to evaluate the effect of an increase of ADF from 18.1 to 18.8% associated with a decrease in dietary starch from 14.3 to 13.8% and an increase in dietary fat from 2.9 to 3.8% on the microbiota composition of caecal content and hard faeces. To this purpose, 576 crossbred rabbits (Hypharm, Groupe Grimaud, Roussay, France) were weaned at 31 d, assigned to the two dietary treatments, and fed the experimental diets until slaughtering (73 d of age), when hard faeces and caecal contents were sampled from 20 rabbits (10 per diet) in the afternoon (h.15:00-16:00) and analysed using a 16S rDNA multi-amplicon sequencing approach. Firstly, sequencing results showed that the microbial diversity and the bacterial community structure of the hard faeces barely differed from that of the caecal content ($P>0.05$). The overall microbial composition was dominated by the phylum of Firmicutes, the Clostridia and Bacilli classes, followed by Ruminococcaceae and Lachnospiraceae as dominant families. Then, as for the diet effect, no differences in alpha and beta diversity of microbiota were detected in rabbits fed the two diets. However, twelve genera, mostly belonging to the family of Lachnospiraceae, increased (Wald test, $P<0.05$) in rabbits fed the diet with the highest fibre and fat contents. Overall, these findings enhance our understanding about gut microbiota in growing rabbits and indicate that even small changes in fibre and fat of the diet may affect the composition of gut microbiota.

Session 63

Poster 13

Gut microbiota-metabolome response to dietary porcine intestinal mucosa hydrolysate in pigletsS. Segarra¹, A. Middelkoop² and F. Molist²¹R&D Bioiberica S.A.U., Esplugues de Llobregat, 08950, Spain, ²R&D Schothorst Feed Research, NA Lelystad, 8218, the Netherlands; ssegarra@bioiberica.com

In piglets, a healthy gut microbiota contributes to regulating the immune system and enhancing resistance to pathogens. The use of porcine intestinal mucosa hydrolysate (PIMH) as an alternative to other protein sources has been reported to improve performance and profitability in piglets. The present study aimed to assess the effects on gut microbiome and metabolome of incorporating PIMH in the diet in piglets. The trial consisted of two treatment groups ($n=16$ pens/treatment; 6 piglets/pen). Pigs in the negative control (NC) group received a weaner I diet containing 3.5% skimmed milk powder and a weaner II diet containing 2.5% soy protein concentrate. In the PIMH group, these protein sources were replaced by 5% PIMH (Palbio 50RD®, Bioiberica S.A.U.) in weaner I and 2.5% PIMH in weaner II. Diets were iso-energetic and iso-protein and with a similar lactose content. At day 34 post-weaning, ileum content from the last 1.5 m before the cecum was collected from ten pigs (1:1 gender ratio) from each group. Digesta was homogenized and snap-frozen and used for microbiota analysis with 16S ribosomal RNA (rRNA) sequencing as well as metabolomics using ultra-high-performance liquid chromatography coupled with a time-of-flight (UHPLC-TOF). A permutational multivariate analysis of variance (PERMANOVA) was used for microbiota data, and an ANOVA comparison was done for metabolomics. Microbiota alpha- and beta-diversity were not significantly different ($P>0.10$) between study groups, but a significantly decreased ($FDR<0.05$) relative abundance of amplicon sequence variants (ASVs) of opportunistic pathogens from the *Streptococcus* genera was seen with PIMH. Metabolomics showed significantly ($P<0.05$) higher concentrations of spermine (protein-derived biogenic polyamine) and lower amino acid concentrations of N-acetyl-L-methionine and L-glutamine in the PIMH group, which could be related to an antioxidant action, and a positive modulation of metabolism, intestinal barrier and maturation, and protein digestibility. In conclusion, the use of PIMH may improve gut health in piglets through modulation of their gut microbiota and metabolome, which could explain the improvements in performance observed previously.

Effects of probiotics isolated from faeces of fast-growing pigs on growth performance of weaning pigs

Y.H. Choi, Y.J. Min, J.E. Kim, Y.D. Jeong, H.J. Park, C.H. Kim and S.J. Sa

Rural Development Administration, Sinbang 1gil, Seonghwan, 31000 Cheonan, Korea, South; cyh6150@korea.kr

The study aimed to evaluate the effect of *Lactobacillus pentosus*, *Lactobacillus petauri*, *Mitsuokella multacida* isolated from faeces of fast-growing pigs given to weanling piglets. The forced feeding procedure was used for transferring the supplements to weaned pigs stomach. Eighty 25-d-old, female crossbred (L×Y×D) piglets were assigned to two experiments (40 pigs per experiment) with four dietary treatments and 10 replicates. Experiment 1 was included a control (CON; no probiotic), *L. pentosus* (LP; 10^{10} per d), *L. petauri* (LPC; 10^{10} per d), and *M. multacida* (MM; 0.1% of diet). Experiment 2 was based on the dose response to *L. pentosus* including 0, 5×10^9 , 10^{10} , and 5×10^{10} cfu/d for each pig. In experiment 1, the LP treatment led to higher ($P < 0.05$) body weight gain and ADG compared to the CON, while the diarrhoea score was reduced ($P < 0.05$) in the LP, LPC, and MM treatments at day 14 and overall. Villus height in the duodenum was improved ($P < 0.05$) in the MM compared to the CON, and villus height in the ileum was increased ($P < 0.05$) in the MM and LP treatments. The concentrations of acetic acid and butyric acid in the cecum digesta were increased ($P < 0.05$) in the LP, LPC, and MM treatments. The concentrations of acetic acid and total short-chain fatty acids in the faeces were increased ($P < 0.05$) in the LP, LPC, and MM treatments, while a higher ($P < 0.05$) concentration of butyric acid, isobutyric acid, and isovaleric acid in the faeces was observed in pigs fed MM compared to the CON. In experiment 2, supplementation with *L. pentosus* resulted in a linear positive response ($P < 0.05$) in average daily gain (ADG) and gain to feed (G:F) at day 14 and 28. The overall growth performance also showed a positive linear response ($P < 0.05$) to an increase in final body weight, ADG, and G:F, with a quadratic response ($P < 0.05$) of overall G:F to *L. pentosus* supplementation. The diarrhoea score was linearly reduced ($P < 0.05$) at day 14, 28, and overall. In conclusion, dietary supplementation with LP improved intestinal integrity and digesta fermentation, leading to improved growth performance during the critical weaning period for piglets.

Session 63

Poster 15

Effect of butyric acid salts on the palatability of feed for pigletsW. Kozera¹, A. Woźniakowska¹, K. Karpiesiuk¹, A. Okorski¹ and G. Żak²¹University of Warmia and Mazury in Olsztyn, ul. Oczapowskiego 5, 10-719 Olsztyn, Poland, ²National Research Institute of Animal Production, ul. Sarego 2, 31-047 Kraków, Poland; grzegorz.zak@iz.edu.pl

The post-weaning period causes severe stress in piglets, which often manifests as low feed intake and gastrointestinal dysfunction. The negative effects of the weaning period can be counteracted by using organic acids in piglet mixes. Butyric acid salts influence the development of the piglets' intestinal epithelium, as well as a decrease in the number of Clostridium bacteria in the colon, which reduces the incidence of diarrhoea. They also increase piglet immunity. The inclusion of sodium butyrate in the diet of weaned piglets can affect feed palatability, which consequently improves feed intake and increases daily gain. The aim of this study was to investigate the effect of butyric acid salts on feed palatability and growth rate in weaned piglets. The experiment started when the piglets reached the age of 35 days. In the 8-day experiment, 32 piglets (homogenous in terms of weight and sex) were divided into 4 treatment groups (n=8), with 4 replicates per group and 2 piglets per replicate, to determine the effect of sodium butyrate on feed palatability. The animals received one of the four experimental diets according to the 4×4 Latin Square design. The diets were fed to piglets 4 times a day, at 8.00 a.m., 11.00 a.m., 2.00 p.m. and 5.00 p.m., by the single stimulus method, with free access to one of the diets for 20 minutes during each feeding session (*ad libitum* access to water). Feed intake was monitored daily. Piglets were weighed on days 1 and 8. The analysed additives had no effect on feed palatability. Sodium butyrate in the amount of 4,000 mg/kg of feed significantly influenced the final body weight of piglets ($P \leq 0.05$). The highest total body weight gains were observed in all piglets receiving diets supplemented with sodium butyrate and a blend of coated calcium butyrate and sodium butyrate, with no effect on average daily feed intake. The addition of 4,000 mg/kg of sodium butyrate had a more beneficial influence ($P \leq 0.05$) on total body weight gains than the addition of 2,000 mg/kg of coated sodium butyrate.

Synbiotics-glyconutrients enhance growth performance and fatty acid profile in finishing pigsC.B. Lim¹, Q.Q. Zhang¹, S. Biswas¹, J.H. Song¹, O. Munezero¹, J.S. Yoo² and I.H. Kim¹¹Dankook University, Department of Animal Resource and Science, Cheonan, 31116, Korea, South, ²Daehan feed company, 13 Bukseongpo-gil, Jung-gu, Incheon, 22300, Korea, South; coqlsdek@naver.com

Glyconutrients are thought to be beneficial to the body by helping in cell communication. In addition, synbiotics appear to be a promising option for improving immune function. Therefore, we hypothesized that combining synbiotics and glyconutrients could enhance pig nutrient utilization. The experiment utilized 150 pigs (Landrace × Yorkshire × Duroc), initially weighing 58.85 ± 3.30 kg of live body weight (BW) to see how finishing pigs supplemented with synbiotics-glyconutrients (SGN) affected growth performance, nutrient digestibility, gas emission, meat quality, and fatty acid profile. The pigs were matched by BW and sex and randomly assigned to one of three diet treatments: control = Basal diet; TRT1 = Basal diet + SGN 0.15%; TRT2 = Basal diet + SGN 0.30%. The trials were conducted in two phases (weeks 1-5 and weeks 6-10). ADG increased linearly from weeks 6 to 10 in pigs fed a basal diet with SGN ($P=0.016$). Moreover, pigs fed with SGN 0.30% tended to improve the BW at week 10 ($P=0.058$), ADFI, and FCR from weeks 6 to 10 ($P=0.058$, $P=0.068$, respectively). However, the ATTD of DM, N, and GE did not differ between treatments ($P>0.05$). Dietary treatments had no effect on NH_3 , H_2S , methyl mercaptans, acetic acids, and CO_2 emissions. SGN 0.30% inclusion linearly improved cooking loss and drip loss on day 7 ($P=0.025$ and $P=0.019$, respectively). The SGN supplemented group had higher levels of margaric acid (C17:0), omega 3 and 6 fatty acids, and their ratio in both fat and lean tissues. Furthermore, the inclusion of SGN improved palmitoleic acid (C16:1) and linoleic acid (C18:2n6c) levels in fat and lean tissues, respectively. Additionally, SGN 0.3% supplementation improved unsaturated fatty acid (USFA) and monounsaturated fatty acid (MUFA). Thus, supplementing SGN improved growth performance, meat quality, and fatty acid profiles of finishing pigs.

Impact of gut health product on appetite associated hormones using ex vivo porcine intestinal cells

N. Browne and K. Horgan

Alltech, Research, Summerhill Rd, Dunboyne, Co. Meath, A86X006, Ireland; nbrowne@alltech.com

In piglets it is observed that early weaning can lead to poor weight gain due to an underdeveloped gastrointestinal (GI) tract which is unsuitable for efficient absorption of nutrients. Short chain fatty acid (SCFA) butyrate has demonstrated an ability to improve intestinal development by increasing cell proliferation which is vital during this transition period when the small and large intestinal tracts are rapidly growing. The palatability of butyrate makes it difficult for animal consumption which has led to encapsulation with more desirable feed components. Gut health product (GHP), a proprietary mix of yeast, SCFA and Zn proteinate was assessed here to determine its impact on cellular growth, metabolism and appetite associated hormones in ex vivo small intestinal pig cells. Pig intestinal cell densities were enumerated after trypsin, centrifugation, and resuspension in equal volumes. Total protein concentrations determined by Qubit and Hormone secretion of Peptide YY (PYY), and Ghrelin determined by ELISA on cell free media from cultured cells in the presence of (150 ppm) GHP, butyrate or the control. Statistics performed by One-way ANOVA ($n=3$). Intestinal cells had greater cell densities with GHP addition compared to the control ($P \leq 0.05$) and butyrate ($P \leq 0.01$) at 24 h, and a significantly higher cell density at 48 ($P \leq 0.05$) and 72 h ($P \leq 0.01$) over the butyrate treatment. Protein uptake in cells receiving GHP was significantly ($P \leq 0.05$) higher than control cells at 48 and 72 h hours. GHP inclusion resulted in a greater ($P \leq 0.05$) Ghrelin (appetite inducing hormone) release over the control and a numerically greater level than butyrate treated intestinal cells at 48 h. PYY (satiety hormone) was significantly lower ($P \leq 0.05$) than the control following GHP treatment at 72 h. Ghrelin was significantly elevated ($P \leq 0.05$) over the butyrate treated cells at 48 h while PYY was significantly lower ($P \leq 0.05$) for GHP treated cells over the control at 72 h and GHP had the lowest amount of PYY secretion from cells. Higher levels of Ghrelin and lower PYY secretion may drive the uptake of protein in cells receiving GHP. Contributing to the higher cell growth density observed with the inclusion of GHP which may enhance pig performance as observed in previous trials.

Development of antimicrobial peptides against multidrug-resistant enterotoxigenic *Escherichia coli*

W.J. Chen, M.Y.W. Kwok, K.C. Wu, K.F. Hua, Y.H. Yu and Y.H. Cheng

National Ilan University, Department of Biotechnology and Animal Science, No.1, Sec.1, Shennong Rd., 26047, Taiwan; wjchen@niu.edu.tw

Post-weaning diarrhoea due to enterotoxigenic *Escherichia coli* (ETEC) is a common disease of piglets and causes great economic loss for the swine industry. Over the past few decades, decreasing effectiveness of conventional antibiotics has caused serious problems because of the growing emergence of multidrug-resistant (MDR) pathogens. Various studies have indicated that antimicrobial peptides (AMPs) have potential to serve as an alternative to antibiotics owing to rapid killing action and highly selective toxicity. Our previous studies have shown that AMP GW-Q4 and its derivatives possess effective antibacterial activities against the Gram-negative bacteria. Hence, in the current study, we evaluated the antibacterial efficacy of GW-Q4 and its derivatives against MDR ETEC and their minimal inhibition concentration (MIC) values were determined to be around 2–32 µg/ml. Among them, AMP Q4-15a-1 with the second lowest MIC (4 µg/ml) and the highest minimal haemolysis concentration (MHC, 256 µg/ml), thus showing the greatest selectivity (MHC/MIC=64) was selected for further investigations. Moreover, Q4-15a-1 showed dose-dependent bactericidal activity against MDR ETEC in time-kill curve assays. According to the cellular localization and membrane integrity analyses using confocal microscopy, Q4-15a-1 can rapidly interact with the bacterial surface, disrupt the membrane and enter cytosol in less than 30 min. Minimum biofilm eradication concentration (MBEC) of Q4-15a-1 is 4× MIC (16 µg/ml), indicating that Q4-15a-1 is effective against MDR ETEC biofilm. Besides, we established an MDR ETEC infection model with intestinal porcine epithelial cell-1 (IPEC-1). In this infection model, 32 µg/ml Q4-15a-1 can completely inhibit ETEC adhesion onto IPEC-1. Quantitative real-time PCR confirmed the anti-inflammatory ability of Q4-15a-1. Overall, these results suggested that Q4-15a-1 may be a promising antibacterial candidate for treatment of weaned piglets infected by MDR ETEC.

Poster 19

Influences of quercetin inclusion to corn-soybean-gluten meal-based diet on broiler performanceS. Biswas¹, Q.Q. Zhang¹, J.H. Song¹, C.B. Lim¹, I.H. Kim¹ and J.S. Yoo²¹Dankook University, Department of Animal Resource and Science, Cheonan, 31116, Korea, South, ²Daehan feed company, 13 Bukseongpo-gil, Jung-gu, Incheon, 22300, Korea, South; sarbani.dream@gmail.com

Quercetin (prevalent flavonoid) is considered to have antimicrobial and antioxidant properties. This trial was conducted to evaluate the impact of graded doses of quercetin (QS) on growth efficiency, nutrient retention, faecal score, footpad lesion score, tibia ash, and meat quality. In a 32-day feeding test, a total of 576 1-day-old Ross 308 broilers (male) were allocated arbitrarily with an average body weight of 41±0.5 g. The trial had four dietary treatments with eight repetitions of 18 birds per cage and a basal diet incorporating with 0, 0.02, 0.04 and 0.06% of QS. As the QS dosage increased, body weight gain increased linearly ($P=0.069$) on days 9-21 and tended to increase linearly ($P=0.079$) during the overall period. Similarly, feed intake increased ($P=0.009$) linearly with the increasing doses of QS on days 9-21. Likewise, there was a linear improvement in dry matter ($P=0.002$) and energy ($P=0.016$) digestibility after QS administration. Moreover, the inclusion of QS supplement linearly increased ($P=0.011$) tibia ash in broilers. However, the faecal score and footpad lesion score showed no significant outcome ($P>0.05$). By giving broilers a graded amount of QS, the relative organ weight of breast muscle ($P=0.009$) and spleen ($P=0.001$) improved linearly, meat colour lightness increased ($P=0.015$) and redness tended to improve ($P=0.065$) linearly, and drip loss decreased ($P=0.015$) linearly. The inclusion of QS in the graded-level diet led to improvements in growth efficiency, nutrient absorption, meat quality, and tibia ash, which recommended it as a beneficial feed additive for the broiler.

Effects of *Bacillus* species – fermented products on growth performance and gut health in broilers

Y.H. Yu, S.H. Hsiao, Y.H. Cheng, W.J. Chen and K.F. Hua

National Ilan University, Department of Biotechnology and Animal Science, No.1, Sec. 1, Shennong Rd., Yilan City, Yilan County 26047, Taiwan; yuyh@niu.edu.tw

This study was aimed to assess the comparative effects of *Bacillus subtilis*-fermented products (BSFPs) and *Bacillus licheniformis*-fermented products (BLFPs) on the growth performance, intestinal morphology and gene expression, and caecal microbiota and microbial virulence factor gene composition in broilers. A total of 160 one-day-old unsexed Arbor Acres broiler chicks were randomly allocated to 4 treatments, with 8 replicates each and 5 chicks per replicate: C = basal diet, E = basal diet plus 10 mg/kg enramycin, BSFP = basal diet plus BSFPs (1×10^8 colony-forming unit (cfu) *B. subtilis* spore/g of feed), and BLFP = basal diet plus BLFPs (1×10^8 cfu *B. licheniformis* spore/g of feed). One-way analysis of variance with Tukey's honestly significant difference test was used for analysing the statistical differences. The significance was defined as $P \leq 0.05$. BLFP treatment resulted in a higher body weight at 35 days of age ($P \leq 0.01$) and average daily gain at 15 to 35 days ($P \leq 0.05$) and 1 to 35 days ($P \leq 0.05$) of age than did the control and BSFP treatments. The average villus heights in the jejunum of the broilers in the BLFP group were higher than those in the BSFP group ($P \leq 0.05$). *MUC2* mRNA expression levels in the jejunum and cecum of the broilers in the BLFP group were higher than those in the BSFP group ($P \leq 0.05$). Principal coordinate analysis of caecal microbiota and microbial virulence factor gene composition showed distinct clustering among the groups. The abundance of *Lactobacillus crispatus* in the caecal digesta was higher in the BSFP group than those in the C and BLFP groups ($P \leq 0.01$). Microbial virulence factor gene analysis showed that the abundance of *clpC* gene in *Bacteroides* species was lower in the BLFP group than in those the C group ($P \leq 0.05$), whereas the abundance of *clpC* gene in *Faecalibacterium* species was lower in the BSFP group than those in the C and E groups ($P \leq 0.01$). These results demonstrated that BSFP and BLFP treatment exhibit differential effects in improving growth performance, modulating intestinal morphology and gene expression, and regulating caecal microbiota and microbial virulence factor gene composition in broilers.

***Lactobacillus ingluviei* C37 improves gut health in lipopolysaccharide challenged broiler chickens**

S. Khempaka, M. Sirisopapong and S. Okrathok

Suranaree University of Technology, School of Animal Technology and Innovation, Nakhon Ratchasima, 30000, Thailand; khampaka@sut.ac.th

Lactobacillus ingluviei C37 (LIC37) is *Lactobacillus* strains isolated from the caecal content of chickens are safe and possess probiotic properties including tolerance to acid and bile salt, antibacterial activity, adhesion activity, antibiotic resistance and cholesterol removal. However, few studies have examined the probiotic properties of *L. ingluviei* on gut health in chickens. Therefore, this study aimed to investigate the effects of LIC37 on gut health through intestinal barrier gene expression and microbial populations in broilers induced with lipopolysaccharide (LPS). Four treatments consisted of: (1) control (orally administered PBS); (2) probiotic LIC37 10^8 cfu/bird/day administered orally; (3) probiotic LIC37 10^9 cfu/bird/day administered orally; and (4) negative control (orally administered PBS). A total of forty, one-day-old male chicks (Ross 308) were distributed to 4 treatments. At 14 days, treatment 2, 3 and 4 chickens were injected intraperitoneally with *Escherichia coli* O55:B5 LPS (1 mg/kg body weight), and the control was injected with sterile PBS. After 24 hours of LPS injections, the chickens were randomly selected in each group, euthanized by exsanguination and their caecal content was immediately collected for analysis of the caecal microbial population. Intestinal mucosa was collected for intestinal tight junction proteins measurement. It was found that LIC37 can increase the population of LAB and *Bifidobacterium* spp. while reducing *Enterobacteria* spp. and *E. coli* in the caecal content of chickens ($P < 0.05$). LPS-challenged LIC37 group showed a significant increase of intestinal TJ proteins and *MUC2* mRNA ($P < 0.05$). The results indicate that LIC37 can improve gut health during LPS-mediated immunological challenge states.

Effects of different probiotics on laying performances, egg quality and gut health in laying hensF. Barbe¹, L. Blanc², A. Sacy¹ and E. Chevaux¹¹Lallemand SAS, 19 rue des briquetiers, 31702, France, ²Aveyron Labo, 195 rue des artisans, 12031 Rodez cedex, France; echevaux@lallemand.com

Probiotic supplementation in layers is already well documented to improve laying performance, while maintaining optimal egg quality and robust general health. The current field interrogation is the existence of differences between probiotics technologies in a context of long cycle production where the challenge of maintaining good performances and optimal shell quality is sought. The aim of this trial was to benchmark 2 commercial live bacteria probiotics on laying performances, faeces quality, egg quality and general health of old laying hens (71 wks old) against a negative control (NC): *Pediococcus acidilactici* I-4622 (PA) at 10^{12} cfu/ton of feed or *Bacillus subtilis* C-3102 (BS) at 3×10^{11} cfu/ton of feed (as per the producers' recommended dose). 104 individually housed Lohmann Tradition laying hens were involved in an 8-week trial where the first 2 weeks were set as adaptation and reference period without any supplementation. Overall, the 2 probiotics improved several parameters related to laying performances, egg quality and hen's general health, with higher beneficial effects observed for some parameters with PA: the comparison intra-group (before/after supplementation) showed a persistence of the laying rate for PA (+4.2%; NS) compared to a significant reduction for the BS hens (-4.1%; $P=0.013$). Eggs weight was significantly improved for both probiotic groups (PA: +2.1%, $P<0.001$; BS: +1.2%, $P<0.01$). FCR was not altered with PA whereas significantly degraded with BS (NC: 3.3; PA: 2.6; BS: 3.1. Proportion of defective eggs was significantly lower with probiotics (NC: 7.9%; PA: 1.8%; BS: 3.8%; $P<0.001$). Concerning general health, faeces scorings (from 1 (firm faeces) to 4 (watery faeces)) were improved with both probiotics (NC: 2.0; PA: 1.7; BS: 1.91; $P=0.058$), suggesting a positive gut microbiota modulation. This trial also showed that every probiotic does not display the same effect looking at the 'lactobacillus/coliforms' ratio in faeces with a significantly higher ratio for PA (1.459; $P=0.032$) compared to BS (1.255). In conclusion, probiotics solutions perfectly fit the need of performance maintenance in extended production cycle, however the expected effects may vary according to the probiotic strains.

Session 63

Poster 23

Simple methodology to evaluate faeces quality on farm and effect of *S. boulardii* on faecal scoringA. Sacy¹, F. Barbé¹, S. Poulain², P. Belloir³, C. Paes³ and E. Chevaux¹¹Lallemand SAS, 31702, Blagnac, France, ²Aveyron Labo, 12000, Rodez, France, ³Ecole d'Ingénieurs de Purpan, 31076, Toulouse, France; echevaux@lallemand.com

Intestinal health is currently widely investigated in poultry: preservation of intestinal barrier is recognized as a major pillar to prevent pathogenic translocation and mature and healthy villi are important components of feed efficiency. However, investigation of intestinal health often required invasive or expensive analyses. Faecal condition can provide an easy insight into how a diet is being digested by the bird and the state of gastrointestinal health. This current study aimed at describing a simple scale to evaluate faeces consistency on farm. A 4-score scale was created: 1: well-formed faeces, firm; 2: softer, more rounded; 3: soft, mushy and losing shape; 4: watery. For the different scores, faeces were analysed for dry matter. There was a significant correlation between the 2 factors (humidity in faeces = $2.97 \times \text{faecal scoring} + 73.14$; $n=48$; $R^2=0.57$). Probiotics are an accepted solution to improve intestinal health and faeces quality is often described as a good visible sign of their effects. The live yeast *Saccharomyces boulardii* CNCM I-1079 (SB) was tested in 2 studies for faeces consistency against a negative control (NC). The first study was done with 96 Bovans GoldLine layers. Faeces scoring and dry matter were determined after 14 weeks of supplementation and showed a significant improvement of both criteria: NC: 2.54 vs SB: 2.04 ($P<0.001$) and NC: 19.01 vs SB: 21.73% ($P<0.001$), respectively, with firmer faeces for SB group. The absence of time by treatment interaction in the first trial indicates a strong and consistent effect of the probiotic on digestive comfort of the hens, from the first sampling starting 4 weeks after the supplementation. The second trial involved 204 Ross PM3 broilers for 35 days. Faecal dry matter was increased with SB (26.89% vs NC: 25.84%; $P<0.05$). Based on dry matter, faeces were significantly drier with SB compared to control group at the end of both trials. This effect has potential direct consequences on litter quality and the reduction of pododermatitis risk. Other investigations on birds' welfare and microbiota analysis on litter would be interesting to measure to confirm these benefits.

A comparison of yeast gut health products ability to limit attachment of *Salmonella* to IPEC-j2 cells

N. Browne, A. McCormack and K. Horgan

Alltech, Research, Summerhill Rd, Dunboyne, Co. Meath, A86X006, Ireland; nbrowne@alltech.com

Salmonella is a leading cause of foodborne contamination for human consumers. This has raised concerns amongst governing bodies for a means to limit the establishment of *Salmonella* strains such as *S. Heidelberg*, *S. Enteritidis* and *S. Typhimurium* in pigs. *Salmonella* contamination of meat can lead to food spoilage and the risk of cross contamination of these harmful strains into the food chain. The supplementation of a yeast cell wall product composed of a mannan rich fraction (MRF), and other yeast cell wall products were assessed for their ability to interfere with the attachment of *Salmonella* strains to IPEC-j2 cells. Adhesion of *S. Heidelberg*, *S. Enteritidis* and *S. Typhimurium* to the surface of IPEC intestinal cells was carried out at a 500:1 ratio in the presence of *Salmonella* strains alone or with MRF, Product A, B or C for 1 hour at 37 °C. Unattached bacteria were washed away, IPEC cells were lysed and diluted prior to plating on MacConkey's agar. Bacterial colonies were enumerated after incubating over night at 37 °C. TNF α (PRFI00158), IL-1 β (SBR5185) and IL-8 (SBR51590) secretion were measured on cell free media by ELISA. Three independent biological replicates were performed, with One-way ANOVA used to test for statistical significance, * $P \leq 0.05$, unless stated otherwise. Attachment of *S. Heidelberg*, *S. Enteritidis* and *S. Typhimurium* to IPEC-j2 cells was consistently impaired with addition of MRF while product A resulted in a greater attachment of *Salmonella* strains compared to the control. Product B and C demonstrated a reduction in attachment by the three strains of *Salmonella* compared to the positive control though higher than with MRF addition. MRF treatment resulted in lower levels of inflammatory markers IL-1 β , IL-8 and TNF α in both *S. Enteritidis* and *S. Heidelberg* challenged intestinal cells compared to the control, and lower IL-8 and TNF α following *S. Typhimurium* challenge. MRF and product B and C impaired the attachment of three *Salmonella* strains to IPEC-j2 cells that led to marked reductions in inflammatory markers. MRF and to a lesser extent products B and C may offer a means to limit the abundance of foodborne strains of *Salmonella* found on pig intestinal cells.

Session 63

Poster 25

Butyric acid and *Bacillus subtilis* 29784 improve cumulatively the intestinal barrier

A. Mellouk, D. Prévéraud, T. Goossens, O. Lemâle, E. Pinloche and J. Consuegra

Adisseo, Research in Nutrition, 8 route noire, 03600 Malicorne, France; amine.mellouk@adisseo.com

We have previously reported the beneficial effects of probiotic *Bacillus subtilis* strain 29784 (BS) on gut integrity and acute inflammation. Butyric acid is a short-chain fatty acid known as primary source of energy for colonocytes and enterocytes that improves gut integrity and maturity. Here we aim to study whether butyric acid and BS have synergistic effects on gut epithelial tight junctions and inflammation under inflammatory stress. Tight junction strength was measured *in vitro* through the transepithelial electrical resistance (TEER) in human derived enterocytes Caco-2 cells. The initial TEER of Caco-2 (753 Ohm/cm²) significantly increased after a preincubation with sodium butyrate or BS reaching 866 and 1,162 Ohm/cm², respectively ($P < 0.01$). When exposed to IL-1, IFN- α and IFN- γ proinflammatory cytokines, Caco-2 TEER decreases from 709 to 594 Ohm/cm². The preincubation with sodium butyrate (2 mM) or BS (2.5×10^5 cfu/well) were able to restore or enhance their TEER (693 and 1,113 Ohm/cm², respectively, $P < 0.01$). Interestingly, the simultaneous incubation with sodium butyrate and BS significantly amplified Caco-2 TEER (1,193 Ohm/cm² in stressful 1,259 Ohm/cm² in normal conditions) showing an additional effect on epithelial cells tight junctions. The Caco-2 treatment with the inflammatory cytokines cocktail induces IL-6 and IL-8 secretion (3.2 and 90 ng/ml respectively). Treatments with butyrate or BS significantly reduced the secretions of IL-6 and IL-8 with a maximal effect in presence of BS (0.3 and 27 ng/ml respectively, $P < 0.01$). The anti-inflammatory effects of butyrate and BS was not cumulative. Finally, multiplex ELISA allowed to confirm our result on inflammatory cytokines and to identify other significantly modulated biomarkers by butyric acid and/or BS like IL-18, HSP60 and Fabp3 known to be involved in inflammatory process, stress response and metabolism. In summary, our data show that the probiotic BS29784 and butyric acid cumulatively improve gut integrity by strengthening the epithelial enterocytes tight junctions in normal and stressful conditions. Treatment with either BS29784 or butyric acid can decrease acute inflammatory factors in the gut and improve the resilience of animals under stressful conditions.

Safety of BSF larvae reared on substrates which are spiked or naturally contaminated with aflatoxins

K. Niermans^{1,2}, E.F. Hoek- Van Den Hil¹, N. Meijer¹, S.P. Salari³, M. Gold⁴, H.J. Van Der Fels-Klerx¹ and J.J.A. Van Loon²

¹Wageningen Food Safety Research, Akkermaalsbos 2, 6708 WB Wageningen, the Netherlands, ²Wageningen University, Laboratory of Entomology, Droevendaalsesteeg 1, 6708 PB Wageningen, the Netherlands, ³InsectoCycle, Bronland 10, 6708 WH Wageningen, the Netherlands, ⁴ETH Zurich, Sustainable Food Processing, Schmelzbergstrasse 9, 8092 Zurich, Switzerland; kelly.niermans@wur.nl

Aflatoxins are contaminants of agricultural crops in many regions around the world and innovative aflatoxin management strategies are needed. Previous research showed that larvae of the black soldier fly (BSFL) could provide such an opportunity as exposure to aflatoxin B1 (AFB1) did not affect growth or survival, and accumulation did not occur. In the current study, BSFL were exposed to substrates spiked or naturally contaminated with aflatoxins. Spiking was performed with either regular or isotopically labelled aflatoxin B1 (AFB1) at the maximum limit (ML) concentration set for feed materials by the European Commission (20 µg/kg). Additionally, BSFL were exposed to two types of substrates naturally contaminated with aflatoxins, peanut press cake and maize. Concentrations of the aflatoxins or known metabolites were determined by an LC-MS/MS-based method and were examined in the feed offered, the larvae and residual substrate material. Additionally, for the spiked diet, tracking of the isotopic label via HRMS analyses was performed with the aim to detect novel metabolites. Data obtained for growth, survival, and accumulation were in accordance with previously conducted studies, and, when spiked, no isotopic label was found back in unknown compounds. The molar mass balance of AFB1 revealed a missing fraction of 38% when spiked whereas a full mass balance was obtained for natural contamination. Formation of the AFB1 metabolite AFP1 was observed in all situations. Overall, results obtained from feeding studies in which the substrate was spiked may not be fully representative for when naturally contaminated side-streams are used. However, transfer of AFB1 from the feed substrate into the BSFL is limited/absent, and provides a promising outlook for the safety of rearing BSFL with the purpose of further using them as feed.

Theatre 2

Transfer of aflatoxin, lead and cadmium from larvae reared on contaminated substrate to laying hens

M. Heuel^{1,2}, M. Kreuzer², I.D.M. Gangnat^{2,3}, E. Frossard², C. Zurbrugg⁴, J. Egger⁴, B. Dortmans⁴, M. Gold^{4,5}, A. Mathys⁵, J. Jaster-Keller⁶, S. Weigel⁶, C. Sandrock⁷ and M. Terranova⁸

¹Agridea, Eschikon 28, 8315 Lindau, Switzerland, ²ETH Zurich, Institute of Agricultural Sciences, Eschikon 27, 8315 Lindau, Switzerland, ³HAFL, Länggasse 85, 3052 Zollikofen, Switzerland, ⁴Eawag, Department Sanitation, Water and Solid Waste for Development, Überlandstr. 133, 8600 Dübendorf, Switzerland, ⁵ETH Zurich, Laboratory of Sustainable Food Processing, Schmelzbergstr. 9, 8092 Zürich, Switzerland, ⁶German Federal Institute for Risk Assessment BfR, Max-Dohrn-Str. 8-10, 10589 Berlin, Germany, ⁷FiBL, Livestock Sciences, Ackerstr. 113, 5070 Frick, Switzerland, ⁸ETH Zurich, AgroVet-Strickhof, Eschikon 27, 8315 Lindau, Switzerland; melissa-terranova@ethz.ch

The use of low-grade substrates can improve the sustainability of insect-based feed production but also poses food safety risks. These include mycotoxins and heavy metals that may be present in substrates for insects. Thereby they might pass the entire production chain and lead to contaminated foods. We studied the transfer of three contaminants to black soldier fly larvae (BSFL) as well as eggs and poultry meat. Four poultry diets were formulated including four partially defatted BSFL meals (200 g/kg diet) produced at two different facilities. In Indonesia, BSFL were reared on not EU-approved meat-containing food waste, either non-spiked or spiked with environmentally relevant concentrations of Cd (1.9 mg/kg) and Pb (19 mg/kg) or aflatoxin B1 (1.5 mg/kg). As an additional control, in Switzerland, BSFL were reared on EU-approved substrates. Nine late-laying hens per treatment were fed the experimental diets for 4 weeks. Only the diet including BSFL reared on Cd contaminated substrate exceeded the EU-threshold for Cd for complete feed (1.7 vs 0.5 mg/kg). No diet affected laying performance or egg quality. Feeding the heavy-metal contaminated diet doubled Cd concentrations in breast meat and elevated Cd concentrations in kidneys and liver compared to the control. However, all eggs, meat and tissues (except kidneys) ranged below permitted limits for food. Our results show that, under certain conditions, even contaminated material can provide a suitable substrate to produce BSFL for use as feeds for poultry.

Determination of minimal nutrient requirements of *Tenebrio molitor* larvaeB. Tamim^{1,2}, T. Parr¹, J. Brameld¹ and A. Salter¹¹University of Nottingham, Sutton Bonington, School of Biosciences, LE12 5RD, United Kingdom, ²King Abdulaziz University, Faculty of Science, Biochemistry Department, 21589, Saudi Arabia; alybt1@nottingham.ac.uk

Tenebrio molitor larvae (yellow mealworms, MW) are often fed on the milling by-product, wheat bran (WB). However, some studies have suggested that they may be able to grow on waste materials, such as polystyrene. The aim of the study was to determine the minimal nutrient requirements of MW. There were six diet groups for the 24-days-trial: 100% wheat bran (WB); 85% cellulose, 15% casein (C+P); 85% cellulose, 15% casein, minerals/vitamins premix (C+P+MV); 85% cellulose, 15% casein, 5% fatty acid (C+P+FA); 85% cellulose, 15% casein, minerals/vitamins premix, 5% fatty acid (C+P+MV+FA); 70% cellulose, 15% casein, 15% glucose, minerals/vitamins premix, 5% fatty acid (C+P+G+MV+FA). MW were divided into 4 replicate containers per diet group, with 250 MW per container. MW were housed at 27°C and 60% humidity and food replenished every 10 days. Dead or pupated MW were removed and weights were determined every 3 to 4 days. Data were analysed by 2- or 1-way ANOVA (Genstat 21st edition). There was a significant time × diet interaction for average individual MW body weight ($P < 0.001$). Overall, MW fed WB achieved the greatest final body weight, while those fed diets not supplemented with MV failed to grow. Of the remaining groups, those with all of the added macronutrients (C+P+G+MV+FA) showed the highest final body weight, though this was still 17% less than those fed WB ($P < 0.05$). However, mealworms fed WB showed the highest level of pupation ($P < 0.001$), with 59% pupating by the end of the trial (compared to 30% in the C+P+G+MV+FA group). As a result, when considered on the basis of the weight of live MW remaining/ plate, the highest values were actually seen in the C+P+G+MV+FA group, with the total weight being 61% higher than in WB fed larvae. The data shows that MW have an absolute requirement of, at least some, vitamins and minerals. It is also shown that growth can be enhanced by the addition of lipids and carbohydrates. However, larvae fed on the 'complete' synthetic diet still do not pupate at the same rate as those fed on WB. The reasons for this remain to be established. These results cast doubt on whether MW can be reared on minimal substrates, such as polystyrene.

Session 64

Theatre 4

FLAgship demonstration of industrial scale production of nutrient resources from mealworms

W. Kihanguila

Ynsect, 207 Rue de Bercy, 75012 Paris, France; whitley.kihanguila@ynsect.com

The FARMYNG project, co-funded within the Horizon 2020 Public-Private Partnership Bio-Based Industries Joint Undertaking framework (topic BBI.2018.F2 – 'Large-scale production of proteins for food and feed applications from alternative, sustainable sources') aims to establish the largest global fully-automated flagship industrial plant to produce premium proteins from insects (*Tenebrio molitor*) for animal nutrition. The world faces a major challenge with the sharp increase in demand for meat and fish by 2050, to which current modes of production, whether through agriculture, aquaculture or fisheries, cannot be sustained. An innovative solution to this predicted shortage of resources, especially protein, lies in insect production and processing which can provide a serious response. However, up to date, no industrial scale production of insect-derived products has been realized. Coordinated by Ynsect, the FARMYNG project has the ambition to develop, on an industrial and automated scale, the breeding and transformation of insects for the production of ingredients, with the strong participation of 19 key actors all along the value chain, from the feedstock supply to the final insect transformation. The FARMYNG project will demonstrate a large-scale, first-of-its-kind bio-based value chain producing sustainable, safe and premium feed products from an innovative origin: the *T. molitor* insect (mealworm). The plant developed for FARMYNG will exploit the physiological capabilities of mealworms physiology to efficiently convert vegetal by-products in mealworm biomass and will transform those mealworms into sustainable proteins and lipids for fish feed and pet food end markets. In parallel, manure will be recovered for soil fertilization applications. The project, responding to the increasing worldwide proteins demand, will transfer the technology from a demo plant to the Industrial Flagship Plant able to produce almost 1,500 tons of proteins and 400 tons of oil per month, reaching production rate that has never been achieved by any other insect-protein production plant in the world.

Tailored vitamins and minerals premix for *Tenebrio molitor* farmingE. Barbier¹, V. Gerfault¹, T. Lefebvre², F. Peyrichou², C. Ricciardi² and N. Tanrattana¹¹MG2MIX, R&D, ZA La Basse Haye, 35220 Chateaubourg, France, ²YNSECT, R&D Biotech, 1 Rue Pierre Fontaine, 91000 Évry-Courcouronnes, France; n.tanrattana@mg2mix.fr

Premixes are complex mixtures of vitamins, minerals, and trace elements incorporated at low levels in the compound feed. These mandatory micro-nutrients permit to meet the nutritional needs of animals, and to improve the efficiency of a diet. A deficit in even one vitamin can lead to decrease the rearing performances in the main animal productions. The literature about the vitamins and minerals requirements in *Tenebrio molitor* (TM) is limited but existing which is notable for a farmed insect. It dates from 50's-70's, mainly with the pioneer works of Fraenkel and Leclercq, then has not been investigated further since. The objective of this study is therefore to consolidate the understanding of the TM's micronutritional requirements, to then formulate a TM-specific premixes as a supplement of its diet. In that way, an experimental design was performed based on 10 premixes of different levels of vitamins, trace-elements and minerals, and regarding the optimization of both physiological and economical performances of TM production. This study focused on the larval stage in the exponential phase of the growth curve. In order to do this, the micronutrients were grouped. The three investigated groups were the following: Core group (consisting of graded levels of B-group vitamins, considered mandatory), Accessory Vitamins (A, D3, E, K3), and Trace-elements (S, Cu, Mn, Se, I). The results showed that the Core group composition has a significative effect on the feed conversion ratio, whereas none among the Accessory Vitamins and the Trace elements groups showed a significant effect on the rearing performances. Besides, high contents of Mg seem to have a significative detrimental effect on the rearing performances. This is in contradiction with studies on other species where the inclusion of Mg increased animal performances by improving the anti-oxidant status linked to the catalase activity. Thanks to these key information, Ynsect and MG2MIX have thus succeeded in designing a new tailored premix for mealworm farming, increasing the performances of conversion by 13%, and finally achieving a world premiere in the industry of insects for feed and food.

Session 64

Theatre 6

***Tenebrio molitor* genomics revealed limited molecular diversity among available populations**L. Panunzi¹, E. Eleftheriou², B. Vacherie³, K. Labadie³, T. Lefebvre⁴ and M.A. Madoui¹¹), Institut François Jacob, Commissariat à l'Energie Atomique et aux Energies Alternatives (CEA), 18 Rte du Panorama, 92260 Fontenay aux Roses, France, ²Génomique Métabolique, Genoscope, Institut François Jacob, Commissariat à l'Energie Atomique (CEA), 2 rue Gaston Crémieux, 91000 Evry, France, ³Genoscope, Institut de biologie François Jacob, CEA, Université Paris-Saclay, 2 rue Gaston Crémieux, 91000 Evry, France, ⁴Ynsect, 1 Rue Pierre Fontaine, 91000 Evry, France; mohammedmain.madoui@cea.fr

Tenebrio molitor is now a promising species for insect farming to produce high protein products with low environmental impact. However, the molecular diversity and the genetic structure in available *T. molitor* populations are understudied. To identify possible sources of molecular diversity that may help future breeding programs, we analysed the genomic structure of 18 populations from 12 countries using Illumina pool-seq data. More than 4 millions SNPs were selected to compute allele frequencies, then multivariate and pairwise F_{ST} analyses were used to estimate the genetic distances between the 18 *T. molitor* populations. Our results showed low to very low genetic distance between 16 *T. molitor* populations. Two very distant populations, one wild population sampled in Serbia and one from Germany presented very distinct genomic structure. These results suggest that more populations should be sampled to increase the molecular diversity that may help future breeding programs. A specific attention should be made on the sampling of wild populations that have more chance to present higher molecular diversity than laboratory or producer's populations. Also, further investigations will use the data generated by the current study to focus on the detection of loci under natural selection.

Assessing the quality of insect-derived products: methods and findings from the FARMYNG projectS. Gofflot¹, A. Pissard¹, F. Debode¹, A.C. Laplaize², B. Lorrette³ and J.F. Morin²¹Walloon Agricultural Research Centre (CRA-W), chaussée de Namur, 24, 5030 Gembloux, Belgium, ²Eurofins Food & Feed France (EAF), Rue Pierre Adolphe Bobierre, 44300 Nantes, France, ³Ynsect, 1 Rue Pierre Fontaine, 91000 Évry-Courcouronnes, France; jeanfrancois.morin@ftfr.eurofins.com

Insects can serve as an alternative source of protein in the current economic and environmental context of European livestock. Several insect rearing industries have emerged in the EU to produce insect meals. The FARMYNG project (BBI-H2020, 2019-2024) aims to develop methods for quality testing of insect-derived products. Quality testing is critical for assessing the insect meals' nutritional value, and it's important to have tools for rapid characterization of insects or insect meals. The primary benefit of insect meals is their high protein content, but caution is necessary when estimating this parameter because the exoskeleton of insects is made of chitin, which contains nitrogen that could be erroneously included in the protein content estimation. Within FARMYNG, two alternative methods to the one used by the insect company for chitin determination were tested, the ADF-ADL and cellulose methods. It was concluded that the Ynsect method, which is more a lab-scale chitin extraction, is likely the most accurate method for chitin determination. However, it is time-consuming (4-5 days) and must be used for precise chitin determination. Alternative methods such as ADF-ADL (2-3 days) or the Cellulose method (1.5 day) could be used for a rapid estimation of chitin content. The analysis time can be significantly reduced with the development of Near Infra-Red (NIR) approaches and appropriate models. NIR also has the potential to predict other parameters related to the quality of insect-derived products. Two approaches were followed: the 'specific' approach, which was only based on insect products collected during the FarmYng project, and the 'global' approach, which included other animal proteins in the database to increase variability in the values. Both approaches showed similar performance. It can be concluded that NIR coupled methods are a valuable tool for predicting humidity, protein, fat, cellulose, and chitin content with relatively low prediction errors.

Session 64

Theatre 8

Authentication of insect-derived products: methods and findings from the FARMYNG projectB. Dubois¹, A. Marien¹, S. Guillot², J.-F. Morin², B. Lorrette³ and F. Debode¹¹CRA-W, chaussée de Charleroi, 234, 5030 Gembloux, Belgium, ²EAF, rue P.A. Bobierre-BP42301, 44323 Nantes, France, ³Ynsect, rue Pierre Fontaine, 1, 91000 Evry, France; f.debode@cra.wallonie.be

Eight insect species are currently authorized by regulation in the European Union as feed for aquaculture, pigs, and poultry. Authenticating insect species is necessary to protect producers and users. When aiming at insect species identification, a morphological examination is not adapted as insects are processed into meals. Genomic methods were then considered. Real-time PCR has proven to be effective in detecting insect species, and methods have been developed and published for *Tenebrio molitor*, *Hermetia illucens*, and *Alphitobius diaperinus*. Methods for *Acheta domesticus*, *Gryllus assimilis*, and *Bombyx mori* are also ready. The method validation is based on performance criteria recommended in international guidelines as specificity, sensitivity, applicability and robustness. It was observed that some commercially available insect species were mislabelled, as *A. laevigatus* instead of *A. diaperinus*. However, real-time PCR is limited to detecting only the targeted species and does not allow for an untargeted approach to identify a mixture of different insect species with potentially contaminating insect species. To address this, we used metabarcoding approaches based on high-throughput sequencing. To select the most appropriate barcodes for this purpose, we designed, compared and tested 34 barcodes based on 12S, 16S, COI, COII, CytB, 18S, and 28S on mock communities, which are artificial samples composed of DNA from multiple species mixed in known proportions, here consisting of 10 insect species. Qualitatively, several primer pairs were found to be effective in detecting all insect species. However, in terms of quantitative analysis, significant differences were observed among the different targets, and none of them could accurately detect proportions of 10% for every species. To analyse the insect composition of various samples, a QIIME2 bioinformatics pipeline was also developed. Multiple datasets were processed using this pipeline to validate its efficiency. The bioinformatics treatment was adapted to handle information from both classical Illumina and Oxford Nanopore technologies.

More than an organic fertilizer: mealworm frass as a substitute to conventional fertilizers

E. Bohuon¹, D. Houben², G. Daoulas¹, M.-P. Faucon² and A.-M. Dulaurent²

¹Ynsect, 1 rue Pierre Fontaine, 91000, France, ²UniLaSalle, AGHYLE, 19 rue Pierre Waguet, 60026, France; emilien.bohuon@ynsect.com

With the rapid growth of the insect production sector, frass (insect excreta) has the ability and capacity to reduce our reliance on conventional fertilizers and improve our sustainability. The main objectives of this study were to investigate mealworm (*Tenebrio molitor* L.) frass (MF) potential to sustain crops needs, improve soil life/quality and reduce our environmental footprint. Its well-balanced nutrient composition (NPK ratio 4-3-2) and its quick mineralization makes MF suitable to be applied on any kind of crop and can be as effective as a conventional fertilizer. Analysis of the MF surface also revealed an even distribution of P, K and Ca within the organic matter which implies an homogeneous soil nutrient distribution after mealworm frass application. These findings suggest a very good MF potential to be used as substitute to conventional fertilizers. Unlike conventional fertilizers, a high organic matter content in MF (around 80%) and composition has the ability to increase soil microbial activity and maintain soil functional diversity. Studies also revealed a synergetic effect between MF and earthworms³ which improves plants capacity to uptake MF nutrients when earthworms are present. Moreover, after MF application, water soluble P is five times lower compared to conventional fertilizers which prevent P loss and sorption improving the P use efficiency. Thus, MF seems to be a better asset to maintain or even increase soil quality and micro/macro organisms biodiversity. Given its capacity to capture carbon into the soil and to reduce agriculture environmental footprint, MF is promising fertilizer. Life cycle assessment revealed that the use of MF as a substitute to conventional fertilizer can significantly reduce crop production environmental footprint (Internal Ynsect source). More than an organic fertilizer, MF has a great potential to stimulate soil life, reduce the use of conventional fertilizer and improve environmental footprint. Considering the exponential or rapid growth of the insect industry, frass will become a commonly used organic fertilizer which has a great potential to ensure a more sustainable agriculture.

Session 64

Theatre 10

The environmental life cycle assessment of Ynsect insect based proteins

K. Hsu¹, A. Eiperle¹ and M. Jouy²

¹Quantis, Badenerstrasse 141, 8004 Zürich, Switzerland, ²Ynsect, 207, rue de Bercy, 75012 Paris, France; karl.hsu@quantis-intl.com

In order to investigate the environmental impacts caused by Ynsect's insect-based protein products, an environmental Life Cycle Assessment (eLCA) will be performed. The objectives of this eLCA is to show the environmental impact across Ynsect's products (main products and by-products) using a number of indicators, such as climate change, land use, water use, and fossil resource use, over the entire value chain for the reference year 2027 due to the production plant currently being constructed. Data was collected for their products (YnMeal, YnFrass, and three by-products) in order to calculate their eLCA. The environmental impact (for all indicators) is expected to be concentrated on the main products YnMeal and YnFrass compared to the by-products, as an economic allocation approach will be used. Further work post eLCA will be carried out in order to compare the impact of using Ynsect products within fertilisers, pet feed, and aqua feed as a replacement to conventional ingredients.

Insects' nutrients – the Animal Frontiers special issueT. Veldkamp¹ and L. Gasco²¹Wageningen University & Research, Wageningen Livestock Research, De Elst 1, 6700 AH Wageningen, the Netherlands,²University of Turin, Department of Agricultural, Forest and Food Sciences, Largo P. Braccini 2, 10095 Grugliasco, Italy; teun.veldkamp@wur.nl

With a growing world population and rising prosperity, the demand for animal-derived product is increasing. To meet this increasing demand, the global feed production has to increase, and new protein sources are being sought worldwide. These proteins must have a good nutritional value and must be produced sustainably. Insects can be part of the solution and the last decade has seen a growing interest in using insects as a sustainable and nutritious source of raw material for animal feed. Insects are high in protein and other essential nutrients and are part of the natural diet of many animal species. In perfect agreement with the circular economy principles, insects can be grown on organic waste, reducing the environmental impact of food waste and converting residual products into high-quality nutrients. The main aim of the special issue of Animal Frontiers is to provide an overview of the development of insects in the global food chain. This special issue tackle different aspects. How these insects should be reared and fed and which is the status of the legislation in the different countries. How to processed insects into protein and lipids and what is the impact of the use of these insect-derived products in animal feed? How to guarantee the safety in the food chain and how sustainable it is to include insects as an important link in the food chain.

Session 65

Theatre 1

Time-course change in lamb composition and reflectance properties: implications for authenticationL. Rey-Cadilhac¹, D. Andueza¹, A. Prunier² and S. Prache¹¹UCA, INRAE, VetAgro Sup, UMR Herbivores, 63122 St-Genès-Champanelle, France, ²INRAE, Institut Agro, UMR PEGASE, 35590 St-Gilles, France; lucille.rey-cadilhac@inrae.fr

Differences in the chemical composition of meat from lambs fed contrasted diets, for example pasture vs a concentrate-based diet indoors, are well known. They are the basis of authentication methods to discriminate between pasture-fed and concentrate-fed lamb meat. However, the question of the timing of appearance of markers of pasture-feeding in lamb meat relative to the start of pasture-feeding is not known. The objective of the present study was therefore to study the kinetics of change in lamb meat composition and to determine whether it was possible to discriminate between different grazing durations in order to authenticate lamb meat production conditions. Four groups of 55 Romane lambs were used: L0, concentrate-fed lambs, no grazing; L21, L42 and L63, with lambs grazing alfalfa for 21, 42 and 63 days before slaughter, respectively. At slaughter, measurements of the commercial and sensory qualities of the carcass and meat were performed, as well as spectral analysis of two fat tissues (perirenal and dorsal fat, PF and DF) and of the longissimus dorsi (LD) muscle using visible and infrared spectroscopy. Regarding authentication purposes: (1) PF skatole concentration (skatole is a compound both responsible for off-flavour and proposed as a marker of grass feeding in some publications) did not allow for a sufficiently reliable classification of pasture-fed lambs vs concentrate-fed lambs; (2) the combination of PF skatole concentration and an indicator of PF carotenoid concentration, using a decision tree, enabled to correctly discriminate L0 lambs from the pasture-fed (L21, L42, L63) lambs, but not to authenticate the duration of pasture-finishing; (3) discriminant analysis on the visible spectrum of PF or DF also allowed to discriminate L0 lambs from the pasture-fed (L21, L42, L63) lambs, but not to authenticate the duration of pasture-finishing. The LD spectral data did not allow to discriminate L0 lambs from L21 lambs and L42 lambs from L63 lambs, but they enabled to reliably discriminate L0 and L21 lambs from L42 and L63 lambs. The perspectives are to expand the spectral range explored using infrared spectroscopy.

Individual adaptive responses of meat ewes facing an abrupt nutritional challenge after lambingE. González-García¹, M. Gindri², L. Puillet² and N.C. Friggens²¹INRAE, PHASE, SELMET, Univ Montpellier, CIRAD, INRAE, L'Institut Agro Montpellier SupAgro, 34060 Montpellier, France, ²INRAE, PHASE, Université Paris-Saclay, INRAE, AgroParisTech, UMR MoSAR, 75005, Paris, France; eliel.gonzalez-garcia@inrae.fr

Simulating a climate change event, responses of Mediterranean meat ewes when facing an abrupt nutritional challenge (NC; i.e. fed with cereal straw of very low nutritional value only) were studied at a very sensitive physiological stage (i.e. just after lambing). Forty Romane ewes were chosen at early-mid pregnancy (around 2 mo) according to parity (20 primiparous, PRIM; 20 multiparous, MULT); feed efficiency genetic line [residual feed intake (RFI); inefficient, RFI-, n= 10 per parity; efficient, RFI+, n= 10 per parity]; litter size (i.e. bearing twins, diagnosed by ultrasonography); and BW and body condition score (BCS) [initial BW and BCS (mean $\pm$ SD): 51.6 $\pm$ 7.41 kg; 2.5 $\pm$ 0.20, respectively; representing average BW and BCS of their parity in the flock]. Effects on intake, ewes' BW and BCS, subcutaneous back-fat thickness (BFT), energy metabolism [plasma NEFA, β -OHB, glucose, urea, tri-iodothyronine (T3)], and lambs' growth were examined before, during and after NC. Individuals' profiles of the response-recovery of each ewe to NC were described using a piecewise mixed-effects model and clustered using principal components analysis and Euclidean distance. MULT presented sharper β -OHB recovery from NC than PRIM ($P \leq 0.05$). Parity or genetic line did not affect the other evaluated traits. Clusters of individuals' response-recovery to NC suggested three different adaptive strategies to NC (i.e. adaptation on acquisition, allocation or trade-off between acquisition and allocation of energy. Interestingly, ewes' response-recovery to NC demonstrated also to be related to lamb average daily gain (ADG, g/d), especially plasma β -OHB and NEFA ($r \geq 0.50$). Results provide new insights in how such short and abrupt NC affect some key physiological parameters, and to what extent the impacts of NC and the ewes' potential response-recovery are influenced by the individual nature of the animals (i.e. observed inter-individual differences in the responses). This work was financed by the PRIMA ADAPTHERD project (<https://www.adapt-herd.eu/>).

Session 65

Theatre 3

Large variation in emission intensities from dual-purpose sheep production system

B.A. Åby, S. Samsonstuen and L. Aass

NMBU, Department of Animal and Aquacultural Sciences, Box 5003, 1432, Ås, Norway; bente.aby@nmbu.no

Sheep currently account for approx. 4% of global GHG emissions from livestock and the demand for sheep products is likely to increase due to human population growth. Thus, to limit GHG emissions from sheep production, it is essential to reduce emission intensities, i.e. GHG emissions from producing one unit of product, e.g. sheep and lamb carcass and wool. Due to large variability in resource base, management practices, and production between individual farms, emission intensities must be calculated at farm level and farm-specific mitigation options need to be implemented. Whole-farm models take into account interactions and trade-offs between different GHG sources; therefore, these models are powerful tools to estimate total farm GHG emissions, assess mitigation options at farm level, and tailor mitigation strategies to specific farms or production systems. HolosNorSheep is such a whole-farm model, based on IPCC methodology, modified to Norwegian conditions. The model estimate GHG emissions from dual-purpose sheep meat and wool production and considers direct CH₄ from enteric fermentation and manure management, direct and indirect N₂O from manure management and soils, and CO₂ emissions from production and use of farm inputs. Emissions are allocated to meat and wool using a biophysical allocation on the basis of net energy requirements for growth and wool production. In this study, emission intensities for sheep and lamb carcass and wool were estimated for 38 farms distributed across Norway with varying climate, natural resource base, feeding and management practices. The data were from year 2019-2021 and several farms had data for more than one year, giving a total of 65 calculations. Animal performances varied considerably across farms and years, e.g. average number of weaned lambs per adult ewe varied from 1.4 to 3.0 while the carcass weight of lambs ranged from 14.5 to 27 kg. Average emission intensity per kg sheep and lamb carcass, and wool was 20.4 ($\pm$ 5.0) and 22.2 ($\pm$ 7.2) kg CO₂-eq, respectively. The most important emission source for all farms was enteric methane. The large variation in calculated emission intensities demonstrates the potential to reduce emission intensities from Norwegian dual-purpose sheep production.

Considering the morphology of cows for comfortable milkingJ. Fazilleau¹, S. Guiocheau² and J.L. Poulet¹¹Institut de l'Élevage, 149 rue de Bercy, 75595 Paris Cedex, France, ²Chambre Régionale d'Agriculture de Bretagne, Aéroport, 29600 Morlaix, France; jean-louis.poulet@idele.fr

ErgoTraite (CASDAR IP project 2021-2023) aims to ensure the sustainability of conventional bovine milking. This requires an overall improvement of milking, by proposing innovative organization models and milking equipment designs. Within this project, measurements were carried out in 7 milk farms in the West of France, with diversified profiles, to verify the adequacy of the recommendations for the design of milking parlours for current herds. 726 udders were characterized, with 2 main dimensions: Udder Floor Height (UFH: vertical distance between highest teat attach on the udder and the platform) and Horizontal Reach Distance (HRD: horizontal distance between the farthest teat and the platform border). Platforms Heights (PH: vertical distance between milker floor and cow platform) had been also measured. Vertical Reach Distance (VRD = PH + UFH) has been calculated by combining 2 previous indicators. Main anatomical characteristics of milkers were also recorded: Milker Height (MH), Elbows (EH) and Shoulders Heights (SH) and length of arms (AL). Indeed, these dimensions make it possible to qualify the areas of intervention for the milkers (adapted from INRS, 1999). 'Comfort zones' are in terms of vertical movements, at $EH < VRD < SH$, and horizontally, at $HRD < 2/3 AL$. From $VRD > EH + 10$ cm or $HRD > AL$, it is considered that intervention is done in a 'painful zone'. In average UHF being at 63.8 cm, VRD were thus quite significant, with extreme teats over 1.85 m, especially in parallel parlours, even for tall milkers (1.80 m) and HRD were at 41.8 cm. By comparing these data with the recommendations, teats can be considered in uncomfortable areas for 88% of VRD and 86% of HRD. HRD is difficult to modify, unless if the stall is adaptable to each animal. It seems essential to consider UFH when dimensioning milking parlours (in addition to milker height, often already considered), as also reported by Cockburn & Al. (2015), current platform height recommendations being no longer adapted to cow morphologies. By doing so, rear stall elements (located at 70 cm from the platform to prevent cow from falling) must be modified to be sure they won't become obstacles to udders visibility and accessibility.

Session 65

Theatre 5

Classification of honeybee flight activity patterns reveals impact of recruitment behavioursG.E.L. Petersen^{1,2}, D. Gupta², P.F. Fennessy² and P.K. Dearden^{1,3}¹FutureBees NZ Ltd, 442 Moray Place, 9016 Dunedin, New Zealand, ²AbacusBio Ltd, 442 Moray Place, 9016 Dunedin, New Zealand, ³University of Otago, Biochemistry, 710 Cumberland Street, 9016 Dunedin, New Zealand; gpetersen@abacusbio.co.nz

Remote sensing technologies are likely to greatly improve our understanding of the livestock species we rely on for the production of food and fibre for human consumption. From walk-over weighing to wearable motion sensors, new technologies are constantly being developed. For the European Honeybee, *Apis mellifera*, numerous hive telemetry systems are available today and can support the decryption of bee behaviours and their impact on hive productivity. Stationary hive telemetry can lend great insight into the flight activity, production and health of honeybee colonies, especially where observations are continuous. Here, we monitored IN activity (No of bees entering the hive over a 10-minute interval), OUT activity (No of bees leaving the hive) and total hive weight over the 3-month nectar flow period on 140 beehives in the Canterbury region of New Zealand. Daily activity patterns were analysed by checking for the presence of local maxima indicating that a spike in flight activity occurred, and then classified into predominantly early activity, predominantly late activity, and two-phase activity, indicating that foraging efforts had been reduced over a mid-day period. Classification results showed that while daily changes in environmental conditions had the biggest impact on flight activity patterns, individual honeybee colonies that were found to express an 'early' or 'late' pattern were more likely to show this pattern again at a later time. Two-phased activity patterns were more common during times that resulted in higher hive weight gain, indicating that the mid-day break present in the activity data is the result of recruitment behaviours between food handler bees inside the hive and returning foragers. The high influx of nectar and pollen results in higher demand for worker bees to move food deep into the hive and make room for a second wave of returning foragers in the afternoon. Colonies with a higher proportion of days with a two-phased activity patterns were found to be more successful in terms of weight gain over the nectar flow period.

Implementation of large-scale climate smart agriculture research on U.S. beef cattle grazing landsK. Cammack¹, A. Blair¹, L.O. Tedeschi², H.M. Menendez Iii¹ and J.R. Brennan¹¹South Dakota State University, Animal Science, 711 N. Creek Drive, 57703, USA, ²Texas A&M University, Animal Science, 474 Olsen Blvd, College Station, Texas, 77843, USA; kristi.cammack@sdstate.edu

Grazing lands are globally crucial for their greenhouse gas (GHG) mitigation and sequestration potential. However, livestock producers are often neglected in enteric GHG reduction and carbon sequestration incentives because cost-effective methods to determine and measure carbon and GHG sinks and sources are lacking. Emerging technologies have bridged that gap, paving the way to develop, implement, and monitor climate-smart agricultural (CSA) practices. Successful implementation and monitoring of CSA practices have the potential to translate to climate-smart livestock commodities that sustainably assign economic incentives to resilient livestock grazing land production systems. Nearly 380 million ha in the U.S. are rangelands dedicated to supporting forage-based livestock production. This land area is more than double that dedicated to row crops and has enormous potential to contribute to U.S. climate change commitments. Recently, South Dakota State University, with 13 other partners, was awarded a CSA commodity development grant to develop markets for Climate Smart Beef in the U.S. Northern Great Plains (NGP), one-fifth of U.S. beef production, through the USDA-NRCS. To achieve this, the SDSU team utilizes an innovative measuring, monitoring, reporting and verification (MMRV) method to evaluate the effectiveness of climate-smart agriculture practices such as prescribed grazing and planting native grasses. This project will integrate precision technologies and data analytics for a large-scale sampling (971,245 ha) of grazing lands. Key metrics include enteric methane emissions and soil carbon sequestration for cow-calf and stocker production phases. The data collected in our project will be utilized to further enhance the COMET-Farm model, a whole ranch carbon and greenhouse gas accounting tool, by improving or validating coefficients regarding practice emission or mitigation potentials across grazing management styles, soil types, and climates; a critical next step in enhancing global sustainability of livestock farming systems.

Theatre 7

Remote monitoring behaviour of bison in captivity: effects of gender, weather and daytimeR.R. Vicentini^{1,2}, D. Moya³, J. Church², A.C. Sant'anna⁴, W. Balan¹, W. Squair¹ and Y.R. Montaholi¹¹Lakeland College, School of Agricultural Sciences, 5707 College Drive, Vermilion, AB, T9X 1K5, Canada, ²Thompson Rivers University, 805 Tru Way, Kamloops, BC, V2C 0C8, Canada, ³The University of Saskatchewan, 52 Campus Dr, Saskatoon, SK, S7N 5B4, Canada, ⁴Federal University of Juiz de Fora, Rua José Lourenço Kelmer, Juiz de Fora, MG, 36036-900, Brazil; yuri.montanholi@lakelandcollege.ca

Studying bison in zoo can provide valuable insights about the behaviours of this species with application in the monitoring and management of commercial herds. Besides this biological characterization, we hypothesize that gender, weather parameters, and daytime periods may affect the behaviours of the bison. The objective of this research was to employ remote video surveillance to identify and quantify the behaviours of bison. Four bison (*Bison bison*; female: 2; male: 2), provided by Zoo Aquarium de Madrid (Madrid, Spain), were video monitored during 26 consecutive days. Three solar-powered cameras with motion sensitive tracking (Reolink Argus PT, Reolink Digital Technology Co. Ltd., Hong Kong, China) were installed surrounding the enclosure of the bison. The footage collected was computed considering five behaviours: laying, walking, standing, drinking and eating. The behaviours were assessed and quantified by a judge as percentage of observation time behaviour and used to perform the means analysis. Preliminary results indicate that the most frequently observed behaviour of the herd was laying (65.8%), followed by standing (16.2%), moving (7.7%), eating (9.4%) and drinking (0.7%). The analyses of the behaviours by gender indicated that males spent more time laying (21.72%, 15.87%) and less time standing (3.57%, 5.73%) than females. The time spent walking (2.04%, 2.40%), eating (2.79%, 2.60%) and drinking (0.31%, 0.09%) were similar in both sexes. Potential effects of weather parameters (i.e. temperature, humidity, sunlight duration, etc.) and daytime periods remain to be evaluated. Further analysis may also evidence the existence of circadian cycle related to behaviours evaluated. The parametrization in development will be of great relevance to monitor bison behaviour in confined spaces, such as observed in commercial feedlots, which will assist optimize the husbandry practices.

Artificial intelligence for measuring the respiration rate in dairy cowsL. Dißmann¹, R. Antia², L. Chinthakayala³, N. Landwehr³, T. Amon¹ and G. Hoffmann¹¹Leibniz Institute for Agricultural Engineering and Bioeconomy (ATB), Department Sensors and Modeling, Max-Eyth-Allee 100, 14469 Potsdam, Germany, Germany, ²dida Datenschmiede GmbH, Hauptstraße 8, 10827 Berlin, Germany, ³University of Hildesheim Foundation, Data Science, Universitätsplatz 1, 31141 Hildesheim, Germany; ldissmann@atb-potsdam.de

The respiration rate (RR) of dairy cows is a very sensitive parameter that can indicate a stress situation (e.g. heat stress, anxiety) as well as pathological processes at an early stage. The common method for determining the RR of cattle is to visually count the flank movements in breaths per minute. However, this method is very time consuming and the close contact with the animal affects the cow's behaviour. Therefore, our approach to record the RR is based on a non-contact method. The novelty here is the use of two imaging techniques. On the one hand, we used infrared thermography (FLIR AX5 series, Oregon, USA) to record the RR in the area of the nostrils based on the temperature difference between inhaled and exhaled air. First, the artificial Intelligence (AI) detected the area of interest (AOI) and extracted afterwards from the average temperature in the AOI a time series from which we derived the RR. On the other hand, we used a depth camera (IntelRealsense D455, California, USA) to record the respiration based on the flank movement of the cow. Here, the AI extracted a RR curve from the maximum expansion difference from the flank area. The gold standard for both methods was the visual counting of the RR due to the flank movements. We conducted multiple tests to assess the accuracy of these image-processing techniques for an automatic detection of RR from various camera positions and angles as well as the feasibility under agricultural conditions. The results showed that it is generally possible to record the RR with both camera systems automatically, but at this stage, the recording is limited to individual animals, as the recordings can only capture 2-3 lying cubicles in the barn with one camera. The project KAMI is supported by funds of the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany via the Federal Office for Agriculture and Food (BLE) under the innovation support program.

Theatre 9

Using millimetre-wave radar for monitoring sow postural activity in individual pen: first resultsD. Henry¹, J. Bailly², T. Pasquereau¹, W. Hebrard², J.F. Bompal¹, E. Ricard¹, H. Aubert³ and L. Canario¹¹INRAE, GenPhySE, Castanet-Tolosan, 31326, France, ²INRAE, GenESI, Surgères, 17700, France, ³CNRS, LAAS, Toulouse, 31400, France; dhenry@laas.fr

A millimetre-wave radar is tested in an INRAE experimental unit to monitor sow postural activity in presence of her piglets. A total of 16 sows of the Large White breed with piglets aging from 7 to 15 days are monitored inside farrowing pens with measurement sequences lasting 2 to 3 hours at different dates. The radar is attached to the farrowing pen entrance at a distance to ground of 1.8m, and the sow's position is remotely estimated from the backscattering of electromagnetic waves. The radar-based detection technique does not require equipping animals with radiofrequency tags. The automatized system records 3D images are built from the simultaneous azimuth (digital) and elevation (mechanical) radar beam scanings with a time resolution of 3 seconds. By applying an algorithm based on Constant False Alarm Rate, undesirable radar echoes from the pen are mitigated and only radar detections of the sow are recorded over time. A clustering algorithm is applied to the detections to obtain the 3D position of the sow. A classification of sow postures is performed from a Quadratic Discriminant Analysis of the 3D positions. Ground-truth postures of sow are annotated manually from video recordings. The two following classes of postures are finally analysed: the 'standing and transition' and the 'lying' classes ('transition' refers here to both 'sitting' and 'kneeling' postures). The training data is composed of radar detections of 4 sows for the total monitoring duration of around 8 hours, or equivalently for 7,097 detections. The tested data is composed of 34,356 radar detections of 12 other sows for a total monitoring duration of 38 hours. The precision and sensitivity are 88.3 and 90% for the 'standing and transition' class, and 97.9 and 98% for the 'lying' class. Precision and sensitivity of the classification may vary from one sow to another due to the difficulty to classify correctly 'transition' postures for some of them. Based on these first encouraging results, future work will be devoted to further develop the radar detection method, and detect the motion of the sow according to changes in her location in the pen.

The environmental variance on daily feed intake as a measure of resilience in pigsC. Casto-Rebollo¹, P. Nuñez¹, S. Gol², J. Reixach² and N. Ibáñez-Escriche¹¹Institute for Animal Science and Technology, Universitat Politècnica de València, 46022 València, Spain, ²Batallé SA, Riudaneres, 17421 Girona, Spain; pedronunez136@gmail.com

To achieve a more sustainable livestock system, knowing how animals cope with environmental factors is crucial. Identifying the best indicators of resilience is challenging, and identifying which animals are resilient remains an active area of research. The environmental variance (VE) of traits, specifically their residual variance, is under genetic control and has been proposed as a promising indicator of overall resilience. However, its biological impact on the health status and welfare of the animals is still unclear. This study aimed to disclose the biological mechanisms of resilience in Pietrain pigs. For this purpose, we used the VE of the daily feed intake (DFI) as a novel indicator of resilience. 780,112 feed intake (FI) records were collected from automated feeders of 1,628 sires aged between 80 and 180 days. VE was calculated using the pre-corrected DFI for batch, feeder, and body weight effects. Animals were classified into three resilience categories using the 25% (Q1) and 75% (Q3) percentiles of VE: resilient (VE less than Q1), moderately resilient (VE between Q1 and Q3), and non-resilient (VE greater than Q3). Survival data from 230,504 offspring were used to calculate the progeny mortality rate per sire (at least 40 offspring). Differences in progeny mortality were found between resilient (mean 36.18%) and non-resilient (mean 43.22%) animals, with a *P*-value of 0.01. Bayesian statistical analysis indicated that the differences in this mortality between the non-resilient and resilient animals averaged 0.44 standard deviations, with a probability of greater than 0 of 99%. These results suggest that the VE of DFI may act as a measure of progeny survival and thus may account for differences in resilience between animals. Therefore, to unravel the biological mechanism underlying animal resilience and to understand its impact on feed efficiency and critical animal health traits, genomic studies using VE of DFI are ongoing.

Session 65

Poster 11

Factors affecting somatic cell count in ewe milk and its effect on milk yield and composition

M. Oravcová, V. Tančin, L. Mačuhová and M. Uhrinčat'

National Agricultural and Food Centre, Hlohovecká 2, 95141 Lužianky, Slovak Republic; marta.oravcova@nppc.sk

The objective of the presented study was to analyse milk traits (daily yield and composition) in dependence on somatic cell count (five SCC classes defined) in purebred and crossbred Tsigai and Lacaune ewes. Variations due to parity, month in milk/month of measurement, genotype, flock, control year and ewe were also taken into account. Ewes (906 heads with 7,608 records available) were bred in two flocks; they produced between 2019 and 2022. Estimates of daily milk yield in individual levels of SCC class decreased as follows: 0.835 ± 0.012 l (<200 ths/ml), 0.817 ± 0.014 l (200 ths/ml < 400 ths/ml), 0.816 ± 0.018 l (400 ths/ml < 600 ths/ml), 0.811 ± 0.018 l (600 ths/ml < 1 mil/ml) and 0.774 ± 0.015 l (≥ 1 mil/ml). Estimates of lactose content in dependence of SSC class decreased from $4.577 \pm 0.008\%$ through $4.540 \pm 0.011\%$, $4.508 \pm 0.015\%$, $4.991 \pm 0.015\%$, to $4.406 \pm 0.011\%$. Estimates of fat content increased from 7.481 ± 0.028 to $7.726 \pm 0.042\%$; estimates of protein content increased from 5.820 ± 0.017 to $6.043 \pm 0.023\%$. Vice versa, the analysis of logarithmic SCC (same factors with exception of SCC class considered) showed their influence on this parameter (increasing trend along with increasing parity, decreasing trend along with month in milk/month of measurement and unclear pattern in SCS across control years revealed). The findings indicate that tissue changes due to udder inflammation were in progress throughout lactation and mastitis (clinical or subclinical) was partly responsible for reduced milk yield. Regular SCC monitoring, which could contribute to improve flock management and milk production efficiency, and further research aimed at prevention of mastitis, are needed. The support of the Ministry of Education, Science, Research and Sports of the Slovak Republic/The Slovak Research and Development Agency (APVV-21-0134 and APVV-15-0072) is gratefully acknowledged.

Digestibility of soybean meal vs toasted soybeans in newly weaned piglets*C. De Cuyper¹, P. Dubois² and S. Millet¹**¹ILVO, Scheldeweg 68, 9090 Melle, Belgium, ²Danis N.V., Knijffelingstraat 15, 8851 Koolskamp, Belgium; sam.millet@ilvo.vlaanderen.be*

In feed evaluation, digestibility coefficients are usually determined in growing pigs between 40 and 100 kg. The same values are used when formulating piglet diets. However, digestive capacity is lower in piglets than in growing pigs and digestibility may therefore be overestimated. In piglet diets, toasted soybeans are often preferred over soybean meal as feed ingredient. Still, feeding tables indicate a higher crude protein (CP) digestibility for soybean meal than for toasted soybeans. We hypothesized that in piglets, CP digestibility is higher for well processed and monitored toasted soybeans compared to soybean meal. Therefore, an experiment was designed to analyse and compare the digestibility of CP and crude fat (CFAT) of both feed ingredients in young piglets. At four weeks of age, a total of 180 piglets were selected and divided over pens of 6 animals (3 barrows and 3 gilts). Pens were randomly assigned to one of the four dietary treatments: a low protein (soy-free) control diet, 2 diets with control + toasted soybeans and 1 diet with control + soybean meal + soy oil. The soybean meal originated from Brazil and contained 46.5% CP. Soybeans were sampled from commercially available batches. An 18-day adaptation period allowed the animals to get used to the test feed. This was followed by a four-day collection period during which faecal samples were collected. After this collection period, pigs were euthanized to sample ileal content. Apparent ileal digestibility (AID) of CP was significantly ($P < 0.05$) higher for toasted soybeans ($77 \pm 8\%$) compared to soybean meal and soy oil ($67 \pm 8\%$), confirming our hypothesis. Moreover, apparent total tract digestibility (ATTD) of CFAT tended ($P = 0.076$) to be higher for toasted soybeans ($84 \pm 4\%$) compared to soybean meal and soy oil ($81 \pm 3\%$). This study also confirmed that digestibility values may be lower in weaned piglets compared to table values, especially in soybean meal. The difference in digestibility according to bodyweight may be ingredient specific. The research was supported by Danis NV through financial funding and providing a batch of toasted soybeans (Danex®).

Session 66

Theatre 2

Effect of variety and technological treatment on intake of lupin seed in pigs*E. Labussiere¹, H. Furbeyre¹, M. Guillevic² and G. Chesneau²**¹PEGASE, INRAE, Institut Agro, Le Clos, 35590 Saint-Gilles, France, ²Valorex, La Messayais, 35210 Combourtillé, France; etienne.labussiere@inrae.fr*

The utilization of lupin seed in pig diets is limited because of anti-nutritional factors that decreased dietary intake when inclusion is higher than 15%. Nevertheless, lupin seed is a feedstuff with a high content in protein which is of interest to diversify protein sources in pig diets. The experiment aimed to test whether differences in variety ($n=3$, *Lupinus albus*, *Lupinus angustifolius*, *Lupinus luteus*) or technological treatment ($n=3$, none, extrusion, dehulling and extrusion) increase feed intake in pigs. The experimental feedstuffs were included in nine diets at an inclusion rate of 25%. Soybean meal, wheat bran, soybean hulls, sugar beet pulp and sunflower oil were used to balance the diets for their content in crude protein (from 21.9 to 23.3% DM), crude fibre (from 6.1 to 6.5% DM) and fat (from 5.3 to 5.5% DM). These diets were offered by pairwise comparisons to two groups of 25 male pigs (mean body weight = 48.5 kg). Each group had access to four automatic feeders filled with two different experimental diets. Each pig can eat to each feeder and feeding behaviour was recorded, allowing to calculate the proportion of each diet in the daily intake as an indicator of pig preference. Each week, the two diets tested for each group changed and the experiment lasted 7 consecutive weeks. It was not possible to test *L. luteus* with no technological treatment because of lacking of feedstuff. Feed intake decreased by 50% the first week the pigs received the diets containing lupin seed but recovered thereafter. Whatever the technological treatment, *L. albus* was the less preferred lupin seed, whereas *L. luteus* was the most preferred (account for 92 to 98% of intake). *L. luteus* and *L. angustifolius* were preferred after dehulling and extrusion than after extrusion only but dehulled and extruded *L. angustifolius* was less preferred than crude seed. Extruding *L. albus* increased intake over crude seed and dehulled and extruded seed. The increase in the intake of lupin-based diets would be related to the reduction of antinutritional factors by the technological treatments. These treatments therefore contribute to increase the interest of these seeds.

Comparative energy values of 10 forages in finishing pigsD. Renaudeau¹, J. Pirault², M. Dumesny³, S. Lombard⁴ and F. Marie⁵¹INRAE, UMR PEGASE Institut Agro, 35590 St Gilles, France, ²INRAE, Domaine de la Motte, 35650 Le Rheu, France, ³DESHYQUEST, 11 rue Louis Raison, 35113 Domagné, France, ⁴ITAB, 9, rue André Brouard, 49105 Angers, France, ⁵IBB, 2, Square René Cassin, 35700 Rennes, France; david.renaudeau@inrae.fr

In specific production systems, forage can make a valuable contribution to pig nutrition and reduce feed costs. Little is known about the energy value of forage in swine. The objective of the present study was to conduct 3 trials to measure the apparent digestibility coefficient (DC) of nutrient and energy and the energy value of 10 forages from different botanical origins and/or with different conservation methods: 3 fresh fodders (chicory, red clover and perennial ryegrass) (T1), 2 dehydrated forages legumes (lucerne and red clover) obtained different drying conditions (130 vs 50 °C at the dehydrator outlet) (T2), 2 hays (lucerne and a mix of 30% red clover and 70% grasses) and a mixed forages legumes (lucerne + red clover) preserved by wrapping (T3). Forages were mixed with a control wheat-soybean mash diet (C diet) and water. The DC of DM, organic matter (OM) and gross energy (GE) of each experimental diet were evaluated with 4 to 5 80 kg BW males pigs. Pigs were adapted to the diet and digestibility cage for 14 d before total collection of faeces and urine over a period of 7 d. The DC of OM and GE was significantly reduced in forages than in C diet ($P < 0.001$) due to the higher ash and fibre contents as well as the lignification degree of fibre. On a DM basis, the digestible energy (DE) values were 28 to 61% lower in forages than in C diet (15.3 MJ/kg DM). In T1, the DE values of fresh chicory, red clover and perennial ryegrass averaged 11.05, 10.39 and 10.66 MJ/kg of DM, respectively. In T2, the reduction of dehydration temperature did not affect the DE value of dehydrated lucerne (9.74 MJ/kg DM on average) whereas it negatively affected the DE value of red clover (10.63 vs 8.69 MJ/kg DM; $P < 0.05$). In T3, hays had lower DE values than forage conserved in wrapped big bale (6.67 vs 10.41 MJ/kg DM). In conclusion, the study provide original information regarding the energy value of forages according to their conservation method. These data have to be complemented by similar results on the nitrogenous fraction.

Session 66

Theatre 4

Implication of different amylose/amylopectin ratio on low protein diet on piglet's performance

P. Trevisi, D. Luise, F. Correa, S. Virdis, C. Negrini and S. Dalcanale

University of Bologna, Department of Agricultural and Food Sciences, Viale G. Fanin 46, 40127, Italy; paolo.trevisi@unibo.it

In pigs, reducing the dietary crude protein (CP) increase the environmental sustainability and reduce the risk for gut health impairment. Anyway, the high rate of free amino acids (AAs) inclusion in low CP diet could increase the asynchronism between the blood picks of amino acids and glucose that results in a low protein synthesis and increased NH_3 excretion. This study aims in maximizing the growth of pigs fed a low CP diet enriched with amylopectin, which would increase the synchronism between the AAs and glucose picks. At weaning (d0), 90 pigs were divided into 3 groups balanced for body weight (BW) and litter (10 box/diet): (1) control diet (CO): standard diet (Phase1: 18%; Phase2: 16.6%; Phase3: 16.7%); (2) low CP diet (LP) (Phase1: 16%; Phase2: 14.7%; Phase3: 14.5%); (3) as LP but with Waxy corn characterized by 99% of amylopectin (LPW). The feeding phases were d0-d14; d15-d28; d29-d49. BW and feed intake (FI) were weekly recorded. Faecal samples were collected at d14 and d49, faecal score (FS) and lesion score index (LSI) for tail and ears were calculated. Data on BW and ADG, faecal NH_3 and calprotectin were analysed using an ANOVA model considering group, box and litter of origin as factors using piglets as the experimental unit. While the ANOVA model for FI, FCR, LSI and faecal score considers group as factor and box as experimental unit. The BW at d7 and d14 did not differ between groups. From d21 to d49, the LP had lower BW than CO ($P < 0.01$). BW of LPW did not differ from the CO until d28, then it was reduced ($P < 0.05$). The ADG d0-14 tended to be reduced in the LP ($P = 0.06$) and was not reduced in the LPW. From d15-d28, d29-d49 and d0-d49, the CO group had a higher ADG compared with LP and LPW groups ($P \leq 0.01$). The FI never differs between the groups. The FCR did not differ from d0-d14 but it was lower in the CO group on d14-d28 ($P \leq 0.01$). The faecal NH_3 and calprotectin, FS and LSI did not differ between the groups. Despite the reduction of the ADG, the reduction of the CP did not affect pigs' FI and health and the LPW diet do not reduce the performance of pigs in the Phase1 Acknowledgment: RDP-Emilia Romagna Region, Piano di Innovazione 'MELioR DIET', 16.2.01, ID:5404635.

Effects of two blends of phytoextracts on growth and gut health of weaning pigs to replace zinc oxideD. Luise¹, F. Correa¹, C. Negrini¹, S. Virdis¹, M. Mazzoni², S. Dalcanale¹ and P. Trevisi¹¹University of Bologna, Distal, Viale G. Fanin, 40127, Italy, ²University of Bologna, Dimevet, Ozzano dell'emilia, 40064, Italy; diana.luise2@unibo.it

Phytoextracts (PY) and essential oils (ES) and their mixture with organic acids (OS) are potential alternatives to pharmacological doses of zinc oxide (ZnO) for their antimicrobial, anti-inflammatory and antioxidant abilities. This study aims to evaluate, compared to ZnO, the effect of two blends of PY containing ES and OS on performance and gut health of weaned pigs. At weaning (d0), 96 piglets (7,058±895 g), balanced for body weight and litter, were assigned to one of 4 groups: CO (control group), ZnO (2,400 ppm ZnO from d0 to d14); Blend1 (cinnamaldehyde, ajowan and clove essential oils, 150 g/100 kg feed); Blend2 (cinnamaldehyde, eugenol and short and medium chain fatty acids, 200 g/100 kg feed). Pigs were weighed weekly. Faeces were collected at d13 and d35 for microbiota (v3-v4 of 16S rRNA gene) and *Escherichia coli* count analysis. At d35, pigs were slaughtered; pH was recorded on gut contents, jejunum was collected for morphological and gene expression analysis. From d0-d7, Blend2 had a lower average daily gain (ADG) ($P<0.05$). ZnO and Blend1 never differ in ADG and feed intake. At d14, Blend1 and Blend2 had lower pH in caecum and colon than ZnO ($P<0.05$). CO had higher number of haemolytic *E. coli* than Blend1 ($P=0.01$). At d13, ZnO group had lower alpha diversity ($P<0.01$) and a different microbial beta diversity ($P<0.001$). At d13, pigs from the ZnO group were characterized by a higher abundance of Prevotellaceae_NK3B31_group (LDA score=4.5, $P=0.011$), Parabacteroides (LDA score=4.5, $P_{adj}=0.005$), Blend1 by Megasphaera (LDA score=4.1, $P_{adj}=0.045$) and Ruminococcus (LDA score=3.9, $P_{adj}=0.015$) and Blend2 by Christensenellaceae_R-7_group (LDA score=4.6, $P_{adj}<0.001$) and Treponema (LDA score=4.5, $P_{adj}<0.001$). Jejunal expression of NFKB2 ($P=0.05$) and IALP ($P=0.08$) was higher in the Blend2 group than in the CO group. In conclusion, Blend1 allowed obtaining the same performance as ZnO through modulation of the gut pH and microbiome and the reduction in haemolytic *E. coli* and inflammatory status of the mucosa. Theatre 6

Effect of olive cake in growing pig diets on faecal microbiota fermentation and compositionD. Belloumi¹, P. García-Rebollar², P. Francino³, S. Calve⁴, A.I. Jiménez-Belenguer⁴, L. Piquer¹, O. Piquer⁵ and A. Cerisuelo¹¹CITA-IVIA, Pol. Esperanza, 100, 12400 Segorbe, Spain, ²UPM, Dept. Produccion Agrarias, ETSIAAB, Av. Puerta de Hierro, 2-4, 28040 Madrid, Spain, ³FISABIO, Salud pública, Av. de Catalunya, 21, 46020 Valencia, Spain, ⁴UPV, ICTA, Camí de Vera, s/n, 46022 Valencia, Spain, ⁵CEU-Cardenal Herrera, C. Tirant lo Blanc, 7, 46115 Valencia, Spain; belloumi_dhea@gva.es

The intestinal microbiota plays a critical role in the metabolism and health of the host. The present study investigated the impact of two types of olive cake on short-chain fatty acid (SCFA) concentrations and the faecal microbiota composition of pigs. A total of 30 pigs (Landrace × Large white) with an initial body weight (BW) of 47.9±4.21 kg were divided into three groups according to the feed they received: control feed (C), feed with 200 g/kg of partially defatted olive cake (PDOC) or feed with 200 g/kg of cyclone olive cake (COC). Faecal samples were collected from each animal after 3 weeks of the feeding trial. Microbiota composition was analysed by sequencing the V3-V4 region of the 16S rRNA gene. The results showed that the COC group had more total SCFAs, acetic acid, butyric acid, and caproic acid ($P<0.05$) than the other two groups. No significant differences were found among groups in alpha diversity ($P>0.05$). At the phylum level, *Firmicutes* and *Bacteroidota* were the predominant phyla across the three groups, with more than 93% of the total community. However, *Spirochaetota* was significantly ($P<0.05$) more present in the C group than in the PDOC group, suggesting a severe possibility of gut inflammation in this group. *Plantomycetota* was significantly more abundant ($P<0.05$) in the PDOC group than in the C group. The relative abundances of *Eggerthellaceae* and *Allisonella* were significantly ($P<0.05$) enriched in the COC group compared to the C group. However, *dga-11_gut_group* was more abundant ($P<0.05$) in the C group than in the COC group. These results suggested that supplementing pigs' diets with olive cakes may beneficially affect pigs' gut health without altering the diversity of microbial communities. This work was supported by the project IVIA-GVA 52201L from IVIA (co-financed by the EU through the ERDF Program 2021-2027 Comunitat Valenciana). BD received PhD scholarship (GRISOLIAP/2020/023).

Impact of increasing dietary sphingolipids on feed intake and growth performance of pigletsS. Chakroun¹, R. Larsen¹, J. Levesque², F. Cerpa Aguila¹, M.-P. Letourneau¹, J.E. Rico³ and D.E. Rico^{1,2}¹Université Laval, 2425 Rue de l'agriculture, Quebec, QC, G1V0A6, Canada, ²CRSAD, 120-A Chemin du Roy, G0A1S0, Canada, ³University of Maryland, 8127 Reagents drive, College Park, MD, 20740, USA; daniel.rico@crsac.qc.ca

The weaning period in piglets is associated with impaired growth and increased oxidative stress and inflammation. Milk fat globular membranes are a rich source of anti-inflammatory polar lipids which may improve performance of animals when included in the diet. Weaned male piglets (n=240; 21 days of age; 6.3±0.5 kg of BW) were blocked by initial weight and distributed into 48 pens of 5 animals in a complete randomized block design with a factorial arrangement, where animals received either a soybean lipid-based (n=24 pens; SD) or a polar lipid-based diet (n=24 pens; PD) from weaning to day 42 of the nursery phase. Within each diet group animals received 1 of 3 milk replacers (MR; 0.5 l/d) for the first 7 d: (1) commercial MR (CO; Control); (2) soybean lipids-based MR (S); (3) polar lipid-based (PO; Polar). Animals were switched to a common diet from d 21 to 42. Feed intake was recorded weekly from d 14 and body weight (BW) on d 0, 7, 14, 21, 28 and 42. Data were analysed in a mixed model with the random effects of pen and block, and the fixed effects of diet, MR, time, and their interactions. A diet by time interaction was observed for feed intake ($P=0.004$) as it was 17% lower in PD relative to SD on d21, but not different at any other timepoint. A 3-way interaction was observed for BW ($P=0.003$), which increased over time and was 14% lower in PO compared with CO in animals fed the PD diet, but not different between other treatments. Similarly, average daily gain was 9% lower in PO compared with CO in animals fed the PD diet only (Diet × MR $P=0.01$). The impact of polar lipids on growth performance of piglets is dependent on the method of feeding.

Faeces microbiota and metabolism correlated with reproductive capacity in early parity sow

J. Wang, Q. Xie and B. Tan

Hunan Agricultural University, 1st Nongda street, Changsha, 410128, Hunan, China, P.R.; jingwang023@hunau.edu.cn

The metabolic status and sow fertility are tightly connected and reciprocally regulated. The aim of this study was to analyse the potential correlation among reproductive performance, colostrum composition and faeces microbiota and metabolites. A number of 32 first and second-parity sows were selected to measure litter size and litter weight at farrowing, and to collect faeces and blood on d 110 of gestation (d110G), as well as colostrum (24 h after farrowing). The live litter size of primiparous sows was lower than those of second parity sows ($P<0.05$). The IgA, IgG, IgM concentrations and protein, lactose, urea nitrogen contents in colostrum of primiparous sows were lower than those in second parity sows ($P<0.05$). Consistently, the concentrations of secretory IgA (sIgA) in serum and faeces of primiparous sows on d110G were lower than those in second parity sows ($P<0.05$). The colostrum sIgA and IgM concentrations were positively correlated with the live litter size (sIgA: Pearson $r=0.259$; IgM: Pearson $r=0.361$) and initial litter weight (sIgA: Pearson $r=0.265$; IgM: Pearson $r=0.376$) ($P<0.05$). Significant differences were observed in the alpha and beta diversities of faeces microbial community on d110G. The Shannon index in second parity sow faeces was higher than in primiparous sow ($P<0.05$), and second parity sow showed difference in faeces microbiota composition ($P<0.05$). The faeces abundance of *Lactobacillus* genus was highly positive correlation with IgM levels in faeces, serum and colostrum and faeces sIgA level ($P<0.05$). A total of 1,923 metabolites were detected in faeces on d110G, of these, 252 metabolites were up-regulated and 260 metabolites were down regulated in second parity sow. KEGG showed that the significantly up-regulated metabolites were mainly involved in protein digestion and absorption pathway. Citrulline, proline, palmitoleic acid, and valerophenone were positively correlated with sIgA, IgA, IgM, IgG levels in faeces, serum and colostrum, as well as the abundance of *Lactobacillus* genus in faeces ($P<0.05$). In conclusion, faeces microbial composition and metabolic status might affect the immunoglobulin levels of colostrum and used as a predictor of reproductive capacity in sows.

Dehydrated sainfoin in rabbit feed: effects of high incorporation on the health and performances ofC. Gayraud¹, P. Gombault², A. Breteau³, H. Hoste⁴ and T. Gidenne¹¹INRAE – Occitanie Toulouse, Animal physiology and farming systems, GenPHYSE, 31326 Castanet Tolosan, France, ²Multifolia, Viapres-le-petit, 10380 Viapres-le-petit, France, ³Arrivé-Bellanné, Nueil-les-Aubiers, 79250 Nueil-les-Aubiers, France, ⁴INRAE Occitanie Toulouse, Interaction Hôte-Agents Pathogènes, ENVT, 31300 Toulouse, France; thierry.gidenne@inrae.fr

In rabbit farming, coccidiosis and fibre deficient diets (especially lignins) can increase the risk of digestive disorders. Sainfoin is a legume rich in lignins, and contains polyphenols and tannins with anti-parasitic properties. Sainfoin also contained a high level of digestible protein (79g/kg) and energy (8.84 MJ/kg). Here, we studied the effects of a high level (26%) incorporation of dehydrated sainfoin (Perly cultivar, first cut, 'DSp') in rabbit feeding on the performances and health of reproductive doe and growing rabbits were analysed in a sub-optimal (with coccidiosis for the two previous batches) professional breeding environment and over two non-consecutive reproductive cycles (2 replicates). Performances and health of does and growing rabbits were compared for 2 groups of 194 does and associated litters, when fed iso-nutritive feeds containing either 0 or 26% DSp. Dietary DSp incorporation had no effect on doe live weight (4,675 g), fertility rate (88.4%), mortality (6.9%), culling rate (0.8%) and doe coccidia excretions levels ($P>0.05$). In replicate 1, kits growth before weaning was similar (24.8 g/d) among the two groups, but was 12% lower for the DSp26 group in the 2nd replicate (significant interaction). The post-weaning growth rate was improved by 4% (37.9 vs 39.3 g/d, $P=0.02$) for DSp26 group. Before weaning, a higher mortality was observed for DSp26 (3.3 vs 1.8%) in replicate 1, while in replicate 2 it was lower (2.1 vs 4.4%). After weaning, the mortality rate decreased (4.5 vs 7.1%, $P<0.001$) for DSp26 group (mean of two replicates). Coccidia excretions of growing rabbits were not affected neither by dietary sainfoin nor by replicates. Thus, a high incorporation of dehydrated sainfoin in the feed can be recommended to improve the health and performance of growing rabbits, without affecting does performances. Sainfoin is thus a good alternative to the alfalfa meal in the rabbit feeding.

Nutritional value of defatted larvae meal and whole larvae from black soldier flyP. Belloir¹, F. Hervé², E. Gambier², L. Lardic², C. Guidou³, C. Trespeuch³, N. Mème⁴, E. Recoules² and B. Méda²¹Ecole d'Ingénieurs de PURPAN, 75 Voie du Toec, 31076 Toulouse, France, ²INRAE, Université de Tours, BOA, 37380 Nouzilly, France, ³MUTATEC, 1998 Chem. du Miton, 84300 Cavaillon, France, ⁴INRAE, PEAT, 37380 Nouzilly, France; bertrand.meda@inrae.fr

Black soldier fly (BSF) larvae is a novel protein source to feed poultry. However, only nutritional values for BSF meals are available in the literature, whereas the use of whole larvae could be a promising strategy, for instance when used as an environmental enrichment material. Thus, this study aimed to investigate the nutritional value of three different BSF products: defatted larvae meal (LM) and whole larvae, either dried (DL) or fresh (FL). On a dry matter (DM) basis, crude protein (CP) and crude fat (CF) contents were respectively of 57 and 10% for LM vs 39 and 34% for whole larvae. A total of 48 Ross 308 male boilers were randomly assigned to individual cages for a digestibility trial. Four treatments were used: a control diet (C), a LM diet containing 75% C + 25% LM and two larvae diets containing, on a DM basis, 75% C + 25% of FL or DL larvae. Whole larvae were distributed on top of pellets in the same feeder. For the three products (LM, DL, and FL), the metabolizable energy (AMEn) and the apparent total tract digestibility (ATTD) of DM, CF, CP, and gross energy (GE) were measured, as well as the standardised ileal digestibility (SID) of amino acids (AA). The ATTD of DM, GE, and CP were significantly higher ($P<0.001$) for DL and FL compared to LM (DM: 83 vs 60%; GE: 85 vs 63%; CP: 68 vs 53%). TTAD of CF was significantly higher for DL (98.2%) compared to LM (94.6%; $P<0.01$) and FL (95.7%; $P<0.05$). The AMEn was significantly lower for LM compared to DL/FL (2,730 vs 4,950 kcal/kg DM; $P<0.001$). The SID of all AA were significantly lower for LM (52-86%) compared to DL and FL (77-98%) with respective values of 84 vs 93% for lysine and 85 vs 95% for methionine+cysteine. These differences could be explained by the higher chitin content in LM, due to defatting process. At high concentration, chitin is indeed known to impair nutrients digestibility. These results provide the first data on the nutritional value of whole BSF larvae and confirm that BSF larvae are a highly digestible source of nutrients for poultry.

Diet taste monotony decreases feed acceptability and preferences in nursery pigs

J. Figueroa¹, E. Huenul², R. Palomo³ and D. Luna³

¹Universidad de O'Higgins, Ruta 90 km 3, San Fernando, 3070000, Chile, ²Universitat Autònoma de Barcelona, Facultat de Veterinària, Bellaterra 08193, Spain., 08193, Spain, ³Universidad de Chile, Facultad de Ciencias Veterinarias y Pecuarias, Av. Santa Rosa 11735, La Pintana, Santiago, 8820000, Chile; jaime.figueroa@uoh.cl

When satiated animals have access to a diet with different sensory properties, they respond with an increase in consumption. However, most commercial diets in swine industry lack sensory variety. Thirty-two nursery pigs (43 days old, 10.9±1.63 kg) allocated in pairs into 16 pens were used to explore the effect of taste variety on their feeding behaviour. Animals were daily exposed for eight consecutive days, to acceptability (n4) and preference tests (n4), to assess sensory-specific satiety for sweet and umami tastes. Pigs were offered for 10 min a commercial feed with an inclusion of 8% sucrose (Suc-feed) or 300 mM of monosodium glutamate (MSG-feed) after being exposed to the same or different feed for the same time (Suc-Suc, MSG-MSG, Suc-MSG, MSG-Suc). Palatability was estimated by consumption patterns (consumption time/n° approaches to the feeder). Preference between Suc-feed and MSG-feed was estimated for 10 minutes after a previous exposure, for the same time, to Suc-feed or MSG-feed. Data was analysed by using the statistical software SAS®. No intake differences were observed between Suc-feed and MSG-feed intake during the acceptability test ($P=0.345$). Feed intake and palatability were affected by the interaction between the taste consumed and the taste previously exposed, where pigs consumed more and perceived the feed more pleasant when a different taste was offered ($P<0.05$). During the preference test, pigs preferred to consume MSG-feed than Suc-feed ($P<0.001$). An interaction between the taste consumed during the preference test and the taste previously delivered was observed ($P<0.001$) where pigs preferred MSG-feed over Suc-Feed, but the magnitude of this differences was lower if pigs that previously consumed MSG-feed (54 vs 23 g) than Suc-feed (72 vs 13 g). Results support that taste monotony may decrease feed acceptability, palatability and preferences in nursery pigs. Therefore, taste variety is relevant to implement in diets to approach the natural feeding behaviour of pigs.

Dietary taste variety improves performance in nursery pigs

J. Figueroa¹, T. Cabello¹, E. Huenul², R. Palomo³ and D. Luna³

¹Universidad de O'Higgins, Ruta 90 km 3, San Fernando, 3070000, Chile, ²Universitat Autònoma de Barcelona, Facultat de Veterinària, Bellaterra 08193, Spain, ³Universidad de Chile, Facultad de Ciencias Veterinarias y Pecuarias, Av. Santa Rosa 11735, La Pintana, Santiago, 8820000, Chile; jaime.figueroa@uoh.cl

The lack of dietary sensory variety decreases hedonism during a consumption episode, being able to reduce food intake and the welfare of domestic animals. Thirty-two nursery pigs allocated in pairs into 16 pens were used to explore the feed taste variety's effect on their performance. From the second week after weaning (28 days old, 6.73±0.45 kg), half of the pens (n8) were exposed for 6 weeks to a commercial feed with the inclusion of 300 mM of monosodium glutamate (MSG-feed; Monotony Group). The other half of the pens (n8) were exposed to a daily rotation between 3 different feeds; MSG-feed, a commercial feed with an inclusion of 8% of sucrose and a standard commercial feed (Variety Group). Pig's body weight, average daily gain (ADG), average daily feed intake (ADFI) and feed conversion ratio (FCR) were weekly estimated. Data were analysed with the statistical software SAS®. Pigs in the variety group tended to have a higher body weight at the end of the experiment (16.3 vs 15.1 kg; $P=0.088$) and presented an overall higher ADG (0.232 vs 0.194 kg; $P=0.008$), observing significant differences in weeks 3, 4 and 6 ($P<0.05$). The ADFI was higher in Monotony group at the beginning of the experiment, observing a significant difference at week 3 ($P=0.038$). However, the Variety Group presented higher ADGs at the middle-end of the experiment, reflected in a significant difference at week 6 ($P=0.018$). Finally, FCR was better in the Variety Group from week 3 until the end of the experiment, with significant differences at weeks 3 and 4 ($P=0.01$), also observing an overall difference (2.45 vs 2.82; $P=0.003$). These results support that a varied diet in taste between days improves performance in nursery pigs, especially from week 4 after weaning compared with animals fed with a sensory monotony diet supplemented with a palatable taste such as MSG. This could improve the productive performance of the swine industry if strategies are developed to promote dietary taste variety.

Impact of some dietary agro-industrial by-products on the gut microbiota of finishing pigs

I. Skoufos¹, A. Nelli¹, C. Voidarou¹, I. Lagkouvardos¹, E. Bonos¹, K. Fotou¹, C. Zacharis¹, I. Giannenas² and A. Tzora¹
¹University of Ioannina, Department of Agriculture, Arta, 47100, Greece, ²Aristotle University of Thessaloniki, School of Veterinary Medicine, Thessaloniki, 54124, Greece; jskoufos@uoi.gr

The optimum composition of the gut microbiota (GM) not only protects the health of finishing pigs but also improves their production performance. This dietary intervention study assessed the effect of a novel silage composed by a mixture of olive mill wastewater, grape pomace, and deproteinized feta cheese whey on the GM of finishing pigs. Eighteen finishing crossbred pigs, were penned individually and randomly assigned to three different dietary treatments: control, 5% silage and 10% silage. The duration of the trial was 40 days, after which all animals were humanely killed and ileal and colonic digesta were collected for bacterial DNA extraction. The 16s RNA gene sequencing was performed using Illumina MiSeq. The bioinformatic analysis was carried out using IMNGS pipeline and Rhea platform. A sharp separation of the group B microbial cluster from the control group was observed in both ileum ($P=0.063$) and colon ($P<0.05$). In the ileum, the relative abundance of *Clostridium* genus (*C. celatum*) was increased in group B compared to the control ($P<0.05$). In the colon, the relative abundance of *Clostridium* genus (*C. celatum*) was increased, and the relative abundance of *Streptococcus* genus (*S. alactolyticus*) was decreased in groups B and C compared to the control ($p\leq 0.05$). Interestingly, the relative abundance of *Bifidobacterium* genus (*B. pseudolongum*) increased in group B compared to the other two treatments ($P<0.05$). These results showed that 5% was the optimum inclusion level of the innovative silage in the diet of finishing pigs associated with beneficial changes in the GM. Therefore, low-cost agro-industrial by-products are promising dietary supplements for pigs lead to value-added final products. This work has been co-financed by Greece and European Regional Development Fund, Greece-China 2014-2020, project code: T7AKI-00313(MIS-5050735), acronym Green Pro.

Effects of Greek aromatic/medicinal plants on health and meat quality characteristics of piglets

G. Magklaras¹, C. Zacharis¹, K. Fotou¹, E. Bonos¹, I. Giannenas², J. Wang³, L.Z. Jin⁴, A. Tzora¹ and I. Skoufos¹
¹University of Ioannina, Department of Agriculture, Arta, 47100, Greece, ²Aristotle University of Thessaloniki, School of Agriculture, Thessaloniki, 54124, Greece, ³Nanjing Agricultural University, Jiangsu Key Laboratory of Gastrointestinal Nutrition and Animal Health, Nanjing, CN-210095, China, P.R., ⁴Guangzhou Meritech Bioengineering Co. Ltd, Guangzhou, 510300, China, P.R.; jskoufos@uoi.gr

The aim of the study was to investigate the effects of aromatic/medicinal plants, on pig health and meat oxidation. Two herbal mixtures consisting of oregano (*Origanum vulgare* subsp. *hirtum*) essential oil, crithmum (*Crithmum maritimum*) essential oil, garlic flour (*Allium sativum*) and camellia flour (*Camellia sativa*) were used in piglet diets at two different proportions. Three groups of weaned piglets were fed either the control diet (A) or one of the enriched diets (B or C, 2 g/kg). After 43 days, meat tissue cuts (biceps femoris, external abdominal, triceps branchii) were collected for chemical analysis and oxidative stability testing. Microbiological analysis of intestinal digesta from the ileum and colon was conducted. Statistical analysis revealed no differences ($P>0.05$) in the body weights and growth rates among the groups, as well as in meat chemical analysis. Haematological and biochemical parameters did not differ between the groups. An increase ($P<0.05$) of total aerobic bacteria was detected in the ileum of group B, while *Escherichia coli* counts were reduced ($P<0.05$) in group C. In the colon, reduction of *E. coli* and Lactobacilli counts were observed in groups B and C. Concentrations of malondialdehyde (MDA) as indicator of lipid peroxidation, were significantly reduced ($P<0.05$) in triceps branchii and biceps femoris for both groups B and C (day 0). A reduction ($P<0.05$) of MDA was noticed in triceps branchii and external abdominal meat samples (day 7) for groups B and C. The two investigated mixtures could be used in weaned piglets' diets with positive results on intestinal *E. coli* count reduction and oxidative stability of the meat. Funded by E.U. and National Greek Funds, 'Greece - China'. Project code: T7AKI-00313. Acronym: 'Green Pro'.

Effects of mint leaf powder on performance and egg nutrient composition of laying hensY.H. Zhang¹, M.M. Bai², H.N. Liu², X.F. Kong² and F.C. Wan¹¹Hunan Agricultural University, 410128, 1 Nongda Road, Furong District, Changsha City, Hunan Province, China, P.R., ²Institute of Subtropical Agriculture, Chinese Academy of Sciences, 410125, 644 Yuanda 'er Road, Furong District, Changsha City, Hunan Province, China, P.R.; liuhn@isa.ac.cn

This experiment was conducted to investigate the effects of mint leaf powder on performance and egg nutrient composition of laying hens in late laying period. A total of 216 laying hens with similar laying rate in late laying period were randomly divided into 4 groups. The control group was fed with basic diet, and the other three groups were added with 0.1, 0.2 and 0.4% mint leaf powder respectively in the basic diet. Each group has 9 replicates, and each replicates has 6 chickens. The whole experiment lasted for 35 days, including 7 days of pre-test and 28 days of trial. Compared with the control group, the addition of mint leaf powder in the diet had no significant difference in the feed to egg ratio, egg production rate and egg weight of laying hens at the later stage of laying ($P>0.05$). At the same time, the addition of 1 and 4% mint leaf powder can reduce the average daily feed intake (ADFI) of laying hens at the later stage of laying ($P<0.05$). The three treatment groups significantly increased the IgG content in serum of laying hens ($P<0.05$). The 0.1% mint leaf powder group significantly increased the number of large white follicles in ovary ($P<0.001$). There was no significant difference in egg weight, egg shape index and Huff unit among the three mint leaf powder supplementation groups ($P>0.05$), and there was a trend to increase the total content of L-phenylalanine, L-tryptophan, L-isoleucine and essential amino acid in egg white ($0.05<P<0.10$). The 0.1 and 0.4% mint leaf powder supplementation groups had no significant effects on fatty acid content in egg yolk ($P>0.05$). In conclusion, dietary supplementation of 0.1 and 0.4% mint leaf powder can reduce the feed intake of laying hens in late laying period, increase the IgG content in the serum of laying hens, increase the weight of oviduct and the number of follicles in laying hens, and have a trend to increase the content of amino acids in egg white, but have no significant effect on the content of fatty acids in egg yolk.

Session 66

Poster 16

Weaned piglets' gut microbiota regulation by dietary olive, winery, and cheese waste by-productsA. Tzora¹, A. Nelli¹, A. Tsinas¹, E. Gouva¹, G. Magklaras¹, S. Skoufos¹, B. Venardou¹, K. Nikolaou¹, I. Giannenas² and I. Skoufos¹¹University of Ioannina, Department of Agriculture, Arta, 47100, Greece, ²Aristotle University of Thessaloniki, School of Agriculture, Thessaloniki, 54124, Greece; tzora@uoi.gr

Gut microbiota (GM) plays a vital role in the nutrition and metabolism of weaned piglets and therefore feed additives have been developed to adjust the composition of GM in order to improve their health and performance. The purpose of this study was to evaluate the effect of dietary use of a novel silage in weaners, created by combining three agro-industrial waste products namely olive mill wastewater, grape pomace, and deproteinized feta cheese whey, on the GM composition. Forty-five crossbred weaned piglets (34 day-old) were randomly allocated to 3 pens, one per dietary treatment. Group A was the control treatment (no added silage), while a diet enriched with 5 and 10% of the novel silage was fed to groups B and C respectively. After a 40-day dietary supplementation, 6 pigs per treatment were humanely killed and ileal and colonic digesta were collected for bacterial DNA extraction. The 16S RNA gene sequencing was performed using Illumina MiSeq. The bioinformatic analysis was carried out using IMNGS pipeline and Rhea platform. In the ileum, no significant differences were observed between treatments. In the colon, the relative abundance of Prevotellaceae family was increased in group B compared to the control ($P<0.05$). At the genus level, the relative abundances of Coprococcus and Alloprevotella were increased in group B compared to the control ($P<0.05$ and 0.635 respectively) and group C ($P<0.05$ for both). The innovative silage at 5% inclusion level in the diet of weaned pigs altered beneficially the composition of the GM indicating its ability to promote their gastrointestinal health as well as production parameters. This work has been co-financed by Greece and European Regional Development Fund, Greece-China 2014-2020, project code: T7ΔKI-00313(MIS-5050735), acronym Green Pro.

Effects of medium-chain fatty acids on feed intake, body weight and egg composition of laying hensF. Cerpa Aguila¹, S. Chakroun¹, M.P. Letourneau Montminy¹, J.E. Rico² and D.E. Rico^{1,3}¹Université Laval, 2425 Rue de l'agriculture, Quebec, QC, G1V0A6, Canada, ²University of Maryland, 8127 Reagents drive, College park, 20740, USA, ³CRSAD, 120-A Chemin du Roy, Deschambault, QC, G0A1S0, Canada; daniel.rico@crsad.qc.ca

Low-protein, high-energy (LPHE) diets may reduce environmental impact of egg production, but may affect animal performance. Medium-chain fatty acids are rapidly oxidized in the liver and could help prevent fatty liver in laying hens fed LPHE diets. In addition, these fatty acids (FA) have been shown to alter egg yolk FA profile. Lohman-white layers (n=100; 25 wk of age; 1.5±0.2 kg of body weight; BW) were blocked by weight and randomly allocated to 1 of 4 diets for 77 days in a randomized complete block design. Treatments were: (1) High-protein, low-energy diet (Control; 2,600 Kcal ME/kg of DM; 17% CP; 3.5% fat); (2) LPHE diet (3,000 Kcal ME/kg of DM; 13% CP; 7% fat) based on medium-chain triglycerides (MCT; 8:0 10:0); (3) LPHE diet based on coconut oil (Coco; 12:0, 14:0); or (4) LPHE diet based on long-chain FA from soybean oil (LCFA; 56% 18:2 n-6). Feed intake (FI) and BW were recorded on d 0, 4, and weekly thereafter. Data were analysed as repeated measures in a mixed model with random effects of block and hen, and the fixed effects of treatment, time, and their interaction. There was a treatment by time interaction for FI, which decreased progressively in all LPHE diets, reaching a nadir on d 42, and being -19% lower than Control ($P<0.001$). Protein intake was reduced progressively in LPHE diets, being 32% lower than in Control (trt × time $P<0.001$). Energy intake of animals was higher 12% higher on d 4 in LPHE relative to Control, but decreased progressively and was 7% lower on d 56, 63, and 70 (trt × time $P<0.001$). There was a treatment by time interaction for body weight ($P<0.001$) as it was 8.9% lower in LPHE diets from day 35 to 77. Egg weight remained constant in the LPHE groups, whereas it increased over time in Control (trt × time $P<0.001$). Treatment had no impact on egg composition, but the proportion of egg yolk was increased whereas that of albumen and shell decreased over time ($P<0.001$). Dietary FA profile had no impact on the overall hypophagic effects of high-fat diets in laying hens.

Open-sourcing behavioural algorithms for ruminant welfare monitoring using raw wearable sensor dataD. Foy¹, T.R. Smith¹ and J.P. Reynolds²¹AgriGates, Philadelphia, 19146, USA, ²Western University College of Veterinary Medicine, 309 E. Second St. Pomona, 91766-1854, CA, USA; d.foy@agrigates.io

Wearable sensors have immense potential in monitoring ruminant welfare metrics, but their Black-Box Algorithms (BBA) and siloed data limit their usage beyond specific insights like oestrus, lameness detection, and rumination. We propose open-source behavioural algorithms and collaborations based on quality raw data (RD) output from sensors that capture individual biometrics and behavioural markers for assessing welfare measurements. Data quality is critical for accuracy, value, and understanding the RD from the available sensor adds to the validity and veracity of data used towards ruminant ML/AI and welfare metrics. We explore the need for a gold standard method to evaluate RD output from 3, 6, and 9-axis sensors and the data quality for monitoring the behaviours of food animal livestock. We discuss how the academic community, in concert with commercial enterprises, can collaborate to define acceptable RD, sensor bias, error rates, edit rates, and key biometric and behavioural markers for welfare by applying open-source behavioural algorithms to quality RD. We suggest that the sector collaborates through entities like the Linux Foundation to overcome the challenges of BBA at the farm level and commercial IP issues that arise, providing the wider sector with a standard so that an agile and scalable platform of quality data for behavioural algorithms to the individual animal of greater value at the farm level and supply chain. This approach can be extended to more ruminant species under varying production systems. Unlocking raw wearable sensor data in livestock farming for welfare monitoring that allows the application to each farm. No two farms or animals are the same, ML/AI needs to be able to adapt and learn within the context of the specific farming system and animal. We conclude that validating food animal livestock wearable RD outputs on and off-animal platforms, independent of the supplier, is crucial for improving decision support, improving ML/AI, and meeting target metrics for welfare monitoring of animals in food animal agriculture, while coordinating collectively as a sector, in an initiative to reduce, understand and map BBA critical for improving food animal welfare.

Evaluation of an automated cattle lameness detection system

N. Siachos, A. Anagnostopoulos, B.E. Griffiths, J.N. Neary, R.F. Smith and G. Oikonomou

University of Liverpool, Department of Livestock and One Health, Leahurst Campus, CH64 7TE, United Kingdom; nektarios.siachos@liverpool.ac.uk

Our aim was to evaluate the performance of an automated lameness detection system (CattleEye Ltd) which is using a 2D surveillance camera mounted over an exit race. A total of 29 whole-herd mobility scoring sessions in 8 medium to large-size herds were performed by 4 experienced veterinarians (VETs) using the 4-grade (0-3) AHDB mobility scoring method. The weekly average score for each cow provided by the system (CE) was also stored and analysed after the end of the study. A total of 27,082 mobility scores were collected and matched to the weekly average CE scores. Agreement between CE and each VET was assessed for the binary transformed scores (0: 0,1; 1: 2,3) using percentage agreement (PA), kappa (κ) and Gwet's coefficients (AC). Moreover, the same VET was present in 17 foot trimming sessions in 3 farms and recorded the presence and severity of sole haemorrhage (SH), sole ulcer (SU), white line disease (WL), toe ulcer (TU), digital dermatitis (DD) and interdigital phlegmon (IP) cases. Lesion records were then matched with the weekly average CE scores, resulting in a dataset of 991 cows. The same VET also mobility scored a subset of 340 cows in 2 farms 1-3 days before foot trimming. Accuracy (ACC), sensitivity (SE) and specificity (SP) were calculated for both CE and the VET; presence (binary) of at least one case of SU grade ≥ 2 , WL grade 3, TU, stage M2 of DD and IP grade 2, was used as the gold standard. Overall PA, κ and AC ranged from 81.5 to 86.3%, from 0.23 to 0.41, and from 0.76 to 0.83, respectively (when agreement between CE and VETs in binary mobility scores was assessed). ACC, SE and SP of CE and VET varied notably among farms, yielding an overall combination of 0.83, 0.40 and 0.88, and 0.80, 0.53 and 0.83, respectively. Based on our results, the agreement between CE and VETs is within the moderate and substantial range, in concordance with that reported between experienced assessors in an initial validation study. Further investigation of farm and cow-level factors that potentially influence the predictive ability of CE in identifying cows bearing foot lesions is needed.

Session 67

Theatre 3

Breath analysis in dairy cattle: going beyond methane emission

I. Fodor¹, E. Van Erp-Van Der Kooij² and I.D.E. Van Dixhoorn¹

¹Wageningen University and Research, De Elst 1, 6700 AH Wageningen, the Netherlands; ²HAS green academy, Department of Animal Husbandry, Onderwijsboulevard 221, 5223 DE 's-Hertogenbosch, the Netherlands; istvan.fodor@wur.nl

Real-time, non-invasive monitoring tools are continuously being investigated in research and deployed in practice in the dairy cattle industry. So far, breath composition of dairy cattle has been typically monitored for methane emissions only. Although, a growing body of evidence suggests that the potential applications of breath analysis go beyond monitoring methane emissions. The results from our systematic review on using breath analysis to detect diseased cattle showed that research focused on cows before 2000, however, calves have been studied more frequently since then. Ketosis has been the most studied cattle disease using breath analysis so far. Our experimental results showed potential of breath analysis to follow ketosis status in postpartum cows, because a rise in serum β -hydroxybutyrate was significantly related to a rise in breath acetone concentration. We also showed that longitudinal records would be necessary to detect increasing breath acetone levels within individual cows, instead of single spot measurements. In another experiment, we found that a lower respiratory exchange ratio (CO_2/O_2 , V/V%) was linked to a larger decrease in body condition score and higher levels of serum β -hydroxybutyrate in the first six weeks postpartum in dairy cows. We also found a link between breath composition and feed efficiency, using data from automated emissions monitoring stations. As an outlook for the future, breath analysis has potential to be used as a practical, non-invasive, real-time monitoring tool on dairy farms, with a broader scope than monitoring methane emissions. Although, more research is needed to further explore the capabilities of this tool, and engineering solutions are also needed to implement this technique on dairy farms.

Dairy cow personality: correlations with age, weight, back fat thickness and activity

P. Hasenpusch, T. Wilder, A. Seidel, J. Krieter and G. Thaller

Christian-Albrechts-University, Institute of Animal Breeding and Husbandry, Olshausenstraße 40, 24098 Kiel, Germany; phasenpusch@tierzucht.uni-kiel.de

Personality traits determine dairy cow reactions to potentially stressful situations such as management procedures and social interactions in group housed dairy cattle. Therefore, identification of personality traits may help to improve animal welfare. A common approach to assess those traits are behavioural tests. Accordingly, the reaction of 200 lactating Holstein-Friesian cows stressed by a novel object and human approach in a known environment was observed. Latencies and quantities of vocalisation, urination, defecation, approaches and contacts as well as the duration of every object contact were measured in the novel object test (NOT). In the human approach test (HAT), the minimal distance and the cow's reaction to three subsequential approaches were documented. Due to the assumption that personality traits could be described by certain combinations of the observed variables, Bartlett's Test of sphericity and Kaiser-Meyer-Olkin Criteria were applied to validate if and which variables could be used for principal component analysis. Correlations between extracted components and age at testing, daily activity (measured via pedometer) and body weight, were estimated ($P < 0.05$). Kaiser Criteria suggested the extraction of four distinct components for the NOT. According to correlations with measured variables those components were named: Explorative (factor loading of 0.6 quantity of contacts; 0.99 contact duration), bold (-0.97 latency of approach; 0.96 latency to contact), nervous (-0.97 latency to urinate/defecate; 0.97 quantity of urinations/defecations) and sociable (-0.89 latency to vocalise; 0.89 quantity of vocalisations). For the HAT, one component named trusting (-0.85 first approach; -0.87 second approach; -0.87 third approach) was extracted. Age (0.14), weight (0.21) and back fat thickness (0.2) correlated with trusting. Variation coefficient of daily activity correlated with being explorative (0.16) and trusting (-0.17). Further behavioural studies are currently underway considering individual and group interactions by precise indoor positioning via ultra-wideband.

Automatic behaviour assessment of young bulls in pen using machine vision technology

A. Cheype¹, J. Manceau², V. Gauthier², C. Dugué³, L.-A. Merle⁴, X. Boivin⁵ and C. Mindus¹

¹Institut de l'élevage, 149 rue de Bercy, 75012 Paris, France, ²NeoTec-Vision, 7 allée de la Planche Fragline, 35740 Pacé, France, ³France Limousin Selection, Pole de Lanaud, 87220 Boisseuil, France, ⁴Ferme des Etablières, route du Moulin-Papon, 85000 la Roche-sur-Yon, France, ⁵Université Clermont Auvergne, INRAE, VetAgroSup, UMR1213 Herbivores, 63122 Saint-Genès Champanelle, France; agathe.cheype@idele.fr

Changes in animal's behaviour may be good indicators of health and welfare variations. However, human observation is time-consuming and labour-intensive. Development of video technology and image processing is a non-invasive method which may offer the opportunity for a better prevention by detecting behavioural and welfare issues continuously and automatically and therefore at an early stage. We are developing deep learning algorithms to analyse routinely the behaviour of young bulls. In the present work, performances of algorithms developed to automatically detect the different activities of bulls on images are evaluated. Bulls originating from 2 different breeds (Limousine, 6 bulls/pen; Charolais, 13±1 bulls/pen) were housed accordingly to the standard management conditions of their respective stations (Pôle de Lanaud, Ferme des Etablières). Two cameras 2 D colour were installed above each pen with different angular views. Nine postures (standing, lying) and behaviours (eating, drinking, moving, autogrooming, fighting, standing up and lying down) were labelled on 1,108 images extracted from the videos. Annotations are evenly distributed with an average of 123 sequences per type of posture or activity and a standard deviation of 37.0. This annotated set of images was used to train the algorithm, an object detection model that uses convolutional neural networks to detect and classify objects in an image. Preliminary training of the algorithm with 419 standing bulls and 373 lying bulls' pictures is promising with 88% sensitivity and 79% precision. Complementary results of algorithm's performances will be presented by valuing the full dataset. This project BeBoP will contribute to the current need for on-farm, operational behavioural welfare indicators that can be easily used to assess not only the individual welfare but also the welfare of the whole group.

Parity and lactation stage preserve a stable structure in the dynamic social networks in cattleH. Marina¹, I. Hansson¹, I. Ren¹, F. Fikse², P.P. Nielsen³ and L. Rönnegård^{1,4}¹Swedish University of Agricultural Sciences, Box 7023, 750 07 Uppsala, Sweden, ²Växa, Ulls väg 26, 756 51 Uppsala, Sweden, ³RISE Research Institute of Sweden, RISE Ideon, 223 70 Lund, Sweden, ⁴Dalarna University, Högskelegatan 2, 791 88 Falun, Sweden; hector.marina@slu.se

Social interactions between cows are a reflection of animal welfare. Positive interactions between dairy cows promote animal welfare and hence increase milk production. A large number of scientific observational studies focused on social interactions in cattle have been published. These types of studies are limited to short periods of time and to a reduced number of animals. Precision Livestock Farming allows the automated monitoring of animals over long periods of time. In this regard, Real-time location systems provide the opportunity to monitor dyadic social interactions of dairy cattle. Spatial proximity between dairy cows has been associated with affiliative social interactions. In this study, we applied the ultra-wideband location technology to explore dyadic social interactions between dairy cows in a commercial free-stall barn with approximately 210 lactating Holstein Friesian cows. Positioning data were collected every second for 14 days. We assumed that a social interaction occurred when a pair of cows spent at least 10 minutes per day within 2.5 m of each other. The spatial interactions observed in the two different functional areas (the feeding area and the resting area) were used to build daily social networks. The main objective of the study was to determine the role of parity and lactation stage in the maintenance of a stable base structure in the dynamic social networks in cattle. Additionally, we analysed the repeatability of the role of the animals in the social networks to improve our understanding of the dynamics of social networks in dairy cattle. Our study enhanced the role of the parity and lactation stage in the preservation of a stable structure in the dynamic social networks in cattle and reveals insights into how the role of animals in social networks evolves over time. Understanding the evolutionary dynamics of social networks in dairy cattle could contribute to the stability of the social structure, promoting animal welfare and production, and to the comprehension of disease transmission in dairy cattle.

Application of rumen boluses to receive welfare parameters from fattening bullsK. Fromm¹, J. Heinicke¹, T. Amon^{1,2} and G. Hoffmann¹¹Leibniz Institute for Agricultural Engineering and Bioeconomy e.V. (ATB), Department Sensors and Modelling, Max-Eyth-Allee 100, 14469 Potsdam, Germany, ²Institute of Animal Hygiene and Environmental Health, Department of Veterinary Medicine, Freie Universität Berlin, Robert-von-Ostertag-Str. 7-13, 14163 Berlin, Germany; kfromm@atb-potsdam.de

Despite the immense importance of beef production to our economy, there is only a minor amount of publications about physiological and behavioural responses of feedlot cattle. In comparison to female bovines, the gap of data collection from bulls is even larger. Especially in regard to the welfare situation of bulls, the tools to collect these parameters are restricted. Due to safety grounds, it is not always possible to get in close contact to the animals. Therefore, researchers and farmers need techniques which can be operated from a distance e.g. scores, behavioural analysis, surrounding conditions. The last decades several new sensors were brought on the market that allow us to get physiological information from bulls without the necessity of exposing people to greater risks. For several reasons, they have not found place yet in our fields. We will discuss one of these systems and investigate the advantages and disadvantages compared to other animal monitoring devices. For our current study, we equipped 60 fattening bulls (initial BW=491±53 kg) with rumen boluses (smaXtec SX 2. EU, smaXtec animal care GmbH, Graz, Austria) that are commonly used for fertility prediction in dairy cows, recording rumen temperature, rumination, activity and daily amount of water intake. Fifty subjects obtained classic boluses, which collected the mentioned parameters and ten bulls were equipped with pH plus boluses, which additionally recorded rumen pH. The animals were observed for 180 days. The investigation showed that the use of the boluses is possible and useful in fattening bulls. They enable an early prediction about health status and subacute ruminal acidosis. Acknowledgements The project InnoRind is supported by funds of the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany via the Federal Office for Agriculture and Food (BLE) under the innovation support program.

Stepwise modelling for improved bovine healthC.M. Matzhold¹, K.S. Schodl¹, C.E. Egger-Danner¹, F.S. Steininger¹ and P.K. Klimek²¹ZuchtData EDV-Dienstleistungen GmbH, Dresdner Str. 89, 1200 Wien, Austria, ²Complexity Science Hub Vienna, Josefstädter Str. 39, 1080 Vienna, Austria; matzhold@zuchtdata.at

The digitisation of livestock farming is generating multiple streams of data that have the potential to significantly improve bovine health when linked and analysed. However, developing models to transform complex integrated datasets into smart decision-making tools often requires a trial-and-error approach. Therefore, we propose a stepwise modelling approach in which specific dimensions of a farm are first analysed separately to reduce data complexity. We analysed over 50 variables from 8,282 farms and an additional 200 for 457 farms. To ensure quality of our analysis, only farms with regular health data reporting are included. The data will be enriched with dynamic information derived from DHI assessments, the National Weather Service, and AMS systems for 1,025 farms, allowing the development of tools to identify at-risk cows based on a score. Our stepwise process allows for more detailed analysis of the effects of individual trait clusters, as demonstrated by our preliminary results on farm traits. These findings indicate that farms with access to alpine pasture exhibit a 50% lower risk of lameness. Leveraging this insight, we developed predictive models for animal health by enriching the dataset with dynamic variables, resulting in a model predicting lameness with high sensitivity and specificity (F1=0.74). We believe that our approach will improve the accuracy of animal health models by enabling individual and collective analysis of datasets, allowing a deeper understanding of their interactions and the development of more accurate models.

Is milking order connected to social interactions?

I. Hansson, H. Marina and L. Rönnegård

Swedish University of Agricultural Sciences, Animal Breeding and Genetics, Ulls väg 26, Box 7023, 750 07, Uppsala, Sweden; ida.hansson@slu.se

Information on the social interplay between cows in a dairy herd can be essential to improve herd management and enhance animal welfare and health. Cows' movement around the barn and their interactions with other herd mates have shown to be non-random. Cows differ in their tendency to stay close to other individuals, and some cows seem to create preferential bonds with individuals with similar attributes. This study aims to investigate if milking order to a milking parlour is connected to the cow's social role in the herd, with a further aim to examine the relationship to milk yield. The social behaviour of dairy cattle and dyadic interactions can be measured using advanced sensor technology and social network analysis. Positioning data of dairy cattle were collected from an ultra-wideband indoor positioning system in a herd with approximately 200 cows. Cow positions were recorded every second, with an accuracy of 50 cm, and were used to see which cows were spending time in proximity to one another. If cows were within a distance of 2.5 m for at least 10 min per day, they were assumed to interact socially. The interactions were predicted in two functional areas within the barn: the feeding and resting areas. Topological network parameters such as betweenness centrality, closeness centrality, degree and eigenvector centrality scores were used to describe the individual cow's role within the social network. Cows were divided into four groups depending if they entered the milking parlour in the first, second, third, or last group. Ordinal logistic regression models were used with the milking order group as the response variable and the topological network parameters as different fixed effects in each model. The results showed positive associations between all network parameters in the resting area and entering the parlour early. These results indicate that cows that contribute more to the network's connectivity, are more closely connected to the rest of the individuals, and have more interactions in the resting area are more likely to enter the milking parlour at an early stage. Further analyses will be conducted on whether milking order and cows' social interactions affect milk yield.

Combining ultra-wideband (UWB) location and accelerometer data for cattle behaviour monitoringS. Benaissa^{1,2}, F. Tuytens^{1,3}, D. Plets², L. Vandaele¹, L. Martens², W. Joseph² and B. Sonck^{1,4}

¹Flanders Research Institute for Agriculture, Fisheries and Food (ILVO), Animal sciences, Scheldeweg 68, 9090 Melle, Belgium, ² Ghent University/imec, Department of Information Technology, iGent-Technologiepark 126, 9052 Ghent, Belgium, ³ Ghent University, Faculty of Veterinary Medicine, Department of Veterinary and Biosciences, Heidestraat 19, 9820, Merelbeke, Belgium, ⁴Ghent University, Faculty of Bioscience Engineering, Department of Animal Sciences and Aquatic Ecology, Coupure links 653, 9000 Ghent, Belgium; said.benaissa@ugent.be

Precision livestock farming (PLF) technologies build on the collection and processing of reliable real-time data at the individual level to efficiently classify animal behaviours for improved monitoring and management systems. The current accelerometer-based systems can monitor only a limited number of behaviours, such as feeding and ruminating (neck collar sensors) or lying and standing (leg sensors). Moreover, the accuracy of detection of behaviours that are less frequently expressed in animals, such as walking or drinking, remains a challenge. The aim of this study was to present a novel efficient method to incorporate indoor location and accelerometer data for improved cattle behaviour monitoring systems. In total, 30 dairy cows were fitted with Pozyx tracking tags (Pozyx, Ghent, Belgium) on the upper (dorsal) side of the cow's neck. A total of 123 hours of video recordings were used for validation. Bland-Altman plots for the correlation and difference between the estimated behaviours (sensors) and the ground-truth behaviours (video) were computed for the performance analysis. In overall, the location-based classification into the correct functional areas was very high ($R^2=0.99$, $P<0.001$). The combination of location and accelerometer data improved the RMSE per bout of the feeding time and ruminating time compared to the accelerometer data alone (2.6 to 1.4 min). Moreover, the combination of location and accelerometer enabled accurate classification of additional behaviours that are difficult to detect using the accelerometer alone, such as eating concentrates and drinking ($R^2=0.85$, and 0.90 , respectively). This study demonstrates the potential of combining accelerometer and UWB location data for designing a robust monitoring system for dairy cattle.

FEMIR report – the new MIR advising toolL.M. Dale¹, A. Werner¹, C. Natterer¹, E.J.P. Strang¹, Emissioncow Consortium², Remissiondairy Consortium³ and J. Bieger¹

¹Regional association for performance testing in livestock breeding of Baden-Wuerttemberg (LKV BW), Heinrich Baumann Str. 1-3, 70190, Germany, ²<https://www.emission-cow.de/>, Adenauerallee 174, 53113 Bonn, Germany, ³<https://remission-dairy.de/>, Erlenweg 23, 49324 Melle, Germany; ldale@lkvbw.de

As part of the ReMission Dairy and eMissionCow project, a report called FeMIR has been developed that provides a good description of the energetic situation of the herd over all lactation stages. Moreover, this report is a new tool that allows a better and easier monitoring of the animals' metabolism. In the last years FeMIR report has been tested in the field by four field workers and three consultants, a field test was carried out in which the new parameters i.e. energy efficiency, feed efficiency, nitrogen efficiency and the fatty acids: DeNovo and Preform were compared with the livestock on the trial farms. As part of the field test farm visits in different sides of Baden Württemberg took place in order to set the guidelines for the new parameters. Here, differences became clear, which made it possible to determine that the report is very helpful as a management tool for feeding and monitoring the metabolism of the animals. The report of the respective farm was performed in the MIR spectral data from the monthly milk recording and as well feed samples was taken and conspicuous animals according to the FeMIR were examined. In addition to the handling and use of the report, the limits of each parameter were determined and established to be able to define an optimal framework in which a farm should be. At this step, the respective physical constitution of the animals, as found on site, confirmed the experts' expectations, which they had derived from the efficiency and energy parameters in the report. On all three farms this assessment could be found, which is why the FeMIR report was also rated by all participants as a valuable and suitable management tool for feeding and monitoring the animals' metabolism.

Heat stress relief of dairy cows by evaporative cooling under Mediterranean summer conditionsS. Pinto¹, C. Ammon¹, F. Estellés², A. Villagra³, T. Amon^{1,4} and G. Hoffmann¹¹Leibniz Institute for Agricultural Engineering and Bioeconomy e.V. (ATB), Department Sensors and Modelling, Max-Eyth-Allee 100, 14469 Potsdam, Germany, ²Universitat Politècnica de València, Camino de Vera, Valencia, Spain, ³Centro de Tecnología Animal (CITA-IVIA), |, Segorbe, Spain, ⁴Freie Universität Berlin, Veterinary Medicine, Institute of Animal Hygiene and Environmental Health, Robert-von-Ostertag-Str. 7-13, Berlin, Germany; severinop@atb-potsdam.de

The warm and humid climate during summer in Mediterranean countries presents a particularly high risk for dairy cows in terms of heat stress. The present study aimed to investigate the effectiveness of evaporative cooling on respiration rate (RR) of lactating dairy cows, considering individual animal factors (standing vs lying). A total of 18 Holstein dairy cows (1st to 5th lactation; mean $\pm$ SD; 41.64 $\pm$ 4 kg milk per day and 150 $\pm$ 4.7 days in milk) were randomly selected in July 2016 from the high-yielding group of a farm. The cows were housed in a loose naturally ventilated barn, located in Bétera, Spain. Cooling sessions were implemented three times a day (05:15, 13:15, and 21:15 h) for 45 minutes each, with side and ceiling fans and sprinklers. RR (bpm; breath per minute) of the cows was hourly measured by visually counting of flank movements, and the body posture (standing vs lying) was documented during the data collection. Data were analysed for differences between factor levels via a linear mixed model with repeated measurements at an overall significance level of 0.05. During the experimental period the temperature-humidity index (THI) inside the barn was recorded (76.6 $\pm$ 4.1). Standing cows decreased ($P<0.001$) the RR in the cooling (54 $\pm$ 11.8 bpm) compared to the cows in the barn (60 $\pm$ 18.9 bpm). In contrast, lying cows (71 $\pm$ 14.8 bpm) inside the barn showed higher RR ($P<0.001$) than standing cows. Regardless of cow body posture, implementing measures of heat relief as evaporative cooling reduced RR in lactating dairy cows under pressure from hot climate conditions. The project was funded by the FACCE-ERANET Plus Initiative 'Climate Smart Agriculture' in Brussels; by the Federal Office for Agriculture and Food (BLE), and a scholarship from the Coordination for Improvement of Higher Education Personnel (CAPES), Brazil.

Poster 13

Performance of subcutaneous thermochips implanted in dairy cows: preliminary reportA.R. Garcia¹, L.K. Zanetti², T.C. Alves¹, L.M. Neira², L.F. Pinho³, A.N. Barreto³, M.J. Moraes³, G.G. Ramos⁴, C.E. Grudzinski⁴ and G.N. Azevedo²¹Brazilian Agricultural Research Corporation, Rod Washington Luiz, km 234, 13560, São Carlos, Brazil, ²UNICEP, R Miguel Petroni, 5111, 13563, São Carlos, Brazil, ³Federal University of Pará, Rod BR 316, 68740-970, Castanhal, Brazil, ⁴University of São Paulo, Av Duque de Caxias, 225, 13635, Pirassununga, Brazil; alexandre.garcia@embrapa.br

The standard technique for measuring the internal temperature of cattle is clinical thermometry (CT), but this does not meet the requirement for automation of data collection in the herds. In this context, the use of microchips for monitoring the temperature of animals has been studied but has its limitations. Therefore, our objective was to evaluate the performance of thermochips for predicting internal temperature. Three $\frac{1}{2}$ Holstein $\times$ $\frac{1}{2}$ Jersey cows (85 $\pm$ 41 m, 592 $\pm$ 132 kg) were used (Bioethical Prot PRT 06/2022). Thermochips (2.1 $\times$ 12 mm, ISO 11784/85, 134.2 kHz) were implanted subcutaneously in the rear udder attachment (RUA), ear base (EB), tail head (TL), and armpit (AP) of each animal. Rectal temperature (RT) was determined using CT as the gold standard. At the same time, the thermochips were read with a universal scanner and the local microclimate data were used to calculate the temperature and humidity index (THI). Evaluations were conducted during the summer at random times of day on eleven alternate days. The average RT was 38.7 $\pm$ 0.57 °C. The average temperatures recorded by the microchips were: TL (38.1 $\pm$ 0.69 °C), RUA (37.8 $\pm$ 0.73 °C), EB (37.6 $\pm$ 0.98 °C), AP (37.1 $\pm$ 0.99 °C), indicating that the absolute values of TL and RUA were closer to RT. Spearman correlation ($P<0.05$) between thermochip temperatures and RT were: RUA (0.93), TL (0.88), AP (0.84), and EB (0.78). Significant correlations ($P<0.05$) with THI were: EB (0.46), TL (0.39), and RUA (0.38). The lower the correlation with THI, the less influence the thermal environment has on the anatomic region. Conversely, the higher the correlation with RT, the more appropriate the indicator would be, since RT is the most important parameter of homeothermy in cattle. In view of this, implantation of a thermochip in the RUA or TL seems to be a promising strategy for digital monitoring of temperature in dairy cows. Since our results are preliminary, further research on this topic is recommended.

Dairy cow behaviour as proxy for heat stress sensitivity in dairy cows

I. Fodor, R.S.C. Rikkers, M. Taghavi and I. Adriaens

Wageningen University and Research, Animal Breeding and Genomics, Droevendaalsesteeg 4, 6708 PB Wageningen, the Netherlands; istvan.fodor@wur.nl

The frequency and severity of extreme weather events are increasing as a result of climate change. To improve and maintain sustainable animal production, it is crucial to quantify and understand the effect of these weather events to our animals. In our research, we aimed to quantify heat stress sensitivity in dairy cows based on its effect on (1) milk production, (2) fertility and (3) health, and predict this sensitivity based on the behavioural changes of the cows. To this end, we quantified individual cow heat stress sensitivity by modelling both the group and the individual production time series of behaviour and production in function of the temperature-humidity index and covariates such as parity and lactation stage with a linear mixed model. By looking at the group trends and the individual trends in relation to the group, we could separate animals that are more or less affected by heat stress. Additionally, re-arranging the residuals of our mixed model in function of the time, also allowed to quantify time-lagged (the so-called recovery or overcompensation period) effects. We found for example that older cows and animals in mid lactation suffer more from heat stress, and that this translates in increased activity, together with more time spent at the drinking troughs and less at the feeding rack. Also within peer-groups, we found that variability across cows exists in how severe individual cows are affected by the events. As with PLF technologies continuous and automated monitoring and comparison with herd-peers is possible, these results offer opportunities for selecting animals that are best adapted to their individual management environment, and for tailoring the management to the individual cows' needs, e.g. by separating animals that are sensitive in better insulated barns or barns sections with fans.

Session 67

Poster 15

Exploring the feeding behaviour of dairy calves: insights from automated milk feedersK.J. Hemmert^{1,2}, M.H. Ghaffari², T. Förster¹, C. Koch³ and H. Sauerwein²¹Förster-Technik GmbH, Gerwigstraße 25, 78234 Engen, Germany, ²University of Bonn, Institute of Animal Science, Katzenburgweg 7-9, 53115 Bonn, Germany, ³Hofgut Neumühle, Neumühle 1, 67728 Münchweiler an der Alsenz, Germany; hemmert@uni-bonn.de

Monitoring the feeding behaviour of dairy calves using automated milk feeders (AMF) became common whereby milk intake and drinking rate are used as indicators of satiety, development, and health. Further detailed information about feeding behaviour can be recorded by modern AMF, such as nudging at the teat, corresponding to natural nudging at the dam's udder. This nudging behaviour has hardly been investigated. In the current study, we aimed at comparing this behaviour between the preweaning phase with high feeding level and the weaning period. Female Holstein calves (n=56) group-housed from d 16 of life has access to 12 l/d of milk replacer (MR, 140 g/l) until d 56 when the daily MR allowance was linearly decreased until d 98 of life per d. Records of feeding behaviour comprised milk consumption [ml/d], drinking speed [ml/min], number of rewarded and unrewarded visits, and power of nudging bouts [per min./visit] via the AMF (VARIO smart and add-on HygieneBox, Förster-Technik GmbH, Engen, Germany). Statistical descriptive analysis and paired sample tests (Wilcoxon) of sensor data were performed using Python 3 and JASP 0.16.4. We evaluated 12,659 rewarded visits from the preweaning period and 11,562 from weaning. The average frequency of AMF visits was 8.5×/d preweaning, 13×/d weaning, entire period: 11×/d and resulted in average intakes of 8.2 l/d. The mean drinking speed was 1.24-fold increased during the weaning time as compared to the preweaning period. Nudging activities during and after a meal were increased ($P<0.001$) during the weaning period as compared to the preweaning time, both in average over all calves, and when using the individuals' averages. The results indicate that calves, beside drinking faster, also increased their natural nudging behaviour during weaning in an effort to increase the MR flow. Despite a relatively long milk feeding period of 14 weeks in total, a high daily allowance for 8 weeks, and early *ad libitum* access to concentrate and forage, the calves seemed to have an urge to satisfy their suckling behaviour and hunger with MR.

Characterization of behavioural anomalies of lameness in dairy cows using sensor technology*N.L. Mhlongo**Wageningen University & Research, Environmental Sciences, Room L-C-107 Droevendaalsesteeg 3, 6708 PB Wageningen, the Netherlands; nokuthulalorraine.mhlongo@wur.nl*

Immediate or gradual behavioural alterations can be important indicators of lameness in dairy cows. Sensor technology offers potential tools to detect these alterations in behaviour. However, to use sensed behavioural patterns as indicators of lameness, differences between lame and healthy cattle need to be known and quantified. Therefore, this study aimed to use sensors to provide distinctive behavioural patterns that are indicative of lameness in dairy cows. Six Dutch dairy farms were visited in 2021 and 2022 from spring to early autumn. Approximately 70 cows that were either healthy or lame were equipped with an accelerometer and GPS for a week to obtain data on mobility characteristics. Visual behavioural observations (15 minutes per observation) were carried out for behavioural classification. During subsequent statistical analyses, descriptive features were computed and later linked to specific behaviours and health status. The results indicate distinct behavioural differences between lame and healthy cows. As expected, lame cows tended to lie down more and had longer individual lying bouts compared to healthy cows. Moreover, the duration lame cows grazed and the frequency at which it occurred decreased in comparison to the healthy cows. The frequency at which lame cows lay down was also higher than those of healthy cows. Overall, lame cows tended to expectedly move at a slower speed compared to healthy cows. Sensor technology is promising and can potentially be used to distinguish the behavioural characteristics of lame from healthy cows. Considering specific behavioural traits expressed by lame cows could further produce clearer lameness indicators in dairy cows.

Poster 17

Test of Bluetooth low energy localization system for dairy cows in a barn*J. Maxa¹, D. Nicklas², J. Robert³, S. Steuer² and S. Thurner¹**¹Bavarian State Research Centre for Agriculture, Institute of Agricultural Engineering and Animal Husbandry, Vöttingerstr. 36, 85354 Freising, Germany, ²University of Bamberg, Chair of Mobile Systems, An der Weberei 5, 96047 Bamberg, Germany, ³University of Erlangen-Nürnberg, Institute of Information Technology, Am Wolfsmantel 33, 91058 Erlangen, Germany; jan.maxa@lfl.bayern.de*

Sensor-based cattle monitoring in a barn is widely used nowadays, especially on large-scale farms. However, there is a lack of animal monitoring systems that reliably provide data on the location of the cows with high frequency, both in the barn and on the pasture. Therefore, we develop a cost-effective and energy-efficient localization system for cattle in combined barn and pasture conditions within the project 'WeideInsight'. The main aim of this study was to test and evaluate the localization accuracy of the new localization system in the dairy barn of the Staatsgut Almesbach (BaySG) in Bavaria. It consisted of Bluetooth tags (Safactory) attached in a housing (Cattle Data) mounted on collars worn by the cows and Bluetooth Low Energy (BLE) beacons installed in the barn and recording cow's position every 5s. During the trial conducted in 2022, ten Simmental cows from the automatic milking system herd were included in the study. Positions of cows equipped with Bluetooth tags, together with their behaviour, were recorded based on video observations and used as a localization reference. Due to data noise and irregular occurrence of less than three beacons close to the cow, trilateration was impossible to determine the cow's exact position in the barn (e.g. cubicle). Therefore, an alternative approach of proximity-based localization was applied where only the closest beacon was returned. Signal strength indicator (RSSI) filters of -50 and -80 dBm were then applied to positioning data. Applied RSSI of -50 dBm resulted in the highest position accuracy compared to raw data and other RSSI thresholds. Positioning data without the application of RSSI threshold resulted in higher inaccuracy due to reflections based on barn facilities and obstacles, cow bodies and other factors. Even though BLE localization of cows in a barn provides less accurate information, its low cost and energy efficiency can be advantageous for certain cattle housing systems.

Integrating inline milk infrared spectra and genomics to predict metabolic profiling in dairy cattle

D. Giannuzzi¹, L.F. Macedo Mota¹, H. Toledo Alvarado², S. Pegolo¹, L. Gallo¹, S. Schiavon¹, E. Trevisi³ and A. Cecchinato¹

¹University of Padua, DAFNAE, Legnaro, PD, Italy, ²National Autonomous University of Mexico, Genetics and Biostatistics, Mexico City, CDMX, Mexico, ³Catholic University of Sacred Heart, DIANA, Piacenza, PC, Italy; diana.giannuzzi@unipd.it

Metabolic disorders in dairy cattle have negative effects on cows' health and welfare, impairing farm efficiency and sustainability. Diverse serum metabolites are known to be valuable indicators of cows' health status and could be used to identify stress-resilient animals. In the era of high-throughput genotyping and phenotyping, the possibility of blood profiling using prediction from milk samples obtained during daily milking routine would be an attractive strategy. We developed calibration equations for 28 blood metabolites related to energy, liver function, oxidative stress, inflammation, and minerals using milk near-infrared (NIR) spectra collected by the AfiLab instrument and applying diverse machine learning (ML) methods. The dataset comprised 385 Holstein cows reared in 1 herd in Northern Italy, fully equipped with PLF tools. Cows were genotyped using the Geneseek Genomic Profiler Bovine 100K SNP Chip assay. Two models (M) were fitted: M1 considered the NIR spectra together with individual animal data (DIM and parity), M2 considered predictors in M1 plus the genomic information. Model performance was evaluated using a 10-fold random cross validation. Considering the best performing ML method (stacking ensemble), the correlation (r) between the observed and predicted phenotypes ranged from 0.48 for paraoxonase to 0.76 for Na. Respect to M1, the integration of genomic information in M2 increased on average the r of 13% for metabolites related to energy, 11% for liver function, 15% for oxidative stress, 9% for inflammation, and 15% for minerals. In conclusion, our study indicates that integrating NIR milk spectra with individual and genomic data ameliorates predictability and could be considered for the prediction of metabolic profile during daily milking procedure. This study was carried out within the Agritech National Research Center and received funding from the European Union Next-GenerationEU (Piano Nazionale di Ripresa e Resilienza (Pnrr)-Missione 4 Componente 2, Investimento 1.4-D.D. 1032 17/06/2022, CN000000022).

Session 67

Poster 19

Influence on the water intake of lactating dairy cows

J. Heinicke¹, C. Ammon¹, T. Amon^{1,2}, G. Hoffmann¹ and S. Pinto¹

¹Leibniz Institute for Agricultural Engineering and Bioeconomy e.V., Sensors and Modelling, Max-Eyth-Allee 100, 14469 Potsdam, Germany, ²Institute of Animal Hygiene and Environmental Health, Freie Universität Berlin, Department of Veterinary Medicine, Robert-von-Ostertag-Str. 7-13, 14163 Berlin, Germany; spinto@atb-potsdam.de

The statement 'drink enough' applies to humans as well as animals. Water is essential, it is involved in all life processes. In dairy cows, water deficiency can lead to reduced feed intake, decreased performance and heat tolerance, and increased susceptibility to diseases. For the production of one litre milk, a cow needs 3-4 l water intake. The recording of individual water intake is often difficult because the entire herd drinks from large collection tanks. A technology (rumen bolus) of smaXtec GmbH (Graz, Austria) enables to record the absorbed amount of water per cow and day. The sensor continuously measures the body temperature in the cow's rumen and registers sudden strong drop as a drinking event. Artificial intelligence is used to determine how much water was consumed. The data show that a lactating dairy cow drinks about 80 to 170 l/d. The presented study investigated the influence of milk yield, lactation stage and climate regarding the water intake. The study was conducted in a naturally ventilated dairy barn in Germany. The herd consisted of 160 lactating Holstein Friesian cows from the 2nd to 7th lactation and had an average daily milk yield of 41.52±5.22 kg. Data from January to December 2022 were analysed. Ambient temperature and relative humidity were recorded within the barn. The temperature-humidity index was calculated to assess the heat stress condition. Cows with a milk yield of approx. 30 l/d showed an increase in water intake from 80 to 130 l per cow and day with a temperature change from 5 to 30 °C. While cows with a higher milk yield (approx. 50 l/d) even had an increase in water intake from 120 to 165 l/d. In conclusion, the exact amount of water intake is important to know for farmers and scientists to identify early warnings and research gaps around animal health, performance and heat tolerance. The project is supported by funds of the Federal Ministry of Food and Agriculture based on a decision of the Parliament of the Federal Republic of Germany via the Federal Office for Agriculture and Food.

Sm@RT: Identifying sheep and goats farmers' technological needs and potential solutions

C. Morgan-Davies¹, L. Depuille², J.M. Gautier², A. McLaren¹, T.W.J. Keady³, B. McClearn³, L. Grova⁴, P. Piirsalu⁵, V. Giovanetti⁶, I. Halachmi⁷, A. Bar-Shamai⁷, R. Klein⁸, F. Kenyon⁹ and I. Llach-Martinez¹⁰

Small ruminant farming systems are important to the sustainability of many European rural communities. Despite recent advances in digital technologies to improve farm practices, uptake by small ruminant stakeholders has been low. Sm@RT (Sm@ll Ruminant Technology) is a Horizon 2020 funded project, involving 8 countries. Sm@RT established focus groups in each country to assess the technology/innovative tool needs of sheep and goats producers regarding 6 topics and proposed solutions. The main needs identified by topic were: (1) grazing/feeding: issues of forage/pasture quality, fencing; (2) for health and welfare: early detection of health issues and diseases and early diagnosis of mastitis; (3) for reproduction: how to optimise AI, animal selection and early pregnancy diagnosis; (4) for herd/flock management: issues of batch management; (5) for fattening: lamb weighing; and (6) for milking, milking machine maintenance. There were differences in the identified needs between countries and system of production (dairy sheep, dairy goats and meat sheep). The 8 Sm@RT countries identified 50 solutions that were subsequently voted by stakeholders during a transnational workshop. Some of the preferred solutions included EID weigh-crate and auto-sorter, milk feeders for kids/lambs, data recording system, automated grass measuring, and milk meters and milking management software. Sm@RT has identified farmers' needs, and identified many existing tools that could help them if adopted and will encourage uptake.

The objective of the thematic network EuroSheep is to increase profitability of sheep production through improved health and nutrition management. EuroSheep involves 8 countries and used multi actor and transdisciplinary approaches, to exchange experience and knowledge among sheep farmers, veterinarians, technicians, advisors and researchers. The project is built on 6 steps starting with the identification of the end users needs and finishing with the definition of a dissemination strategy and a research exploitation. To identify the needs, a survey was developed and launched asking stakeholders what were their main needs regarding the nutrition and health of 3 categories of sheep (adults, lambs and replacements). Nearly 1,300 surveys have been completed across Europe and Turkey. To address the identified needs, 96 solutions (47 on nutrition and 49 on health) were collected as proposed by stakeholders in the different countries. During national workshops, the stakeholders within each country selected the 10 solutions they preferred. In the nutrition category, the 2 solutions preferred were 'nutrition plan of ewe lambs from weaning to mating' and 'guidelines for interpretation of milk urea concentration in sheep milk'. In the health category, the 3 solutions which were preferred were 'design and strategy of the hoof bath', 'booklet on how to recognize lameness' and 'mixed grazing of cattle and sheep to limit parasite infestation'. Following this choice, 44 solutions have been further assessed by the end users in different countries. Persistent gaps to the main needs (needs without a proposed solution) have been identified for further research exploitation.

Sm@RT: Innovative technologies training for small ruminant producers

L. Depuille¹, J.M. Gautier¹, A. McLaren², T.W.J. Keady³, B. McClearn³, L. Grøva⁴, P. Piirsalu⁵, V. Giovanetti⁶, I. Halachmi⁷, A. Bar Shamai⁷, R. Klein⁸, F. Kenyon⁹, I. Llach¹⁰ and C. Morgan-Davies²

Across Europe, there is a low uptake of digital and precision livestock farming technologies and innovative solutions by small ruminant producers. The thematic network Sm@RT (Sm@ll Ruminant Technology), which involves 8 countries, aims to improve this level of uptake by farmers by identifying existing tools and technologies that can help farmers. To date, the network has selected 50 relevant tools. To encourage uptake, Sm@RT is organising training/demonstration days on digifarms (research/demonstration farms) and innovative commercial farms. During training days, stakeholders can work, and evaluate different tools and technologies in real situations. Farmers attending the events complete questionnaires before and after evaluating a technology, to gauge if their opinions change after the training. The tools vary from simple electronic identification (EID) stick readers to more complex milking machines and virtual fence collars. Demonstration days are held in a different context, relying on peer-to-peer exchanges between farmers. The innovative farmers show other farmers how they use tools or technologies, in practice, on their farm. The demonstration days allow for more discussion between farmers on the benefits and problems of using the tools. A series of online videos are also available showing how tools and technologies are used and can be accessed by those who did not attend the on-farm training days. These approaches will yield invaluable information regarding barriers and drivers to uptake of technologies on small ruminant farms.

Session 68

Theatre 4

EuroSheep: end-users assessments of flock health and nutrition best practices

P.G. Grisot¹, B. Fança¹, A. Carta², S. Salaris², C. Morgan-Davies³, I. Beltran De Heredia⁴, R. Ruiz⁴, S. Ocak yetisign⁵, T.W.G. Keady⁶, B. McClearn⁶, R. Klein⁷, L. Perucho⁸ and C. Ligda⁸

¹Institut de l'Elevage, 570 avenue de la libération, Institut de l'Elevage, 04100, Manosque, France, ²AGRIS, Localita Bonassai Ss, 07100 Sassari, Italy, ³SRUC, West Mains, EH93JG Edinburgh, United Kingdom, ⁴NEIKER, Campus Agroalimentario de Arkaute s/n 01192, 01192 Arkaute, Spain, ⁵Ondokuz Mayıs University, Department of Animal Science, Faculty of Agriculture, 55139 Samsun, Turkey, ⁶Teagasc, Athenry, Co Galway, Ireland, ⁷Unideb, Egyetem Ter 1, 4032 Debrecen, Hungary, ⁸HAO, Thessaloniki, 57100 Thessaloniki, Greece; pierre-guillaume.grisot@idele.fr

A series of 96 Best Practices (BP) addressing sheep health and nutrition issues suggested by the 8 partner countries in the EuroSheep thematic network were identified. During the 3rd national workshops series undertaken in each EuroSheep country, stakeholders selected their 10 most preferred best practices from other countries. These 51 preferred BPs have then been the subjects of cost benefit analyses and the sustainability impacts of their implementation have been evaluated. A total of 147 assessments on 44 different best practices (24 health and 20 nutrition) were subsequently completed by farmers who implemented the practice or by farmers, veterinarians, advisors or other stakeholders who experienced the outcomes of the implementation of the practice. Commercial farmers, research farm staff and veterinarians completed 98, 15 and 34 assessments, respectively. Completed assessments indicated whether the respondent implemented the practice, and the equipment, cost, specific labour and prerequisites required to implement it, as well as the overall acceptance, observed benefits, implementation facility and potential limits to implementation. Overall, most of the BPs implemented received a good satisfaction rating (68%) and only 2 received a poor satisfaction rating. For some of them (27%), assessments were contradictory depending on the farming systems.

Sm@RT: main lessons from New Zealand on PLF uptake in small ruminants

J.M. Gautier¹, C. Morgan-Davies², L. Depuille¹, A. McLaren², B. McClearn³, L. Grøva⁴, P. Piirsalu⁵, V. Giovanetti⁶, I. Halachmi⁷, A. Bar-Shamai⁷, R. Klein⁸, F. Kenyon⁹, E. Gonzalez-Garcia¹⁰ and T.W.J. Keady³

¹Institut de l'Elevage, BP42118, Castanet Tolosan, 31321, France, ²SRUC, West Mains Road, Edinburgh, EH9 3JG, United Kingdom, ³Teagasc, Athenry, Co Galway, H65, Ireland, ⁴4NIBIO, Gunnars veg 6, Tingvoll, 6630, Norway, ⁵EULS, Fr.R. Kreutzwaldi 1, Tartu, 51006, Estonia, ⁶AGRIS, Viale Adua, Sassari, 07100, Italy, ⁷ARO, The Volcani Centre, Rishon LeTsiyon, 7505101, Israel, ⁸UNIDEB, Egyetem Ter 1, Debrecen, 4032, Hungary, ⁹MRI, Bush Loan, Penicuik, EH26 0PZ, United Kingdom, ¹⁰INRAe, UMR SELMET, Montpellier, 34000, France; jean-marc.gautier@idele.fr

Sm@RT (Sm@ll Ruminant Technology) is a thematic network, involving 8 countries, with the objective of improving the uptake of digital and precision livestock farming (PLF) technologies by sheep and goat producers, for labour efficiency and farm profitability. In 2023, representatives of the nine partners undertook a fact-finding tour to New Zealand (NZ) to study (1) the use and uptake of innovative PLF approaches; (2) barriers to PLF uptake; and (3) means to facilitate PLF uptake, for the small ruminant sectors. Similar barriers exist in NZ as in EU, namely cost, perceived lack of return on investment, lack of producer interest, additional management input, ease to use, lack of follow-up support, data interoperability and network coverage. A further issue identified in NZ is the absence of compulsory electronic identification (EID) in sheep. Simple tools instead are used at flock level (not at animal level), e.g. weight crate and manual drafting systems to sort lambs according to weight. As in EU, PLF uptake in NZ is higher in the dairy sector (sheep and goat) both for genetic and flock management. For the emerging dairy sheep sector, some companies propose a PLF package that includes digital tools, advice and training for uptake by their suppliers. Findings from the study tour suggest the following steps for PLF uptake: (1) identify issues at farm level; (2) determine if they can be solved without PLF; (3) if not, identify potential relevant PLF tools; (4) purchase and transfer the technology. The use of digital technologies by NZ researchers is important and can inspire EU researchers for digital, landscape management and agroecological studies.

French regional project SO-PERFECTS: project methodology

C. Douine¹, L. Sagot^{1,2}, A.S. Thudor¹, M. Miquel², M. Bernard^{1,2}, M. Goyenette¹ and D. Gautier^{1,2}

¹CIRPO, Le Mourier, 87800 Saint Priest Ligoure, France, ²Institut de l'élevage, 149 rue de Bercy, 75595 Paris, France; mickael.bernard@idele.fr

Future sheep farms have to combine efficient production with resilience production and adapted production to societal expectations. The attractiveness of the sheep farming profession and adaptation to climate change are also at the heart of this project. The SO-PERFECTS project contributes to providing solutions to these issues by implementing a working method based on operational groups in Nouvelle Aquitaine region. These groups are made up of actors such as breeders, technicians, teachers, researchers, sharing the same issues. In total, 17 partners participated to promote agro-ecological sheep farming systems that combine economic, environmental and social performance. The objective is to guide farmers in answering the set challenges by relying on the experience of innovative farmers. Indeed, many of them are changing their technical and financial choices in order to adapt to climatic and economic hazards. The objective is to share them. In order to identify innovative themes, the partners met and listed all the themes related to agroecology and innovation. 3 groups of themes were selected: forage resource, herd health, adaptation of breeding systems. Ideas related to ongoing projects, such as tannin plants, were excluded. When the themes were chosen, bibliographic research was carried out in order to identify technical and scientific knowledge. Trials were then set up in livestock farms, agricultural high schools and experimental sites. In total, 15 themes were worked on with 122 farmers who participated in the construction of innovative solutions and the testing of solutions before their transfer. 93 studies were carried out on farms or in agriculture high schools. The results were synthesized in the form of technical sheets, slide shows, panels, press articles and a motion design.

French regional project SO-PERFECTS: trial results

M. Bernard^{1,2}, L. Sagot^{1,2}, A.S. Thudor¹, C. Douine¹, M. Miquel², M. Goyenette¹ and D. Gautier^{1,2}

¹CIIRPO, Le Mourier, 87800 Saint Priest Ligoure, France, ²Institut de l'élevage, 149 rue de Bercy, 75595 Paris, France; mickael.bernard@idele.fr

Various topics were studied in this project. Two of them are presented here: identification of success factor for spring mating and the interest of shearing grass-fed lambs returned to the sheepfold. In spring, some sheep breeds have the ability to reproduce in natural mating, but success rates are subject to wide variations. In 2020 and 2021, 3,459 ewes of different breeds from 9 farms in the Nouvelle-Aquitaine region were monitored. Various measurements, related to the management of the herd, were carried out on animals, including a body condition score. The average fertility rate was 71% with two farms below 50% and five above 80%. Three factors seem to be of prime importance for successful mating: the interval between lambing and mating must be sufficient, with 80% success rate when it is greater than 160 days. The ewes must be in a dynamic weight gain or in good body condition and the duration of the mating must be at least 3 cycles (51 days). Some farmers shear their grass-fed lambs when they return to the sheepfold, the main reasons being to save on concentrate feed and animal welfare. Few recent references exist on this topic. Thus, 7 trials were carried out between 2020 and 2022 in an experimental station and in French farmers in Haute-Vienne (87) and Creuse (23). In total, 448 lambs were divided into two groups, sheared or not at the entrance to the sheepfold. Various measurements were made on animals, regarding performance, feeding and animal welfare. On average, shearing improves performances little with a 3-day reduction in fattening time for sheared lambs, but there were large differences between farms. During high heat (30-35 °C), shearing significantly improves lamb comfort with a 50% reduction in panting time and the fleeces are much cleaner.

Session 68

Theatre 8

Use of innovative and precision tools in research stations with small ruminants: the INRAE case

I. Llach¹, H. Caillat², A. Fatet², S. Breton³, T. Aguirre-Lavin⁴, D. Dubreuil⁴, A. Eymard⁵, J. Boucherot⁶, T. Fassier⁶, D. Marcon⁶, S. Parisot⁷, C. Durand⁷, G. Bonnafe⁷, D. Portes⁷, C. Morgan-Davies⁸ and E. González-García¹

¹INRAE, UMR SELMET, 34060 Montpellier, France, ²INRAE UE1373 FERLus, Les Verrines, 86600 Lusignan, France, ³INRAE, UE1277 PFIE, 37380 Nouzilly, France, ⁴INRAE UE1297 PAO, CR Tours, 37380 Nouzilly, France, ⁵INRAE UMR0791 MoSAR Chèvrerie expérimentale, Route de la ferme, 78850 Thiverval-Grignon, France, ⁶INRAE UE0332 P3R, La Sapinière, 18390 Osmoy, France, ⁷INRAE, UE0321 La Fage, 12250 Roquefort-sur-Soulzon, France, ⁸SRUC, West Mains Road, EH9 3JG Edinburgh, United Kingdom; eliel.gonzalez-garcia@inrae.fr

An extensive survey was carried out in experimental units (EU) of INRAE using small ruminants (SR), to get insights in current and historical uses of innovative technologies in their facilities, and staff viewpoints. Ten EU use SR in INRAE (in France and overseas); 6 were visited in 2022 (addresses in the abstract; 3 with sheep -2 meat, 2 both meat and dairy-; and 3 with dairy goats). A detailed questionnaire was prepared. A total of 78 technologies were inventoried. From that, ~10% are invented or co-produced by INRAE, from which 7 are appreciated i.e. automate weighing device (Baléa); sorting gates (3 exits); DH20 (water consumption monitoring and weighing indoor); DAC (automatic distributor of concentrate); DAF (automatic distributor of forage); Gély test tube (individual milk yield monitoring); and Walk-over-Weighing (WoW). Five tools are used by 100% of EU i.e. EID for individual identification; Baléa for weighing; PDA (Personal Digital Assistant); temperature and humidity sensors (mandatory); and sorting gates. Interviewed staff are favourable to techs' use, but mostly for research purposes and they unanimously agreed in positive effects to alleviate workload and routine. Internet connectivity was revealed however as a serious constraint in certain areas. Four techs are recommended for farmers, recognising price may limit adoption: conveyor belt for feeding supply indoor; mixer (with tractor) for preparing total mixed rations; milk tank weighing; Combi clamp (to ease handling). The P3R EU is the best example of phenotyping EU with promising and effective techs for both research and management purposes. Information will be completed, with further upcoming visits to 100% of EUs.

FEC check: development of an online tool to aid farmer understanding of roundworm faecal egg counts

E. Geddes¹, A. Duncan^{2,3}, K. Lamont³, J. Duncan¹, F. Kenyon¹ and L. Melville¹

¹Moredun Research Institute, Edinburgh, EH260PZ, United Kingdom, ²University of the Highlands and Islands, Inverness, IV2 5NA, United Kingdom, ³Scotland's Rural College (SRUC), Centre for Epidemiology and Planetary Health, Inverness, IV2 5NA, United Kingdom; eilidh.geddes@moredun.ac.uk

Faecal egg counts (FECs) are a simple, inexpensive, and accessible tool for sheep producers to monitor the gastrointestinal nematode (GIN) challenge facing their livestock. GINs are the cause of significant production losses to the industry, and now with increasing anthelmintic resistance and pressure to reach environmental goals, sustainable and effective control is key. FECs are being increasingly utilised by producers to guide treatment timings, estimate pasture contamination and test anthelmintic efficacy. However, interpretation can be challenging. To support the effective interpretation of FEC results, a free web-based application ('FEC Check') was co-designed with stakeholders. A prototype tool was developed using R Shiny which provides farmers with a visual representation of the clinical importance of their FEC results. This is accompanied by guidance to support effective decision-making. Subsequently, to ensure the app is tailored to stakeholder needs, the prototype was trialled by farmers, veterinary clinicians, and animal health advisors in four focus groups across two geographically distinct locations in Scotland. The app was trialled by 33 stakeholders, composed of 17 farmers, and 16 vets/advisors. Most farmers (87%) currently used FECs on their farm, however agreed that the level of interpretation and clinical guidance provided with the results varied substantially between test providers. Upon introduction to the app, both the farmers and advisors liked the simplicity of the design. They also highlighted the benefits of being able to download the results to build a picture of the parasite challenge and anthelmintic efficacy over time, information which could be used for future health planning and breeding stock selection. With further development to optimise the app for smartphones and the ability to handle longitudinal data, all participants agreed that this tool could improve utilisation and understanding of FEC results within the industry.

Session 68

Theatre 10

Assessing sheep behaviour in an human-animal interaction test using infrared thermography

M. Almeida^{1,2,3}, A. Afonso¹, C. Guedes^{1,2,3} and S. Silva^{1,2,3}

¹University of Trás-os-Montes e Alto Douro, Quinta de Prados, 5000-801, Vila Real, Portugal, ²Associate Laboratory for Animal and Veterinary Sciences (AL4Animals), Portugal, Portugal, Portugal, ³Veterinary and Animal Research Centre (CECAV), University of Trás-os-Montes e Alto Douro, Quinta de Prados, 5000-801, Vila Real, Portugal; mdantas@utad.pt

The objective of this work was to evaluate behaviour and stress in sheep of the Ile de-France (IF), and Churra da Terra Quente (CTQ) breeds subjected to a human-animal interaction test (arena test). Thermographic imaging analysis was performed as a non-invasive stress assessment tool. The avoidance distance in the pen (ADP) and ocular temperature (IRT) were assessed before and after the presence of an operator. Several behaviours were also registered using an ethogram. It was found that, in general, IF sheep are more reactive to the presence of the operator, which translates into a higher ADP (3.41 vs 2.66, $P < 0.05$, respectively). The IRT also shows that IF ewes show lower eye temperature than CTQs (34.47 vs 34.60 °C, $P < 0.05$, respectively). These indicators were also associated with higher time to resume activity, showing that IF ewes might be more reactive to human presence. It was possible to conclude that in general there are differences between the two breeds of sheep, for behavioural indicators, which supports the theory that IF sheep are more reactive than CTQ. Finally, it is possible to conclude that thermography may be a useful non-invasive tool to assess sheep behaviour. This work was supported by the projects UIDP/CVT/00772/2020 and LA/P/0059/2020 funded by the Portuguese Foundation for Science and Technology (FCT).

Detection of interchromosomal rearrangements in bulls using large genotype and phenotype datasetsJ. Jourdain^{1,2}, H. Barasc³, T. Faraut³, C. Grohs¹, C. Donnadié⁴, A. Pinton³, D. Boichard¹ and A. Capitan^{1,2}¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, G2B, Domaine de Vilvert, 78350 Jouy en Josas, France, ²Eliance, 149, Rue de Bercy, 75012 PARIS, France, ³GenPhySE, Université de Toulouse, INRAE, ENVT, 23 Chemin des Capelles, 31320 Castanet-Tolosan, France, ⁴INRAE, US 1426, Université Fédérale de Toulouse, GeT-PlaGe, Genotoul, France Génomique, 24 chemin de borde rouge, Auzeville, 31326 Castanet-Tolosan, France; jeanlin.jourdain@inrae.fr

Interchromosomal rearrangements (IR), which result from the transfer of genetic material from one chromosome to another, can have severe phenotypic consequences due to gene dosage defects. Artificial insemination (AI) bulls are not currently screened for IR before their semen is used. Most IR have been detected by surveillance for the t(1;29) Robertsonian fusion or by targeted controls of low fertility bulls. Here, we developed a method to detect IR using linkage disequilibrium (LD) across chromosomes and applied it to 5,571 paternal halfsib families genotyped for genomic evaluation. Thirteen progeny groups (0.23%) showed significant LD, and 12 were confirmed by cytogenetic analyses: one Robertsonian fusion, 10 reciprocal translocations, and the first case of insertional translocation reported in cattle. Using national databases, reciprocal translocation carriers were all found in the worst percentile of their breed for male fertility and their carrier daughters were subfertile. The insertional translocation carrier was the worst bull for mortality with 44% of daughters dying before 365 days of age. We used long-read sequences for 7 bulls to characterize breakpoints and detect genes putatively affected in their expression, possibly leading to deviating phenotypes in balanced progeny, such as the observed delayed growth and high death rate in some balanced daughters. In addition to systematic karyotyping of bulls to avoid IR diffusion, our study highlights the importance of computing LD in halfsib groups with our method to detect remaining smaller IR and to manage carriers in the population. This study is the most comprehensive scan of the cattle population scan and paves the way for follow-up studies on the origins and consequences of IR. JJ is a recipient of a CIFRE PhD grant with the financial support of ANRT and APIS-GENE.

Session 69

Theatre 2

Functional information embedded in the unmapped short reads of whole-genome sequencingG.B. Neumann¹, P. Korkuć¹, M. Reißmann¹, M.J. Wolf², K. May², S. König² and G.A. Brockmann¹¹Humboldt-Universität zu Berlin, Albrecht Daniel Thaer-Institute for Agricultural and Horticultural Sciences, Invalidenstrasse 42, Ostbau, 10115 Berlin, Germany, ²Justus-Liebig-Universität, Institute of Animal Breeding and Genetics, Ludwigstr. 21, 35390 Gießen, Germany; guilherme.neumann@hu-berlin.de

Livestock genomics involves resequencing genetic information from additional individuals of the same species with an established reference genome. Short-read sequencing generates DNA sequences of 150-300 bp, which are mapped to the reference genome. Unmapped reads are typically discarded, but they may contain information about pathogenic DNA and structural variants (SVs) not present in the reference genome. In this study, we analysed unmapped reads from whole-genome sequencing of 302 German Black Pied cattle (DSN) to explore these hypotheses. The unmapped reads retrieved from the 302 DSN animals were assembled into scaffolds and blasted against the NCBI's database for reference and representative genomes of all available species. Scaffolds mapping against those genomes covering at least 10% of their respective reference genomes were kept for further analysis. SVs were detected for both mapped and unmapped short reads using Delly and SvABA, respectively. Among the unmapped reads of 302 sequenced DSN animals, 116 contained assembled DNA sequences covering >10% of the genome of eleven different species of bacteria and six viruses. Of those species, Mycoplasma and bovine parvovirus 3 are known pathogens infecting cattle. DNA sequences covering more than 10% of foreign eukaryotes were not found in the assembled unmapped reads. All 302 DSN animals had assembled unmapped reads aligned to Bos species with an average length of 341.3 kb per animal. Using unmapped reads, 26,593 SVs were detected in addition to 19,410 SVs that had been detected with mapped reads. While metagenomics is typically used to detect pathogens, unmapped reads of whole-genome sequencing can also provide valuable information on the presence of pathogens which is crucial for epidemiologists. Furthermore, the examination of unmapped reads revealed additional SVs that could not be identified through the alignment to the Bos taurus reference genome. This emphasizes the need for high-quality long sequence reads to accurately detect SVs.

Expanding the capabilities of single-step GWAS with *P*-values for large genotyped populations

N. Galoro Leite, M. Bermann, S. Tsuruta, I. Misztal and D. Lourenco

University of Georgia, 425 River Rd, 30602, Athens GA, USA; mbermann@uga.edu

With the availability of genomic information, there is an increasing interest in genome-wide association studies (GWAS). Most of the methods used for GWAS can account for population structure but do not consider phenotypes for non-genotyped individuals. Single-step methods can combine information on genotyped and non-genotyped individuals because of the use of a joint pedigree and genomic relationship matrix. Single-step GWAS can be utilized in large genotyped populations; however, only SNP effects and variance explained were possible in such a case. A significance test based on *P*-values was available only for small genotyped populations, i.e. up to 50k, depending on the model. This is because *P*-values rely on the prediction error variance (PEV) for each SNP effect, which is back-solved from the prediction error covariance for animals, requiring the inverse of the left-hand side (LHS) of the mixed model equations. When using more than 50k genotyped animals, single-step genomic BLUP (ssGBLUP) methods rely on a sparse representation of the inverse of the genomic relationship matrix (G^{-1}) computed with the APY algorithm. In APY, genotyped animals are split into core and noncore, and recursions on the core animals are used to compute G^{-1} at a low cost. With APY, the PEV of SNP effects relies only on the information of core animals, varying from 4k to 6k in pigs and chickens and 10k to 15k in cattle. Instead of using the inverse of the LHS, we approximated the PEV for core animals, then computed PEV and obtained *P*-values for SNP effects. We obtained similar GWAS resolution between the inverse and approximation using 50k genotyped animals, 1.5M animals in the pedigree, and 850k phenotypes. We then ran ssGWAS with *P*-values using 450k genotyped animals. As expected, a better resolution was observed when using 450k genotyped animals compared to 50k. Having single-step GWAS for large genotyped populations is feasible and allows including all available data in association studies.

The Life-Functions Ratio: a new indicator trait of trade-offs to go beyond genetic correlationsN. Bedere¹, O. Cado¹, N.C. Friggens² and P. Le Roy¹¹PEGASE, INRAE, Institut Agro, 35590, Saint-Gilles, France, ²Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 91120, Palaiseau, France; nicolas.bedere@inrae.fr

We aim to study the adaptation abilities of a genotype in terms of both the ability to be consistent across different environments (i.e. robustness) and the ability to cope with perturbations of the environment (i.e. resilience). This means making trade-offs between life functions, especially when resources are limited. Usually, to study those trade-offs between functions, geneticists calculate genetic correlations, which indicate the common genetic share of two traits, and thus common requirements for biological processes and resources. The main drawback of genetic correlations is that they are population parameters. However, we know that individuals in a population will make different trade-offs. To study the inter-individual variability of trade-offs, we have developed an individualized indicator based on resource acquisition and allocation concepts: the Life-Functions Ratio (LFR). We focused on the trade-off between two traits first, to establish the link between LFR and the genetic correlation between both traits. LFR is defined as a product of the transformed traits. It is mathematically related to the conversion efficiencies of both traits and the resource allocation coefficient (alpha). To describe this new indicator trait, LFR between backfat and egg number was calculated on a pedigreed purebred layers' population from the breeding company Novogen, late in the laying period (80 wk of age), when a trade-off occurs between body reserves and egg production. Traits displayed moderate heritabilities: 0.23 for egg number, 0.52 for backfat, 0.45 for LFR, and 0.31 for alpha. LFR was favourably genetically correlated with backfat (+0.79) and with egg number (+0.76). LFR was genetically very different from alpha with a genetic correlation of 0.02. We are currently exploring the genetic architecture of LFR, expecting to find cryptic quantitative trait loci for backfat and egg number. We are also exploring the effect of selecting for LFR on the initial genetic correlation across generations through simulations. Future works will focus on integrating more traits into the equation.

Impact of pedigree errors on the quality of predicted genetic merit from animal models*E.C.G. Pimentel, C. Edel, R. Emmerling and K.-U. Götz**Bavarian State Research Center for Agriculture, Institute of Animal Breeding, Prof.-Dürrwaechter-Platz 1, 85586 Poing-Grub, Germany; eduardo.pimentel@lfl.bayern.de*

Pedigrees used in genetic evaluations contain errors. Because of such errors, assumptions regarding the relatedness among individuals in genetic evaluation models are wrong, which may have an impact on prediction quality. In the Single-Step model, which combines both pedigree and genomic information, pedigree errors also cause inconsistencies between the pedigree-based relationship matrix A and the genomic relationship matrix G . The objective of this work was to investigate the effects of pedigree errors on the quality of predicted genetic merit. We used a real pedigree ($n=361,980$) and real genotypes ($n=25,950$) of Fleckvieh cattle, sampled in a way to provide a good consistency between A and G . Given the real pedigree and genotypes, true breeding values were simulated to have a covariance structure equal to the matrix H assumed in a Single-Step model. Based on true breeding values, phenotypes were simulated with a heritability of 0.25. Genetic evaluations were conducted with a conventional animal model (i.e. without genomic information) and a Single-Step animal model under scenarios using either the correct pedigree or a pedigree containing 5, 10 or 20% of wrong records. Prediction quality was assessed in terms of correlation and regression of true on estimated breeding values, as well as standard deviation of estimated breeding values. These metrics were calculated for all animals and for different groups of animals, such as progeny tested bulls and young selection candidates. The increasing rates of pedigree errors led to decreasing correlations between true and estimated breeding values, larger deviations of the regression coefficients from the expected values and lower standard deviations of predictions. We further investigated the impact of data truncation on the measures of prediction quality under the different simulated scenarios.

Bias in estimated variance components and breeding values due to pre-correction of systematic effect*P. Duenk and P. Bijma**Wageningen University and Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6708 PB Wageningen, the Netherlands; pascal.duenk@wur.nl*

In animal breeding, the size of data sets for estimation of heritabilities and breeding values is growing all the time, also because of the increasing availability of genomic data. To be able to analyse such large data sets efficiently, two-step procedures are common. In the first step, systematic effects are estimated as fixed or random effects, for e.g. the sex, herd or litter of the individual. The data is then pre-corrected by subtracting the estimated effects from the raw phenotypes. In the second step, heritabilities or (genomic) breeding values are estimated from the pre-corrected phenotypes. This two-step procedure simplifies the analysis of big data. Even though pre-correction is widely used in animal breeding, the consequences for estimated variance components and breeding values have received little attention. Our results show that pre-correction creates bias in the estimated variance components. For balanced data, we provide simple mathematical expressions for the bias, showing that variance components are underestimated unless the reliability of the pre-correction is one. Bias occurs both with fixed and random effect pre-correction, albeit the use of fixed effects resulted in stronger bias. These theoretical results were consistent with the results from simple simulations. For realistic reliabilities of systematic effects, bias of estimated variance components was about 10% when systematic effects were fitted as random, and about 16% when they were fitted as fixed. We will present further results on the consequences of pre-correction for estimated variance components and (genomic) breeding values. Those results include simulation of more realistic data sets with family structure and genotypes, and the use of an actual data set from a Dutch breeding company. Our research will help to better understand the effects of data pre-correction, and will ideally provide a solution for the resulting bias.

Improving computing performance of genomic evaluations by genotype and phenotype truncationF. Bussiman¹, C. Cheng², J. Holl², A. Legarra^{3,4}, I. Misztal¹ and D. Lourenco¹¹University of Georgia, Animal and Dairy Science, 425 River Rd, 30602, USA, ²Pig Improvement Company, 100 Bluegrass Commons Blvd, Ste 2200, 37075, USA, ³Council on Dairy Cattle Breeding, 4201 Northview Dr, 20716, USA, ⁴INRA, GenPhySE, 23 Avenue des Capeles, 31076, France; fob@uga.edu

The use of historical data collection is a common practice for genomic evaluation; however, the more data, the more computing power is needed, and fitting the same model to both current and historical data may be inappropriate. This study investigated the use of data truncation to reduce computing costs of genomic prediction with large datasets. Data truncation is usually done for phenotypes and pedigree; however, the increasing number of genotyped animals raises a question on whether all genotyped animals should be included in the evaluations. Data from terminal and maternal pig lines were analysed through different truncation scenarios: TARGET, which removed genotyped animals without own and progeny phenotypes; AGE, where old genotyped animals were removed; TARGET + AGE, which combined the two scenarios above; and ALLGEN, which kept all genotyped animals. Phenotypes were removed (in all scenarios) based on birth year, and pedigree depths were 2, 3, or all generations. We analysed growth and mortality on a terminal line and preweaning and reproductive traits on a maternal line using single-step GBLUP. Validation was based on the linear regression method, and the focal animals were the selection candidates born in 2019. Reliability did not change among scenarios except when truncating the phenotypes in less than two generations of data. The phenotype/genotype truncation or the pedigree depths did not affect the dispersion, except when using the entire pedigree with truncated phenotypes and genotypes. Tracing up to three generations of pedigree is enough for reliable predictions. Data truncation caused a slight drop in reliability when genotyped animals had no phenotypes. Keeping all genotyped animals for truncated datasets did not increase the reliability and resulted in poor convergence. Removing unneeded genotypes, phenotypes, and pedigree increases computing efficiency by up to 90% without compromising predictions for selection candidates.

Session 69

Theatre 8

A single-step evaluation of functional longevity of cows including data from correlated traitsL.H. Maugan¹, T. Tribout¹, R. Rostellato², S. Mattalia³ and V. Ducrocq¹¹GABI, Université Paris Saclay, INRAE, AgroParisTech, 78350 Jouy-en-Josas, France, ²Geneval, 3 rue du Petit Robinson, 78350 Jouy-en-Josas, France, ³Institut de l'Élevage, UMT eBIS, 78350 Jouy-en-Josas, France; vincent.ducrocq@inrae.fr

A routine genetic evaluation of dairy bulls based on the length of productive live (LPL) of their daughters corrected for milk production was developed in France in 1997. Initially, only the functional longevity (FL) breeding values of males were available. The FL genetic evaluation was then progressively improved by accounting for time-dependent changes in environmental factors and by computing approximate FL evaluations for cows. It was also found during the following decade that there were routinely collected traits related to fertility, conformation or udder health which could serve as predictors of FL, using an approximate multiple trait approach. Combining these direct and indirect sources of information led to more robust FL genetic evaluations of bulls and cows. With strong selection on production, the economic importance of functional traits such as FL and its predictors gradually increased. At the same time, genomic evaluations and selection became central. However, genomic evaluations of low heritability traits such as FL were usually characterized by poor reliabilities. We propose a 'combined' Single-Step (CSS) approach to obtain genomic evaluations (GEBV) of FL mimicking multiple-trait evaluations. This is illustrated in the context of the Montbéliarde breed, using or not information from predictor traits. Survival curves of a complete cohort of cows born in 2014-2015 were calculated, showing a large superiority of the CSS evaluation: among genotyped cows, 50% of the best 10% cows with the univariate SS reach a productive life of about 1,400 days, i.e. 402 days more than the worst 10% cows. This difference reaches 501 days with the CSS evaluation. The corresponding figures for ungenotyped animals are substantially smaller (187 vs 258 days). In other terms, CSS evaluations allow farmers to detect at birth the genotyped heifers that are more likely to have a long productive life in their herd. In contrast, CSS evaluations of males are much less pertinent to select young bulls, because selection intensity of males is much higher in selection programs.

Expected values of genomic prediction validation parameters for non-random validation sets

M.P.L. Calus, M. Schrauf, T. Pook, L. Ayres, R. Bonifazi, J. Ten Napel and J. Vandenplas

Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands; mario.calus@wur.nl

Dispersion bias of genomic estimated breeding values (GEBV) measures whether GEBV contain too much or too little variation. Dispersion bias of GEBV is evaluated by regressing a variable that reflects true breeding values (TBV) on the GEBV being validated. For GEBV without dispersion bias, the expected value for the regression coefficient (b1) estimator is usually considered to be 1, while it may deviate from 1 if the validation set is not a random sample of animals. We aimed to compute expected b1 values for final GEBV with accuracies ranging from 0.4 to 0.9, for a set of validation animals that was progressively more intensely selected (100 to 10%) based on initial GEBV with an accuracy of 0.3. TBV, initial GEBV and final GEBV were drawn from a trivariate normal distribution, where information used to estimate initial GEBV was assumed to also be used to estimate final GEBV (dependent final GEBV), or not (independent final GEBV). For independent final GEBV of unselected validation groups, b1 values were 1 as expected. With 500 animals in the validation group, standard deviations (SD) of b1 were 0.11 and 0.02 for final GEBV with accuracies of 0.4 and 0.9. With 5,000 validation animals the SDs reduced to 0.03 and 0.01. For a selected validation set of 10% of the full data, b1 values were 0.93 (0.98) for final GEBV with an accuracy of 0.4 (0.9), while SDs of b1 increased up to three-fold compared to validating on the full data. For dependent final GEBV, b1 values were all ~1, while SDs were similar as for independent final GEBV. Accuracies, computed as correlations between final GEBV and TBV, were more reduced with more intense selection based on initial GEBV; this reduction was relatively small with independent final GEBV, and considerably larger for dependent final GEBV. Considered scenarios will be extended to other practical situations where validation is based on comparing GEBV based on partial and whole data. It is concluded that this approach is useful to efficiently compute expected values for parameters used in validation of genomic prediction.

Unknown parent groups and metafounders in genomic evaluation of Norwegian Red cattle

T.K. Belay¹, A.B. Gjuvsland², J. Jenko², L.S. Eikje² and T. Meuwissen¹

¹Norwegian University of Life Sciences, Animal and Aquacultural Sciences, Oluf Thesens vei 6, 1433 ÅS, Norway, ²GENO SA, Storhamargata 44, 2317 Hamar, Norway; tesfaye.kebede.belay@nmbu.no

Appropriate ways of accounting for missing parents and incompatibility between the base populations of the pedigree-based (A) and the genomic relationship (G) matrix are crucial for unbiased single-step genomic prediction. Here, we tested the effects of alternative ways of fitting unknown parent groups (UPG) on biases (level-bias and inflation) and stability (ratio of accuracies) of genomic predictions and genetic trends in Norwegian Red cattle. We fitted the UPG as random effects accounting for relationships among all the 52 UPGs, calculated using a recursive method (UPG_γ) and among 14 metafounders (MF). We also fitted UPG as in the recently published method, 'Q-Q+', which fits fixed group effects corrected for the part that can be explained by genotypes. The models were evaluated using cross-validation by masking phenotypes of 5,000 young-genotyped cows. Inclusion of relationships among the UPGs or MF introduced biases to the genomic predictions compared to other models where these relationships were not considered. The biases were further increased when G both weighted by 10% A and scaled by alpha (mean difference between A and G) was used in the UPG_γ models. The Q-Q+ models performed best in terms of inflation and stability but had higher level bias than the routine model where relationships among UPGs were not considered. Stability of genomic predictions was comparable across the other genomic models with the exception for MF which showed less stability. The Q-Q+ models predicted the highest genetic trends while the MF model predicted the lowest genetic trends, and the genetic trends for the UPG_γ models were in between the Q-Q+ and MF models. The genetic trend for routine model was slightly below the Q-Q+ models. In conclusion, the routine method performed best in terms of level bias while the Q-Q+ model with 0.5 allele frequency and unweighted G produced the lowest inflation and most stable genomic predictions. Inclusion of relationships among the UPGs introduced biases especially when scaled G was used and reduced predicted genetic trends. The latter is probably due to the assumed correlations between early and recent UPGs.

Exploring non linear genetic relationships between correlated traitsF. Shokor^{1,2}, P. Croiseau¹, R. Saintilan^{1,2}, T. Mary-Huard¹, H. Gangloff¹ and B.C.D. Cuyabano¹¹Université Paris Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²Eliance, 149 Rue de Bercy, 75012 Paris, France; fatima.shokor@inrae.fr

Genetic evaluation has emerged as a crucial tool in livestock breeding, enabling decisions about which individuals to keep in a breeding program, based on a selection index that oftentimes considers multiple traits of commercial interest, and the accuracy of selection indexes depends on the accuracy of breeding values (BV) predicted by the model. Different traits may be affected by a same QTL region, resulting in a genetic correlation between such traits, and the current models used to perform genetic evaluations impose a linear genetic correlation between traits. However, if the genetic relationship between two traits is non-linear, the current models fail to comprise this assumption, resulting in less accurate predicted BV. A preliminary study with simulated data indicated that when using gaussian models (i.e. GBLUP) to evaluate two traits with the same heritability (0.3) and genetic correlation of 0.5, the estimated genetic correlation captured by the model was of 0.53 (SD=0.03) when the true genetic correlation was linear. However, when this correlation was non-linear (and in fact quadratic in this preliminary study), the captured correlation decreased to 0.46 (SD=0.02), and GBLUP failed to identify the non-linear genetic relationship. Methods able to account for non-linear genetic relationships between traits may increase the accuracy of predicted BV, and improve the individuals' final selection index, enabling more efficient breeding strategies. The non-parametric nature of machine learning (ML) methods provide the necessary flexibility to account for non-linear genetic correlations, and may thus provide new insights into the underlying genetic architecture of correlated traits. Our preliminary study indicated that, although prediction accuracy obtained with a two-trait ML model was comparable to that of GBLUP for both linearly and non-linearly correlated traits (0.52; SD=0.3 and 0.48; SD=0.03 respectively), our ML approach was able to reveal the non-linear relationship between traits, an information of relevance to improve the selection index accounting for multiple traits.

Session 69

Theatre 12

Single-Step Genomic Prediction in six German Beef Cattle BreedsD. Adekale^{1,2}, H. Alkhoder², Z. Liu², D. Segelke² and J. Tetens¹¹Georg-August-Universität Göttingen, Department für Nutztierwissenschaften (Abteilung Functional Breeding, Burckhardtweg 2, 37077 Göttingen, Germany, ²vereinigte informationssysteme tierhaltung w.v, Biometrie, Heinrich-Schröder-Weg 1, 27283 Verden (Aller), Germany; damilola.adekale@vit.de

The estimation of breeding values for production traits in German Beef cattle breeds is carried out routinely by a multi-trait pedigree BLUP (PBLUP) method. This study aimed to investigate the potential of implementing single-step SNPBLUP (ssSNPBLUP) genomic evaluation in six German Beef cattle breeds. Following linear regression methods, the (G)EBV of the validation animals from the single-step full evaluation was regressed on the (G)EBV obtained from the truncated evaluation. The correlations of (G)EBVs obtained between the full and truncated evaluations ranged between 0.72 and 0.83 for the PBLUP evaluation. The maximum improvement was a 3% increase in correlation with the ssSNPBLUP evaluation. In general, ssSNPBLUP only showed a 1-2% increase in correlation across all traits and breeds. This indicates slightly more stable breeding values with the inclusion of genotypes. The b1 values only show a slight deviation from the expectation of 1 for the PBLUP and ssSNPBLUP evaluations. This suggests that an evaluation with PBLUP or a ssSNPBLUP is neither inflated nor deflated. The SNP effect estimates from the truncated evaluation were highly correlated with the full evaluation, ranging from 0.79 to 0.94. The correlation of the SNP effects is influenced by the number of genotyped animals shared between the full and truncated evaluations. The regression coefficients of the SNP effect of the full evaluation on the truncated evaluation were all close to the expected value of 1, indicating unbiased estimates of the SNP markers. Based on the (G)EBV of the validation population, the single-step model only showed a slight improvement relative to a PBLUP. This is not an unexpected, given the low number of animals with genotype and phenotype records. However, given that the results were slightly better with the inclusion of genotype data, this study can recommend adopting a single-step SNPBLUP evaluation. Furthermore, with increasing number of genotype and phenotype records, the ssSNPBLUP will result in higher accuracy, less bias, and more stability for future genomic evaluations.

Incorporating QTL genotypes in the model to predict phenotypes and breeding valuesJ. Yang¹, T.H.E. Meuwissen², Y.C.J. Wientjes¹, P. Duenk¹ and M.P.L. Calus¹¹Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6708 PB Wageningen, the Netherlands, ²Norwegian University of Life Sciences, Box 5003, 1432 Ås, Norway; jifan.yang@wur.nl

With the accumulation of genotyped individuals, increasingly more QTL are being detected. Including genotypes of those known QTL in genomic prediction models can help to improve the accuracy of predicted breeding values and phenotypes. However, it remains unknown how much genetic variation a QTL should explain in order to see a benefit when it is included in the model. The aim of this study is to investigate at which proportion of genetic variance explained by QTL included in the model the highest prediction accuracy is achieved. A population under selection was simulated, with per generation 20 breeding males being mated with 2,500 breeding females. We considered that QTL effects followed either a gamma or a normal distribution. A standard GBLUP model based on ~58,000 SNPs was used as a benchmark. We then extended the standard GBLUP by including QTL as a separate variance component (hereafter we call it 2GBLUP). The proportion of genetic variance explained by the QTL included in the model was varied from 5 to 99%. This was achieved by adding increasingly more QTL in the model, after sorting them by decreasing genetic variance explained. In addition, weighted 2GBLUP was considered which assigns to each QTL its known genetic variance as a weight, instead of making the prior assumption that each QTL explains the same amount of genetic variance. The results showed that: (1) the highest prediction accuracy was obtained when 80% of the total genetic variance was explained by the QTL included in the model, and prediction accuracies increased approximately linearly as long as the proportion <80%; (2) using weighted 2GBLUP could further increase the prediction accuracy when more than 80% of the genetic variance was explained by the QTL; and (3) with Gamma distributed QTL effects both higher accuracies and stronger bias were obtained than with normally distributed QTL effects. As a next step, we will investigate the potential to include QTL in machine learning models, while still including all SNPs as was done in the 2GBLUP model. The aim of this analysis is to investigate if machine learning models can compete with the 2GBLUP models.

Improving the efficiency of genomic evaluations with random regression modelsA. Alvarez Munera¹, D. Lourenco², I. Misztal², I. Aguilar³, J. Bauer⁴, J. Šplíchal⁴ and M. Bermann²¹Universidad Nacional de Colombia, Cra. 65 #59a-110, 4309000, Medellin, Colombia, ²University of Georgia, Department of Animal and Dairy Science, 420 River Road, 30602, Athens, GA., USA, ³Instituto Nacional de Investigación Agropecuaria (INIA), Ruta 48 km 10, Rincon del Colorado, 90100, Montevideo, Uruguay, ⁴Czech Moravian Breeders' Corporation, Benešovská 123, 252 09 Hradištko, Czech Republic; mbermann@uga.edu

Random-regression models (RRM) are used worldwide to model longitudinal traits in dairy cattle breeding. Due to a more complex structure, RRM present more challenges than other models for longitudinal traits like multiple-trait repeatability models. These challenges include the convergence of the solvers, and approximating accuracies of genomic estimated breeding values (GEBV). These problems might worsen when genomic information is included by single-step genomic best linear unbiased predictor (ssGBLUP). The objectives of this study were to test efficient methods for implementing RRM with ssGBLUP for national dairy evaluations with the BLUPF90 software suite and to develop a method to approximate accuracies in RRM with genomic information. We used Czech dairy data to test the proposed methodologies. Data comprised 30 million test-day records for milk yield across three lactations. The pedigree had 2.5 million animals, from which 55,000 were genotyped. A block-diagonal preconditioner including correlated random traits was used to improve the solver's convergence. To approximate accuracies for 305-days GEBV, 305-days accuracies without genomic information were back-solved to effective record contributions (ERC), which were used as weights in a GBLUP model. Final reliabilities were calculated with ERC obtained from the last model while removing double counting of information. The proposed preconditioner reduced the number of iterations by half. Approximated accuracies were compared with those calculated with the inverse of the coefficient matrix. The correlation between them was 0.98, while the slope and the intercept of the regression were 1.01 and 0.01, respectively. Further research will focus on including the fixed effects block to the preconditioner, adding genetic groups or metafounders to the model, and testing different methods for including external information in the evaluation.

Comparison of two software to estimate breeding value in cattle by single-step approach

M. Jakimowicz¹, D. Słomian², T. Suchocki^{1,2} and J. Szyda^{1,2}

¹Wrocław University of Environmental and Life Sciences, Department of Genetics, Koźuchowska St. 7, 51-631 Wrocław, Poland, ²National Research Institute of Animal Production, Krakowska 1, 32-083, Balice, Poland; tomasz.suchocki@upwr.edu.pl

The main goal of the presented study was to compare predictions of breeding values for stature, using single step SNP-BLUP and G-BLUP models respectively implemented in the MiXBLUP and BLUPF90 software. In both programmes the same variance components were used, where genetic was equal to 5,50058 and residual to 4,63406. The data comprised 134,960 genotyped animals, and 1,098,611 phenotyped cows, and 141,686 bulls with pseudo-phenotypes expressed by Interbull-MACE (Multiple across country evaluation). The complete pedigree information used in the analysis included 8,451,809 animals and 36 phantom parent groups that have been defined based on birth year, sex and country of origin. The Data came from the national routine polish genetic evaluation for stature (December 2021) and was provided by the National Research Institute of Animal Production. To compare the results obtained by both of the models, we create rankings of the 100 of the best individuals and 1000 of the best individuals. The rankings were created separately for each sex, based on, the type of data available for animals (genotypes and phenotypes, and non-genotyped animals), and year of birth. We used Venn diagrams and Pearson correlation coefficients to check if there was any overlap between models from both programmes.

Estimating (co)variance components using Monte Carlo EM-REML in a multi-trait SNPBLUP model

H. Gao, M.H. Lidauer, M. Taskinen, E.A. Mäntysaari and I. Strandén

Natural Resources Institute Finland (Luke), Myllytie 1, 31600 Jokioinen, Finland; hongding.gao@luke.fi

The analytical REML-based methods typically used for (co)variance component (VC) estimation require elements from the inverse coefficient matrix of the mixed model equations (MME), i.e. prediction error variances (PEV). Making and inverting a dense and large MME is computationally challenging when genomic information has been used extensively in the breeding programme. To overcome this issue, we implemented the EM-REML method combined with Monte Carlo (MC) algorithm for multi-trait SNPBLUP. The PEV was approximated without explicitly making or inverting the MME coefficient matrix using solutions from MME having observations generated from the same distributions as the original data and current VC estimates. The MME solving step used the preconditioned conjugate gradient iteration and iteration on data, allowing fast computations and high memory scalability. The aims of this study were: (1) to estimate VCs using the MC EM-REML approach in a multi-trait SNPBLUP model, and (2) to assess its scalability in terms of computational time with different numbers of genotyped individuals. Data were simulated based on 10,000 markers and three traits with heritabilities of 0.44, 0.32, and 0.34 and genetic correlations of 0.80, 0.71, and 0.98. Simulated phenotypes had general means, genetic effects based on simulated marker effects, and random residual effects. We investigated six scenarios based on the number of genotyped individuals: 5,000, 10,000, 15,000, 20,000, 25,000, and 30,000. Computations in a three-trait SNPBLUP model used MC EM-REML with three MC samples generated within each REML round. The final VC estimates were in line with the simulated values. The computing time increased linearly with respect to the number of genotyped individuals, given a constant number of markers. Thus, MC EM-REML is well-suited to dense systems and can serve as a viable alternative for estimating VCs for large-scale genomic datasets.

Molecular phenotyping to predict neonatal maturity

L. Liaubet¹, N. Marty-Gasset¹, L. Gress¹, A. Bonnet¹, P. Brenaut² and E. Maigné³

¹GenPhySE, Université de Toulouse, INRAE, INPT, ENVT, 24 chemin de Borde Rouge, 31326 Castanet-Tolosan, France, ²IFIP-Institut du Porc, Le Rheu Cedex, France, La Motte au Vicomte, 35650 Le Rheu, 35650 Le Rheu, France, ³Université de Toulouse, INRAE, UR MIAT, 24 chemin de Borde Rouge, 31326 Castanet-Tolosan, France; laurence.liaubet@inrae.fr

Improved piglet survival during the suckling period is a strong expectation for breeders. This notably involves taking into account the maturity of the piglet at birth. An immature piglet, which has not reached its full development, will have a greater risk of early death. These piglets have a characteristic morphology: A steep, dolphin-like forehead, bulging eyes and head/body asymmetry. Based on image analysis, the Pic'Let project (CASDAR-RT 2019) aims to offer breeders an innovative tool for phenotyping piglet maturity. On this study, 298 newborns (99 Landrace, 98 Large White, 98 LR×LW) were classified for their maturity level. Furthermore, a metabolomic analysis was also performed by 1H-NMR on blood sample (serum) collected on piglet. Raw spectra were analysed with the R package ASICS and 55 metabolites with non-zero variance have been used in following statistics. A first analysis with PCA suggested a common metabolic profile may be identified whatever the genotype. Next, two predictive models were developed to explain immaturity (23%, severe or light) vs maturity (77%). The first model uses the 55 available metabolites and is based on Random Forests and Lasso methods for the prediction. The second model uses a subset of 14 metabolites selected with the Lasso method and is based on random Forests and GLM methods. The imbalance characteristic of the dataset was adjusted by down sampling and model aggregation. The two models predict 100% of the severe immaturity status in the training and the test samples. Some piglets morphologically determined as mature are expected to be immature with a strong confidence [80-100%] according to metabolic data. Altogether, we identified a molecular signature based on metabolic data able to predict the neonatal maturity status. To validate this method, the next step will be to apply it to another dataset of newborns, where the same metabolomic analysis has been performed, and to study the relationship between the prediction and proxy variables such as piglet birth weight.

Comparison of genetic maps from different cattle breeds

X. Ding¹, H. Schwarzenbacher², F.R. Seefried³ and D. Wittenburg¹

¹Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, ²ZuchtData GmbH, Dresdner Straße 89/B1/18, 1200 Vienna, Austria, ³Qualitas AG, Chamerstrasse 56, 6300 Zug, Switzerland; wittenburg@fbn-dummerstorf.de

The proximity of loci on a genome can be measured in physical (base pairs) or in genetic distance units (Morgan), where the latter is of special importance for animal breeders. It is expected that one crossover event occurs on average during meiosis at one Morgan distance. Hence, the genetic distance between loci allows drawing inferences, for instance, on genetic variation of not yet born progeny and provides valuable information when searching for top breeding animals. Genetic diversity among cattle breeds and different breeding objectives for meat, dairy or dual purpose require breed-specific genetic maps. We analysed genotype data from seven commercial cattle breeds with sample size ranging from 4,181 to 298,850. Since various assays were used for genotyping the animals, we standardised the data preparation and analysed the data with our pipeline 'hsrecombi'. We investigated the frequency of paternal recombination events and derived genetic-map coordinates of about 50K SNP markers. Additionally, estimates of recombination rate between intra-chromosomal pairs of markers enabled the localisation of further putatively misplaced markers or regions in the bovine genome assembly ARS-UCD1.2. Estimates of map length varied from 23.99 M to 27.36 M between breeds. Two to 49 misplaced candidates were detected in each breed, mostly overlapping among breeds. Furthermore, a genomewide association study on the number of recombination events among progeny revealed 13 significant SNPs in total. A subset of these hits was located in or near two genes with known impact on recombination activity providing options to counteract genetic erosion in breeding populations in future. To explore recombination activity interactively and to evaluate differences between breeds, we implemented all results in an R Shiny app 'CLARITY'.

Genomic relationships across metafounders using partial EM algorithm and average relationships

A. Legarra¹, M. Bermann², Q. Mei³ and O.F. Christensen⁴

¹CDCB, 4201 Northview Drive, 20716 Bowie MD, USA, ²University of Georgia, Animal and Dairy Science, 425 River Rd, 30602 Athens GA, USA, ³Huazhong Agricultural University, No.1, Shizishan Street, Hongshan District, 430070 Wuhan, China, P.R., ⁴Aarhus University, Center for Quantitative Genetics and Genomics, C. F. Møllers Allé 3, bld. 1130, 8000 Aarhus C, Denmark; andres.legarra@uscddb.com

Genomic relationships describe relationships among animals previously assumed as unrelated through pedigree, either within or across-breeds. Missing relationships can be modelled using the theory of metafounders, where relationships within and across base populations (metafounders) are encapsulated in a matrix Gamma. Values in Gamma are often hard to estimate, because, first, founder individuals are too far from genotyped individuals, second, the use of several metafounders within-breed to model missing pedigree, and third, many individuals are mixtures of several metafounders. Here we propose a hybrid method to estimate gamma within and across breeds. We use a partial EM maximum likelihood algorithm to estimate Gamma across breeds. We decompose the 'complete' likelihood of markers given Gamma and pedigree into a part that is a direct function of Gamma and a part that is a function of Mendelian sampling variance. We then approximate the first derivative by ignoring the Mendelian sampling variance. The following approximated EM algorithm consists in (1) postulate an initial value of Gamma (2) set up the H-inverse matrix as a function of G-inverse and A-inverse, with A-inverse including rows and columns for metafounders (3) invert the block of H-inverse corresponding to metafounders to obtain $H(1:MF, 1:MF)$ (4) set Gamma to the block $H(1:MF, 1:MF)$; iterate again. At convergence, we obtain an estimate of Gamma. The algorithm is completed by a check that the (total) log-likelihood is maximized at each iteration. Tests using simulated data show that the algorithm is accurate if the metafounders are not too distant from genotyped animals. For metafounders within breed along time, Gamma can be inferred using a structure that models the increase of relationships and relies on (1) the initial gamma parameter at foundation of the breed and (2) the increase of average relationships within breed along time, measured through pedigree analyses.

Impact of the correlation between SNP effects in different breeds on the accuracy of predictions

¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²Eliance, 149 rue de Bercy, 75012, Paris, France; pascal.croiseau@inrae.fr

Rotational crossbreeding schemes in dairy cattle are an efficient way for breeders to obtain more adaptable and robust animals, as well as more sustainable breeding systems. It takes advantage of breed complementarities and of heterosis. Its practice is currently expanding among cattle breeding systems. Aiming to achieve a correct representation of crossbred animals in genomic evaluation, methods to account for the breed of origin of alleles (BOA) have been developed (BOA-GBLUP). Their results regarding the prediction accuracy of genomic estimated breeding values (GEBV), however, have not yet overcome those obtained with a standard GBLUP, which ignores the BOA, especially when true QTL-effects are similar across breeds. Using simulations, we studied the impact of the correlation between QTL-effects in different breeds, on the accuracy of the predicted GEBV using the standard GBLUP and the BOA-GBLUP. 50k SNPs in linkage disequilibrium were simulated for three different breeds; among these simulated SNPs a random subset of 200 were assigned as QTL for all breeds, and ten scenarios varying the levels of correlation, from high (0.9) to low (0), between the QTL effects on the different breeds were generated. Four traits were investigated with heritabilities ranging from 0.01 to 0.65, and each breed of purebred animals was selected for a different trait, while crossbred animals were selected for all four with a selection index weighting all traits equally. After evolving 10 generations under this scheme, A training population of 20,000 animals (6,000 purebred animals from 3 breeds and 2,000 crossbred animals) was used to predict the GEBV of 2,000 crossbreds in the final generation. Finally, the accuracy of the predicted GEBV and of the estimated SNP effects within breed allowed us to assess under which conditions of QTL-effects correlation, the use of BOA-GBLUP is beneficial for genetic evaluations in rotational crossbreeding schemes. This project has received funding from APIS GENE and from the European Union's Horizon 2020 research and innovation program – GenTORE – under grant agreement No. 727213.

Early prediction of lactation persistency of multiparous cows managed for extended lactation*C. Gaillard¹, M. Boutinaud¹, J. Sehested² and J. Guinard-Flament¹**¹Institut Agro, PEGASE, INRAE, 16 Le Clos, 35590 Saint Gilles, France, ²ICROFS, Aarhus University, Blichers Allé 20, 8830 Tjele, Denmark; charlotte.gaillard@inrae.fr*

Early prediction of lactation persistency will potentially be an important management tool influencing decisions on reproduction and feeding management. Primiparous cows have a relatively stable and high persistency while it is quite variable for multiparous cows. Therefore, the objective was to predict multiparous cows' lactation persistency, within the first 6 weeks of lactation, based on two or three variables. The dataset used contained 19 production data and blood biomarkers of 36 multiparous Holstein cows managed for extended lactation (insemination at 8 months) with access to a milking unit. The persistency was calculated as the ratio of total milk produced during a defined period of 100 days (P1: from 100 to 200 days, P2: from 200 to 300 days, or P3: from 300 to 400 days) over the first 100 days of production (Method 1); as the quantity of milk produced at day 100, 200, 300, or 400 over the quantity produced at day 60 of lactation (Method 2); and as the slope of the smoothed milk yield curve at day 100, 200, 300, and 400 (Method 3). For each method, the cows were divided into 3 groups (12 cows per group) with a low, medium or high persistency. A clustering method ($k=3$) was then applied on a pair or trio among the data measured at week 1, 3, or 5. Using a trio of variables to predict persistency only improved the maximum accuracy of 3.7% (average over the methods, weeks and periods) compared to a pair of variables, and the highest accuracy obtained with a pair of variables varied from 43 to 70%. With a pair of variables, the highest accuracy was obtained with Method 1, considering milk yield and lactose in milk measured at week 1 to predict the persistency over P3. The second best pair belonged to Method 3 and involved dry matter intake and milking frequency measured at week 5 to predict persistency over P1. To conclude, Method 1 gave the highest accuracies and with this specific data set, a pair of variables in early lactation may be used to predict the persistency of the lactation at different stages of the lactation with a moderate accuracy.

Poster 22

Accuracy of genomic prediction by singular value decomposition of the genotype matrix*L. Ayres¹, M.P.L. Calus¹, J. Ødegård^{2,3} and T. Meuwissen³**¹Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands, ²AquaGen AS, Postboks 1240, 7462 Trondheim, Norway, ³Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Oluf Thesens vei 6, 1433 Ås, Norway; lucas.ayres@wur.nl*

Reference populations for genomic prediction are continuously growing, and there is a tendency to use more single nucleotide polymorphisms (SNPs) from animal genomes. Both developments lead to increasing the dimensions of the genotype matrix, which poses a computational challenge for genomic prediction. To reduce the dimensionality, we applied singular value decomposition (SVD) to the genotype matrix. The objective of this study was to evaluate the effect of the number of SVD components on the accuracy of genomic prediction. To predict the breeding values, we simulated the phenotypes by generating 1000 quantitative trait loci (QTL) randomly drawn from the SNPs of chromosome 1 of Atlantic Salmon. We employed SVD-based principal component ridge regression (PCRR) to estimate breeding values. Accuracies increased steeply for the first few principal components until stabilizing around 100-300 components, and no meaningful gain was obtained with additional components. Maximum accuracies were obtained at around 50-250 components, marginally higher than when the original genotype matrix was used. Our results indicate that, within an appropriate range of components, SVD can be used in genomic prediction to reduce computational burden, while not compromising prediction accuracy.

Enhancing long-term genetic gain through a Mendelian sampling-based similarity matrix

A.A. Musa and N. Reinsch

Research Institute for Farm Animal Biology (FBN), Institute of Genetics and Biometry, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany; musa@fbn-dummerstorf.de

Indices combining the expected breeding value and Mendelian sampling variance (MSV; variability in full-sibs breeding values) of a parent have been recently proposed as alternative selection criteria to expected breeding value to sustain long-term genetic gain. However, such an index tends to select similar parents with a high MSV potential, resulting in the loss of favourable haplotypes and jeopardizing long-term genetic gain. Through simulation, we show that long-term genetic gain can be enhanced using a Mendelian sampling-based similarity matrix which restricts the selection of parents with MSV caused by the same chromosomal segments. Here, we compare several recurrent selection schemes derived by combining breeding value or index with truncation selection (TS) or optimum mate allocation using the similarity matrix (OMA). Our simulation consisted of 500 males and 500 females per generation, and we performed 50 generations of selection, allocating one male to 50 females. This ratio was sometimes lower in schemes involving OMA. Finally, we assumed random mating and known additive marker effects for a trait with a heritability of 0.25. We found that selection schemes involving OMA outperformed TS. Compared to TS on the index, for example, combining the index and similarity matrix realized up to 7% more genetic gain, preserved up to 2,177% more genetic variability, and reduced inbreeding by up to 30% in the terminal generation. Furthermore, up to 25% more favourable quantitative trait loci alleles and up to 24% more single nucleotide polymorphisms were retained in the terminal generation. While further studies are needed, we believe that the inherent benefits of including the similarity matrix in the genomic selection apply to many practical breeding programs and represent a significant step towards efficient long-term genomic selection.

Mining the convergence behaviour of a single-step SNP-BLUP model for genomic evaluation of statureD.S. Dawid Słomian¹, J.S. Joanna Szyda^{1,2} and K.Ż. Kacper Żukowski¹*¹National Research Institute of Animal Production, Sarego 2, 31-047 Cracow, Poland, ²Wroclaw University of Environmental and Life Science, Biostatistics Group, Department of Genetics, Koźuchowska 7, 51-631 Wroclaw, Poland; dawid.slomian@iz.edu.pl*

The single-step model is becoming increasingly popular for national genetic evaluations of dairy cattle, offering several benefits such as joint breeding value estimation for genotyped and ungenotyped animals. However, the model's high parameterization and correlations among millions of effects can lead to significant computational challenges, especially in terms of the accuracy and efficiency of the preconditioned conjugate gradient method used for the estimation. This study aimed to investigate the effect of pedigree depth on the overall convergence rate of the single-step SNP-BLUP model and the convergence of its different components. The results showed that the data set with a truncated pedigree converged twice as fast as the full data set. Both data sets had very high Pearson correlations between predicted breeding values. The study also compared the top 50 ranking bulls between the two data sets and found a high correlation in predictions of their genetic merits. The convergence patterns of different animal groups and SNP effects were analysed, revealing heterogeneity in convergence behaviour. Pedigree depth influenced the convergence rate of the single-step SNP-BLUP model, with SNP effects converging the fastest and phantom parent groups converging the slowest, reflecting the difference in information content available in the data set for those effects. Among different animal groups, genotyped animals with phenotype data converged the fastest, while non-genotyped animals without their own records required the most iterations. In conclusion, data structure markedly impacts the convergence rate of the optimization, and the truncated data set is more efficient than the full data set.

Increase in prediction accuracy can be achieved by combining multiple populationsA. Ajasa^{1,2}, S. Boison³, H. Gjølven¹ and M. Lillehammer²

¹Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Arboretveien 6, 1430 Ås, Norway, ²Norwegian Institute of Food, Fisheries and Aquaculture Research, Breeding and Genetics, Osloveien 1, 1432 Ås, Norway, ³Mowi Genetics AS, Sandviksboder 77AB, 5035 Bergen, Norway; afees.ajasa@nofima.no

The accuracy of genomic prediction is in part determined by the size of the reference population. In aquaculture breeding programs, the generation interval is usually three or four years, and thus three or four parallel populations (year-classes) usually exist at any point in time. A reasonable strategy to increase the reference population size can then be to combine multiple year-classes. However, results from terrestrial species have in general indicated limited or no impact on prediction accuracy when combining multiple populations, partly because of the inconsistency of linkage disequilibrium phase between markers and quantitative trait loci (QTLs) across populations. In this study, we evaluated the impact on prediction accuracy when selecting SNPs that have the same phase with the QTLs across populations. This was achieved by including a genome wide association analysis step before the genomic prediction was done. This was to identify markers with similar signs of allele substitution effect across populations (without recourse to whether these markers were significant or not). The data set utilized in this study was gill score records of Atlantic Salmon infected with amoebic gill disease from three year-classes genotyped with a 55K SNP, and the genomic evaluation model was a Genomic best linear unbiased prediction. Utilizing the whole genotype data, combining multiple year-classes, resulted in no or limited increase in prediction accuracy when compared to within year-class prediction accuracy, whereas utilizing selected markers resulted in about 10-20% increase in prediction accuracy, with bias ranging from 0.93-0.98. Our findings suggest that including multiple populations in genomic prediction may enhance accuracy, provided that appropriate marker selection methods are employed to account for the inconsistency of linkage disequilibrium phase between populations.

Enhancing bovine genome SNP call accuracy with autoencoder analysis of nucleotide impact with AIK. Kotlarz¹, M. Mielczarek^{1,2}, B. Guldbrandtsen³ and J. Szyda^{1,2}

¹Wrocław University of Environmental and Life Sciences, Department of Genetics, Kozuchowska 7, 51-631 Wrocław, Poland, ²National Research Institute of Animal Production, Krakowska 1, 32-083 Balice, Poland, ³University of Copenhagen, Department of Veterinary and Animal Sciences, Grønnegårdsvej 8, 1870 Frederiksberg C, Denmark; krzysztof.kotlarz@upwr.edu.pl

A critical step in the analysis of NGS data is variant calling, which involves comparing the sequences to a reference genome to identify variants like, e.g. single-nucleotide polymorphisms (SNPs). However, variant calling is a challenging operation and errors happen for several reasons. Our research focused on the identification of the effects of nucleotide context around an identified variant on incorrect SNP calls. For that purpose, an anomaly detection procedure was implemented via an autoencoder (AE) model. Whole-genome sequences (WGS) of four Danish Red Dairy Cattle bulls were sequenced on the Illumina HiSeq2000 platform and genotyped with the Illumina BovineHD Bead Array. Incorrect SNPs were defined as mismatches between these two technologies. For the classification, the variables from a VCF file with 3 downstream and 3 upstream reference nucleotides were used. The training data set composed data from three bulls and consisted of 2,227,995 correct (97.93%) and 47,093 incorrect SNPs, with a stratified 30% validation subset, while the test data set consisted of data from one bull with 749,507 correct (97.85%) and 16,468 incorrect SNPs. The AE algorithm was implemented via the Keras library with mean square error (MSE) loss function. The training process resulted in a final MSE of 0.147 and 0.239 in the validation dataset. The reconstruction loss of incorrect SNPs was significantly higher ($P=1.19 \times 10^{-8}$) than the reconstruction loss of correct SNPs. To further evaluate the effectiveness of the AE, the trained model was evaluated on a test dataset that archived MSE of 0.229 and a significant ($P=1.00 \times 10^{-3}$) difference between correct and incorrect SNP subsets. Our results demonstrated: (1) there is still a considerable number of incorrectly identified SNP genotypes originating from WGS data; (2) by mining the underlying pattern of their explanatory variables in a post-calling analysis one can identify a large proportion of incorrect SNPs.

Efficient SNP calling: Nextflow vs Bash on the whole genome bovine sequence

P. Hajduk¹, M. Sztuka¹, K. Liu¹, K. Kotlarz¹, M. Mielczarek^{1,2} and J. Szyda^{1,2}

¹Wrocław University of Environmental and Life Sciences, Department of Genetics, Kozuchowska 7, 51-631 Wrocław, Poland, ²National Research Institute of Animal Production, Krakowska 1, 32-083 Balice, Poland; 121687@student.upwr.edu.pl

Variant calling is a process that involves comparing sequences to a reference genome, allowing for the detection of single-nucleotide polymorphisms (SNPs). It is especially useful when working with NGS data, which has become more popular in recent years. However, due to the sheer size of the data used in this process, time and memory usage become a concern when creating variant calling pipelines. This study compares those aspects for different approaches to SNP-calling pipeline parallelization with the use of Nextflow. Data used in this study included the genomic DNA of five Polish Holstein-Friesian cows, which were sequenced with the Illumina HiSeq2000 platform in the paired-end mode. The bioinformatic pipeline consisted of (1) quality control, (2) alignment to the reference genome, (3) post-alignment processing step, and (4) SNP calling. Three different approaches were compared for various levels of parallelisation expressed by the numbers of cores. The first was a plain bash script in which calculations for each cow were executed in parallel. The second was a bash script wrapped in a single NextFlow process. Third was a NextFlow script with each step of the pipeline treated as a separate process. Results demonstrated that on average the multi-process NextFlow script performed the fastest, no matter the number of CPUs used, with the biggest increase in time when each process was on 10 cores, where the average time difference was 47%. When comparing RAM usage, the only significant differences occurred between scripts given 1 core per process and slight differences when given 5 cores per process. For all other constellations, no differences were found. Nextflow is an efficient computing environment not only for creating pipelines but also for managing them. It offers a lot of tools for visualization during processes as well as after completion, which helps with monitoring each process during its run-time. Even though there were no significant differences regarding RAM usage, there was a noticeable decrease in execution time between NextFlow and plain Bash pipelines.

Variant calling and genotyping accuracy of ddRAD-seq: comparison with WGS in layers

M. Doublet, F. Lecerf, F. Degalez, S. Lagarrigue, L. Lagoutte and S. Allais

UMR 1348 PEGASE INRAE, Institut Agro, 16 Le Clos, 35590 Saint-Gilles, France; mathilde.doublet@inrae.fr

Since the advent of Next Generation Sequencing, sequencing has been used for many applications, including obtaining genotypes for animal genomic selection. However, as full depth whole genome sequencing (WGS) is either unaffordable or inappropriate for certain applications, alternative approaches have been developed. Amongst them, double digested Restriction-site associated DNA sequencing (ddRAD-seq) offers a high sequencing depth on a targeted part of the genome. This type of approach reduces costs compared to full depth WGS and limits the inter-individual variability of a low depth WGS approach. A method such as ddRAD-seq could benefit the laying hen industry by providing low-cost genotyping, assuming it is of sufficient quality. The objective of this study was to evaluate the suitability of ddRAD-seq sequencing to detect variants and obtain bi-allelic SNP genotypes, using different sets of quality control filters. The study was conducted on a population of 50 males of a Rhode Island laying line for which sequences were obtained by ddRAD-seq with the TaqI/PstI enzyme couple and by 20X sequencing. First, the variant calling results were compared between 20X and ddRAD-seq. Then, the genotype concordance rate between ddRAD-seq and WGS 20X was calculated on the common SNPs. Finally, the variation of this concordance rate was calculated based on different filter combinations on the average sequencing depth (DP) per SNP and the SNP call rate (CR). 9,270,491 SNPs were genotyped in 20X and 350,490 in ddRAD-seq. The average SNP CR (55%) and the mean SNP DP value (11X) in ddRAD-seq were lower than in 20X (99% and 16X respectively). 327,364 SNPs were detected in both methods and were distributed on all the chromosomes. For these common SNPs, the mean of the concordance rate per SNP (CcR) between the genotypes obtained in ddRAD-seq and those obtained in 20X was on average 82%. The relationship between the CcR, the CR, the DP and the percentage of retained SNPs should allow future users of ddRAD-seq to choose the best filtering thresholds for their analyses.

Performing single-step genomic evaluation for superovulatory response traits in Japanese Black cowsA. Zoda¹, R. Kagawa¹, H. Tsukahara¹, R. Obinata¹, M. Urakawa¹, Y. Oono¹ and S. Ogawa²¹Research and Development Group, Zen-noh Embryo Transfer Center, Kamishihoro, Hokkaido, 080-1407, Japan, ²Division of Meat Animal and Poultry Research, Institute of Livestock and Grassland Science, NARO, Tsukuba, 305-0901, Japan; zouda-atsushi@zennoh.or.jp

Japanese Black cattle are famous for their excellent meat quality. The value of Japanese Black calves is much higher than that of calves of other beef breeds. Therefore, Japanese Black embryos, which have been produced by superovulation treatments, are widely used for embryo transfer. Previously, using pedigree data, we reported that genetic improvement of superovulatory response traits seems possible. Here, we performed genomic prediction for superovulatory response traits in Japanese Black cows via a single-step approach. Records of the total number of embryos and oocytes (TNE) and the number of good embryos (NGE) per flush were obtained from 1,874 Japanese Black donor cows during 2008-2022. The number of records was 25,332 per trait. Overall, 575 out of the 1,874 cows had genotype information on 36,426 single-nucleotide polymorphisms (SNPs) on autosomes, according to ARS-UCD1.2. A two-trait repeatability animal model was exploited. Variance components were estimated using the BLUPF90+ software with the method VCE option. Pedigree-based and genome-based relationship matrices (A and H matrices) were fitted. Estimated heritabilities of TNE and NGE were slightly lower when using the H matrix than when using the A matrix, although the estimated repeatabilities were similar to each other. When the variance components were fixed in breeding value prediction, the mean reliability was higher when using the H matrix than when using the A matrix. This advantage seems more prominent for cows with low reliability when using the A matrix. The results imply that introducing a genomic prediction scheme could boost the rate of genetic improvement.

Production traits in Nellore cattle classified by residual feed intake

J.A. Muñoz, R.H. Branco, R.C. Canesin, J.N.S.G. Cyrillo, M.E.Z. Mercadante and S.F.M. Bonilha

Instituto de Zootecnia, Rodovia Carlos Tonanni, km 94, Sertãozinho, SP, 63-14160-900, Brazil; julianmunoz@alumni.usp.br

In beef cattle, there is considerable variation in feed intake that is independent of size and growth rate and can be calculated as residual feed intake (RFI), which is a measure of the efficiency of feed utilization by the animals. We aimed to evaluate the effects of RFI classification on productive traits of Nellore cattle with different growth potential (GP) finished in the feedlot. A total of 45 non-castrated Nellore males with 528 ± 30 days of initial age and 377 ± 8.87 kg of initial body weight were evaluated in a 2×2 factorial scheme: RFI (low or high) and GP (HG: high growth potential; LG: low growth potential) to determine performance and carcass traits. RFI classification of animals was based efficiency test performed after weaning. Dry matter intake (DMI), weight gain (ADG), body weight (BW), hot carcass weight (HCW), carcass yield (CY), rib eye area (REA), backfat thickness (BF), and rump fat thickness (RF) were analysed by SAS MIXED procedure considering as fixed effects RFI and GP, as covariate age at slaughter, and as random effect diet. Differences between means were verified using the t-Student test with $\alpha=0.05$. RFI class did not affect the carcass traits of the animals ($P>0.05$). However, there was a trend towards lower DMI in feedlot (10.0 vs 10.6 kg/d; $P=0.099$) in low RFI animals, compared to high RFI animals, regardless of their GP. There was a lower RF (3.50 vs 6.30 mm; $P=0.022$), as well as trends towards lower BW (424 vs 458 kg; $P=0.074$) and lower HCW (240 vs 260 kg; $P=0.095$) in the comparison between HG and LG. It is noteworthy that ADG had an interaction between the factors (RFI and GP), having LG and low RFI animals lower ADG than LG and high RFI animals (1.10 vs 1.56 kg; $P=0.033$) and than HG and low RFI animals (1.10 vs 1.48 kg; $P=0.049$), respectively. In this context, Low RFI Nellore animals, possibly with lower feed intake during the feedlot, had performance equivalent to commercial standards without any difference in carcass traits. Animals with high growth potential (selected for growth) had better performance in the feedlot. However, genetic associations with RFI did not affect traits of economic importance. Acknowledgments: FAPESP Process 2022/12347-4.

Effect of paternal breeding values for residual feed intake on reproductive performance of heifers

T. Devincenzi, M. Lema, L. Del Pino, A. Ruggia and E.A. Navajas

Instituto Nacional de Investigación Agropecuaria, Av. Italia 6201 Edificio Los Guayabos, 11500, Uruguay; tdevincenzi@inia.org.uy

We evaluated the effect of sires' efficiency for RFI on productive and early reproductive performance of Hereford heifers grazing native pastures in Uruguay. We studied an offspring of 98 females born from 7th September to 25th November 2020 in an experimental herd which belong to a Hereford genetic information nucleus. Animals were classified into two groups according to their paternal estimated breeding values (EBV) for RFI (percentiles $\leq 20\%$ for high; H; n=41, $\geq 70\%$ for low; L; n=57). Animals were managed together from weaning to 12 m and then were split into two contemporaneous groups. Body weights were recorded at birth, weaning, and then monthly until 25 m of age before heifers first insemination. Average daily gain (ADG) was calculated by seasons (fall/winter-2021, spring/summer-2021, fall/winter-2022 and spring/summer-2022). Ovarian activity (OA) was assessed by ultrasonography at 12, 15, 18 and 25 m of age and heifers presenting a corpus luteum were registered. Growth performance data were subjected to ANOVA and the frequency distribution of OA was compared by Qui2 test. The statistic model included EBV for RFI group as a class fixed effect. Dam age and the split group were tested but later excluded from the model because they were not significant. The sire EBV group affected birth weight ($P=0.00306$). Animals from H group were lighter than L group (38.6 ± 5.06 and 40.8 ± 5.01 kg, for H and L groups respectively). EBV group did not affected heifers' performance ($P>0.05$). Weaning weight was 184.4 ± 19.23 kg at ADG from birth to weaning was 0.773 ± 0.085 g/day. Animals weighted 236.3 ± 25.37 , 270.2 ± 23.55 , 313.8 ± 26.92 and 384.9 ± 31.65 kg at 12, 15, 18 and 25 m respectively. ADG was 0.218 ± 0.133 , 0.520 ± 0.122 , -0.014 ± 0.132 and 1.166 ± 0.291 g/day during fall/winter-2021, spring/summer-2021, fall/winter-2022 and spring/summer-2022 respectively. There was no effect of the EBV group on OA ($P>0.05$). The frequencies of OA were 2.06, 21.4, 51.5 and 73.9% at 12, 15, 18 and 25 months, respectively. In our study paternal EBV for RFI did not affect the productive and early reproductive of female performance, however efforts must be done to include a larger number of animals from different generations in future studies.

Species identification of animal/pig DNA in non-animal food

M. Natonek-Wiśniewska and P. Krzyżściński

The National Research Institute of Animal Production, Department of Animal Molecular Biology, Krakowska 1 Street, 32-083 Balice, Poland; malgorzata.natonek@iz.edu.pl

Resignation from the consumption of pork or animal products in general is most often related to health care, religious beliefs or cultural affiliation. Regardless of the reasons for the phenomenon, representatives of the above-mentioned social groups are interested in consuming products devoid of animal or, in particular, pork ingredients. Although in Europe there is an obligation to declare the composition of food products (EU 1169/2011), there are cases of food adulteration – intentional or accidental due to poor production or storage conditions. For these reasons, there is a need to control food for the potential addition of undesirable ingredients in the food that is assumed to contain only plant components. The work aimed to develop a method for identifying animal and pork DNA in fruit juice and chocolate. DNA obtained from juice and chocolate was fortified (1, 0.1 and 0.01%) with pork DNA obtained from meat and analysed by PCR with animal and pork primers. DNA from juice and chocolate without the addition of foreign DNA was used as blank controls. No PCR products were obtained for blank controls, while for fortified samples a product indicating the presence of animal/pig DNA was obtained. The obtained results indicate the biological specificity of the method in the tested matrix and the lack of inhibitors. The LOD of the method is 0.01%.

Development of a proxy for feed efficiency prediction in dairy cows based on mid-infrared spectra*M. Raemy¹, T. Haak^{2,3}, F. Schori³ and S. Ampuero Kragten¹**¹Agroscope, Method Development and Analytics, 1725 Posieux, Switzerland, ²University Bonn, Institute of Animal Science, Bonn, Germany, ³Agroscope, Ruminant Nutrition and Emissions, 1725 Posieux, Switzerland; marlyse.chatton@agroscope.admin.ch*

The present study is an evaluation of the potential of mid-infrared (MIR) spectra of milk to predict feed efficiency (FE) of lactating cows. Feed efficiency can be expressed as: feed conversion ratio (FCR), residual feed intake (RFI), nitrogen use efficiency (NUE), residual nitrogen intake (RNI) and residual energy intake (REI). The advantage of milk MIR spectra is that they can be readily used to predict FE traits since they are routinely collected as part of milk recording of cattle. Fleckvieh and Holstein lactating cows (76) were used, from three feeding trials. In the first trial, the cows grazed almost exclusively, in the second they ate fresh herbage in the barn, and in the third they were offered total mixed rations with two different protein contents. Milk samples were scanned with a MilkoScan RM® from FOSS®, from 929 cm⁻¹ to 3,000 cm⁻¹. Different data pretreatments were applied to the raw spectra: multiplicative scatter correction, standard normal variate, Savitzky-Golay smoothing and derivative. Partial least squares regressions with leave one out cross validation (CV) were used to develop the prediction models with all available data except 10 samples kept for independent validation (val) on all FE traits. The prediction models showed moderate to good results with R²_{CV} of 0.90, 0.81, 0.80, 0.75 and 0.59 for RNI, FCR, NUE, REI and RFI respectively. The R²_{val} showed lower values 0.83, 0.69 and 0.77 for RNI, FCR and NUE respectively and even lower values for REI (0.27) and RFI (0.31). The residual prediction deviation (standard deviation of calibration-set / root mean square error of prediction of validation-set) showed 1.98 for RNI, 1.63 for NUE, 1.57 for FCR, 1.21 for REI and 1.07 for RFI. These results indicate that milk MIR spectra are a promising tool to predict FE traits, probably with the exception of REI and RFI. It is therefore important to expand the variability of the dataset to further improve the robustness of the prediction models in order to be able to use them for the selection of dairy cows. This would be easier through international collaborations.

Session 69

Poster 34

Improving taste and flavour in dairy product through analysis of free fatty acid by MIR spectroscopy*O. Christophe¹, R. Reding², J. Leblois³, D. Pittois⁴, C. Guignard⁴ and F. Dehareng¹**¹Walloon Agricultural Research Center (CRA-W), 24, Chaussée de Namur, 5030 Gembloux, Belgium, ²Convis, 4, Zone artisanale et commerciale, 9084 Ettelbruk, Luxembourg, ³Elevéo asbl, 4, rue des Champs Elysées, 5590 Ciney, Belgium, ⁴Luxembourg Institute of Science and Technology, Department Environmental Research & Innovation (ERIN), 41, Rue du Brill, 4422 Belvaux, Luxembourg; o.christophe@cra.wallonie.be*

The dairy sector deals with a recurring issue: a taste alteration due to degradation of fat, commonly called lipolysis. Lipolysis happens after the milking, through the physical shocks induced by freezing, pumping, transfer and storage of the milk. Physical break of fat globules makes triglycerides accessible to enzymes and degraded into free fatty acids (FFA). Among them, the volatile short chain FFA lead to organoleptic issues through undesired tastes. An easy quantification of these individual short chain FFA, responsible of taste alteration, is very difficult. Historically, the lipolysis was quantified with the BDI methods by the measurement of the fat acidity. On the other hand, the analysis of a wide range of FFA is now possible by Gas Chromatography coupled with tandem mass spectrometer (GC-MS/MS). This analysis is time consuming, expensive and difficult to apply for routine analysis on a large set of samples. In order to bring a new way of preventive and corrective action for dairies and farmers, this project aims to develop predictive models based on milk mid Infrared spectroscopy (FT-MIR) to quantify FFA. For this purpose, milk samples from four different countries were collected and analysed by MIR spectroscopy as well as GC-MS/MS. The different models provided moderate R² for long-chain FFA and relatively low R² for short-chain FFA. Indeed, most of short chain FFA were under the limit of quantification. The lack of short-chain FFA concentration was solved by testing different mechanical induced lipolysis without interfering with the MIR spectrum. Among them, time milk homogenization has demonstrated a clear increase of short chain FFA value leading to better predictive models. More than 600 analyses were collected (classical and mechanical induced lipolysis included) to setup this model. R² is ranged from 0.3 to 0.8 for the different FFA (C4 to C18).

Modelling growth curves in challenged mice lines divergently selected for birth weight variabilityV. Mora-Cuadrado¹, I. Cervantes¹, J.P. Gutiérrez¹ and N. Formoso-Rafferty²¹Facultad de Veterinaria, UCM, Animal Production, Avda. Puerta de Hierro s/n, 28040 Madrid, Spain, ²ETSIAAB, UPM, Agronomic Production, C/Senda del Rey 18, 28040 Madrid, Spain; nora.formosorafferty@upm.es

Selection for homogeneity can affect feed efficiency, and may benefit productivity and animal welfare, even when feed restrictions are applied. This fact has been proved in a selection experiment in mice for birth weight (BW) variability. After more than 30 generations of selection the Low line (L-line) showed benefits over the High line (H-line) regarding growth, feed efficiency, litter size, survival, and longevity. The objective of this study was to model the growth curves during a feeding restriction challenge in both lines. A total of 80 females (40 from each line) from generation 14 of the experiment were analysed. During the growth stage from weaning (21 days) to 63 days, the mice were separated in two groups per line (20 females per line and group), and received two types of diet: *ad libitum* and a restricted one consisting of 85% of the food consumption *ad libitum*. Animals were weekly weighed and the data were used to estimate the growth curves of each animal using the Brody, Gompertz, Logistic, and Von Bertalanffy growth functions. These functions provided coefficients for the asymptotic weight of the animals and their growth rate. AIC, BIC and r^2 were used as criteria for the selection of the models. A GLM was performed for BW, for the asymptotic BW and for growth rate of each function. The litter size, diet, line, diet $\times$ line and days (linear and quadratic only for BW) were included in the models. Differences between the four functions were small. However, the Logistic function was the one with the worst fit in all cases. All effects were relevant showing that the influence of the diet effect was very different between lines, showing a difference of 1.98 g in H-Line and 0.27 g in L-line. L-line animals were more robust and resilient, having a better support of the stress caused by feed restriction, while H-line animals proved to be less homogeneous and susceptible to stress, despite reaching higher weights.

Poster 36

Genomic prediction of commercial layers' bone strengthM. Sallam¹, H. Wall¹, P. Wilson², B. Andersson³, M. Schmutz³, C. Benavides⁴, M. Checa⁴, E. Sanchez⁴, A. Rodriguez⁴, I. Dunn², A. Kindmark⁵, D.J. De Koning¹ and M. Johnsson¹¹Swedish Uni. of Agricultural Sciences, Ulls väg 26, Uppsala, Sweden, ²Roslin Institute, Edinburgh EH25 9RG, Scotland, United Kingdom, ³Lohmann Breeders, Am Seedeich 9-11, Cuxhaven, Germany, ⁴Uni. de Granada, Mineralogía y Petrología, Granada, Spain, ⁵Uppsala Uni., Akad. sjukhuset, Uppsala, Sweden; mohammed.abdallah.sallam@slu.se

The high prevalence of bone damage is frequently reported on commercial layers (hybrids). The direct selection of hybrids for stronger bone is not possible because they never participate in breeding practices. One possible strategy is to estimate SNP effects of hybrids' bone strength, then use them as parameters for selecting grand-parents of hybrids. We hypothesize that accurate SNP effects of hybrids' bone strength can be obtained with a relatively small reference population. Genotypes on 50k SNPs and tibia strength phenotypes were available from two brands of hybrids (White Bovans and Leghorn Selected Lohmann Classic) housed in two housing systems (cages and pens). This resulted in 4 classes (hybrid-housing combinations) of bone strength: Bovans kept in cages (n=220), Lohmann kept in cages (n=218), Bovans kept in pens (n=217), Lohmann kept in pens (n=218). In addition, we included the tibia strength of a Rhode Island Red breeding line (n=924). Each hybrid-housing combination was fitted separately into single-trait GBLUP. Then multi-trait GBLUP approaches were used to fit hybrid-housing combinations simultaneously: of the same hybrid but housed in different systems, of different hybrids but housed in the same system, of different hybrids housed in different systems, or the latter in combination with RIR data. Single-trait GBLUP has an average accuracy of 0.29. Combining data simultaneously across hybrids resulted in an average accuracy of 0.34. Tibia strength showed genomic-based heritability estimates of 0.1-0.64 and approximately 261-1,891 independent chromosomal segments. Genomic predictions of commercial layers' bone strength can be obtained with a relatively small reference population. Further study is required to test whether the proposed marker effects can be used as parameters for selecting breeding lines with an expected genetic gain in the forward batches of the hybrids.

Variability of daily milk yield during the first 100 days of lactation in Holstein cows

E. Kašná, L. Zavadilová and J. Vařeka

Institute of Animal Science, Genetics and Breeding of Farm Animals, Přátelství, 10400 Prague, Czech Republic; zavadilova.ludmila@vuzv.cz

Fluctuations in daily milk yield (DMY) can be used as an indicator of the health and resilience of dairy cows. We evaluated the variability of DMY during the first 100 days of lactation of cows from three cooperating farms. The dataset included 75,000 DMY records of 548 Holstein cows. The data were collected between October 2022 and January 2023. Cows were required to have records for at least 20 successive days and the first day in milk (DIM) must have been lower than 50. DMY ranged between 1 and 78 kg with a mean of 36 kg of milk per cow and day. The variances of DMY for each cow were log-transformed (LnVar) to achieve their normal distribution. The estimation of heritability ($h^2=0.15$) and breeding values (BV) for LnVar was based on a single trait linear animal model and performed with the BLUPF90 family of programs. The model included fixed effects of the farm, the month of calving, the lactation order and the first observed DIM, the random effect of animals included in the three-generation pedigree and the random residual. We calculated the correlations of sires' BV for LnVar with their BV for production, fertility, exterior and health traits to indicate their possible genetic correlations. The higher BV(LnVar) were associated with the higher BV for milk, fat and protein yield (kg), and the lower BV for milk protein and fat content (%). The higher BV(LnVar) were related to the deep and wide rear udder and negatively correlated with locomotion, a final class for legs and feet and body condition score. The lower LnVar was associated with better longevity and fertility traits, but the correlations were non-significant. The lower BV(LnVar) were also favourably correlated with health traits BV (somatic cells count, retained placenta, metritis, ovarian cysts, clinical mastitis, ketosis, feet disorders) but the correlations were weak and non-significant. The study was supported by the Ministry of Agriculture of the Czech Republic, project QK22020280 and institutional support MZE-RO0723.

Theatre 1

Single-step GBLUP for growth and carcass traits in Nordic beef cattleA. Nazari Ghadikolaei¹, F. Fikse² and S. Eriksson¹¹Swedish University of Agricultural Sciences (SLU), P.O. Box 7023, 75007 Uppsala, Sweden, ²Växa, P.O. Box 288, 75105 Uppsala, Sweden; *anahit.nazari@slu.se*

Single-step genomic prediction (ssGBLUP) has been applied for more accurately estimating genomic breeding values (GEBVs) using pedigree, phenotype and genotype information. The aim of this study was to investigate the use of ssGBLUP in the Nordic beef cattle evaluation of Charolais and Hereford. Genotypes for about 44,000 SNP for in total 4,321 Charolais and 4,532 Hereford were analysed together with phenotype information for in total 358,198 Charolais and 406,857 Hereford animals provided by the Nordic Cattle Genetic Evaluation. Because the number of genotyped Danish animals was low, we here present results for Swedish and Finnish animals. The BLUPF90 family of programs was used for estimation of breeding values for 10 growth and carcass traits. We compared two different weights, alpha values of 0.95 ($a_{0.95}$) and 0.70 ($a_{0.70}$), for genomic information while building the H matrix. The Legarra-Reverter (LR) method was used to estimate relative accuracy improvement (RAI) and dispersion (b1) values. Reduced data was created by removing observations made after 2018. The ssGBLUP and pedigree BLUP (PBLUP) was considered as the whole and partial model respectively. RAI was calculated as the accuracy ratio obtained from ssGBLUP and PBLUP minus 1, and the b1 value was defined as the regression coefficient GEBVs from ssGBLUP on EBVs from PBLUP in the validation set (animals born after 2018). The estimated RAI ranged from 5% for Europe conformation class (SCONF) in Finnish Charolais animals to 71% for post weaning gain (PWG) in Swedish Hereford animals when using $a_{0.95}$. Using $a_{0.70}$ resulted in lower RAI (on average for all traits 15.3 and 30.3% in Charolais and Hereford, respectively) compared to using $a_{0.95}$ (average RAI 23.6% in Charolais and 43.0% in Hereford). The b1 values ranged from 0.80 to 1.05 in both Charolais and Hereford using $a_{0.95}$ and were only slightly, and not consistently, influenced by the alpha value used. We conclude that introducing ssGBLUP in Nordic beef cattle breeding would be feasible and beneficial to improve the accuracy of breeding values especially for young, genotyped animals.

Genetic parameters of pig birth weight variability

Y. Salimiyekta¹, S.B. Bendtsen¹, K.V. Riddersholm¹, M. Aaskov¹ and J. Jensen²

¹Danish Genetics, Lysholt Alle 10, 7100 Vejle, Denmark, ²Aarhus University, quantitative genetics and genomics, C.F. Møllers Alle 3, 8000 Aarhus, Denmark; yas@danishgenetics.dk

The objective of this study was to estimate genetic variance and heritability of birth weight variability in the Landrace and Yorkshire pig populations in Denmark. The data set consisted of 1,352 litters from 1,155 Landrace sows and 1,758 litters from 1,432 Yorkshire sows farrowing in the period from 2021 and 2023. Variance components and breeding values were estimated using single-step genomic BLUP (ssGBLUP) method and the average information restricted maximum likelihood approach (AI-REML). The heritability of birth weight variability was estimated to be 0.100 and 0.114 for Landrace and Yorkshire, respectively. These results show that birth weight variability is heritable and minimizing the total within litter variance through selection is possible. Lower variability in the size of piglets can lead to less preweaning mortality and better growth during sucking in the pig population of Denmark.

Session 70

Theatre 3

Disentangling paternal and maternal components of within litter birth weight variability in mice

N. Formoso-Rafferty¹, L. El-Ouazizi El-Kahia², I. Cervantes² and J.P. Gutiérrez²

¹ETSIAB, UPM, Producción Agraria, Senda del Rey 18, 28040, Madrid, Spain, ²Facultad de Veterinaria, UCM, Producción Animal, Avda. Puerta de Hierro s/n, 28040, Madrid, Spain; nora.formosorafferty@upm.es

Animal production is searching for homogeneity, as it has been related to robustness, that improves functional traits whilst maintaining high production potential. Selection for homogeneity has resulted in more robust animals resilient to environmental challenges improving the animal welfare. A divergent selection experiment for birth weight (BW) environmental variability in mice has been successfully performed during 32 generations. Selection for low variability (L-line) was beneficial for traits usually considered robustness indicators such as birth weight homogeneity, growth, feed efficiency, litter size, survival and longevity. In this mice experiment, it was not possible to differentiate the within litter variability attributable to the father or to the mother because of the one to one mating design. The objective of this study was to ascertain the maternal or paternal nature of the genetic component of birth weight variability crossing mice selected lines between them and with the control line. H-line, L-line and C-line were mated simultaneously all with all, giving 9 different groups. Females were allowed to have up to two parturitions. Observed values for variance (V), standard deviation (SD) and coefficient of variation (CV) of BW, litter size (LS), mean birth weight (MBW), and individual pup birth (BW) and weaning (WW) weights were analysed. The model included the maternal and paternal lines, the interaction between them as an heterosis indicator, parturition number, the sex (for BW and WW) and the litter size (except when it was used as trait) as fixed effects. The model was solved by using TM software. Maternal significant differences between L-line and H-line were 19.2, 8.5, 7.0, 4.6, 1.3, 1.3 and 2.6 times the paternal differences between lines for respectively V, SD, CV, LS, MBW, BW and WW, being the paternal differences significant only for MBW, BW and WW. C-line performed intermediate between lines for all the traits except for LS in which there were no differences with L-line. Heterosis was not relevant. These results showed that variability within litter is a maternal trait.

(Co)variances between anogenital distance and fertility in Holstein-Friesian dairy cattleM.A. Stephen^{1,2}, C.R. Burke², N. Steele², J.E. Pryce^{3,4}, S. Meier², P.R. Amer⁵, C.V.C. Phyn² and D.J. Garrick¹¹Massey University, AL Rae Centre for Genetics and Breeding, Ruakura, Hamilton, 3214, WKO, New Zealand, ²DairyNZ, NZAEL, 605 Ruakura Road, 3240, WKO, New Zealand, ³La Trobe University, School of Applied Systems Biology, Bundoora, 3083, Victoria, Australia, ⁴AgriBio, Agriculture Victoria Research, Bundoora, 3083, Victoria, Australia, ⁵AbacusBio, Central Dunedin, 9016, Dunedin, New Zealand; melissa.stephen@dairynz.co.nz

Reproductive performance is an economically important trait for dairy farmers, particularly in pasture-based, seasonal farm systems that use an annual calving pattern to align pasture growth with the feed demands of the herd. Traditional fertility phenotypes are lowly heritable and expressed late in an animal's life, which contributes to relatively slow progress from genetic selection for those traits. Anogenital distance (AGD) is a moderately heritable candidate trait for predicting fertility estimate breeding values (EBVs) in dairy cattle. The objectives of this study were twofold. First, to estimate the genetic and phenotypic (co)variances between AGD measured at two ages and subsequent fertility traits expressed during lactation. Second, to estimate the genetic (co)variances between AGD and body conformation traits. We measured AGD, shoulder height, body length and body weight at 11±0.5 months of age in a population of 5,010 Holstein-Friesian and Holstein-Friesian × Jersey cows, born in 2018 and farmed across 54 seasonal, pasture-based herds. We also measured AGD at 29±0.7 months of age in a subset of 17 herds (n=1,956 cows). Calving, breeding, and conception dates were recorded for all available animals in first and second lactations, which commenced when animals were approximately 24 and 36 months of age, respectively. We report moderate heritabilities of 0.23 and 0.29 for 11-month and 29-month AGD, respectively. Both AGD measures exhibited moderate genetic correlations between 0.19 and 0.63 with calving, breeding, and conception traits. Genetic correlations between both AGD measures and body stature traits were weak (≤ 0.16). We conclude that AGD is a promising candidate predictor for fertility EBVs in dairy cattle, and genetic selection for shorter AGD in female cattle should result in improved fertility outcomes during lactation.

Session 70

Theatre 5

Genetic relationships between productive and reproductive traits on Friesian cows

S. Abomselem, A. Badr and A. Khattab

Faculty of Agriculture, Tanta Univ., Animal Production Department, Campus of Siberbia, 35712, Egypt; adelkhattab@yahoo.com

A total of 2166 normal lactation records of Friesian cows, kept at Sakha Farm, belonging to Animal Production, Research Institute, Ministry of Agriculture were used to study the relationship between productive and reproductive traits. Variables studied were total milk yield (TMY), 305 day milk yield (305 d MY), lactation length (LL), number of service per conception (NSC), first service period (FSP), days open (DO) and calving interval (CI). Means of TMY, 305 d MY, LL, NSC, FSP, DO and CI were 2,875 kg, 2,680 kg, 302 d, 3.1, 76.2 d, 159.0 d and 433.2 d, respectively. Direct heritability (h^2) for TMY, 305 d MY, LL, NSC, FSP, DO and CI were 0.20, 0.19, 0.09, 0.03, 0.04, 0.05 and 0.06, respectively. Genetic correlations between TMY, 305 d MY and LL were positive and ranged from 0.936 to 0.944. While, genetic correlation among TMY, 305 d MY, LL and NSC, FSP, DO and CI were negative and ranged from -0.10 to -0.30. Phenotype correlations among different traits are similar to genetic correlation. The present results indicated that the genetic improvement in milk production can be achieved through selection breeding program while, low h^2 estimates for LL, NSC, FSP, DO and CI indicated that improving the managerial techniques should lead to a considerable decrease in length of lactation length, number of service per conception, first service period, days open and calving interval.

Heritabilities of the mid-infrared spectra of sheep milk throughout the lactation*C. Machefert¹, C. Robert-Granié¹, J.M. Astruc² and H. Larroque¹**¹GenPhySE, Université de Toulouse, INRAE, ENVT, 31326 Castanet-Tolosan, France, ²Institut de l'Elevage, CNBL, 75595 Paris, France; coralie.machefert@inrae.fr*

Fourier transform infrared (FTIR) milk spectral data were routinely used to predict milk component concentrations and could be considered as predictors reflecting the physiological status and performance of animal. The genetic variability of milk FTIR spectra is well documented in cattle and goat. This study aimed to explore genetic variability of FTIR spectra in sheep milk by estimating heritability at each individual spectral point in the mid-infrared region from French Lacaune dairy sheep's milk obtained in SMARTER European project. The FTIR spectrum of milk provided by spectrometers contains 1,060 points, called wavenumbers (5,012 to 926 cm⁻¹), based on transmittance. Milk was sampled during two years (2020-2021) in 8 commercial farms. After data editing, the number of records available was 41,143 FTIR spectra from 5,281 ewes with a mean of 8 records per ewe for the whole testing period. 1,794 ewes were genotyped with low-density chip then imputed to SNP50 Bead-Chip. Heritability at each wavenumber was estimated, with all records and at each lactation stage, by a single-trait animal model using AI-REML including pedigree and genomic relationships. Parity and a vector of flock-year-stage of lactation were included as fixed effects and an additive genetic effect on the animal, permanent environmental effect and residual as random effects. The pattern and variability of the FTIR spectrum was similar to those estimated in dairy cattle and goat. Heritability estimates ranged from 0 in water absorption regions to 0.42 in regions linked to milk composition. A moderate repeatability of FTIR spectra (0 to 0.53) was observed. Two different heritability patterns were observed between the first three and last lactation stages considered. These results will be analysed regarding the evolution of the farming conditions during lactation. Additional analyses will allow to characterize groups of ewes with similar patterns and genetic correlations between wavenumbers and milk production traits will be estimated. This information will contribute to propose less invasive and cheaper predictors for the characterization of adaptability of dairy ewes. Study financially supported by INRAE and Occitanie region.

Session 70

Theatre 7

Genetic parameters for the composition of milk fatty acid of Holsteins*Y. Masuda**Rakuno Gakuen University, Ebetsu, Hokkaido, 0698501, Japan; yutaka@rakuno.ac.jp*

A negative energy balance of milking cows may lead to infertility and metabolic disorders. Fatty-acid (FA) content in milk represents the energy balance, and the measurement can be used to monitor the health condition of a cow. The FA content is now measured by Fourier-transform mid-infrared spectroscopy (FT-MIR) in the dairy milk recording program in Japan. This study aimed to estimate genetic parameters for the FA traits in the first three lactations of Japanese Holsteins. Data included 1,448,373 test day records from 211,462 Holstein cows in the 1st lactation, calving in Hokkaido, Japan, between April 2021 and October 2022. Two groups of FA, de novo FA (between C4 and C14) and preformed FA (equal to or greater than C18), were measured with FT-MIR for a milk sample. The de novo FA percentage (DNF%) and preformed FA percentage (PFF%) were calculated as the ratio of the predicted FA content to the total FA content. The dataset was divided by lactation stage, defined as every 30 days in milk (DIM) in each lactation, i.e. DIM 6 to 35 as stage 1, DIM 36 to 65 as stage 2, and so on. Variance components were estimated with an animal model. For each trait, (co)variances were estimated with a two-trait model for phenotypes between two different stages. In the first lactation, heritability at stage 1 for DNF% was 0.24, for PFF%, 0.30, and the value decreased up to stage 7 (DIM 215) in the first lactation. For both traits, stages 1 and 2 showed lower genetic correlations with later stages, e.g. for DNF%, 0.21 between stages 1 and 5. The genetic correlations of stage 3 or later were high (>0.90) up to stage 7. Similar trends in heritability and genetic correlations were observed in the second and third lactations. Further research will focus on genetic relationships between health and reproductive traits and the FA content, particularly at stages 1 and 2, where the negative energy balance may cause an issue in a milking cow.

External and genetic factors influencing fertility in Latxa dairy sheep breed

C. Pineda-Quiroga, I. Granado-Tajada, E. Ugarte and A. Basterra-García

NEIKER, Animal Production, Campus Agroalimentario de Arkaute, 01080, Spain; igranado@neiker.eus

Pregnancy rate at artificial insemination (AI) is largely variable and dependent on genetic and non-genetic factors. In Latxa breed, herds within the breeding program make use of high genetic value rams to inseminate their ewes once per year. Despite the relevance of the success of AI on the breed's genetic progress and on farms' productivity, this trait has not been up to now explored in this sheep population. To this aim, 135,351 edited AI records from 63,480 Latxa Cara Negra from Euskadi ewes, collected between 2000 and 2021, were used. The outcome of an AI event was treated as a binary response of either success or failure in becoming pregnant. To identify the environmental variables influencing the AI outcome, a multiple logistic regression was first calculated. After that, using the relevant factors identified in the previous step, a threshold model was used to estimate the genetic components of the trait in females and males. Results show that the AI success is higher in ewes having their first parturition at 1 year of age than at 2 or 3 year of age (Odd Ratio [OR] 1.04 and 1.08, respectively), in those with high prolificacy in the lambing previous to the AI event (OR 1.04 and 1.13 by having 2 or 3 lambs, respectively, vs 1 lamb), in those with a larger lambing-AI interval (OR 1.07 and 1.35 for intervals between six months or more, respectively, vs three months interval), as well as in those who had the previous parturition from an AI event compared to natural mating (OR 1.39). In counterpart, the higher the milk produced in the nearest milking AI date, the poorer the AI results (OR 0.92 when producing more than 450 ml vs producing up to 300 ml). Moreover, ewes older than five years and six lambings have less AI success with respect to younger ewes (OR 0.78). Regarding genetic parameters, the heritability and repeatability were 0.090 ± 0.007 and 0.200 ± 0.007 in females and 0.013 ± 0.006 and 0.025 ± 0.002 , respectively, in males. These results indicate that there are extensive and diverse external factors influencing the AI success, while the additive component is low. Although the trait shows genetic variability susceptible of selection under the breeding scheme, the genetic progress would be slow.

Session 70

Theatre 9

Single-step genome-wide association for milk urea concentration in Walloon HolsteinH. Atashi^{1,2}, Y. Chen², C. Bastin³, S. Vanderick², X. Hubin³ and N. Gengler²¹Shiraz University, Department of Animal Science, Shiraz, 7144113131 Shiraz, Iran, ²University of Liège, GxABT, Pass. des Déportés 2, 5030 Gembloux, Belgium, ³Elevéo asbl Awé Group, Ciney, 5590 Ciney, Belgium; hadi.atashi@uliege.be

Milk urea (MU), a normal non-protein nitrogen component in milk, is a by-product of the protein metabolism. It has been shown that MU is correlated with milk production, milk composition, cheese-making properties, nitrogen utilization efficiency and reproductive performance in dairy cattle. Therefore, selection for reducing MU can result in reducing N pollution, improving feed efficiency and animal health, and increasing milk quality and reproductive performance. The aims of this study were to estimate genetic parameters for MU and to conduct a single-step genome-wide association (ssGWAS) to identify candidate genes associated with MU in Walloon Holstein. The used MU data have been collected from 2014 to 2020 on 78,073 first-parity (485,218 test-day records), and 48,766 second-parity (284,942 test-day records) Holstein cows distributed in 671 herds in the Walloon Region of Belgium. Data of 730,539 single nucleotide polymorphisms (SNP), located on 29 *Bos taurus* autosomes (BTA) of 6,617 animals (1,712 males) were used. The proportion of the total additive genetic variance explained by windows of 50 consecutive SNPs (with an average size of ~216 Kb) was calculated, and the top-three genomic regions explaining the largest rate of the total additive genetic variance were considered promising regions and used to identify potential candidate genes. Mean (standard deviation) MU was 25.38 (8.02) mg/dl and 25.03 (8.06) mg/dl in the first and second lactation, respectively. Mean heritability estimates for daily MU were 0.21 and 0.23 for the first and second lactation, respectively. The top-3 regions combined explained 1.22 and 1.04% of the total additive genetic variance of MU in the first and second lactations, respectively. The identified regions were located from 80.61 to 80.74 Mb on BTA6, 103.26 to 103.41 Mb on BTA11, and 1.59 to 2.15 on BTA14. Genes including *PAEP*, *SOHLH1*, *GLT6D1*, *LCN9*, *DGAT1*, *CYHR1*, *CPSF1*, *SCX*, *SCRT1*, and *SPATC1* were identified as positional candidate genes for the MU. The findings of this study provide a better understanding of the genomic architecture underlying MU in Holstein cattle.

Genome-wide association study for milk production traits in the Cyprus Chios sheep

A.N. Georgiou, G. Maimaris, S. Andreou, A.C. Dimitriou and G. Hadjipavlou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516, Nicosia, Cyprus; ageorgiou@ari.moa.gov.cy

The identification of genetic markers affecting traits of economic interest such as milk performance provide practical benefits for the dairy sheep industry, enabling genomic prediction of the breeding value, based on single nucleotide polymorphisms (SNPs). The present study focuses on the identification of genetic variants associated with total milk yield in Cyprus Chios sheep, which is the most commercially important dairy breed in Cyprus. In this pilot study, total milk yield measurements for the first lactations were recorded over a period of 11 years (2011-2022) for 393 Chios ewes. All animals were genotyped using Illumina Ovine 50k Genotyping Beadchip. A principal component analysis (PCA) was performed to assess genetic diversity among individuals while a genome-wide association analysis (GWAS) was conducted aiming to identify candidate SNPs related to available phenotypes. After quality control, a total of 39,115 markers (over 26 autosomal chromosomes) and 386 ewes were retained for further analysis. The PCA analysis revealed a substructure within the dataset, identifying two principal clusters in the population. The GWAS analysis identified two SNPs, that were associated with total milk yield at a genome-wide significance ($P < 1 \times 10^{-4}$). The two SNPs were located in the non-coding region of *KIAA1217* (chromosome 13) and *CAMD1* (chromosome 15) genes respectively. More than 4,000 ewes across various flocks in Cyprus will be genotyped in the near future to further validate the primary findings of the GWAS analysis, and to enable the identification of further promising biomarkers for milk production (quantity and quality) in the Cyprus Chios sheep. The findings of the current study are anticipated to improve sheep productivity in Cyprus through the estimation of individual genetic merit and subsequently genomic evaluation and improvement of milk performance through the AGRICYGEN (Cyprus AGRicultural GENomics Centre) project.

Characterization of additive, dominance, and runs of homozygosity effects inbreeds of dairy cattleH. Ben Zaabza¹, M. Neupane², M. Jaafar³, K. Srikanth³, S. McKay¹, A. Miles², H.J. Huson³, I. Strandén⁴, H. Blackburn⁵ and C.P. Van Tassell²¹USDA, Animal Genomics and Improvement Laboratory, ARS, Beltsville, MD, USA, ²University of Vermont, Department of Animal and Veterinary Sciences, Burlington, VT, USA, ³Cornell University, Department of Animal Science, Ithaca, NY, USA, ⁴Natural Resources Institute Finland, Jokioinen, FI, Finland, ⁵National Center for Genetic Resources Preservation, Fort Collins, CO, USA; hafedh.ben-zaabza@uvm.edu

The global application of genomic selection in dairy cattle has raised interest in characterizing dominance effects for a better understanding of inbreeding depression (IB). We believe that a richer understanding of additive (ADD), dominance (DOM), and runs of homozygosity (ROH) effects in purebred and crossbred dairy cattle will help to understand the impact of these factors on IB and heterosis. To identify and localize genomic regions associated with ADD, DOM, and ROH effects we performed a single-SNP GWAS analysis, where SNPs were fit as fixed effects for the ADD, DOM, and ROH one locus at a time. The current analysis has been performed using 125,000 US Holstein cows genotyped on 79,294 SNP markers. We have analysed 3 production traits, 3 fertility traits, and somatic cell score (SCS). For the production traits, SNPs on BTA14 had the largest ADD effects. For fertility traits, SNPs on BTA1 had the most significant ADD effects. SCS had no significant DOM effects. Few DOM effects were detected for production traits and these effects had lower significance than ADD effects. Estimates of fertility trait DOM were detected with similar statistical significance as the ADD effects. The ROH revealed less prominent $-\log_{10}(P)$ peaks than the ADD effects for all traits. Genome-wide inbreeding depression will be examined for all traits. Correlations between ROH and ADD effects were close to 0. Correlations between ROH and DOM effects calculated by ADD-DOM model were 0.006. However, correlations between ROH and DOM effects calculated by ADD-DOM-ROH model were 0.31. These findings suggest that confounding exists between ADD and ROH effects – and that DOM and ROH components capture the same variance. This study will be further extended to a genomic dataset comprising over 4 million (1 million) genotyped purebred Holstein (Jersey) cows and all available crossbreds.

A genome-wide association study identified a major QTL affecting the red colour in nitrate free hamsJ. Vegni¹, M. Zappaterra¹, R. Davoli¹, R. Virgili², N. Simoncini², C. Schivazappa², A. Cilloni³ and P. Zambonelli¹¹Alma Mater Studiorum University of Bologna, Scienze e Tecnologie Agroalimentari (DISTAL), section: Animal Science, Viale Fanin 46, Bologna, 40127, Italy, ²Stazione Sperimentale per l'Industria delle Conserve Alimentari (SSICA), Viale Faustino Tanara 31/A, Parma, 43121, Italy, ³Fratelli Galloni S.p.A., Via Roma 84, Langhirano (Parma), 43013, Italy; jacopo.vegni2@unibo.it

Meat colour is an important quality parameter in dry-cured protected designation of origin (PDO) hams where the use of any additives, including nitrates, are not allowed. The typical colour of dry-cured hams, like Parma ham, is due to the formation of the red pigment Zinc protoporphyrin (ZnPP) in which Zn(II) is inserted in protoporphyrin IX. The synthesis of ZnPP has been suggested to be totally or partially enzymatic, and a role was assigned to the endogenous ferrochelatase enzyme. In this work, we carried out a genome-wide association study (GWAS) to identify candidate gene regions affecting meat colour in nitrate-free dry cured hams. A total of 238 commercial hybrid pigs were genotyped using the GeneSeek® Genomic Profiler genome-wide porcine genotyping array. The activities of ferrochelatase (FECHA) enzyme (responsible for meat red colour) in *Semimembranosus* muscle were determined through fluorimetric assays. The GWAS identified 12 single nucleotide polymorphisms (SNPs) that were significantly associated with FECHA activity. These SNPs were located in the chromosome region that harbours the FECHA gene, suggesting a direct role of variants in this gene with the investigated parameters related to meat colour. Additional studies will be needed to validate the obtained results and identify the causative mutation of this relevant QTL for meat quality parameters.

Session 70

Poster 13

Genetic relationships between milk fatty acids at early lactation and fertility in Holstein cowsT. Yamazaki¹, A. Nishiura², S. Nakagawa³, H. Abe³, Y. Nakahori³ and Y. Masuda⁴¹Hokkaido Agricultural Research Centre, NARO, Sapporo, 062-8555, Japan, ²Institute of Livestock and Grassland Science, NARO, Tsukuba, 305-0901, Japan, ³Hokkaido Dairy Milk Recording and Testing Association, Sapporo, 060-0004, Japan, ⁴Rakuno Gakuen University, Ebetsu, 069-8501, Japan; yamazakt@affrc.go.jp

To address the negative energy balance in early lactation is important for improving fertility of dairy cows, and milk fatty acid (FA) compositions are thought to be related to energy status. Our objective here was to investigate the genetic relationships between FA compositions during the early stage of lactation and fertility traits in the first and second lactations of Japanese Holstein cows. We used the insemination and monthly test-day records of Holstein cows that calved between 2019 and 2021 in the Hokkaido region of Japan (33K cows for first lactation and 21K cows for second). We analysed three types of test-day milk FA compositions (de novo FA (C4 to C14) composition on a milk basis (DNM), de novo FA composition on a total FA basis (DNF) and preformed FA ($\geq$ C18) composition on a total FA basis (PRF)) during 95 days in milk (DIM) as FA composition traits and conception rate at first insemination (CR) and days open (DO) as fertility traits. We estimated the genetic correlations between FA composition and fertility traits within each lactation by using two-trait (each FA composition traits and CR or DO) linear model, with month and age of calving for FA composition traits, and, month, age, and DIM at first insemination for fertility traits as fixed effects. We also included herd-year, service sire at first insemination (for fertility traits), additive animal, and residual effect as random effects. The genetic correlations of DNM, DNF, and PRF within 35 DIM with fertility traits in the first lactation were 0.31, 0.44, and -0.25 for CR, and -0.26, -0.27, and 0.25 for DO, respectively. These results suggest that genetic improvements in milk FA composition within 35 DIM could help to increase fertility in the first lactation.

Genetic parameters for early-life racing performance in pigeonsP. Duenk¹ and D. Shewmaker²¹Wageningen University and Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6708 PB Wageningen, the Netherlands, ²Shewmaker Genetics, 5575 Pyracantha Dr, 95682 Shingle Springs, USA; pascal.duenk@wur.nl

Pigeon racing is a popular sport in many countries. Races range from local club competitions to international One Loft Races where prize money can be over one million US dollars. Although breeders have been successful in improving racing performance over the years by means of selection, selection decisions are usually based on observations that may be weakly correlated with racing performance. In addition, racing performance traits are not clearly defined, and accurate estimates of genetic parameters for such traits are scarce. Finally, inbreeding is often not monitored, while mating of close relatives is quite common. Breeders may therefore benefit from data driven, structured breeding programs that improve racing performance while monitoring genetic diversity. Before such programs can be designed, however, some questions need to be answered. The objectives of this study are therefore to: (1) define the traits of interest in a breeding program for racing pigeons; (2) estimate genetic parameters of these traits; and (3) calculate historical rate of inbreeding. Data will be collected on young birds (born in 2023) from a single loft, between March and July 2023. During this period, the birds will be trained to return back to the loft, where the distance between release location and the loft will be incrementally increased up to about 450 km. The data will consist of approximately seven contemporary groups, each consisting of 100 birds. Across and within contemporary groups, there may be half- and full-sibs. We will record distance and direction of release location, individual total flight time, and weather conditions. In addition, we will collect pedigree data of up to seven ancestral generations. Genetic parameters will be estimated using a linear mixed model that corrects for environmental and contemporary group effects. Inbreeding rate will be computed from the pedigree. Overall, this study will provide knowledge on the importance of genetics for racing performance in pigeons, and may contribute to the development of more sustainable and efficient racing pigeon breeding and evaluation programs.

Session 70**Poster 15****Genetic parameters for milk urea in Swiss dairy cattle breeds**

A. Burren and S. Probst

Bern University of Applied Sciences BFH, School of Agricultural, Forest and Food Sciences HAFL, Länggasse 85, 3052 Zollikofen, Switzerland; alexander.burren@bfh.ch

The objective of this study was to estimate repeatability scores and variance components (VC) for milk urea in the Swiss cattle breeds Braunvieh (BV), Original Braunvieh (OB), Holstein (HO), Montbéliard (MO), Red Holstein (RH), Swiss Fleckvieh (SF) and Simmental (SI). For this purpose, milk urea results from 2,315,437 standard lactations yields (BV=955,231; OB=80,016; HO=265,775; MO=44,590; RH=474,289; SF=367,720; SI=127,816) with totally 2,335,267 pedigree records (BS=676,368; OB=73,927; HO=416,634; MO=70,635; RH=526,760; SF=431,080; SI=139,863) were used. The data were collected in the years 2010-2019. Genetic variances and covariances were estimated by REML using the software ASReml 4.2. The model to estimate VC and repeatabilities included the fixed effects number of lactation and milk yield, the random effects farm and sire, as well as a random additive genetic component and a permanent environmental effect. Estimated heritabilities and standard errors were 0.37±0.004, 0.52±0.012, 0.32±0.007, 0.20±0.013, 0.27±0.005, 0.34±0.006, 0.38±0.009 in BV, OB, HO, MO, RH, SF and SI breed, respectively. The repeatability coefficients varied between 0.30±0.008, 0.34±0.003, 0.40±0.003, 0.40±0.003, 0.44±0.006, 0.45±0.002 and 0.56±0.006 in MO, RH, SF, HO, SI, BV and OB, respectively (±standard error). The results are consistent with other studies and show that genetic modification of milk urea by selection is possible.

Estimation of genetic correlations between predicted energy balance and fertility in HolsteinsA. Nishiura¹, O. Sasaki¹, S. Yamaguchi², Y. Saito¹, R. Tatebayashi¹ and T. Yamazaki³¹*Institute of Livestock and Grassland Science, NARO, Tsukuba Ibaraki, 3050901, Japan,* ²*Livestock Improvement Association of Japan, Koto Tokyo, 1350041, Japan,* ³*Hokkaido Agricultural Research Center, NARO, Sapporo Hokkaido, 0628555, Japan; akinishi@affrc.go.jp*

It is important to improve the energy balance (EB) of dairy cows in lactation to prevent the deterioration of fertility and health. Our objective was to investigate relationships between predicted EB (PEB) from milk traits and fertility. The datasets we used to predict EB consisted of test-day milk records for the first three lactations of Holstein cows calved in 2015-19. There were 1,185,020, 966,742 and 676,416 records of first, second and third lactation cows each. We calculated average PEB of cows in each class of first conception rate (FCR), number of insemination (NI) and days open (DO) in early lactation. We estimated genetic correlations between PEB and FCR, NI and DO using random regression model. We included herd-test day, region-calving month and parity-calving age as the fixed effects in the model for PEB. We included herd-year, month and parity-age at first insemination as the fixed effects in the model for FCR, NI and DO. Additive genetic and permanent environmental effects were also included in both models as the random effects. The PEB of cows not conceived at first insemination were lower than those of cows conceived especially in multiparous cows. The PEB of cows with higher NI were lower than those of cows with lower NI especially in multiparous cows. The PEB of cows with longer DO were lower than those of cows with shorter DO especially in multiparous cows. Genetic correlations between PEB and FCR were estimated 0.16 to 0.19 in early lactation and became smaller in mid to late lactation. Genetic correlations between PEB and NI were estimated -0.14 to -0.10 in early lactation and became smaller in mid to late lactation. Genetic correlations between PEB and DO were estimated -0.26 to -0.21 in early lactation and became positive in late lactation, 0.10 at 305 days in milk. There were desirable genetic correlations between PEB and fertility traits in early lactation. It would be possible to improve fertility by improving EB in early lactation and PEB could be used as the index of EB.

Comparison of random regression test-day models for production traits of South African Jersey cattle

M.G. Kinghorn, E.D. Cason, V. Ducrocq and F.W.C. Naser

University of the Free State, Animal, Wildlife and Grassland Sciences, P.O. Box 339, Bloemfontein 9300, South Africa; naserfw@ufs.ac.za

Fixed regression test-day (TD) models are currently implemented for genetic evaluation of South African (SA) Jersey Cattle. The lactation curve is determined by fixed effects only and assumes that random effects are constant throughout the lactation, implying a genetic correlation of one between TDs. Random regression TD models (RRTDM) don't make the same assumption and split the lactation curve into two parts: a fixed part that accounts for similarities of lactation curves within specific groups and a random animal part that provides information on individual deviations from the fixed lactation curve. Furthermore, inferences can be made about persistency (PER). Our objective was to identify an appropriate RRTDM for SA Jersey cattle using Legendre polynomials (LP) to model the lactation curve by estimating genetic parameters with single- (S) and multiple- (M) lactation RRTDMs. TD records from 3 lactations were analysed using AIREMLF90. Goodness of Fit was assessed using Bayesian information Criterion (BIC). Varying orders of fit for LP were tested with S-RRTDMs, the resulting (co)variance components were used as starting values in the M-RRTDM for each trait (milk (MY), fat (FY) and protein (PY)). S-RRTDMs with a 3rd order LP fit best. For M-RRTDM a 2nd order LP was the best fit. Genetic correlations for total production (TP) between lactations were high for all traits (0.90-0.98), but lower for PER (0.54-0.97). Heritability estimates obtained for TP ranged between 0.20-0.25 (MY), 0.13-0.15 (FY) and 0.19-0.21 (PY) and were similar to those obtained by Interbull for the current SA Jersey model. The current model does not have a comparative heritability estimate for PER. PER estimates obtained in this study were low; 0.08-0.14 (MY), 0.07-0.10 (FY) and 0.08-0.12 (PY), but highest in the 2nd lactation. Stronger relationships for TP and PER in later lactations suggest that more effective selection could be made using a M-RRTDM that accounts for performance in later lactations. Similar heritability estimates (Interbull) for TP, plus the addition of a heritable measurement for PER suggest that the M-RRTDM proposed in this study is an appropriate alternative model to the current SA model.

Application of single-step genomic method in routine evaluation of Czech Holstein cattle

J. Bauer, J. Šplíchal, D. Fulínová and E. Krupa

Czech Moravian Breeders' Corporation, Genetic Evaluation, Benešovská 123, 25209 Hradištko, Czech Republic; bauer@plemdat.cz

Single-step genomic evaluation of Holstein Cattle in Czech Republic was in development since 2011 with support of prof. Ignacy Misztal of University of Georgia, USA. At first, the original procedures and programs for prediction of genomic breeding values (GEBVs) were exclusively written inhouse in Cobol and Rxx languages. However, with higher number of genotypes the computational time was considerably increasing and limitations of optimizations of these programs became more apparent. For this reason, the Blupf90 family software was adopted for prediction of GEBVs by single-step method. In 2015 all traits participating in national index for Holstein Cattle (SIH) had prediction of GEBVs which allowed to publish SIH together for all genotyped and non-genotyped animals. In the year 2015 Interbull validated and used Czech single-step GEBVs for milk production as input into genomic Multiple Across Country Evaluation (genomic MACE). It was first time when GEBVs predicted by single-step GBLUP were included at all. Because of the intensive exchange of genetic material between the Czech Republic and other countries, the eventual high genetic quality of imported bulls was often low rated in GEBVs due to lack of information. The issue was solved by development of integration of breeding values from MACE performed by Interbull. The data from international evaluation of bulls is since 2019 integral part of official GEBVs published in Czech Republic for milk production traits, udder health, linear traits, and fertility. Since then, the linear traits were also included in genomic MACE. The current routine genomic evaluation uses advanced techniques such as Algorithm for Proved and Young (APY) and further enhancements like utilization of weighted single-step BLUP are tested. Additionally, more traits will be soon implemented with cooperation with Institute of Animal Science Prague. The highest priority was given to health traits (e.g. mastitis resistance, infectious and non-infectious claw disorders). However, GEBVs of other traits are also in implementing process or are already published such as GEBVs for gestation length making total of 37 traits with predicted routine GEBVs.

A meta-analysis of the genetic parameter estimates for lamb survivalS. Fernandes Lazaro¹, H. Rojas De Oliveira² and F. S. Schenkel¹¹*University of Guelph, Department of Animal Biosciences, 50 Stone Rd E, Guelph, ON, N1G 2W1, Canada, ²Purdue University, Department of Animal Sciences, 610 Purdue Mall, West Lafayette, IN, 47907, USA; sirlene@uoguelph.ca*

Genetic factors are known to play a role in Lamb survival (LS) and knowing its heritability and genetic correlations with other economically important traits is required to optimize the inclusion of LS into sheep breeding programs. The goal of this study was to perform a meta-analysis on the genetic parameters for LS. The dataset comprised 24 heritabilities and 33 genetic correlations between LS and other important traits, which included birth weight, BWT; lambs born per ewe bred; NLB; lambs weaned per ewe bred; NLW; weaning weight, WWT; and lambs born per lambing ewe, LL. All genetic parameters included in this study were estimated using animal linear models. The meta-analysis was performed using a random-effects model, in which the parameter estimates were assumed independent, and normality distributed. The I² index was used to quantify the degree of heterogeneity among studies, and the effects of breed group (maternal, terminal, wool, and dual purpose), year of publication (from 1994 to 2010 and from 2010 to 2022), and continent (America, Africa, Asia, Europe, and Oceania) were tested. High variability among estimates from different studies were observed (I²>99.58%), which was mostly associated with the continent. The pooled heritability estimated for LS was 0.05 (95% confidence interval (CI): 0.02;0.07), which confirms that genetic improvement through selection is possible. Low to moderate genetic correlation estimates were observed between LS and BWT (0.16, CI: -0.07;0.39), LS and NLB (-0.16, CI: -0.30;-0.01), LS and WWT (0.39, CI: 0.15;0.63), LS and NLW (0.67, CI: 0.56;0.77), and LS and LL (-0.17, CI: -0.34;-0.01), suggesting the importance to directly include LS in the breeding programs. Overall, LS seems lowly heritable and shows low to moderate genetic correlation with the other traits analysed. Genetic parameters reported here support genetic evaluation for LS when reliable population specific parameter estimates are available.

Survival analysis in the conservation program of an endangered wild ungulate (*Nanger dama mhor*)S. Domínguez¹, I. Cervantes², E. Moreno¹ and J.P. Gutiérrez²¹Estación Experimental de Zonas Áridas-CSIC, Ctra. De Sacramento s/n, 04120 La Cañada de San Urbano, Spain, ²Faculty of Veterinary, UCM, Department of Animal Production, Avda. Puerta de Hierro s/n, 28040 Madrid, Spain; sdominguez@eeza.csic.es

Juvenile survival is a relevant aspect in the *ex situ* breeding programmes of threatened species, since it directly affects the viability of these populations in the short and long term. It is known that dams and sires can have a great influence on the survival of their offspring, both for their genetic and environmental effect. The objective of this study was to evaluate the genetic component of juvenile survival in the captive population of the critically endangered mhor gazelle (*Nanger dama mhor*). The analysed dataset included records of 2,222 calves from 502 different females and a total pedigree of 2,739 individuals. Juvenile survival was studied separately for different ages: 0-15 days, 16-30 days and 31-180 days of life. Sex, type of birth (primiparous or multiparous), year and season of birth were included as systematic effects in all models. As random effects, combination of sire, dam and calf genetic effects were included, beside the residual effect. Models were solved with a continuous and a threshold approach, and then compared using logCPOP values. All analysis were performed in a Bayesian frame using the TM program. The logCPO values indicated that the models with the highest predictive power were the sire-calf threshold model for survival in the first 15 days of life, the dam-calf threshold model for survival in the second fortnight of life and the dam-calf threshold model for survival from one month of life to weaning. The heritability values resulting from these models ranged between 0.02 and 0.50. In the period of 0-15 days, the heritability was 0.07 (SD 0.04) for the sire and 0.50 (SD 0.08) for the calf; with 16-30 days, it was 0.02 (SD 0.01) for the dam and 0.03 (SD 0.02) for the calf; and with 31-180 days, it was 0.05 (SD 0.03) for the dam and 0.08 (SD 0.04) for the calf. These preliminary results suggest the existence of genetic component in the juvenile survival in different ages in the mhor gazelle. It could be a starting of a selection program as part of the conservation strategy of the species.

Genetic parameters of maturing rate index and asymptotic adult weight in French beef cattleA. Lepers^{1,2}, S. Aguerre^{1,2}, J. Promp^{1,2}, S. Taussat^{1,3}, A. Vinet¹, P. Martin¹, A. Philibert², A. Laramée² and L. Griffon²¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, rue de la manufacture, 78350 Jouy-en-Josas, France, ²Institut de l'Élevage, 149 rue de bercy, 75012 Paris, France, ³ELIANCE, 149 rue de bercy, 75012 Paris, France; armance.lepers@idele.fr

In beef cattle, animals that grow and reproduce the fastest are desirable to maximize productivity while limiting the environmental footprint. In order to investigate the genetic basis of this phenomenon, genetic parameters were estimated for both adult weight and maturing rate index. Weights from birth to post-weaning and slaughter weights were collected for commercial suckling females from five different breeds: Charolaise (n=27,341), Limousine (n=56,142), Blonde d'Aquitaine (n=21,529), Parthenaise (n=16,275) and Aubrac (n=1,797). Based on these weights, asymptotic adult weight and maturing rate index phenotypes were estimated using Brody equation. The five breeds studied show slightly different earliness growth curves with the Aubrac breed being the most precocious with a Brody coefficient for maturing rate index of 0.0017 (corresponding to almost 56% of adult weight reached at 15 months). The Parthenaise breed was the less precocious, with only 44% of its adult weight reached at the same age (equivalent to 0.0012 for brody's coefficient of maturing rate index). Genetic parameters of these two traits were estimated for the four breeds with enough data using a bivariate animal model. Results were highly similar across breeds, with heritability estimates close to 0.41 for asymptotic adult weight and 0.24 for maturing rate index. The two traits were highly correlated with an average genetic correlation of -0.64 and a phenotypic correlation of -0.67. The coefficients of genetic variance associated to adult weight and maturing rate index had a mean value of 6.2 and 9.1% respectively. In conclusion, this study shows a significant variability in growth precocity between breeds and confirms that animals with a high adult weight have a lower maturing rate index. The studied phenotypes are heritable and show high genetic standard deviations, which enables their possible consideration for genomic selection.

Genetic architecture of the persistency of production, quality, and efficiency traits in laying hensQ. Berger¹, N. Bedere², P. Le-Roy², T. Burlot³, S. Lagarrigue² and T. Zerjal¹¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, 78350, Jouy-en-Josas, France, ²INRAE, Institut Agro, PEGASE, 35590, Saint-Gilles, France, ³NOVOGEN, 5 rue des Compagnons, 22960, Plédran, France; quentin.berger@inrae.fr

The laying hen industry aims to extend the laying production career to 90 weeks or more to increase profitability and promote ethical and environmental benefits. However, this can be challenging due to declining egg production and quality as well as reduced efficiency in aging hens. To investigate persistency in egg production, quality, and feed efficiency, we studied 1,024 purebred hens from the nucleus of Novogen between 70 and 90 wk of age. We recorded daily egg production throughout the period and measured individual feed intake twice a week for three weeks, starting at 70, 80, and 90 wks of age, as well as body weight at the start and at the end of each feed intake recording period. Egg quality was assessed at 70 and 90 wk. Random regressions models were used to study trait variation on a trajectory of time and genotype by time interactions. Among the measured traits, egg weight, feed conversion ratio, weight gain, and Haugh unit showed persistency over the measured period. Daily feed intake, egg mass, residual feed intake, and laying rate decreased over time, while body weight and yolk percentage increased during the late period of production. To assess the viability and ways of selecting for trait persistency (i.e. stability over time), we estimated the genetic variance of the slope and its correlation with the intercept. We found that for laying rate and egg weight, the genetic variance of the slope was negligible, indicating that selection for persistency on these traits requires other means. On the contrary, for other traits such as residual feed intake, there is significant additive genetic variance in the slope. In addition, the genetic correlation between the intercept and the slope was -0.19, meaning that already decreasing residual feed intake level would also reduce the negative slope and help improve persistency. This can be further improved by integrating the slope in the selection criteria. Projects funded by the European Union's Horizon 2020 research and innovation programme under grant agreement N°101000236 and the National research agency under the decision code ANR-20-CE20-0029.

On the potential of improving daily milk yield by extending productive lifespan

A. Bieber, F. Hediger, F. Leiber, C. Pfeifer and M. Walkenhorst

Research Institute of Organic Agriculture, Ackerstrasse 113, 5070 Frick, Switzerland; anna.bieber@fibl.org

Productive lifespan (PL) is a key factor for the sustainability of dairy farming. A long productive lifespan amortizes the rearing costs over a longer period of time and dilutes resource consumption and emissions. In addition, beef and milk production can be combined to a greater extent, which is advantageous in terms of emissions compared to specialized (separate) production of meat and milk. Nevertheless, the productive lifespan of dairy cows has been decreasing across main milk producing countries for many years. We aimed at describing the development of production level, productive lifespan and culling reasons from 1999 to 2019 by analysing herdbook data of 2.60 Mio. cows of the breeds Braunvieh (BV, n= 1.011.192), Swiss Fleckvieh (SF, n= 652.299), Holstein from swissherdbook (HO_SHB, n= 497.467), Holstein from Holstein Switzerland (HO_HOS, n=262.359), Simmental (SI, n=128.920), and Original Braunvieh (OB, n=50.063). We compared the increase in daily lifetime milk yield achievable over an extended PL with the increase in daily lifetime milk yield achieved over time from 1999 to 2019. Average milk yield per day of life continuously increased in all studied breeds, ranging from 7.5±4.1 (SI) to 12.1±5.5 (HO_HOS) kg/d in 2019. Average length of productive lifespan in 2019 ranged from 3.0±2.1 (HO_HOS) to 3.8±2.8 (SF) years. In contrast to international reports it increased (and stabilized) in all studied breeds, apart from OB where it decreased. Culling rates during first and second lactations were high, ranging from 40 (SF) to 51% (HO_SHB). Main culling reasons were fertility, udder health and leg/ claw problems in pronounced dairy breeds, while insufficient milk production was relevant in dual-purpose breeds. The comparison revealed that increase of daily lifetime milk yield during 20 years had the same size as could be achieved through extension of the PL by 1.3 years. Therefore, efforts to increase the number of completed lactations per cow may be expected to pay off with greater dynamics than the combined developments in selection for milk yield, improved feeding and housing over time.

Genetic trends in a selection process using electronic feeders to improve feed efficiency in rabbit

J.P. Sánchez, M. Pascual and M. Piles

IRTA, Animal Breeding and Genetics Program, Torre Marimon, 08140 Caldes de Montbui, Spain; juanpablo.sanchez@irta.es

An improvement of the efficiency in the use of the feed will have positive consequence on both the economic balance of the rabbitries and on their environmental fingerprint. With the aim to generate animal material with enhanced feed efficiency we have conducted a selection experiment for 7 generations -34 batches- to improve feed efficiency in 3 rabbit lines. ADGR, RFI and GRP lines have been selected for growth under feed restriction, individual residual feed intake and cage-average (4 animals) residual feed intake, respectively. In spite of animals in lines ADGR and RFI were raised in groups (6 animals), as we used electronic feeders an individual recording of the feed intake was possible. The studied traits were average daily gain (ADG), average daily feed intake (ADFI) and feed conversion ratio ($FCR=ADFI/ADG$). In the line GRP they were cage-average records ($n=873$) while in RFI ($n=2,482$) and ADGR ($n=2,343$) lines they were individual records. The reported genetic trends are the regression coefficients of the within year-of-birth average predicted breeding values on the year-of-birth. Breeding value predictions were obtained with REML. The estimated genetic trends in RFI and ADGR lines were 0.03 ((g/d)/year) ($P>0.05$) and 1.20((g/d)/year) ($P<0.01$) for ADG; -1.79 ((g/d)/year) ($P<0.01$) and 0.34 ((g/d)/year) ($P<0.05$) for ADFI; and -0.09 ((g/d)/year) ($P<0.01$) and -0.01 (((g/d)/(g/d))/year) ($P<0.05$) for FCR. In the line GRP the genetic trends were 0.04 ((g/d)/year) ($P>0.05$), -1.67 ((g/d)/year) ($P<0.01$) and -0.07 (((g/d)/(g/d))/year) ($P<0.01$), for ADG, ADFI and FCR, respectively. The genetic trends on ADG were never accompanied with environmental trends; however, environmental trends of opposite sign were observed for ADFI and FCR which is an evidence of up-bias in the genetic trends. The environmental trends can be explained by changes over the selection process in the configuration parameters of the electronic feeders. We can conclude that the selection to improve feed efficiency in rabbits raised in collective cages seems to be effective. These trend-based response results are being further validated with experiments using an unselected control population.

Maturity, a heritable trait in French dairy goatM. Arnal^{1,2}, M. Chassier², V. Clément² and I. Palihière¹¹GenPhySE, Université de Toulouse, INRAE, ENVT, 24 chemin de Borderouge, 31320 Castanet Tolosan, France, ²Institut de l'élevage, 24 chemin de Borderouge, 31320 Castanet Tolosan, France; mathieu.arnal@idele.fr

Maturity can be defined as the ratio of first parity milk yield on third parity milk yield and can be, according to the literature, associated with poor longevity. As longevity has been declining for several years in French dairy goats, maturity seems to be interesting to investigate. The objective of this work was to estimate the phenotypic and genetic coefficient of variation of maturity, its heritability, and genetic correlations with milk yield at first, second and third parity in dairy goat, in order to evaluate the feasibility of a future selection on this trait. The data set consisted of 32,807 first parities, 19,215 second parities, 9,386 third parities, and 9,386 maturity phenotypes of Saanen dairy goats. 66,300 animals were in the pedigree. The model developed was a multi-trait model with four traits: maturity, milk yields at first, second and third parities. The heritability of maturity was moderate and equal to 0.12 ± 0.02 , suggesting that this trait could be selected. The genetic correlations with production were equal to 0.30 ± 0.07 , -0.17 ± 0.08 and -0.40 ± 0.07 for first, second and third parities respectively. The genetic correlations of milk yield between parities were close to those estimated in a previous study: 0.87 ± 0.02 between first and second parity, 0.75 ± 0.03 between first and third parity, and 0.95 ± 0.02 for the correlation between second and third parity. These correlations show that the production capacity of the first and third parity is not the same and that there is variability captured by the maturity trait. The phenotypic coefficient of variation was higher for maturity than for milk yield: 0.26 for maturity, 0.19 for the first parity, 0.21 for the second parity and 0.23 for the third parity. The genetic coefficients of variation were close whatever the trait: 0.09 for maturity, 0.11 for first parity, 0.11 for second parity and 0.12 for third parity. The correlation between maturity EBVs and longevity EBVs of AI bucks with at least 15 offspring was equal to 0.4. This correlation makes this trait interesting for use as a predictor of longevity. A future study will implement different predictors of longevity to improve the accuracy of longevity.

Multivariate genome-wide associations for immune traits in two maternal pig linesC. Große-Brinkhaus¹, K. Roth¹, M.J. Pröll-Cornelissen¹, A.K. Appel², H. Henne², K. Schellander¹ and E. Tholen¹¹Institut of Animal Science, University of Bonn, Endericher Allee 15, 53115 Bonn, Germany, ²BHZP GmbH, An der Wassermühle 8, 21368 Dahlenburg-Ellringen, Germany; cgro@itw.uni-bonn.de

The genetic foundation of immune traits, which determines the immune competence of piglets has not been fully uncovered, so far. Because of the well-known high genetic correlations among immune traits, pleiotropic or linked genetic markers can be expected. Usually, GWAS explores phenotypes in a univariate (uv), trait-by-trait manner, whereas multivariate (mv) methods, which should have a higher QTL detection power, have not been commonly used. Here, two uv GWAS methods and four mv GWAS approaches were applied on sets of 22 immune traits for Landrace (LR) and Large White (LW) pig lines. In total 433 (LR: 351, LW: 82) associations were identified with the uv approach implemented in PLINK and a Bayesian linear regression uv approach (BIMBAM) software. The identification of causal relationships among immune traits before performing mv GWAS helps to reduce extensive computation effort impaired by the realization of all possible mv combinations for all available immune phenotypes. Immune trait combinations of interest were created by performing Bayesian network analyses and principal component analyses. Mv GWAS approaches detected 647 associations for different mv immune trait combinations comprising 133 QTL. SNPs for different mv trait combinations (n=66) were observed with more than one mv method. Most of these SNPs are associated with red blood cell-related immune trait combinations. Functional annotation of these QTL revealed 453 immune-relevant protein-coding genes. With uv methods shared markers were not observed between the breeds, whereas mv approaches were able to detect two common SNPs for LR and LW. In conclusion, the mv methodology outperformed compared with uv methods. Our results indicate that one single test is not able to detect all the different types of genetic effects in the most powerful manner and therefore, the methods should be applied complementary. The study was supported by funds from the German Government's Special Purpose Fund held at Landwirtschaftliche Rentenbank (FKZ 28-RZ-3-72.038).

Estimation of heritability for digital dermatitis in Polish Holstein-Friesian cows

M. Graczyk-Bogdanowicz, K. Baczekiewicz and K. Rzewuska

Polish Federation of Cattle Breeders and Dairy Farmers, Centre for Genetics, 79A Dabrowskiego, 60-529 Poznan, Poland; m.graczyk@cgen.pl

Claw disorders are listed as one of the top three reasons for culling in dairy cows. Claw health traits are being included in an increasing number of selection indices to improve genetic resistance to hoof lesions. The high incidence of dermatitis digitalis (DD) has been the main reason for the focus on improving genetic resistance to this disease. The aim of this study was to estimate genetic parameters of DD for the Polish Holstein-Friesian cows. In 2017 a Polish web-based application was launched to record claw health data. Hoof trimmers involved in the 'CGen trimming' project have recorded information on cow health status and hoof disorders during routine farm visits. Identification of lesions was based on 'ICAR Claw Health Atlas'. Data edits and the model were prepared according to the EuroGenomics Golden Standard guidelines for claw health. Data collected by hoof trimmers from 2017 to 2022 were used for this analysis. Data included 166,911 records from 63,131 cows. Multi lactation animal model was used for estimation of genetic parameters. The fixed effects of: age at calving×year, herd-trimming×year, trimmer×year, stage of lactation×year and month of calving×year were included. The variance components were estimated by Bayesian methods with Gibbs sampling, using GIBBS2F90. Results showed that DD was the most frequent hoof disease in Poland, equal to almost 42% of new cases. The estimated heritability of resistance to DD is not high but stays on the typical level for this trait. Heritability for the DD was 4.9, 4.7 and 4.5% for lactations 1, 2, 3+, respectively. The genetic correlation between lactations 1 and 2 was 84%, between 2 and 3+ equal to 80% and the least correlated were lactations 1 and 3+ with 70%. Genetic variation exists which suggests that genetic selection can be performed in this population. Results of this study serve as a basis for routine genetic evaluation for claw health in Polish Holstein-Friesian cows which is currently being developed. Further studies are planned to assess the genetic correlations with other collected lesions and to establish a Polish hoof health index.

Genetic parameters for β -hydroxybutyrate concentration in milk in Spanish dairy cowsI. Cervantes¹, M.A. Pérez-Cabal¹, N. Charfeddine² and J.P. Gutiérrez¹¹Universidad Complutense de Madrid, Dpto. Producción Animal, Facultad de Veterinaria, 28040 Madrid, Spain, ²Spanish Holstein Association, (CONAFE), 28340 Valdemoro, Madrid, Spain; icervantes@vet.ucm.es

Nowadays, breeding for disease resistance is a priority in most breeding programs across species. Subclinical ketosis is diagnosed by an increase of β -hydroxybutyrate (BHBA) concentration in blood, due to a negative energy balance at the early lactation. Spanish Holstein Association (CONAFE) is collecting BHBA concentration in milk since 2013. The objective of this study was to evaluate the genetic component of β -hydroxybutyrate concentration in milk as a proxy for a potential selection criterion against subclinical ketosis. Dataset contained a total of 872,302 records of 317,522 different cows from 5 to 68 days in milk (DIM). The analyses were performed separately for first lactation (L1), second lactation (L2) and third or more lactations (L3+). The BHBA was log transformed. The tested models included DIM (as covariate or as discontinuous variable), year (10 levels), region (8 levels), herd (between 1,886 and 1,740 levels), herd-year (between 7,678 and 6,700 levels), region-year (between 35 and 37 levels), age at first calving in days and parturition number (14 levels) as fixed effects in different combinations. Herd-year and environmental permanent effects were included as random variables besides residual and additive genetic effects. The ASReml v.4.2 and VCE6.0 software were used to estimate genetic parameters. The pedigree contained a total of 665,876 individuals. Model election was based on Akaike Information Criterion (AIC). Best model included age at first calving, DIM (as covariate for L2 and as discontinuous effect for L1 y L3+), region-year and parturition number (L3+) as fixed effects. The heritabilities ranged between 0.044 (0.003) for L1 to 0.027 (0.002 for L3+). The ratio of herd-year was higher than the genetic component, being 0.06 for L1 and 0.05 for the rest of traits. Environmental permanent effect ratio ranged between 0.08 for L2 and 0.03 for L3+. These preliminary results indicated that the genetic component of BHBA concentration is low, but enough to include the Spanish Holstein breeding programs, and a genetic evaluation could be performed in following steps for this trait.

Comparison of self-assessment and objective indicators of attributes driving farms resilienceD. Martin-Collado¹, B. Soriano², J. Lizarralde³, J.M. Mancilla-Leyton⁴, N. Mandaluniz³, P. Gaspar-García⁵, Y. Mena-Guerrero⁴ and A. Prat-Benhamou¹¹AgriFood Research and Technology Centre of Aragon, Av. Montañana, Zaragoza, Spain, ²Polytechnic University of Madrid, Pº de la Senda del Rey, Madrid, Spain, ³Basque Institute for Agricultural Research and Development, Campus Agroalimentario, Arkaute, Spain, ⁴University of Sevilla, Ctra. de Utrera, Sevilla, Spain, ⁵University of Extremadura, Av. de Elvas, Badajoz, Spain; dmartin@cita-aragon.es

Strengthening farming systems' resilience is on the top of the EU and national political agendas. Given the relative novelty of resilience research field, several approaches have been proposed to develop this concept, but there is a lack of methodological consensus to assess resilience at a farm level. Commonly, resilience assessments have been based on objective or subjective measures, assuming that each approach have different strengths and weaknesses. However, very little is known about how subjective self-assessment and objective indicators-based resilience measures compare. Our study aims to fill this research gap in the farming system's field by providing a comparison of both measurement approaches. We understand resilience as result of farm and personal attributes contributing differently to farm robustness, adaptability, and transformability, through the resilience principles set by the Resilience Alliance: system reserves, diversity, tightness of feedbacks, openness, and modularity. Based on this, we identified attributes as specific factors measuring each principle and we did an evaluation of them using self-assessed statement and objective indicators separately. Finally, statistical analyses were based on 149 face-to-face farmer surveys covering four representative small ruminant farming systems in Spain. Results show a moderate correlation between indicators and self-assessed measures, which vary across attributes (-0.27/0.45), suggesting that the two types of measures are not interchangeable. However, in most cases, a positive correlation exists. The clearest alignment between the two measurements is found in attributes of social capital, redundancy, and knowledge networks, while the highest discrepancy is found in farmer life quality. We argue that our results have new highlights for the understanding of farm resilience assessments.

Inventory and analysis of needs towards resilient dairy farming in 15 EU countries*A.M. Menghi and C.S.S. Soffiantini**Centro Ricerche Produzioni Animali (CRPA), Economics, Viale Timavo 43/2, Reggio Emilia, 42122, Italy; a.menghi@crpa.it*

Within the R4D – Resilience for Dairy H2020 UE founded thematic network, an inventory of needs for dairy farmers to be resilient have been created. The inventory is a result of an online questionnaire spread by R4D partners across 15 EU Countries, 535 answers have been collected. In the survey, a list of 43 needs have been selected and proposed to stakeholders, asking them to assign a score from 0 to 5 to each of them according to the potential to improve farm resilience. The key areas explored across the survey were: (1) technical efficiency; (2) environment, animal welfare and society friendly production systems; and (3) economic efficiency and social resilience. Responders have also been asked to add other relevant needs, with an open-ended question. Moreover, information about their background and, when applicable, their farm has been asked. The results have been elaborated according to geographic distribution, sex, age, level of education, profession and dimension of the farm. Regardless regional specificities, it is clear that the improvement of work-life balance and the necessity of a transparent and effective communication with civil society are in the top 10 issues that farmers have to face, to be resilient in the future, just on the same level of other more technical challenges, like animal health/welfare and energy self-sufficiency.

Session 71

Theatre 3

Assessment of solutions for resilient dairy farming in fifteen European countries*A. Kuipers¹, J. Zijlstra¹, R. Loges² and S. Ostergaard³**¹Wageningen University and Research, De Elst 1, 6708 WD, the Netherlands, ²Kiel University, Grass and Forage Science/ Organic Agriculture, Hermann-Rodewald-Strasse 9, D 24118 Kiel, Germany, ³Aarhus University, Department of Animal and Veterinary Sciences, Blichers Alle 20, Dk-8830 Tjele, Denmark; abele.kuipers@wur.nl*

An assessment scheme was developed based on 5-scale questions related to the sub-categories social resilience (less to more); economic resilience, technical efficiency, environment, animal welfare, societal perception items, readiness and acceptability (low to high). This assessment scheme was applied to 185 practices, techniques and tools (named solutions), which were collected in 15 European countries as part of the EU-Resilience for Dairy project. 62 experts from universities and research institutes from 15 EU-countries scored these solutions with in total 3,300 assessments. The same sub-categories, with focus on readiness and acceptability, were also scored by farmers and stakeholder in local workshops in all 15 countries. The scoring took place with in mind farm types or systems where the solution is applicable and attractive. When answering the question about the impact of the solution, the average dairy farm in the region was taken as a reference. Practices and techniques were analysed within the four composed categories: socio-economic, technical, animal welfare and environment, and readiness. It appeared that top ranking solutions by the experts different in several cases from those chosen by the farmers and stakeholders. Moreover, the choice of solutions was locally coloured.

Knowledge needs and solutions related to resilience in the European dairy sectorK. Kuoppala¹, M. Rinne¹, N. Browne² and V. Brocard³¹Natural Resources Institute Finland, Production systems, Tietotie 2, 31600 Jokioinen, Finland, ²Teagasc, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy, Co. Cork P61 P302, Ireland, ³Idele, Dairy Unit, 8 route de Monvoisin, 35650 Le Rheu, France; valerie.brocard@idele.fr

The EU dairy sector is currently facing many challenges, which leads to multiple needs both within the farm gate and across other stakeholders. In the project Resilience for Dairy (R4D, funded by European Commission), the knowledge needs of 15 European countries were derived from an on-line survey and meetings of the National Dairy AKIS (Agricultural Knowledge and Innovation Systems) of the R4D project partners. Several solutions were also identified that could improve the resilience of the dairy sector. The most urgent needs were categorised within: (1) ecological and environmental footprint/mitigation of climate change/inputs efficiency; (2) financial needs; and (3) social issues: building society friendly dairy systems. Solutions were most often sought within: (1) ecological and environmental footprint/mitigation of climate change/inputs efficiency; (2) labour conditions; (3) dairy cattle management; and (4) animal nutrition and grassland management. Category 'Ecological and environmental issues' scored highest in terms of both needs and solutions. The reasons for that are probably two-fold: the pressure from the society, and the dependency of individual farm success on local weather and biotic resources. The second highest topic was related to financial and labour issues, which are the core of running resilient dairy businesses. Practical management issues related to dairy cow care, nutrition and feed production were emphasized as solutions, which is logical as they can be controlled at farm level. There were clear differences in the top scoring areas between regions. Direct comparisons of the needs and solutions across regions is hampered by the non-standardized format, as they were presented as open questions to NDA representatives, but on-line survey was standardized. Although animal welfare scored high in the on-line survey, it was not emphasized in the NDA outputs, which could mean that although an important topic regarding the image of the dairy chain, it is not experienced as a matter limiting the resilience of dairy farms.

Session 71

Theatre 5

Resilience of contribution to food security of specialized Walloon dairy systemsC. Battheu-Noirfalise^{1,2}, E. Froidmont², D. Stilmant² and Y. Beckers¹¹ULiège GxABT, Passage des Déportés 2, 5030 Gembloux, Belgium, ²Walloon Agricultural Research Centre, Rue du Serpent 100, 6800 Libramont, Belgium; c.battheu@cra.wallonie.be

The contribution to food security of dairy systems was mainly addressed through its dimension of food availability, including ('net indicators') or not ('gross indicators') the penalizing use of human-edible feeds. Here, we approach its dimension of stability of supply for both cases. Using accounting data, we calculated the annual gross (GP) and net protein productivity (NP) of 80 dairy farms of the Walloon region (Belgium) over a ten-year interval (2011-2020). We clustered the farms based on nine management parameters using a kmeans algorithm. The difference between the clusters was tested with a mixed model. We calculated the production resilience indicator ($\text{mean}^2/\text{sd}^2$) for each cluster and estimated the significance of their differences with a Monte-Carlo procedure. Last, we calculated those indicators on two periods separated by the end of milk quotas (2015) in order to analyse its impact on GP and NP resilience. Three clusters were identified. The first farm type was intensive and grass-based (IG). It reached a high GP (302 kgCP/ha) and NP (269 kgCP/ha) associated with the highest resilience for both indicators (81 and 53 for GP and NP, respectively). The second type was also intensive but rather maize-based (IM). It used the same amount of concentrates as the first type but with a higher CP-content. This type reached similar GP (302 kgCP/ha) as the first type but its NP (232 kgCP/ha) was lower. Moreover, its resilience was lower for both GP (55) and NP (21). The last type was extensive and grass-based (EG). It used less concentrates than the two previous types with similar CP-content compared to IG. Its GP (185 kgCP/ha) and NP (202 kgCP/ha) as well as its resilience of GP (49) were the lowest. However, it reached a higher resilience in terms of NP (41) than IM but still lower than IG. Between 2011-2015 and 2016-2020, all types showed a decrease in the resilience of NP and GP linked with type-specific management changes. IG showed an increase in milk production and a decrease in concentrate use and CP-content of concentrates. IM showed an increase in milk production and fodder yield. EG showed a decrease in the use of maize silage.

Innovative solutions supporting resilience of dairy farms in Netherlands*P.J. Galama, J. Zijlstra and A. Kuipers**Wageningen University and Research, Wageningen Livestock Research, De Elst 1, 6700 AH, the Netherlands; paul.galama@wur.nl*

Resilience for Dairy (R4D) will tackle urgent sustainability challenges faced by dairy producers by bringing together dairy farmers, farming organisations, advisors, researchers and all relevant actors across 16 member states to close the divide between research and innovation in Europe. R4D is built around the multi-actor approach to implement more intense cooperation between researchers, advisors, farmers and relevant actors to facilitate greater exchange and acceptance of co-created solutions. R4D draws on the EU, national and regional connections of the 17 consortium members to appropriate networks, on the three related key themes of economic and social resilience, technical efficiency and environmental and society friendly production systems. In each of the 16 countries meetings with farmers and stakeholders have been organized to identify needs and solutions to make the dairy sector more resilient. These relate to the farm, the farmer and the dairy chain. The solutions are focusing on the resilience items of robustness, adaptation or transformation. A list of most important shocks and challenges for the dairy sector are made and solutions are selected. The results of the meetings in Netherlands will be shown. Topics are development of new revenue models like credits for CO₂ reduction, CO₂ storage and energy production, or care farming or valorisation of dairy products like A2 milk; increasing soil fertility; grassland management in relation to biodiversity; new housing systems in relation to cow comfort, less emissions and manure quality; personal development in relation to communication with society and cooperation between farmers. It is noticeable that the Dutch farmers and stakeholders present in the meetings had a relatively strong interest in a 'nature kind of approach' to farming. This implies a lot of focus on solutions in the area of quality of soil and crop and grassland farming. There was also quite some interest expressed in socio-economic topics, like communication with society and cooperative forms of manure management along the chain, instead of more detailed techniques and practices at farm level. The group of farmers was forward looking, but deeply concerned about the present discussions and policies in the public domain in the country.

Session 71**Theatre 7****Needs of the dairy sector: a Hungarian overview***L. Czeglédi, B. Béri, I. Komlósi and E. Török**University of Debrecen, Department of Animal Science, 138. Böszörményi Street, 4032, Hungary; czegledi@agr.unideb.hu*

The current distribution of the Hungarian cow population is 60% dairy, 35% beef, and 5% dual-purpose. The Holstein-Friesian is the dominant dairy breed (97%) having an average of 10,804 kg milk production in a 305-day lactation. The Hungarian dairy sector can be characterized as intensive milk production and farms of 440 cows in average. 46% of cows are kept on farms with more than 500 cows and 31% on farms with 300-500 cows. Deep bedding, laying boxes, two or three milking a day, and a high proportion of concentrate in the daily ratio are common in most of the farms. Grazing of dairy cows is not common due to the low yields of pastures. An online survey was conducted where respondents, Hungarian dairy farmers and dairy stakeholders, were asked to select their level of interest in a range of needs within three different fields: technical efficiency; environment, animal welfare, and society friendly production systems; economic efficiency and social resilience. Concerning all areas, the innovative systems (milking strategies; feeding system; analysis for early detection of diseases), the improvement of welfare conditions and the effective communication to the general public of agricultural practices were the main issues identified by the respondents. Innovative devices for measuring grass growth and techniques for grazing management, environmental footprint assessment techniques as well as feed additives to mitigate methane emissions were not identified as crucial needs. In the field of technical efficiency, the main needs were relationship with the application of innovative milking, feeding as well as animal health monitoring systems. The improvement of welfare conditions of calves and cows, and the effective communication to the general public of agricultural practices, and the role of agriculture in society proved to be the main issues within the field of environment, animal welfare, and society friendly production systems. Within the economic efficiency and social resilience field, the main requirements were the using of innovative and reliable information channels as well as the salary.

Eco-efficient low-cost pasture based dairy production on a mixed farm in Northern Germany*R. Loges and F. Taube**Kiel University, Grass and Forage Science/Organic Agriculture, Hermann-Rodewald-Str. 9, 24118 Kiel, Germany; rloges@email.uni-kiel.de*

Recent intensification in European agricultural production is accompanied by serious environmental trade-offs questioning the sustainability of current specialized production systems for both all arable cash crops and animal products. Under the temperate conditions of North-West Europe, ruminant-based integrated crop-livestock systems are considered as a strategy towards ecological intensification. This is the background for the interdisciplinary project: 'Eco-efficient pasture-based milk production' established 2016 at the organic research farm Lindhof in Northern Germany. The project aims at fulfilling relevant ecosystem services linked to dairy systems: high quantity and quality of agricultural commodities; low nutrient surpluses, a low carbon footprint and contributions to agrobiodiversity. Data are presented based on a 98 spring-calving Jerseys/crossbred dairy herd on an organic former arable farm as an alternative to traditional specialized systems. Measurements include: productivity, production costs, nitrate-losses and product-carbon footprint compared to typical regional dairy farms. The results illustrate the capability of a rotational ley grazing system to provide both a high milk performance per ha combined with low environmental footprints and additionally offer significant yield benefits for the arable crops in the crop rotation. Lindhof acts as pilot-farm in the EU-Horizon2020-project R4D – Resilience for Dairy.

Session 71

Theatre 9

Factors contributing to the financial resilience of spring-calving pasture-based dairy farms*G. Ramsbottom¹, B. Horan², K.M. Pierce³, D.P. Berry⁴ and J.R. Roche⁵**¹Teagasc, Animal and Grassland Research and Innovation Programme, Teagasc, Oak Park, Carlow, R93 XE12, Ireland,**²Teagasc, Animal and Grassland Research and Innovation Programme, Teagasc, Moorepark, Co. Cork, P61 C996, Ireland, ³University College Dublin, School of Agriculture and Food Science, Belfield, Dublin 4, D04 R7R0, Ireland,**⁴Teagasc, Animal and Grassland Research and Innovation Programme, Teagasc, Moorepark, Co. Cork, P61 C996, Ireland, ⁵University of Auckland, School of Biological Sciences, Private Bag 92019, Auckland, 1142, New Zealand; george.**ramsbottom@teagasc.ie*

The objective of this study was to identify factors contributing to the financial resilience of spring-calving pasture-based dairy farms when ranked by average operating profitability (i.e. net profit/ha). A dataset of 315 Irish pasture-based dairy farms with complete records for 8 consecutive years was used in this analysis. The farms were characterized by expansion and intensification during the 8-year study period, as evidenced by the annual increase in milk fat and protein yield per cow (+15%; $P < 0.001$); mean annual pasture DM consumed/ha also increased linearly (+19%; $P < 0.05$); production costs increased linearly ($P < 0.01$) while net profit was highly variable between years. The 8-year average net farm profit/ha was €1,611/ha, €1,189/ha, €937/ha and €630/ha for the highest, second highest, second lowest and lowest profit quartiles respectively ($P < 0.001$). The highest profit quartile contained, on average, smaller farms (59 ha) with greater technical efficiency (stocking rate 2.42 LU/ha; 5,511 litres milk/cow; and, 9.9T pasture DM/ha utilized) ($P < 0.001$) than the other profit quartiles. When affected simultaneously by a combination of milk price reduction and adverse weather, they experienced the greatest nominal reduction but highest nadir farm profitability ($P < 0.001$). The highest 8-year average net profit quartile experienced a reduction of €850/ha and nadir profit of €763/ha in the adverse year but profit recovery the following year of €743/ha. The second highest, second lowest and lowest profit quartiles had reductions of €730/ha, €625/ha and €562/ha; nadir profits of €478/ha, €311/ha and €46/ha; and, net profit recoveries the following year of €618/ha, €533/ha and €478/ha respectively.

Planning for resilient dairy farms in the USA*A. De Vries**University of Florida, 2250 Shealy Drive, Gainesville, FL 32608, USA; devries@ufl.edu*

Resilience implies to many dairy farmers in the USA the capacity to withstand unplanned changes to their production environment with as little impact as possible. The production environment may include physical aspects of dairy production, such as weather, crops, animal disease, energy, and labour availability. It can also include prices for milk, feed, and access to buyers and suppliers. In the presentation I will give examples of common practices that are used on dairy farms in the USA. The need for resilient dairy farms and a more resilient dairy sector was highlighted during the COVID pandemic when milk plants were shut down and feed could not be delivered. This led to dumping of milk, unwanted changes in rations, and forced reductions in herd sizes. An example of resilience related to changing weather is the increase in the number of barns equipped with heat abatement and raising dairy heifers indoors year-round. Dairy farmers also maintain their own power generators in case the power goes off due to storms. Related to cropping, dairy farmers may grow different varieties of corn, the main forage source, depending on maturity, yield, and disease resistance. Many farmers also maintain a one-year supply of corn silage, so that disappointing crop yields do not lead to the need to purchase forages. Forward contracting of feed stuffs is also common, as is hedging of milk, such that future prices are known and variation in prices is reduced. Dairy farmers may also maintain several suppliers of the same goods to not become reliable on a single supplier. Most dairy farmers keep ownership of their own heifers, even when they may be raised by a heifer grower in another state. This practice reduces their risk to high heifer purchase prices and biosecurity. To account for unplanned culling, dairy farmers often raise a buffer of 5 to 10% more heifers than they need. On average, this practice reduces cow longevity. Cross training of farm labour is common so that different people can do the same jobs. Some dairy farmers even pay potential workers to be on stand-by in case their help is needed. In summary, resilience is on the mind of many US dairy farmers, and they use a large variety of practices to keep a resilient dairy farm.

Session 71

Theatre 11

Towards a socially sustainable dairy sector with cow-calf contact systems*H.W. Neave, M. Bertelsen, E.H. Jensen and M.B. Jensen**Aarhus University, Department of Animal and Veterinary Science, Blichers Alle 20, 8830 Tjele, Denmark; heather.neave@anivet.au.dk*

The intensification of the dairy sector has led to social sustainability challenges. To address concerns around animal welfare and societal values, alternative systems that provide cow-calf contact have been proposed. Such systems have been shown to increase work satisfaction for farmers, which also relates to social sustainability. However, cow-calf contact systems also present challenges with reduced saleable milk and high animal stress during later separation. Some proposed solutions include reducing daily contact duration and novel weaning methods. We conducted two studies (48 and 56 cow-calf pairs each) providing either full-time (23 h/d) or part-time (10 h/d during daytime) cow-calf contact for 8 wk. We used three methods to wean off milk and separate calves from their dams (using a fence-line): two-step (milk and dam removal separated by a week) or gradual (time with the dam reduced to 50% then 25%, over 2 wk), compared to simultaneous (milk and dam removal occurred together). Our findings suggest that cow and calf behaviour in part-time contact systems also foster strong bonds between cows and calves. However, calves become hungry during daily separation periods, and the vocal response to separation is not reduced, compared to full-time contact systems. A two-step (vs simultaneous) weaning process reduced behavioural and vocal responses of calves to separation, but both cows and calves were similarly vocal during gradual weaning (vs simultaneous). Thus, dividing the weaning and separation process into two steps may be one strategy to reduce the negative behavioural responses of calves at weaning. Further scientific exploration is needed to address welfare, economic and staff labour concerns regarding cow-calf contact systems. In doing so, there can be transformative, proactive development of alternative management systems that support social sustainability and thereby a more resilient dairy sector.

Resilient, healthy or efficient? The ideal animal according to breeders of small ruminants in Europe*E. Janodet and M. Sautier**INRAE, GenPhySE, Chemin de Borderouge, 31320, France; estelle.janodet@inrae.fr*

Health, resilience and efficiency of herds is a major issue for the sustainability and profitability of farms. Genetic selection is one of the means for increasing the performance of animals for those three traits. Our study aimed at better understanding the diversity of breeders' preferences with respect to the relative importance of traits related to animal resilience, health, and efficiency (SMARTER H2020 project). Data were obtained through preference surveys based on choice experiment that were administered to small ruminants breeders in 5 countries and for 14 breeds ($n > 600$) with the decision-making software 1000minds. Results highlight differences in preferences between the proposed traits with a lower degree of importance for feed efficiency ($P < 0.05$) and prolificity ($P < 0.05$) compared to the other 6 traits (dairy production, dry matter in milk, mastitis resistance, parasitism resistance, mortality at weaning, functional longevity). We present divergent preference profiles identified through cluster analysis and characterize them. We investigate the correlations between preferences profiles and: (1) livestock systems; and (2) breeder's profile. Our results may contribute to inform small ruminants industries' experts, especially on the revision of breeding objectives for more resilient and efficient animals.

Session 71

Poster 13

Strategies and cases of resilience from dairy farming community in Slovenia*M. Klopčič**University of Ljubljana, Biotechnical Faculty, Dept. of Animal Science, Groblje 3, 1230 Domžale, Slovenia; marija.klopccic@bf.uni-lj.si*

Milk production is the most important production sector of Slovenian agriculture. Dairy cattle farming has been concentrated and specialized since the mid-1990s, which is reflected in the reduction of the number of dairy farmers, the increase in the average size of the herd per farm, the increase in the milk yield of cows and the higher quality of milk. The milk production sector in Slovenia is characterized by family farms with an average of 19 dairy cows per herd, with a large proportion of tied-in housing systems (70%) and with a very unfavourable land structure (a large number of small plots (35), which complicates the development and efficiency of Slovenian dairy farms. Within the R4D – Resilience for Dairy H2020 EU founded thematic network, Slovenian dairy farmers together with researchers, advisers and stakeholders (NDA) discussed about future challenges and solutions for dairy sector in Slovenia. Given that Slovenia is dominated by permanent grassland, they think that 'Increase grazing vs indoor feeding to meet customer desires and added milk value' can be one of the most suitable solutions. In order to improve the well-being of the animals and to make their work easier, there is a distinct desire for freewalk housing system to improve animal welfare and animal health. They also think that personal development on a wide spectrum of topics to increase resilience skills of dairy farmers is very important in this uncertain time. Given that the ownership structure of agricultural land is very unfavourable, there is a clear need for land consolidation to be more efficient. In Slovenia, diversification and the search for additional sources of income through added value are very important, because we have many hilly and mountain dairy farms with small herds (e.g. PDO/PGI/AOP, organic, hay milk/meat, A2A2 milk, agro-tourism, forestry, etc.) to increase income for farmers. Also the topic about reducing emissions of ammonia and GHG is fully in discussion.

How farm management influences the longevity of dairy cows: a comparative study of Swiss dairy farms

R.C. Eppenstein, A. Bieber, M. Lozano-Jaramillo and M. Walkenhorst

Research Institute of Organic Agriculture FiBL, Animal Science, Ackerstrasse 113, 5070, Switzerland; rennie.eppenstein@fibl.org

Increasing the productive lifespan of dairy cows is an important means to lowering the environmental impact of dairy production. Farm characteristics, such as location, production type and breed are fix characteristics for most farms. However, farm management strategies can influence the longevity of their dairy herds in the medium- and short-term. Within the framework of the research project 'Longevity of Swiss Dairy Cows' (Nutzungsdauer Schweizer Milchkühe), we aimed at identifying management choices that affect the productive lifespan of dairy cows. Based on data from the Swiss census and the major breeding organizations, we built a database of 142 farms. We defined 15 farm types that best represent the diversity of Swiss dairy production with regard to geographic regions, production zone, breed and production type (organic vs conventional). We allocated 10 dairy farms per farm type. Five of the 10 farms were chosen for having a low average productive lifespan (APL) of their dairy herd. The other five farms were chosen for having a high APL. APL was defined as the average lactation number of all cows culled 5 years in retrospective. From the initial 142 farms, 68 farms participated in a survey to assess the differences in management practices. From these participating farms, 30 were further clustered into matched pairs and were visited on-farm. Farms with low APL did not differ from those with high APL regarding their milk production and average dairy herd size. However, they significantly differed with regard to their APL, thus confirming a successful selection strategy of matched pairs. On average, dairy cows from farms with low APL were culled 2 lactations earlier than cows from farms with comparable characteristics, but with a high APL. Compared to farms with low APL, farms with high APL were characterized by a higher percentage of loose housing systems, a higher percentage of energy rich feed rations, better fertility and more animals being inseminated with meat breeds. No statistical differences were found in relation to antibiotic treatment incidences and other health parameters.

Session 71

Poster 15

High herd exit rates existence of small herds: a case study from North West Province, South AfricaM.D. Motiang¹ and E.C. Webb²*¹Agricultural Research Council, Animal Production, Old Olifantsfontein Road, Irene, 0062, South Africa, ²University of Pretoria, Department of Animal and Wildlife Sciences, University of Pretoria, Pretoria, 0002, South Africa; dan@arc.agric.za*

The aim of this paper was to compare herd balance between different herd sizes. Data were collected from 308 randomly selected cattle farmers from RSM District North West Province in 2012. Data were divided into four herd size categories of 1-10, 11-30, 30-70 and >70. Data were analysed using IBM SPSS statistics 22 (2013). The GLM multivariate analysis was performed to test effect of herd size category on calving, herd mortality and off-take rates. Means were separated using least significant differences (LSD) tests. Results show that the average calving rate of 55% and cumulative exit of 27.3% resulting from 10% mortality, 15% offtake and 2.3% slaughter rates. Although calving rates did not differ significantly across herd size categories, small herds of 1-10 had significantly higher values for herd exit rates than larger ones. Herd mortality rates ranged from 6% in large herds of >70 to 18% in small herds of 1-10 while offtake rates were 16 and 23%, respectively. Small herds also herd significantly ($P < 0.05$) higher slaughter rates (3%) than large herds (1%). Overall herd exit for small herds was 43% compared to 20-21% for other herd categories. On average small herds of 1-10 had 5.9 head of cattle consisting of 3.84 cows that produce 2.06 calves but lose 2.57 head of cattle through sale, slaughter and mortality, which results in a negative herd balance of -0.5 as compared to the average of 0.85 for all herds. This negative herd balance implies that small herds will shrink and ultimately disappear in 12 years if the status quo continues. Herd size categories of 11-30, 30-70- and >70 recorded herd balance of 1.08, 0.95 and 12.02, respectively. Although small herds recorded the highest herd exit values, their average offtake rate of 23% was within the national average of between 25 and 30%. However, 18% mortality rate for these herds was higher than previously reported of approximately 10%. It is recommended that farmer development programmes focus on herd mortality in order to stimulate growth of small herds in the study area.

Building on a resilient dairy sector- highlights and discussion

A. Kuipers¹, V. Brocard² and M. Klopčič³

¹Wageningen University & Research, De Elst 1, 6708 WD Wageningen, the Netherlands, ²Institut de l'Elevage, 8 route de Monvoisin, 35650 Le Rheu, France, ³University of Ljubljana, Biotechnical Faculty, Dept. of Animal Science, Groblje 3, 1230 Domžale, Slovenia; abele.kuipers@wur.nl

This seminar intends to contribute to sharing insights on how best to support dairy farmers in coping with change to achieve a more resilient operation and peace of mind. The concept of resilience and indicators from a technical, environmental and socio-economic perspective, and analysis of needs and solutions, gathered in 15 EU countries in the context of resilience, will be presented, as well as interesting cases of resilience in the field. The focus will be on herd, farm management and communication with society, with aim to answer two key questions: How does the dairy farmer/farm family cope with shocks, barriers and uncertainty in market and environmental policies in the management of the farm? This time slot will be utilized to summarize the findings and farm cases, and discuss the various presentations of this seminar.

Session 71

Economic and environmental impacts of cattle longevity extension by altered reproductive management

R. Han, A. Kok, M. Mourits and H. Hogeveen

Wageningen University and Research, Wageningen, 6706 KN, the Netherlands; ruozhu.han@wur.nl

Introduction: Prolonging dairy cattle longevity is regarded as one of the options to contribute to a more sustainable milk production. Since reproduction failure is the primary reason of culling, this study investigates the effect of extending cattle longevity on farm's gross margin and greenhouse gas emissions (GHG) by altered reproductive management. **Materials and Methods:** An adapted model of Kok *et al.* is used to stochastically simulate the dynamics of a Dutch dairy herd of 100 cows, by modelling individual cow lactations and calving intervals, while accounting for culling for fertility reasons, mastitis, lameness and other reasons (i.e. general culling). Moreover, the model computes the GHG emissions using a life cycle approach. To extend cattle longevity, two altered strategies for reproduction management were evaluated: (1) the insemination extension strategy, in which the maximum number of inseminations (AI) per cow before she is culled for infertility was raised from 4, to 5 or 6 times; and (2) the reduction in subfertility culling standard strategy, in which the milk production threshold for culling non-pregnant cows was reduced from 20 kg to 15 or 10 kg/day. The model was run for 500 herds of 100 cow places for each reproductive management strategy alternative. **Results and Discussion:** Age of culled cows increased with the increased maximum number of AI from 2,040 to 2,195 days. The change was larger from 4 to 5 times AI (108 days) than from 5 to 6 times AI (47 days). Annual gross margin increased from €165,847 to €167,570, while GHG decreased from 0.926 to 0.915 CO₂-equivalents per kg FPCM. With the decrease in the subfertility culling standard from 20 to 10 kg/day, the age of culled cows increased from 1,968 to 2,132 days. Annual gross margin decreased with € 168,188 to minimal €161,210, while GHG increased with 0.002 CO₂-equivalents per kg FPCM. **Implications:** The increased maximum number of AI and subfertility culling standard can benefit a dairy farm economic and environmental sustainable development.

Economic sustainability of different levels of extensiveness in fattening pig farms*P. Ferrari, C. Montanari and L. Giglio**CRPA Research Centre for Animal Production, Economics and Agriculture Engineering, Viale Timavo 43/2, 42021, Italy; p.ferrari@crpa.it*

Consumers generally believe that extensive livestock farming systems is synonymous to better meat products quality. This holds particularly for livestock species such as pigs that are kept at relatively high stocking density. The mEATquality project aims to develop novel solutions that address societal demands, environmental concerns and economic needs on farm and in the chain. The ‘extensiveness’ of production is the key issue, and will be developed in a stepwise approach during the project. The first step surveys extensive husbandry factors in relation to intrinsic meat quality, through data collection on conventional, free-range and organic farms. Standardized sustainability assessment protocols are developed for on-farm data collection across 80 pig farms in Denmark, Italy, Poland and Spain. The protocols include: (1) general farm description; (2) environmental issues; (3) animal welfare assessment; and (4) farms productivity and economics information that will be collected. The starting point for each section was the protocol developed and used by the ERA-net SusAn project ‘SusPigSys’ (<https://suspigsys.fli.de/en/home/>) which assessed the sustainability of pig farms in 8 EU Member States. Each protocol was adapted to focus on the extensiveness of production. Farm’s economic resilience will be estimated through indicators related to profitability, labour productivity, animal performance, entrepreneurship, risk management and resilience of resources. Economic pig farm protocol includes information about volumes of inputs and outputs both at pig barn level and at crop level used for own produced pig. The focus will be on the degree of ‘extensiveness’ of the farms surveyed, in particular in relation to their economic results. Data collected will be used to gain insight in the economic performance and its variability according the different degree of pig farms extensiveness. To this end, economic indicators will be calculated such as revenues minus feed costs per animal place, production costs, profit/loss accounts, farm income per labour unit and returns to capital. In addition, technical efficiency of the production process is of great importance and will be included.

Session 72

Theatre 2

How to characterise the European livestock production systems?*E. Bailly-Caumette¹, S. Moakes², C. Pfeifer³ and D.R. Yáñez-Ruiz⁴**¹ENS Lyon, Biology, Lyon, 69342, France, ²Aberystwyth University, Aberystwyth, SY23 3FL, United Kingdom, ³FiBL, Frick, 5070, Switzerland, ⁴CSIC, Granada, 18008, Spain; elea.bailly@ens-lyon.fr*

In the context of the European Green Deal, the EU PATHWAYS project aims to identify practices and innovations that will ensure a sustainable evolution of European livestock systems, that also address societal expectations. This process requires a characterisation and assessment of existing livestock systems to support development of improved ones. Whilst describing a livestock system is straightforward, difficulties lie in differentiating between livestock systems within the high diversity within Europe, and a single framework or database describing livestock systems in Europe does not exist. We have therefore developed a methodology to utilise and blend data from different existing sources, including Eurostat and FADN databases at NUTS2 level, combined with an expert survey conducted through a questionnaire. Variables linked to farm practices and economy were identified from the databases and analysed through hierarchical clustering to cluster NUTS2 regions with similar livestock system attributes. In parallel, a survey of experts and stakeholders was conducted to gain quantitative (e.g. feed, pasture) and qualitative data (e.g. importance of system, location), resulting in 171 described systems from 12 countries. The combination of these data sources identified specific systems for 8 livestock categories: dairy cows, suckler cows, finishing beef, meat and dairy sheep, goats, breeding and finishing pigs, laying hens and broilers. Maps and a dataset were generated to highlight the systems’ attributes and distribution at NUTS2 level, which were further discussed with experts and stakeholders to refine and validate the outcomes. This holistic approach moves beyond existing databases and explores context specific husbandry practices, livestock management and economic performance, highlighting regional tendencies at European level. Although limitations remain, this could serve as an improved knowledge base for livestock’s role and impacts, highlighting diversity and complexity of livestock systems and allowing more nuanced sustainability assessments that can inform current political decisions and debates regarding livestock production.

The IntaQt project's stakeholders' involvement: impact on the research work?F. Bedoin¹, C. Couzy¹, C. Laithier¹, C. Berri² and B. Martin³*¹Institut de l'Élevage – French Livestock Institute, 149, rue de Bercy, 75012 Paris, France, ²INRAE, Université de Tours, BOA, Nouzilly, France, ³INRAE, Université Clermont Auvergne, VetAgro Sup, UMR Herbivores, Saint-Genès-Champagnelle, France; florence.bedoin@idele.fr*

Multi-actor research projects are still a recent trend, putting at work together researchers with non-academic partners, like representatives of food chain actors. The INTAQT project (INnovative Tools for Assessment and Authentication of chicken meat, beef and dairy products' QualiTies) has chosen to play the game fully: the project was set up with stakeholders' consultations at the heart of the project and with their recommendations implemented in the research. Stakeholders from the beef, dairy or poultry sectors in seven European countries are involved from producers to retailers, including processors and other relevant actors in each context. They were consulted at three levels: first through individual qualitative interviews then invited to national group discussions and some of them to European group meetings. Their role was to give their opinions and suggestions for the choice of farming systems to be studied in the project and on the choice of quality criteria to take into account and on analysis to be conducted. They will be involved all along the project life with their contribution next year to the co-construction of the multi-criteria scoring tool. This presentation is based on analysis of interviews with the project's Work Package leaders and Task Leaders in order to confirm or refute the following hypotheses: (1) there was an a priori reticence of some of the researchers about the importance and relevance of including stakeholders' voices in a research project; (2) after almost of 2 years in the process, there is an interest in the world of research, but also difficulties in effectively integrating positions that are difficult to reconcile (temporality, decision-making methods, governance, etc.). Globally we reflect on how multi-actor approach like the one in INTAQT questions a research project.

Session 72

Theatre 4

EU policy impacts on the sustainability of the livestock sector, insights from the PATHWAYS projectN. Roehrig¹, A. Sans², K.-E. Trier-Kreutzfeldt³, M.A. Arias Escobar³, F.W. Oudshoorn³, N. Bolduc², E. Regnier², P.-M. Aubert² and L.G. Smith^{1,4}*¹University of Reading, School of Agriculture, Policy and Development, Earley, Reading RG6 6BZ, United Kingdom, ²Institut du Développement Durable et des Relations Internationales, 41 Rue du Four, 75006 Paris, France, ³Innovationscenter for Økologisk Landbrug, Agro Food Park 26, 8200 Aarhus, Denmark, ⁴Swedish University of Agricultural Sciences, Department of Biosystems and Technology, Box 190, 234 22 Lomma, Sweden; n.roehrig@reading.ac.uk*

How can EU policies be modified to enhance the sustainability of livestock production systems? To find answers to this question, which is central to achieving environmental goals while maintaining adequate production levels, the PATHWAYS project is working towards formulating policy trajectories for sustainable livestock production in Europe by 2050. As part of this work, we have conducted a review of the scientific evidence on the impacts that EU policy has had on the sustainability of livestock systems and identified reasons why they were not successful in promoting sustainability in various areas. This is combined with an analysis of the current and prospective policy framework to determine what already has been done and how EU policies can be expected to shape the sustainability of livestock systems in the future.

Stakeholders' perception of pig and chicken local breeds – a broad survey by the GERO NIMO project

M.J. Mercat¹, A.J. Amaral², R. Bozzi³, M. Čandek-Potokar⁴, P. Fernandes⁵, J. Gutierrez Vallejos¹, D. Karolyi⁶, D. Laloč⁷, Z. Luković⁶, H. Lenoir¹, G. Restoux⁷, A. Vicente², V. Ribeiro⁸, T. Rodríguez Silva⁹, R. Rouger¹⁰, D. Škorput⁶ and M. Škrlep⁴

¹Ifip-Institut du Porc, BP35104, Le Rheu, France, ²Univ. of Évora, Largo dos Colegiais 2, Évora, Portugal, ³DAGRI-UNIFI, Via delle Cascine, Firenze, Italy, ⁴KIS, Hacquetova 17, Ljubljana, Slovenia, ⁵ANCSUB, Largo do Toural, Vinhais, Portugal, ⁶UniZG, Fac. of Agriculture, Svetosimunska 25, Zagreb, Croatia, ⁷INRAE, GABI, Jouy-en-Josas, France, ⁸AMIBA, Rua Domingos Marques, Vila Verde, Portugal, ⁹FEUGA, Santiago de Compostela, A Coruña, Spain, ¹⁰SYSAAF, INRAE Val-de-Loire, Nouzilly, France; marie-jose.mercat@ifip.asso.fr

As part of the European Union project GERO NIMO, a broad survey with actors (breeders, managers and processors) involved in the preservation of chicken and pig local breeds (LB) was conducted. The aim was to characterize the LB conservation or breeding programmes and to collect the stakeholders' views. The survey was designed in seven languages including English and conducted mostly online. More than 550 stakeholders from 12 countries, representing 31 pig and 94 chicken LB participated in the survey, with unbalanced representation of breeds and countries. The responses collected showed similarities between species such as free-range and pure-bred breeding on small farms. Although breeding animals are selected mainly on external phenotypes like the breeds' standard, participants showed interest in selection, especially for productive or reproductive traits. However, many barriers to the implementation of breeding programmes exist in both species. Moreover, preserving genetic diversity is the main motivation of the surveyed actors. Leisure activity is the second most important motive for the chicken breeders who have marginal economic activities related to LB. In contrast, with a median income percentage of 42% linked to LB, economic activities constitute the second most important motive of the pig LB actors. Finally, participants expressed concern about the sustainability of LB, especially for economic reasons, and expect more support from public authorities. The project is funded by the European Union's Horizon 2020 research and innovation programme under grant agreement N°101000236.

Session 72

Responding to stakeholder needs and consumer-driven demands in the dairy goat and poultry sectors

C. Bonardi and M. Gerevini

Tecnoalimenti S.C.p.A., Research, Via Gustavo Fara 39, 20124 Milan, Italy; c.bonardi@tecnoalimenti.com

Code: Re-farm project aims to understand the relationship between intrinsic product quality and husbandry systems in goat and poultry production systems, through consumer driven demands. As a first step, stakeholders' future changes and challenges were identified together with consumer demand drivers. The industries expect tougher regulations on animal welfare and health, supply chain transparency, and food safety along with challenges related to environmental issues and innovation in emissions reduction, feed footprint, and genetics. Local production and animal welfare standards currently affect consumers' behaviours, with a strong impact on alternative product pricing. There are growing concerns about the impact of food products on the environment. Locally made products, high product quality and food chain traceability, are some of the current drivers of the consumer-demands, expected to intensify and reshape the ways consumers choose products. Based on the stakeholders' and consumer inputs, Code: Re-farm tests several novel tools for product quality monitoring methodologies, specialized instrumentation and benchmarking tools capable of reliably indicating differences between intensive and extensive farming systems without bias. As part of the project's visualised data and responding to the consumers' requests for better transparency in the dairy milk and poultry value chains, a new App is developed that will enable product quality monitoring and producer data, animal welfare and health conditions. This work was funded by EU (HORIZON H2020) under the 'Code Re-farm: Consumer-driven demands to reframe farming systems' (Grant No: 101000216).

The INTAQT project: stakeholders' opinions on future multicriteria scoring tools for animal products

Agri-food chain actors (AFAs) lack reliable information to meet consumer expectations in relation to multiple facets of intrinsic quality of chicken meat, beef, and dairy products from the various European livestock systems. One of the challenges of the INTAQT project is to build, with AFAs, multi-criteria scoring tools related to products global quality. This tool should combine safety, sensory, and nutritional results obtained during the project-based on collection of poultry/beef/dairy samples and possibly other quality criteria. Multi-actor participatory approach was applied to present and discuss the concept of a multicriteria scoring tool, collecting opinions, fears, and expectations on this tool. On a consumer side, it was felt that such a multi-criteria score placed on products could be a clear and simple representation of a complex reality. However, some disadvantages were expressed about its reliability or implementation. For their part, AFAs had varying opinions on the tool's target, mainly about its possible use as an internal tool or for consumer information, with different pros and cons expressed on both aims. Fears dealt with the building of the tool, and its relevance, representativeness, practical use, and the potential dangers, especially if safety aspects were included. However, both consumers and AFAs agree on the need to include in this tool extrinsic criteria such as farming system sustainability and animal welfare.

Co-designing Agroecology farming concepts to increase food sovereignty in the Global South

M. Simataa, R. Valkenburg and H. Romijn

Eindhoven University of Technology, Den Dolech 1, 5612 AE Eindhoven, the Netherlands; m.simataa@tue.nl

Food sovereignty encompasses a community's right to produce, access, and control food. It faces severe challenges in the Global South. Even though intensified peri-urban farming improves food system resilience, poverty reduction, and nutrition security in low- and middle-income countries, concerns rise about the potential adverse effects on health and the environment. A crucial question arises: 'is there a future for small-holder farmers in the Global South?' Applying the principles of *Agroecology* through a *One Health* approach can help address these challenges. *Agroecology* mimics natural systems, reduces reliance on external inputs and promotes local resilience and food sovereignty. The unique historical, social, and economic circumstances and the limitations of traditional development models should be recognized, and an inclusive approach that considers the agency and perspectives of local actors should be applied to address agroecology transition in Africa. Stakeholder engagement and co-creation are critical to designing and implement sustainable business models. This study aims to understand the current state of the African agro-food sector by starting from the needs, priorities, and challenges of all different stakeholders and recognizing the everyday struggles of African food sovereignty. We will conduct case studies in six countries: Morocco, Senegal, Nigeria, Burkina-Faso, Benin, and Ghana. Data will be gathered through interviews with agro-food actors in these countries and relevant reports and articles. The study has two objectives: (1) to identify stakeholders and their roles; and (2) to diagnose opportunities for value creation towards sustainable transition. Using the value framework Den Ouden developed, we will assess the potential for sustainable business models in agroecological farming. We will showcase our perspective on possible solutions to make agriculture more sustainable in Africa. The European Union's Horizon 2020 program supports the research under grant agreement No. 101059232 – Project Urbane.

Mapping of value chains in the Italian bovine sector

M. Finocchi, M. Moretti, A. Mantino, A. Ripamonti, G. Conte and M. Mele

University of Pisa, Dipartimento di Scienze Agrarie, Alimentari e Agro-ambientali, Via del Borghetto, 80, 56124 Pisa, Italy; matteo.finocchi@phd.unipi.it

The transformation of Europe into a zero-pollution economy by 2050 can be achieved through innovation in agro-industrial systems. Globally, animals provide more than 30% of the protein and substantial employment of rural populations. Livestock farming is the most important agri-food sector for greenhouse gases emissions, accounting for 60-70% of emissions, generated mainly by enteric fermentation, deposition of manure on pasture and its storage. In this scenario, the whole European livestock sector is challenged by the need to continue to produce while limiting environmental impacts and respecting the environment and animal welfare. The mapping of value chains in the dairy and beef cattle sector is fundamental to understand the general picture of national production, from farm to processing industry, distribution, and final consumption. The main aim of the present work is the identification of leverage points along the value chain to foster sustainable transformation in the Italian dairy and beef cattle sector. The analysis of the governance structure of dairy and beef cattle value chains in Italy was investigated through surveys and semi-structured interview with various actors of the chains aimed at describing the power dynamics, the transmission of prices between the different nodes and the policies of both sectors. The main results revealed different physical-economic aspects of the value chain and can be summarized in: (1) main characteristics of the production structure; (2) national and international trade relationship; (3) main actors and governance structure of the value chains. The analysis of the production structure included the volume of production and the localization of the farms, as well as the historical trend in the Italian territory and the regional differences with GPS representations. Results allowed to investigate different scenarios for the ecological transition of the Italian dairy and beef cattle sectors. For example, it provides the info needed to estimate the emissions of both sector through the adoption of predictive models to each single part of the whole value chain since the beginning of the last decade.

Session 72

Theatre 10

The INTAQT project: stakeholders' expectations on husbandry systems and innovative practicesR.C. Eppenstein¹, V. Bühl¹, I. Legrand², A. Nicolazo De Barmon², B. Martin³, F. Albert², M. Berton⁴, M. Bourin⁵, A. Cartoni Mancinelli⁶, D.A. Kenny⁷, E. Kowalski⁸, S. McLaughlin⁹, G. Plesch¹, F. Bedoin², C. Couzy², C. Berri¹⁰ and C. Laithier²

The INTAQT project aims to establish the relationship between intrinsic and extrinsic quality criteria of animal products and European husbandry systems. Another aim is to evaluate the impact of innovative husbandry practices on the quality of the products. In order to determine, which husbandry systems and practices the project should study, a European-wide stakeholder consultation of the chicken, beef and dairy value chains was conducted. Stakeholders were presented with a preselection of husbandry systems and were requested to modify or add systems according to their interest, and to name innovative practices to be tested. In total, 161 face-to-face interviews took place between October 2021 and March 2022, followed by 12 national and 3 European group meetings. Overall, stakeholders of all value chains were satisfied with the initially selected systems. Suggestions covered both mainstream systems as well as new, innovative ones, which are emerging due to the growing societal rejection of intensive farming practices. These included systems that improve the farms' self-autonomy, use local resources or a circular economy, or improve animal welfare and environmental impact. Similarly, actors in all three value chains suggested innovative practices that centre on increased animal welfare and environmental sustainability, thus reflecting a willingness to respond to societal demands.

The INTAQT project: stakeholders' perceptions and points of view on products quality

C. Laithier¹, F. Bédoin¹, F. Albert¹, I. Legrand¹, A. Nicolazo De Barmon¹, M. Bourin², M. Berton³, V. Bühl⁴, R. Eppenstein⁴, A. Cartoni Mancinelli⁵, D.A. Kenny⁶, E. Kowalski⁷, S. McLaughlin⁸, G. Plesch⁴, C. Couzy¹, C. Berri⁹ and B. Martin⁹

¹Institut de l'Elevage, 149, rue de Bercy, 75595 Paris cedex 12, France, ²ITAVI, L'Orfrasière, 37380 Nouzilly, France, ³University of Padova, DAFNAE, Viale dell'Università 16, 35020 Legnaro, Italy, ⁴FIBL, Ackerstrasse 113, 5070 Frick, Switzerland, ⁵University of Perugia, Borgo XX Giugno, 7406121 Perugia, Italy, ⁶Teagasc, Oak Park Rd, Pollerton Little, Carlow, R93 XE12, Ireland, ⁷Ghent University, Coupure Links 653, 9000 Gent, Belgium, ⁸The Queen's University of Belfast, 19 Chlorine Gardens, Stranmillis, United Kingdom, ⁹INRAE, 147, rue de l'Université, 75338 Paris, France; cecile.laithier@idele.fr

The INTAQT project aims to characterize the links between husbandry systems and the quality of poultry meat, beef and dairy products after consulting at national and European levels the actors of each sector on their expectations. The first step was to identify their perceptions and points of view in terms of product quality and this communication focuses on results obtained with producers, processors, retailers and some representatives of citizens' associations. In addition to the intrinsic quality criteria already foreseen in the project (health, nutrition, organoleptic), stakeholders spontaneously expressed the importance of considering extrinsic criteria related to sustainability (animal welfare, environment, socio-economic aspects) as well as technological quality. The other criteria were mentioned in a variable way depending on the type of stakeholder, the country and the sector concerned. These results are consistent with consumers' views and they have been taken into account to include other quality criteria in the project.

Life cycle assessment of different pig production systems around Europe: mEATquality project

C. Reyes-Palomo¹, A. Pignagnoli², S. Sanz-Fernández¹, P. Meatquality Consortium³ and V. Rodríguez-Estévez¹

¹Universidad de Córdoba, Ctra. Madrid-Cádiz km 396, 14071, Spain, ²Centro Ricerche Produzioni Animali, V.le Timavo, 43/2, 42121, Reggio Emilia, Italy, ³Project mEATquality, Consortium, <https://meatquality.eu/>, Denmark; v22repac@uco.es

One of the main objectives of the H2020 mEATquality project is to generate information about producing more sustainably through extensive husbandry practices, meeting animal welfare and environmental concerns. The life cycle assessment (LCA) will be the main tool used for the environmental sustainability of the farms evaluated. This LCA study will collect data from 80 fattening pig farms from 4 countries (Denmark, Italy, Poland, Spain) and covering a wide range of models and husbandry practices, ranging from large intensive farms to small, organic, and extensive ones. The enteric fermentation and manure handling emissions will be calculated using Tier 2 equations on IPPC guidelines. The not differentiable emissions such as C sequestration in pasture-based systems will be assessed by economic approach, and environmental impacts will be calculated with Agribalyse database. The limit of the system will be 'cradle to gate'. It is expected that the presence of different pig breeds, with different productive ranges, diverse farming systems and level of extensification will lead to differentiate the environmental impact of the systems and link it to the extensiveness practices. This work will cover a large representation of the different pig husbandry systems around Europe. It is supposed that the inclusion of C sequestration makes the difference in the extensive farms, even though the intensive systems have better performances. This project has received funding from the European Union's Horizon 2020 research and innovation program under Grant Agreement No 101000344.

Consumer expectations for beef in the French region Auvergne-Rhône-AlpesS. Chriki^{1,2}, J. Normand³, C. Brosse², L. Hallez², L. Vallet², V. Payet² and J.F. Hocquette¹¹INRAE, VetAgro Sup, UMR1213 Herbivores, Theix, 63122, France, ²Isara, 23 rue Jean Baldassini, 69364, France, ³Institut de l'Élevage, Agradole, 23 rue Jean Baldassini, 69364, France; schriki@isara.fr

In France, beef consumption has been steadily decreasing for many years. The reasons are multifactorial, linked to the: (1) controversial image of beef (its environmental impact, the competition between feed and food, the respect of animal welfare); (2) the modification of consumption patterns (decrease of daily time dedicated to cooking and eating); (3) its high price; and finally (4) its variable sensory quality. Thus, consumers are not always satisfied with the organoleptic quality of beef. In this context, the scientific project OABov-AURA (2022-2024) was conducted. An online survey was carried out to study consumer expectations regarding the intrinsic and extrinsic qualities of beef, in the region Auvergne-Rhône-Alpes (AURA) (the 2nd largest beef cattle breeding region in France). This study involved 509 respondents, mostly female (62%), young (52%<35 vs 32%>45 years old), students (28%) and executives (38%), with a good knowledge of farming (57%), and preferring to buy beef in butcher shops (31%). Among those surveyed, 52% say that eating beef for pleasure is their primary motivation. The majority of consumers are not disappointed with raw (86%) or cooked (58%) beef. Origin (89%), proximity (83%) and SIQO (Identification signs of quality and origin) (82%) are the most important extrinsic criteria. However, taste, tenderness and freshness are the most intrinsic important criteria of beef for the respondents. Consumers also prefer meat that is bright red (50.7%) and rather fatty (57%). The two main reasons for the decrease in beef consumption are economic (28% of responses) and environmental (27%). In conclusion, it is important that consumers in the AURA region have access to a varied supply of meat in butcher shops, of French origin and under quality signs.

Session 72

Poster 14

Analysis of preferences and perception of cheese products by Portuguese consumersV.M. Merlino¹, M. Renna², M. Tarantola², A. Ricci², A.S. Santos³, A. Monteiro³ and J. Nery²¹University of Turin, Dept. Agricultural, Forest and Food Sciences, L.go Braccini 2, 10095, Italy, ²University of Turin, Dept. Veterinary Sciences, L.go Braccini 2, 10095, Italy, ³FeedInov CoLab, Qta da Fonte Boa, 2005-048, Santarém, Portugal; manuela.renna@unito.it

In a critical dairy chain context, small producers must understand the consumers' needs and the strategies for a winning marketing communication. The aim of this study was to assess consumer preferences and profiles to better define marketing stimuli of cheese consumers in Portugal. A total of 218 Portuguese consumers filled in a structured questionnaire developed to collect information about: (1) socio-demographic traits; (2) cheese purchasing habits and preferences; and (3) attitudes and familiarity towards new cheese products and marketing stimuli. Data were analysed using Principal Component (PC) analysis to assess different preference patterns of consumers towards different cheese attributes (i.e. origin, quality, and certification). Cluster analysis of the PCs was used to classify consumers according to their choice orientation patterns towards cheese quality. Clusters composition was examined using the consumer characteristics as independent variables. Correspondence analysis was performed to identify the association between clusters and the suggested marketing stimuli to improve new product visibility and acceptability. Two PCs were defined as 'Tradition is sustainable' and 'Local is better'. Respondents were divided into 3 groups: 'Terraphilia' (57%), 'Sensitive to local origin' (38%) and 'Undecided' (5%). The 'Terraphilia' group is encouraged to try new cheese products through appealing packaging and detailed information on traceability and sustainability of the supply chain. The 'Sensitive to Local Origin' group is primarily attracted to products with lower price point, clear indications of origin, and a longer shelf-life. The 'Undecided' cluster instead showed the most negative attitude toward new products, being attracted by visual messages conveyed by brands. Portuguese cheese consumers are sensitive to sustainable local production chains. Enhancing the marketing of cheese in this context could be achieved through packaging improvement and information on product origin, sustainability and traceability. Funded by EIT FOOD, 2021(project number: 21324).

How a risk-based strategy could contribute to a more sustainable agri-food system?*B. Grossiord¹ and M.P. Ellies-Oury^{1,2}**¹Bordeaux Sciences Agro, Feed &Food, 1 cours du Général de Gaulle, 33170 GRADIGNAN, France, ²INRAE, UMR1213 Recherches sur les herbivores, Vet AgroSup Clermont-Ferrand, 63122 Saint Genès Champelle, France; benoit.grossiord@agro-bordeaux.fr*

Nowadays, members of the agri-food systems are the targets of much criticism but also the bearers of many hopes with regard to the challenges facing our society when considering sustainable development. Their contribution to the achievement of the Sustainable Development Goals is crucial and a key element of the coming transition. Their responsibility is engaged more than ever and they must lead the change by knowing the expectations of their stakeholders and managing the risks related to their activities. In order to reach that goals, they can use tools or methods which are available and could contribute to the improvement of the quality of their products, practices and organization. Such tools are successfully used by operators of the food chain, especially those with an industrial size. Small producers, due to harder work conditions and lack of time and means, are not familiar with such approaches although very useful for the improvement of their overall performance and long term viability. In relation to the growing expectations of the consumers and the society, they must consider diversifying their activity at multiple levels and propose new products, follow different quality schemes or change their modes of production. Short food supply chains are part of the many answers they can develop in order to improve the value of their products both at the intrinsic and extrinsic levels. Here we show that many issues around governance, social benefits, environmental impacts, animal welfare, health and nutrition dimensions can be integrated in a global approach of the short food supply chains. For that purpose, the concomitant utilization of tools, methods, guidelines or standards already available is recommended. Using management systems requirements with a consideration to intrinsic and extrinsic quality attributes allows the construction of an integrated approach with a continual improvement spirit. Such an organization will mobilize risk management tools applied to several stakes, like quality of the products, occupational health and security, environmental impacts, and so on, therefore allowing a better global performance.

Session 72

Poster 16

Perceptions of meat quality of UK stakeholders: from intrinsic to extrinsic factors*S. McLaughlin¹, F. Bedoin², C. Couzy², I. Legrand², A. Nicolazo De Barmon², C. Laithier² and N. Scollan¹**¹Queen's University Belfast, School of Biological Sciences, Institute for Global Food Security, 19 Chlorine Gardens, Stranmillis, BT9 5DL Belfast, United Kingdom, ²IDELE, 149, rue de Bercy, 75595 Paris cedex 12, France; s.mclaughlin@qub.ac.uk*

Aim: To understand attitudes and perceptions of livestock product quality held by supply chain actors within the agri-food sector across the UK. **Methods:** 15 interviews with actors across the UK beef supply chain, from farmers, processors, retailers, animal welfare, research, professional and quality assurance bodies. Qualitative analysis using inductive thematic analysis procedures. Interviews conducted December 2021-February 2022. **Results:** For UK stakeholders extrinsic attributes of product quality were most important. These include animal welfare and the price of the product. Age at slaughter and carbon footprint of production were also emerging characteristics of quality. Grass fed production and use of native breeds, such as Aberdeen Angus and Hereford breeds were associated with better quality. In terms of intrinsic quality, taste, fat and intramuscular fat, tenderness, appearance, consistency, and flavour were the most cited attributes. Eating quality was often used synonymously with product quality. **Conclusions:** Both intrinsic and extrinsic of livestock product quality are important to actors within the beef supply chain in the UK.

Transforming livestock practices by federating around common values

S. Nade

Obione, 239 rue Fernand Léger, 71000 Mâcon, France; sarahnd57@gmail.com

Today, environmental and animal welfare issues are real concerns for the marketing of animal products. In the image of One Welfare, the environment, animal welfare and, above all, the farmer's welfare are the three essential and inseparable elements for obtaining 'healthy' livestock and for meeting societal expectations. Obione therefore imagined a project in which farmers, veterinarians, processors and consumers would be united around a common objective and shared values. First of all, activities and meetings will be held between farmers, processors and veterinarians to improve communication between them. Indeed, Obione will offer training courses on value creation for and by farmers, on animal and farmer welfare and on the importance of each actor in the chain and the link between them. To improve and facilitate the dissemination of information and communication between the four parties, a website will be created. This site will include each producer registered in the process as well as the people involved in the structure (with their agreement). The aim is to enable consumers to know and understand the design of the products they consume. It will then be possible to directly involve consumers in the tasks carried out on the farms thanks to meetings organised via a connected diary. The Happy system, created by Obione to promote 'happy' farms, will then be offered to all breeders and associated veterinarians, thus enabling them to be valued, to take pride in their work and to report on the well-being of their farms. Indeed, Happy is an approach that evaluates the well-being of the animals and the breeder as well as respect for the environment. This project aims to strengthen the links between the players in the sector and the consumer by informing, sharing and enhancing the value of each of them, while showing the importance of livestock farming for human nutrition, biodiversity, the environment and even within a territory, for its development.

Session 73

Theatre 1

Genetic response of red yeast supplementation in feed to mycotoxin contamination in laying hensS. Hosseini¹, B. Brenig¹, W. Tapingkae² and K. Gatphayak²

¹University of Goettingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Goettingen, Germany, ²Chiang Mai University, Department of Animal and Aquatic Sciences, 239 Huay Kaew Road, 50200 Chiang Mai, Thailand; shahrbanou.hosseini@uni-goettingen.de

Feed contaminated with toxic fungi in farm animals can lead to impaired immune function, renal function, hepatotoxicity, and genetic mutations. Consumption of contaminated animal products is a global concern for human health. Mycotoxins are toxigenic chemical products of fungi that play a crucial role in liver disease, resulting in reduced production performance and high mortality in animal husbandry system. To minimize the harmful effects of mycotoxins, red yeast, an organic compound, was used as a mycotoxin binder in the poultry industry. Hence, the main goal of this study was to investigate the genetic response underlying feeding with red yeast supplementation in interaction with the mycotoxin in the liver of laying hens. For this purpose, the animals were fed for 63 days with four different diets: control diet (CON), CON with red yeast supplementation 1.0 g/kg (RY1.0), CON with contaminated corn containing 100 µg/kg mycotoxin (MT100), and CON with a combination of RY1.0 and MT100 (RY1.0+MT100). The liver tissue of four animals from each experimental group were collected after the feeding period and the total RNA was isolated for RNA sequencing using Illumina platform. The standard pipeline for RNA read alignment and counting, differential gene expression and functional enrichment analysis was performed for all samples. The results showed a high number of significant differentially expressed genes (DEGs, $p_{adj} < 0.05$) in MT100 vs CON group (1,553). This number of DEGs was considerably reduced to 858 genes, when RY was added to the RY1.0+MT100 diet compared to the CON group. As expected, the number of significant DEGs in the diet with RY1.0 was negligible compared to the CON group (8 genes). We identified a set of genes in MT100 and in RY1.0+MT100 diet, which play key roles in phase I (e.g. *CYP2C23a*, *CYP2C23b*) and phase II (e.g. *UGT1A1*, *GSTO1*) detoxification process of xenobiotics. Additionally, other genes involved in antioxidant mechanisms (e.g. *CHAC1*, *SOD1*) and immune response (e.g. *IL2RA*, *SERPINB10B*) were also detected in the liver of hens in this study.

Faecal starch content as an indicator of starch digestibility by fattening Japanese Black cattle*M. Matamura, S. Uzawa and M. Kondo**Mie University, Graduate School of Bioresources, 1577 Kurimamachiya, Tsu-city, Mie-Pref, 514-8507, Japan; masaya_matamura0@yahoo.co.jp*

A total of 2.6 million fattening cattle in Japan are fed approx. 10,000 t of starch every day. However, we do not know how much starch the cattle digest efficiently. To estimate starch digestibility in fattening cattle, a single linear regression equation based on the faecal starch (FS) content has been reported in the USA. As the digestion of nutrients is affected by several factors, regression equations developed under different feeding systems may not be applicable to Japanese Black cattle. Thus, the aim of this study was to develop a method for estimating starch digestibility from the faeces of fattening Japanese Black cattle. Moreover, we compared the developed equation with those obtained from studies in other countries. Total-tract starch digestibility (TTSD) was measured in a total of 116 fattening Japanese Black cattle. A linear regression model was developed to estimate TTSD from the FS content. In addition, research papers on fattening cattle published from 1993 to 2022 conducted in other countries were collected. Based on these data, a linear model between FS and TTSD was also developed. As a result, TTSD ranged from 83.9 to 99.8% and FS ranged from 0.2 to 15.3% in Japanese cattle. A negative linear relationship was observed between these variables, and the following equation was obtained to estimate TTSD: $TTSD (\%) = 99.7 (\%) - 0.85 FS (\%DM)$, $n=116$, $R^2=0.89$, $RMSE=1.00$. The slope of the regression equation obtained from fattening Japanese Black cattle (-0.85) was significantly greater ($P<0.001$) than that from fattening cattle in other countries (-0.47). Mathematically, the slope of the regression equation represents the ratio of DM indigestibility to dietary starch content. The mean values of DM indigestibility and dietary starch content obtained in this study were 29.5 and 32.5%, respectively, which are significantly different ($P<0.001$) from those reported by studies conducted in other countries (23.3 and 48.7%, respectively). Therefore, the greater slope of the equation obtained from Japanese Black cattle compared to cattle from other countries could be attributed to the higher DM indigestibility and lower dietary starch content.

Session 73

Theatre 3

Impact of isoacids on performance and digestibility in gilts fed different dietary fibre sources*W. Schweer¹, B. Kerr², M. Socha¹, A. Cornelison¹ and L. Rodrigues¹**¹Zinpro Corporation, Eden Prairie, MN, USA, ²USDA-ARS, Ames, IA, USA; wschweer@zinpro.com*

Isoacids are short, branched chain volatile fatty acids produced by microbial degradation of branched chain amino acids. In ruminants, isoacids are growth factors for cellulolytic bacteria which leads to improved digestibility of fibrous ingredients. The objective of this study was to determine if feeding isoacids to pigs could improve performance and digestibility of high fibre diets. Two groups of 45 gilts (BW=139 kg) were individually penned and fed 1 of 9 dietary treatments for 28 days ($n=10$ per treatment). Diets were arranged in a factorial manner consisting of diet type: corn-soybean meal (CSBM), a CSBM diet with 40% inclusion of distillers dried grains with solubles (DDGS), or a CSBM diet with 40% inclusion of sugar beet pulp (SBP); in combination with no isoacid (NO) or the addition of 0.50% isobutyrate (IB) or 0.88% inclusion of isoacid mixture (MX). IB and MX diets were formulated to have equal levels of isobutyrate. Gilts were limit fed 2 kg per day. Performance metrics (ADG, ADFI, G:F) were determined for the 28 day period. Faecal samples were collected on day 26 to determine apparent total tract digestibility (ATTD) of gross energy (GE) and nitrogen (N), and a faecal VFA profile. There was no diet type by isoacid interaction and no main effect of isoacids on performance ($P\geq 0.22$). Diets with DDGS or SBP reduced ADFI and increased G:F compared to pigs fed CSBM diets ($P=0.01$). Interactions existed for ATTD ($P=0.01$), where IB increased ATTD of GE and N in diets containing DDGS compared to DDGS diets with no isoacid. In contrast, MX decreased ATTD of GE and N compared to NO in DDGS diets. In diets containing SBP, IB or MX both decreased ATTD of GE and N compared to no isoacid addition. In CSBM diets, no differences in ATTD of GE or N were noticed between IB and NO ($P>0.05$); however, MX addition decreased ATTD of GE and N compared to NO. Total faecal VFA tended to be increased by MX in CSBM and SBP diets, but not DDGS diets, leading to an interaction of diet by isoacid ($P=0.06$). Faecal isobutyrate was increased by IB, but not MX, compared to NO ($P=0.01$). These results suggest that IB may have an impact on digestibility in diets higher in insoluble fibre compared to soluble fibre.

The enterotype is associated with the phenotype variation in the pigs treated with dietary fibre*H. Li and B.E. Tan**Hunan Agricultural University, No.1 Nongda Road, Changsha, 410128, China, P.R.; bietan@hunau.edu.cn*

The gut microbiota degraded DF in hindgut and fermented to producing short chain fatty acids (SCFAs) that provide energy or produce health benefits for pigs. Enterotype was a method of dividing individuals based on the composition of gut microbial community and could be a key factor to determining the phenotype of DF-treated pigs. Therefore, the current study was conducted to analysis the linkages between the dietary fibre (DF) utilization and enterotype in pigs. Based on 8,872 16S rRNA gene sequencing data from fresh faeces or rectal contents from around the world, pigs were stratified into three main intestinal types, named ETL, ETP, ETC according to the feature genera of the gut microbiome. The ETL and ETP were dominated by *Lactobacillus* and *Prevotellaceae* members, respectively. Whereas ETC had the microbial communities formed with *Christensenellaceae_R_7_group* as the core genus. The α diversity index of ETC and ETP was generally higher than that of ETL. It was verified that changing the DF source or breed of pigs did not affect the grouping effect of enterotype on pig individuals. Diets with higher soluble dietary fibre (SDF) increased the proportion of ETC and decreased the proportion of ETL in pigs compared to the diet with lower SDF. Additionally, enterotype significantly affected the apparent total tract digestibility (ATTD) of DF and the coefficient values of the DF ATTD in pigs. Further, it was identified that the ratio of SCFAs, mainly produced by fermentation of dietary fibre, also varied due to enterotype changing. ETC was more inclined to acetate production, while ETC may have more butyrate production. In summary, it was expected to provide more accurate nutritional strategies for the application of dietary fibre when considering the proportion of different enterotypes in pig herds.

Session 73

Theatre 5

A high rumen degradable starch modulates jejunum microbiota and bile acids in dairy goats*L.M. Wang, J.H. Yao and Y.C. Cao**Northwest A&F University, Yangling, Shaanxi, 712100, China, P.R.; wanglamei1216@126.com*

Fat is the major energy component in milk and accounts for many of the physical properties, manufacturing characteristics, and organoleptic qualities of milk and milk production. Milk fat can be affected by factors that influence the processes from dietary lipogenic precursors to milk fat, in the rumen, intestine, liver, and mammary tissues and so on. This study uncovered the effect of digestive processes and liver metabolism of lipogenic precursors on milk fat synthesis in dairy goats. Eighteen lactating goats were allocated equally into low RDS (LRDS=20.52%), medium RDS (MRDS=22.15%), and high RDS (HRDS=24.88%) diet groups. After 5 weeks of feeding, the HRDS diet increased the relative abundance of Firmicutes and *Ruminococcus_2* in jejunum. Firmicutes, which are gram-positive bacteria, are the predominant bacteria able to deconjugate and dehydroxylate primary bile acids into secondary bile acids. *Ruminococcus* perform epimerization during the conversion from primary to secondary bile acids. The expression of bile acid receptor FXR in jejunum and ileum and TGR5 in jejunum were decreased by HRDS treatment, indicating the negative feedback regulation of bile acid synthesis was inhibited in liver. The increase expression of CYP7A1, the rate-limiting enzyme of the bile acid biosynthetic from cholesterol, indicate the increased bile acids synthesis in liver. We also found the HRDS group increased the bile acids TCDCA and TDCA, and disordered the phosphatidylcholines in liver, as well as upregulated TNF α expression. We further measure the genes expression related to lipid metabolism, and found that HRDS group increased the expression of the transcription factor peroxisome proliferator-activated receptor α (PPAR α) and its downstream target gene CPT1. This study demonstrated that HRDS diet feeding modulates jejunum microbiota and alters enterohepatic circulation of bile acids, and promote lipid oxidation in dairy goats.

Development of a novel endolysin, RalLys8, for the specific inhibition of *Ruminococcus albus*

J. Moon, H. Kim and J. Seo

Pusan National University, Department of Animal Science, 1268-50 Samrangjin-ro, Miryang, Gyeongsangnam-do, 50463, Korea, South; mantis0044@pusan.ac.kr

Ruminococcus albus (*R. albus*) is the most important cellulolytic bacterium in the rumen. It ferments one mole of glucose, producing ethanol, acetate, carbon dioxide, and a high concentration of hydrogen. Ruminal methanogens use hydrogen to reduce carbon dioxide to methane, which is a potent greenhouse gas, and also a loss of energy for ruminants. Endolysins, bacteriophage-encoded peptidoglycan degrading enzymes, have emerged in recent years as a novel agent to kill target bacteria specifically. Thus, the study hypothesized that if a novel endolysin could specifically kill *R. albus*, it could potentially reduce hydrogen production and mitigate methane emissions. Whole genome sequence of *R. albus* strains and related bacteriophages were collected from the National Center for Biotechnology Information database, and the candidate gene for RalLys8 was isolated based on amino acid sequences and conserved domain database (CDD) analysis. The lytic activity of RalLys8 was evaluated under various conditions (dosage, pH, temperature, NaCl, and metal ions) to determine the optimal lytic conditions. CDD analysis revealed that RalLys8 possesses only the catalytic domain of PGRP superfamily which includes a zinc dependent N-acetylmuramoyl-L-alanine amidase located at the N-terminal without cell wall binding domain. The RalLys8 reduced the optical density of the *R. albus* dose-dependently above a concentration of 3.125 µg/ml, and the activity of RalLys8 was the highest at a concentration of 25 µg/ml. The highest lytic activity of RalLys8 against *R. albus* was observed at pH 9.0 and 31.25 mM NaCl, and this activity was maintained over a temperature range of 16 to 60 °C. The lytic activity of RalLys8 was recovered by treatments with Mg²⁺ and Co²⁺. However, treatments with Ca²⁺ and Zn²⁺ reduced the activity of RalLys8 by approximately 40 and 20%, respectively. In conclusion, we have successfully developed a novel endolysin, RalLys8, which exhibits potent lytic activity against *R. albus*. Therefore, further studies are needed to evaluate the effect of RalLys8 against *R. albus* and its impact on rumen microbiota under *in vitro* anaerobic condition.

Session 73

Theatre 7

Dietary microalgae (*Nannochloropsis limnetica*) and probiotic on performance and intestine of pigletsM.F. Pedro¹, D.F.P. Carvalho¹, A.M. Almeida¹, R.J.B. Bessa², A.J.M. Fonseca³, A.R.J. Cabrita³ and J.P.B. Freire¹¹LEAF, TERRA, ISA, Universidade de Lisboa, 1349-017 Lisboa, Portugal, ²CIISA, AL4AnimalS, FMV, Universidade de Lisboa, 1300-477 Lisboa, Portugal, ³REQUIMTE, LAQV, ICBAS, Universidade do Porto, 4050-313 Porto, Portugal; mfpedro@isa.ulisboa.pt

Study of alternative feeds can provide solutions that consider both current issues and future requirements, with resource usage and their ecological implications. Feedstuffs often directly compete with human-edibles and are produced with arable land. Microalgae have interesting nutritional and industrial properties but require further study. This work evaluated the effects of *Nannochloropsis limnetica* dietary inclusion and a commercial probiotic (LBC ME10) on growth performance and intestinal physiology of weaned piglets. 120 piglets (Large White × Landrace × Piétrain), with 7.7±0.9 kg live weight (28 d) were blocked by weight in trios and randomly assigned to one of the experimental diets: C – Control diet (wheat/maize/soybean meal); N2.5 – 2.5% *Nannochloropsis*; N5 – 5% *Nannochloropsis*; N2.5P – 2.5% *Nannochloropsis* and Probiotic; and N5P – 5% *Nannochloropsis* and Probiotic. Piglets were housed in three per pen, in a total of 40 pens (8 pens per treatment) with *ad libitum* feeding and water. After 3 days of adaptation, piglets were fed for 5 weeks, with liveweight and feed intake determined weekly and faecal scores daily. At week 5, one piglet from each pen was slaughtered and gastrointestinal contents collected. Performance indicators, viscosity and pH of intestinal contents were determined and data analysed by ANOVA. Diets did not affect average daily gain (498±88 g/d), average daily feed intake (648±103 g/d), nor feed conversion ratio (1.32±0.23). Faecal consistency, viscosity of intestinal contents in upper small intestine (4.2±0.6 cP) and ileum (4.6±0.4 cP), as well as pH of stomach (4.2±0.9), upper small intestine (5.7±0.3), ileum (6.6±0.4), cecum (5.6±0.2) and colon (6.1±0.2) contents were similar within each sampling site for all treatments. Overall, results indicate that *N. limnetica* inclusion in weaned piglet diets up to 5% does not affect growth performance nor faecal consistency, suggesting it may be effectively used in piglet diets with good feed acceptance. Further work is needed to understand effects on digestive physiology.

Muramidase inclusion reduces gut inflammation in weaned piglets, especially in high protein dietsU.M. McCormack¹, J. Schmeisser², E. Bacou², P. Jenn², F. Amstutz² and E. Perez Calvo¹¹DSM Nutritional Products, Wurmisweg 576, 4303 Kaiseraugst, Switzerland, ²DSM Nutritional Products, 1 Bd d'Alsace, 68128 Village-Neuf, France; estefania.perez-calvo@dsm.com

Weaning compromises gastrointestinal functionality (GIF), including changes in digestion, absorption, microbiology and immunology, resulting in clinical signs like post-weaning diarrhoea (PWD) and reduced growth performance. High protein diets elevate proteolytic fermentation, altered microbial communities and intestinal physiology increasing PWD incidence. Muramidases (MUR) are enzymes that hydrolyse peptidoglycans (PGN) from bacterial cell debris present in the gut, which play an important role in maintaining intestinal homeostasis by down-regulating inflammatory responses. This study assessed dietary MUR inclusion on GIF in early weaned piglets fed either low (LP) or high (HP) protein diets. Sixty-four male 21 d old pigs (initial BW 6.1±0.6 kg) were used in a 14 d study, randomized into 4 treatments: LP: 167 g of CP/kg, LP+: LP supplemented with MUR, HP: 210 g of CP/kg and HP+: HP supplemented with MUR. Bodyweight was recorded on d0 and 14. On d14, plasma urea nitrogen (PUN) and concentrations of Vit A and E were measured. Faecal dry matter (DM), and lipocalin as a biomarker of inflammation were evaluated. Additionally, inflammatory gene expression was analysed by PCR array targeting 42 genes in mesenteric lymph nodes, ileal peyer patches and lamina propria. Treatment differences were determined by two-way ANOVA (JMP® software) considering protein level and MUR inclusion as main effects. HP pigs had higher ADG and plasma Vit A ($P<0.05$) and higher faecal DM ($P=0.06$) compared to LP pigs. Adding MUR increased faecal DM and plasma Vit A ($P>0.05$) and reduced PUN ($P<0.05$) which could explain the trend to increase ADG ($P=0.10$). No interaction was detected, except for lipocalin ($P<0.05$) which was reduced in HP, only when MUR was included. Moreover, a downregulation of inflammatory genes (CCL2, CXCL12, CXCL9, IL10RA, IL18, IL27; $P<0.05$) was found in the different tissues from MUR pigs. A downregulation in IL17B indicating reduced inflammation was also found in HP+. In conclusion, MUR supplementation for 14 d post-weaning reduces gut inflammation, improves nitrogen utilization and Vit A absorption, resulting in lower PWD, especially in HP diets.

Session 73

Theatre 9

Utilization of tryptophane by kynurenine, indoles and serotonin pathways are modified by fructoseA. Gual-Crau¹, M. Jarzaguet¹, D. Dardevet¹, D. Rémond¹, A. Lefèvre², A. Bernalier-Donadille³, P. Emond^{2,4} and I. Savary-Auzeloux¹¹UCA, INRAE, UNH, 63000 Clermont-Ferrand, France, ²iBrain, Université de Tours, Inserm, 37000 Tours, France, ³UCA, INRAE, MEDIS, 63000 Clermont-Ferrand, France, ⁴CHRU de Tours, MEDIS, 63000 Clermont-Ferrand, France; didier.remond@inrae.fr

Tryptophane (Trp) is an essential amino acid used for protein synthesis and in 3 metabolic pathways: Kynurenine (KYN), indoles and serotonin. If Trp deficiencies are known to reduce growth and appetite in monogastrics, less is known on Trp's fate in overfeeding, when animals develop insulin resistance (IR). In humans, increased levels of Trp and metabolites occur in type 2 diabetes. Our aim is to determine if Trp can mark the onset of IR-related metabolic perturbations and what can be the consequences on Trp requirements in a monogastric model: mice. C57BL/6 mice were fed one month with a control diet (CON) (n=8) or CON diet with 10% starch substituted by fructose (n=8) (FRU). Trp and metabolites (from the 3 pathways) were assayed in arterial serum, jejunum, colon, faecal content and liver (LC-HRMS) in the fasted state. Insulin and glucose were measured in serum (ELISA and enzymatic method). Comparisons between groups: ANOVA, post hoc: Tukey. Although weight gain, intake and serum insulin /glucose were not differentially altered in the two groups, Trp increased ($P<0.05$, +21.8%) in FRU vs CON as well as KYN, 3-OH-KYN, picolinic acid and KYN/Trp ratio. This suggests a stimulation of KYN pathway by fructose. On the contrary, the indole pathway, controlled by gut microbiota activity, is inhibited in FRU (indole-3-sulfate (-25.6% – $P<0.05$). Lastly, 5-OH Try, a precursor of serotonin, is increased in FRU ($P<0.05$) but other are unaltered. The activation of KYN pathway in FRU also occurs in jejunum but not colon for 3-OH KYN and 3-OH Anthranilic acid ($P>0.05$), suggesting an intense activity of KYN pathway in this tissue. Additionally, quinolinic acid (QA), endproduct of KYN pathway, is increased in faeces and liver ($P<0.05$), preventing an accumulation of QA in blood as QA is neurotoxic. Other pathways are under investigation. We show that Trp's fate in serum and tissues can be strongly altered during the onset of IR. In fast fattening animals, this altered Trp metabolic fate may occur and should require further investigation.

Regulation of glucose metabolism in rumen epithelium of cows transitioned from forage to high-grain

S. Kreuzer-Redmer¹, A. Sener¹, C. Pacifico¹, F. Dengler², S. Ricci¹, H. Schwartz-Zimmermann³, E. Castillo-Lopez¹, N. Reisinger⁴ and Q. Zebeli¹

¹Institute of Animal Nutrition, Vetmeduni, Veterinärplatz 1, 1210 Vienna, Austria, ²Institute of Physiology, Vetmeduni, Veterinärplatz 1, 1210 Vienna, Austria, ³IFA-Tulln, iBAM, BOKU, K.L.-Str. 20, 3430 Tulln, Austria, ⁴DSM, BIOMIN Research Center, Technopark 1, 3430 Tulln, Austria; susanne.kreuzer-redmer@vetmeduni.ac.at

The bovine rumen epithelium has a crucial role in the uptake and metabolism of fermentation products. Yet, little is known about the uptake of hexoses and their metabolism. Thus, we have examined the transcriptome of rumen papillae from cows when transitioned from a forage-based to a high-grain diet. Rumen biopsies were collected from ruminally cannulated non-lactating Holstein-Friesian cows fed a forage diet (FD; 0% concentrate, n=9) as baseline or a high-grain diet for 4 weeks (HG; 65% concentrate, n=9). Transcriptome analysis identified 9,481 differentially expressed genes (DEGs) between FD and HG. Within the top 5 most significant DEGs, we detected SLC7A8, which is associated with the transport of glucose and other sugars. A more in-depth analysis of known glucose transporters revealed that GLUT2, GLUT3, GLUT4, GLUT9, GLUT10, SGLT2 and SGLT3 were all up-regulated when cows were transitioned to the HG diet, suggesting an increased uptake of glucose, which might be used for the increased energy demands of cells to proliferate and enlarge papillae, or simply for storage. Targeted anion exchange chromatography-HRMS-based metabolomics detected carboxylic acids, sugars and sugar-phosphates in rumen fluid and Spearman correlation analysis revealed positive correlations of hexoses with the differentially expressed glucose transporter genes. Particularly strong and significant correlations were found for GLUT3, GLUT9, SGLT3 and SLC7A8 ($R^2 > 0.6$, $P < 0.05$). We were able to confirm our NGS results via qPCR on transcript level. In addition, we were able to prove the ruminal abundance of GLUT2, GLUT3, SGLT1, SGLT3 and SLC7A8 on protein level by Western blotting in ruminal papillae. Our data confirm a direct involvement of the rumen epithelium in glucose metabolism. Further experiments are essential to evaluate and deepen our understanding of glucose metabolism within the rumen epithelium.

Session 73

Theatre 11

Altering nutrients supply modified dynamics of milk components synthesis in dairy cows

J.C. Anger^{1,2}, C. Loncke³, R. Bidaux¹ and S. Lemosquet²

¹Provimi, Cargill ANH, 35320 Crevin, France, ²PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France, ³Université Paris-Saclay, INRAE, AgroParisTech, UMR MoSAR, 91120 Palaiseau, France; jean-charles.anger@inrae.fr

This study aimed to analyse the dynamics of milk component synthesis in response to increasing starch and balancing amino acids (AA) during mid-lactation in dairy cows. We hypothesized that altering the nutrient supply could modify the persistency of lactose, protein, and fat differently. Thirty-two multiparous dairy cows were involved in a randomized complete block design. They received 2 levels of starch (LS: low starch; HS: high starch) and 2 levels of AA supplies (AA- vs AA+) through rumen-protected AA according to a factorial design from 56 to 180 days in milk (DIM). The LS and HS diets provided (in g/kg DM) 155 vs 233 of starch, 384 vs 380 of NDF, 138 vs 142 of CP, 89.5 vs 94.5 of MP, and 6.54 vs 6.20 MJ/kg, respectively. The AA- vs AA+ diets were formulated to provide [in % of MP]: 6.4 vs 7.1% Lys, 2.0 vs 2.4% Met, and 2.1 vs 2.4% His, respectively. Milk protein and fat contents were measured twice a week, and lactose content once a week. Milk lactose, protein, and fat yields were modelled by linear regression with DIM, starch, AA, and covariates as predictors, and cow as a random effect. The slope of each milk component model was assumed to be an estimator of persistency. Lactose and protein yields were higher on HS than on LS diets (1,708 vs 1,895 g; $P < 0.001$; 1,085 vs 1,201 g; $P < 0.001$, respectively). The slope of lactose, protein, and fat yields models were higher on HS than on LS diets (-3.41 vs -1.41 g/d, $P < 0.001$; -1.31 vs 0.29 g/d; $P < 0.001$; -2.43 vs -0.43 g/d, $P < 0.001$, respectively). This effect could be due to the stimulation of mammary synthesis by starch or by slightly higher supply of MP in the HS diet. Balancing AA increased the slope of lactose yield (-2.78 vs -2.04 g/d, $P = 0.01$), however the effect tended to be not additive (at LS level: -4.05 vs -2.77 g/d; at HS level: -1.50 vs -1.31 g/d; AA × starch on slope: $P = 0.06$). With the LS diet, balancing AA tended to increase the slope of fat yield (at LS level: -2.90 vs -1.96 g/d, AA × starch on slope: $P < 0.05$). These results suggest that increasing starch or better balancing AA increased the persistency of milk components.

Phytogenic effects on layer performance, egg quality and cytoprotective response in the ovaries*I.P. Brouklogiannis¹, E.C. Anagnostopoulos¹, V.V. Paraskeuas¹, E. Griela¹, G. Kefalas² and K.C. Mountzouris¹*¹Agricultural University of Athens, Animal Science, Iera Odos 75, 11855, Athens, Greece, ²Nuevo SA, Schimatari Viotias, 320 09, Viotia, Greece; gbrouk@outlook.com

The aim of this work was to investigate the inclusion level effects of a natural phytogenic blend (PB) on layer production performance, egg quality and underlying detoxification (aryl hydrocarbon receptor; AhR), antioxidant (Nuclear factor erythroid 2-related factor 2; Nrf2) and inflammatory (nuclear factor-kappa B; NF-κB) responses in the ovaries. Laying hens (n=385; 21-wk-old; Hy-Line Brown) were allotted to 5 dietary treatments with 7 replicates of 11 hens each, for a 12-week feeding trial. Treatments received a corn-soybean meal basal diets with no PB (CON) or supplementation with PB at 250 (PB250), 750 (PB750), 1000 (PB1000) and 1,500 mg/kg diet (PB1500), respectively. The PB consisted of selected Mediterranean plants having olive oil polyphenols, carvacrol and thymol among its main bioactive components (NuPhoria®; Nuevo SA, Greece). Performance and egg quality parameters were determined weekly for a 12-week period (i.e. 33rd wk of layers age) and reported as overall. Ovarian samples from 33-wk-old layers were collected and stored deep frozen, until gene expression analysis with qPCR. Data were analysed by ANOVA and statistical significance was determined at $P < 0.05$. Linear and quadratic patterns of biological responses to PB inclusion levels were studied via polynomial contrasts analysis. Increasing PB inclusion, enhanced quadratically egg laying rate and egg mass, with PB750 birds being higher ($P < 0.05$) compared to CON. Albumen height and Haugh unit increased quadratically with increasing PB inclusion and peaked at PB750 ($P < 0.05$). In the ovaries, increasing PB inclusion level down-regulated ($P < 0.05$) the expression of most of AhR pathway genes (80%), while increased the expression of most of the Nrf2 pathway genes (87.5%) assessed. Additionally, most of the genes related to NF-κB pathway (75%) were down-regulated ($P < 0.05$) with increasing PB inclusion level. Conclusively, phytogenic inclusion beneficially enhanced the birds' adaptive cyto-protection and anti-inflammatory capacity and documented further production and egg quality improvements, with PB750 displaying the optimal benefits.

Session 73

Poster 13

Phytogenic effects on layer performance, and cytoprotective response in the ceca*E.C. Anagnostopoulos¹, I.P. Brouklogiannis¹, V.V. Paraskeuas¹, E. Griela¹, G. Kefalas² and K.C. Mountzouris¹*¹Agricultural University of Athens, Animal Science, Iera Odos 75, 118 55 Athens, Greece, ²Nuevo SA, Schimatari Viotia, 320 09 Viotia, Greece; vagosanagn@gmail.com

The aim of this work was to evaluate the effect of a natural phytogenic blend (PB) inclusion level on production performance and underlying detoxification (aryl hydrocarbon receptor; AhR) and antioxidant (nuclear factor erythroid 2-related factor 2; Nrf2) molecular responses in layer ceca. The PB consisted of selected Mediterranean plants having olive oil polyphenols, carvacrol and thymol among its main bioactive components (NuPhoria®; Nuevo SA, Greece). A total of 385 21-wk-old Hy-Line Brown layers were placed into 5 dietary treatments with 7 replicates of 11 hens each, for a 12-week feeding trial. Treatments received a maize-soybean meal basal diet without PB (CON) or with PB supplementation at 250 (PB250), 750 (PB750), 1000 (PB1000) and 1,500 mg/kg diet (PB1500), respectively. Laying rate, egg mass, feed intake and feed conversion ratio were determined weekly and presented for periods: 1-6 wks and 7-12 wks. Caecal intestinal samples were collected in the 6th and 12th week of the experiment. The data were analysed by ANOVA procedure and statistical significance was determined at $P < 0.05$. Results revealed that PB inclusion, improved ($P < 0.001$) egg laying rate, egg mass and feed conversion ratio in the period 7-12 wks, mainly at PB750 treatment, compared to control. Furthermore, dietary PB inclusion up-regulated ($P \leq 0.05$) the expression of the majority of the Nrf2 pathway antioxidant genes in the ceca, both in 6th and 12th week of the experiment, compared to CON. Additionally, the AhR pathway related genes were down-regulated ($P < 0.05$) with PB inclusion level at both sampling points. Conclusively, including PB in layers' diets beneficially modulated the caecal antioxidant and detoxification responses along with a performance enhancement, with PB750 diet being the most prominent inclusion level.

Effects of guanidinoacetic acid supplementation on growth performance in Nellore cattle

O.R.M. Neto^{1,2}, I.M.S.C. Farias^{1,2}, R.N.S. Torres², R.V. Ribeiro^{1,2}, W.A. Baldassini^{1,2}, R.A. Curi^{1,2}, L.A.L. Chardulo^{1,2} and G.L. Pereira^{1,2}

¹São Paulo State University, School of Agricultural and Veterinarian Sciences, Prof. Paulo Donato Castellane, 14884900, Jaboticabal, São Paulo, Brazil, ²São Paulo State University, School of Veterinary Medicine and Animal Science, 3780 Universitária Ave, 18610160, Botucatu, São Paulo, Brazil; otavio.machado@unesp.br

Guanidinoacetic acid (GAA) has been used as a feed additive to improve growth performance, feed efficiency and meat quality in non-ruminant animals. However, there is little information about its use in feedlot beef cattle. In this context, the aim was to evaluate the effect of the inclusion of GAA in the diet of non-castrated Nellore cattle finished in feedlot, on the dry matter intake (DMI), performance (ADG), feed efficiency (FE) and carcass traits (CT). We used 120 Nellore bulls, with initial body weight of 345 ± 18.31 kg, blocked by weight and distributed in 24 collective pens ($n=12/\text{treatment}$), receiving two treatments: Control = without GAA and treatment with the inclusion of 1.0 g/kg of DMI of GAA. The experimental period lasted 101 days. In the first 20 days, the animals were submitted to the step-up adaptation protocol, with an increase in the concentrate:roughage ratio in the diet from 64:36 (step 1), 72:28 (step 2), 80:20 (step 3), until the final ratio of 87:13. The final diet contained 13.60% CP; 20.90% NDF and 9.87% Forage-NDF. The inclusion of GAA in the diet in the adaptation phase (1-20 days) did not affect dry matter intake (8.73 vs 8.90 kg/d; $P>0.05$), however it improved FE (0.17 vs 0.20 ; $P=0.018$). In addition, a trend towards an increase in ADG (1.50 vs 1.76 kg/d; $P=0.067$) was observed with the inclusion of GAA. The inclusion of GAA in the finishing diet (21-101 days) did not affect ($P>0.05$) DMI, ADG, FE and CT. The improvement in FE and the trend towards greater daily weight gain only during the adaptation phase can be attributed to the higher NDF content in the diet during this period, since, according to the literature, GAA has stimulatory effects on cellulolytic microbial growth. The inclusion of GAA in the diet improves FE during the adaptation period, demonstrating the potential of this additive in diets of feedlot cattle.

Session 73

Poster 15

In feed histidine supplementation improves muscle carnosine content and meat quality in pigs

M. Paniagua¹, B. Saremi², B. Matton² and S. De Smet³

¹Quimidroga SA, R&D Department Food and Feed, tuset 26, 08006, Spain, ²CJ Europe GmbH, Research Center, Main Airport Center, Unterschweinstiege 2-14, 60549, Germany, ³Ghent University, Laboratory for Animal Nutrition and Animal Product Quality, Coupure Links 653, block F, 9000, Belgium; b.matton@cj.net

Nowadays low crude protein (CP) diets in swine are mandatory to improve sustainability by reducing nitrogen emission. Low CP diets, although following the ideal protein concept, reduce the availability of some amino acids such as histidine (His). Thus, carnosine synthesis and meat quality could be compromised. Herein, we test His impact in low CP diets in fattening pigs on meat quality and carnosine content. On a commercial farm, Pietrain genetic pigs ($n=2,440$) were assigned to control (CON) or HIS (3 kg of BestAmino™ L-His HCl – CJ BIO for the last 12 weeks before slaughter) group. Animals received the same feed formulas based on barley, corn and soybean meal during the growing (CP 14.6%) and finishing (CP 14.1%) phase, where SID His:Lys ratio was 0.37 in CON diet and 0.60 in HIS group. Animals were slaughtered at approximately 130 kg of final BW in 4 consecutive weeks (305 animals per treatment per week). Carcass weight was measured at the slaughterhouse, and samples from the longissimus dorsi (LD) and the semitendinosus (ST) muscles were obtained to analyse the carnosine content and meat quality parameters, such as pH and drip loss. Carcass weight was not affected by treatment (105.5 ± 2.0 and 105.4 ± 1.3 kg for CON and HIS, respectively). Carnosine content was greater ($P<0.05$) in the LD of HIS (307 ± 4 mg / 100 g muscle) compared with CON animals (269 ± 7 mg / 100 g muscle), whereas only a numerical increase was observed in ST of HIS pigs. Additionally, pH at 24 h *post-mortem* was higher ($P<0.01$) in HIS group (5.68 ± 0.02) than in CON pigs (5.58 ± 0.03), and drip loss was lower ($P<0.05$) (2.49 ± 0.19 and $1.96 \pm 0.12\%$ for CON and HIS, respectively). The improvement in both parameters might be explained by the higher carnosine content in LD and ST. In conclusion, supplementing L-His in fattening pigs increased muscle carnosine content and improved meat quality, whereas it did not affect carcass weight. Thus, more research is needed to elucidate the effects of low CP diets on meat quality.

Impact of functional amino acids on performance parameters in post-weaning pigletA. Simongiovanni¹, K. Fenske², F. Witte², H. Westendarp² and T. Chalvon-Demersay¹¹METEX Animal Nutrition, 32 Rue Guersant, 75017 Paris, France, ²Hochschule Osnabrück, Fakultät Agrarwissenschaften und Landschaftsarchitektur, Am Krümpel 31, 49090 Osnabrück, Germany; aude.simongiovanni@metex-noovistago.com

Weaning is a critical period during which piglets are faced with many changes causing stress, with negative effect on feed intake. Commonly, weaned piglets are offered high quality proteins and supplemental amino acids (AA) to balance the diet. Functional AA and polyphenols may provide additional benefits to secure a good start after weaning. Therefore, 192 piglets weaned at 27 days of age were allocated to 16 pens (12 piglets/pen; 50:50 castrated males:females). The diets were offered during 3 post-weaning (PW) phases: from weaning (d0) to d14 PW, from d15 to d28 PW and from d29 to d49 PW. Two dietary treatments were compared: a control commercial diet based on wheat, barley, corn (broken), and soybean meal in varying concentration, or the same control diet supplemented 'on-top' with 0.1% of a mixture of glutamine, arginine, cystine and grape extract polyphenols. Piglets were individually weighted at weaning, d14, d28 and d49 and the average daily gain (ADG) was calculated for the periods between weighting dates. Average daily feed intake (ADFI) and feed conversion ratio (FCR) were calculated per pen for the same periods. No significant differences were found during the first period, though ADG (+12%), ADFI (+8%), and FCR (-4%) were numerically improved for the supplemented group. During phase 2, a significant better growth (+35 g/d ADG; $P=0.005$) translated in a significant higher body weight (BW) at d14 (+664 g; $P=0.022$) in the supplemented group. A trend for a better ADFI for the supplemented group can be as well underlined for this period (+29 g/d; $P=0.077$). If we consider the total period of the trial (d0-49), piglet ADG was significantly improved in the supplemented group (+24 g/d; $P=0.026$) which may be explained by the trend towards an increased feed intake (+30 g/d ADFI; $P=0.068$). The final BW at d49 was significantly higher for the supplemented group with +1.2 kg BW more compared to the control group ($P=0.026$). Collectively, the supplementation with a mixture of functional AA and polyphenols improved piglet performance during the PW phase.

Phytobiotics from *Thymus* species in poultry feed – thymol, carvacrol and rosmarinic acid

M. Taghouti

FeedInov CoLab, Integrated production systems, Estação Zootécnica Nacional, Qta da Fonte Boa, Rua Prof. Dr. Vaz Portugal, 2005-424, Portugal; myriam.taghouti@feedinov.com

Phytogenic feed additives (PFAs), also known as phytobiotics are herbal extracts, essential oils (EO) and other plant-derived products that have health promoting potential such as antioxidant, antimicrobial and anti-inflammatory activities. With the increasing interest in using safe alternatives to conventional antibiotics in livestock farming, more focus was given to the in-feed inclusion of PFAs, especially in poultry and swine. Polyphenols are among the molecules that were highly studied and used as feed natural additives such as rosmarinic acid (RA), thymol (TH) and carvacrol (CA). (RA) is a water soluble phenolic acid and is the major component of aqueous and hydro-ethanolic extracts from several *Thymus* species such as *T. vulgaris*, while (TH) and (CA) are monoterpene phenols and are the major compounds in chemotypes of different *Thymus* spp. essential oils. Several studies investigated the *in vivo* effect of inclusion of *Thymus* spp. plants and/or their extracts and EO in the broilers and laying hens diets. General observations confirm the beneficial outcome in animals' welfare, growth performance, meat and egg quality. Described mechanisms behind these improvements are mainly the stimulation of gastrointestinal (GI) beneficial flora, the contribution to a more balanced GI ecosystem by the inhibition of pathogenic microorganisms and modulation of immune response. Effects are dose-dependent which requires an adequate inclusion in the diet taking into consideration the bioavailability of the molecule in the target tissues. Synergy between the different compounds, such as TH and CA relevant synergistic antimicrobial effect, is also an important factor that should be investigated for market-scale formulations. Novel techniques for administration of bioactive molecules, such as encapsulation, enhanced the effectiveness of supplementation resulting in better growth performance, lower feed conversion rates and improved health status. Also, *in ovo* injections are earning more interest especially for the protection from post-hatching infections and early health disorders.

Dietary microalgae (*Chlorella vulgaris*) and probiotic on performance and intestine of pigletsM.F. Pedro¹, D.F.P. Carvalho¹, A.M. Almeida¹, R.J.B. Bessa², A.J.M. Fonseca³, A.R.J. Cabrita³ and J.P.B. Freire¹¹LEAF, TERRA, ISA, Universidade de Lisboa, 1349-017 Lisboa, Portugal, ²CIISA, AL4AnimalS, FMV, Universidade de Lisboa, 1300-477 Lisboa, Portugal, ³REQUIMTE, LAQV, ICBAS, Universidade do Porto, 4050-313 Porto, Portugal; mfpedro@isa.ulisboa.pt

Study of alternative feeds can provide solutions that consider both current issues and future requirements, with resource usage and their ecological implications. Feedstuffs often directly compete with human-edibles and are produced with arable land. Microalgae have interesting nutritional and industrial properties but require further study. This work evaluated the effects of *Chlorella vulgaris* dietary inclusion and a commercial probiotic (LBC ME10) on growth performance and intestinal physiology of weaned piglets. 120 piglets (Large White × Landrace × Piétrain), with 7.4±1.0 kg live weight (28 d) were blocked by weight in trios and randomly assigned to one of the experimental diets: C – Control diet (wheat/maize/soybean meal); CV2.5 – 2.5% *Chlorella*; CV5 – 5% *Chlorella*; CV2.5P – 2.5% *Chlorella* and Probiotic; and CV5P – 5% *Chlorella* and Probiotic. Piglets were housed in three per pen, in a total of 40 pens (8 pens per treatment) with *ad libitum* feeding and water. After 3 days of adaptation, piglets were fed for 5 weeks, with liveweight and feed intake determined weekly and faecal scores daily. At week 5, one piglet from each pen was slaughtered and gastrointestinal contents collected. Performance indicators, viscosity and pH of intestinal contents were determined and data analysed by ANOVA. Diets did not affect average daily gain (562±56 g/d), average daily feed intake (706±74 g/d), nor feed conversion ratio (1.27±0.12). Faecal consistency, viscosity of intestinal contents in upper small intestine (3.8±0.8 cP) and ileum (4.9±1.4 cP), as well as pH of stomach (4.3±0.7), upper small intestine (5.7±0.2), ileum (6.6±0.2), cecum (5.7±0.3) and colon (6.1±0.2) contents were similar within each sampling site for all treatments. Overall, results indicate that *C. vulgaris* inclusion in weaned piglet diets up to 5% does not affect growth performance nor faecal consistency, suggesting it may be effectively used in piglet diets with good feed acceptance. Further work is needed to understand effects on digestive physiology.

Session 74

Theatre 1

Effects of linseed oil, a brown seaweed and seaweed extract on methane emissions in beef cattleE. Roskam^{1,2}, D.A. Kenny^{2,3}, V. O'Flaherty¹, M. Hayes⁴, A.K. Kelly³ and S.M. Waters^{1,2}¹University of Galway, School of Natural Sciences and Ryan Institute, Galway, H91TK33, Ireland, ²Teagasc Grange, Animal and Bioscience Research Department, Dunsany, Co. Meath, Ireland, ³University College Dublin, School of Agriculture and Food Science, Dublin, D04 C1P1, Ireland, ⁴Teagasc Ashtown, Food Research Centre, Ashtown, Dublin, Ireland; emily.roskam@teagasc.ie

Enteric methane (CH₄) is a by-product of fermentation of feed in ruminants, accounting for two-thirds of Irish agricultural GHGs. Nationally, Ireland are legally bound to reducing agri-GHGs by 25% by 2030, including a 10% reduction in CH₄, thus research into strategies to reduce enteric CH₄, such as anti-methanogenic feed additives particularly those which are naturally derived, has increased. Linseed oil (LSO) is high in PUFAs and can be grown in the European climate. *Ascophyllum nodosum* (ASC), an indigenous brown seaweed that is found in abundance on Irish coastlines, and a treatment of ASC (TR1) generated to improve palatability and shown to include phlorotannins, were assessed for their ability to reduce CH₄ in beef cattle. Seventy two beef bulls were used in this study. The basal diet was 60:40 (w:w) forage:concentrate. Fresh silage was allocated each morning (09:00), and concentrate supplementation containing the feed additive, twice daily (08:00 and 15:00). Following a 7 d covariate period, animals were offered 1 of 4 dietary treatment groups for a 10 week feeding period; Control (CON), LSO, ASC and TR1 (n=18 per group), included at 0, 4, 2 and 2% of DMI respectively. Gaseous emissions were measured using four GreenFeed systems. A mixed model, including fixed and covariate effects of the treatments and a random effect of block, was applied using SAS 9.4. No effects on DMI or FCR were observed ($P>0.05$), however TR1 reduced ADG relative to CON ($P=0.05$). LSO reduced CH₄ g/d and CH₄ g/kg DMI by 18 and 17% respectively ($P<0.05$). TR1 reduced CH₄ g/d by 7% ($P<0.05$), while ASC had no effect on CH₄ emissions ($P>0.05$). Twice daily supplementation of LSO and TR1 are effective strategies to reduce CH₄ production *in vivo*, and have potential for use in pasture-based scenarios with concentrate supplementation at grass.

Effect of whey on methane emission and systemic comparison of *in vivo* and *in vitro* methane formation

H. Luisier-Sutter^{1,2}, M. Terranova³, S.L. Amelchanka³, K. Schweingruber², S. Hug², K. Müller², L. Isele¹, K. Sommer² and M. Schick^{1,2}

¹University Hohenheim, Institute for Agricultural Engineering, Garbenstrasse 9, 70539 Stuttgart, Germany, ²Strickhof, Division Animal Husbandry & Dairy Production, Eschikon 21, 8315 Lindau, Switzerland, ³ETH Zurich, AgroVet-Strickhof, Eschikon 27, 8315 Lindau, Switzerland; helene.luisier@strickhof.ch

Methane is an important greenhouse gas whose global warming potential is 25-times greater than that of carbon dioxide. Ruminants, through their digestive processes, are one of the main sources of anthropogenic methane emissions worldwide. Thus, adaptations in feeding strategies can inhibit methanogenesis. Whey is a by-product of caseation that is abundantly available and cheap. It is rich in water-soluble carbohydrates and proteins and thus an energy-dense feedstuff interesting for animal production. In a former study by Agroscope (unpublished), supplementing grass-fed heifers with whey reduced methane emissions by 37%. However, the mitigating potential of whey in dairy cows has not yet been examined. Therefore, in this study, the inhibitory potential on methanogenesis of whey from Emmentaler cheese production and whey powder was investigated more closely. Four Original Swiss brown dairy cows were used in a 3×3 cross-over design. All 4 cows received a roughage-based ration consisting of grass-silage, grass pellets, hay and maize-silage and were consecutively supplemented with Emmentaler whey or whey powder. The animals were adapted to each diet for a minimum of 2 weeks and then placed in respiration chambers for 2 days methane emission measurements. After exiting the chambers, rumen fluid was extracted from each cow and incubated *in vitro* using the Hohenheim Gas Test (HGT) method. The diets used for incubation were exact replicates of those fed to the cows previously *in vivo*. Preliminary results did not show an effect on *in vivo* methanogenesis of either Emmentaler whey or whey powder. The *in vitro* methane production behaved similarly. Interestingly, when *in vitro* methane production was correlated to the digestive organic matter, the addition of Emmentaler whey produced an inhibitory effect, but only in two of the four animals. Therefore, our *in vitro* results suggest that the effect of whey is dependent on animal-individual characteristics.

Session 74

Theatre 3

Effects of feeding fresh white clover on digestibility and methane emission in lambs

X. Chen¹, S. Ormston², S. Stergiadis², K. Theodoridou³, O. Cristobal-Carballo¹ and T. Yan¹

¹Agri-Food and Biosciences Institute, Hillsborough, BT26 6DR, United Kingdom, ²School of Agriculture, Policy and Development, University of Reading, Reading, RG6 6AR, United Kingdom, ³Institute of Global Food Security, Queen's University Belfast, Belfast, BT9 5DL, United Kingdom; xianjiang.chen@afbini.gov.uk

This study aimed to investigate the effects of dietary inclusion of white clover on feed intake, dry matter (DM) digestibility and enteric methane (CH₄) emissions in sheep fed zero-grazed herbage. Twelve ewe hoggets (Texel, 12 months old) were allocated in a 3 (diets) × 3 (periods) Latin Square design study with 3 weeks/period. The 3 diets were (DM basis): 100% perennial ryegrass (PRG, Control), 70% PRG and 30% medium leaf size white clover (Chieftain, MLS), and 70% PRG + 30% large leaf size white clover (Barblanca, LLS). In addition, each sheep received concentrate pellets at 158 g/day. All lambs were housed as a single group with 6 auto-feeders with CH₄ and hydrogen emissions measured using a GreenFeed unit during day 1 to 14 of each period. Afterwards, sheep were placed in individual metabolism crates for 7 days, with faeces and urine outputs collected in the final 6 days. Pure grass and pure white clover herbage were harvested daily and chopped to a length of 5 cm, totally mixed (for MLS and LLS) and offered to lambs for *ad libitum* twice a day (5% refusal). In each period, concentrate pellets were offered daily to lambs using a GreenFeed unit (5 visits/d) during day 1 to 14 and as top dressing in 2 equal amounts in the am and pm feeding during day 15 to 21. Results showed dietary treatments (Control, MLS and LLS) had no significant effect on DM intake (1.33, 1.45 and 1.46 kg/day), final body weight (68.5, 68.6 and 68.8 kg) or DM digestibility (790, 788, 783 g/kg). Average daily CH₄ emissions for Control, MLS and LLS treatments were 35.6, 37.6 and 37.0 g/day (SED=0.90, P=0.140), respectively. When expressed per kg of DM intake or body weight, CH₄ emissions were not affected significantly by dietary treatments. However, hydrogen emissions were lower (P<0.001) for Control (56.0 mg/day) than for MLS (68.3 mg/day) and LLS (76.1 mg/day). In conclusion, feeding white clover had no significant effect on feed intake, DM digestibility or CH₄ emissions in sheep.

Algae for reducing methane from dairy cows: what expectation with French local resources?B. Rouille¹, H. Marfaing², F. Dufreneix², S. Point³, M. Gillier⁴, R. Boré¹, J. Jurquet¹ and N. Edouard⁵¹Institut de l'Élevage, 149 rue de Bercy, 75595 Paris, France, ²Centre d'Etude et de Valorisation des Algues, 83 Rue de Pen Lan, 22610 Pleubian, France, ³Agro Innovation International TIMAC Agro, 18 av. Franklin Roosevelt, 35400 Saint-Malo, France, ⁴AS Les Trinottières, La Fûtais, 49140 Montreuil sur Loir, France, ⁵INRAE, Institut Agro PEGASE, 16 Le Clos, 35590 Saint-Gilles, France; benoit.rouille@idele.fr

METH'ALGUES project aims at evaluating the anti-methanogenic capacity of algae available on the French coasts with *in vitro* and *in vivo* trials. From a review of the literature, the species *Ascophyllum nodosum*, *Chondrus crispus*, *Fucus vesiculosus*, *Ulva* sp. and *Arthrospira* sp. were identified as candidate to reduce CH₄ emissions thanks to their bromoform and polyphenol concentrations. *In vitro* fermentation tests on rumen juice were carried out on the identified species to select those with the highest methanogenic power and the lowest impact on ruminal fermentations. *F. vesiculosus* and *C. crispus* were selected to proceed the *in vivo* trials. Indeed, *F. vesiculosus* decreased by almost 100% the production of CH₄ but had an impact on fermentations. *C. crispus* reduced CH₄ production and contain bromoforme. Based on these results, an *in vivo* experiment was carried out with *C. crispus* and *F. vesiculosus* as well as a mix of additives (Roullier Group), compared to a control diet, on the performance of dairy cows and enteric methane emissions. The experiment was conducted in a Latin square design with 20 mid-lactation Holstein cows during four 3-week periods. The basal diet consisted of maize silage, dehydrated alfalfa and concentrates. Enteric methane emissions were recorded with a Greenfeed system. Individual DM intake (25.6±0.3 kg DM/cow/day) and milk production (34.6±0.8 kg/cow/day) did not differ between treatments, suggesting that there were no palatability problems with the addition of algae. There was also no difference in enteric CH₄ emission between treatments (533±4.5 gCH₄/cow/day). However, the inclusion rate was lower than expected due to higher-than-expected DM intake levels. As a complement to the first *in vivo* experiment, a second experiment is ongoing testing higher algae inclusion rates for longer periods with two groups of 28 Holstein cows and will end in April 2023.

Session 74

Theatre 5

Managing the rumen microbiome to reduce methane emissions through dietary interventionsG. Pugh¹, O. Cristobal Carballo², T. Yan², C. Creevey¹ and S. Huws¹¹Queen's University Belfast, Institute for Global Food Security/ School of Biological Sciences, 19 Chlorine Gardens, Belfast BT9 5DL, United Kingdom, ²Agri-Food and Biosciences Institute, Large Park, Hillsborough BT26 6DR, United Kingdom; gpugh01@qub.ac.uk

Methane is a natural product resulting from enteric fermentation in the rumen forestomach of ruminants. The majority of CH₄ produced is the rumen derives from the conversion of carbon dioxide and hydrogen. The latter is a consequence of microbial digestion of plant material resulting in formation of volatile fatty acids (VFAs), which are a source of energy for the animal. Increasing concerns over greenhouse gases produced by livestock and their subsequent heating potential has led to an increase in research into mitigating enteric methane from ruminants. Feed additives, such as 3-NOP, have been shown to reduce methane emissions, but apart from 3-NOP, other potential additives have not been studied to a great extent. This study investigated the methane reducing potential of a peroxide-based oxidising inhibitor (OI). *In vitro* studies using a rumen-simulating batch culture system were used to incubate varying inclusion levels of the additives with artificial saliva, rumen fluid and grass silage. Bottles were incubated until the measuring time points (4, 24, 48h). At each time point, pH was measured, gas samples were taken for methane analysis using gas chromatography and liquid samples were analysed for VFAs and ammonia analysis. The OI significantly reduced methane emissions compared with the 0% control when added at 0.375, 0.75, 1.5, 2.25 and 3% ($P=0.014$). The additive is now under investigation at 2.25 and 3% levels in an animal experiment using 60 ewes. Greenfeed data will be available within the next month and individual animal methane emissions can be analysed. The second animal trial will involve feeding the OI to 70 ewes with twin lambs, to investigate the additive effect on early-life programming of the rumen microbiome. For both animal trials, shotgun sequencing of rumen fluid samples will elucidate the changes occurring at microbiome level and mechanisms of action of this compound. Continuation of laboratory analysis, paired with both animal experiments will offer a novel intervention for methane reduction in ruminants.

Production and enteric methane emissions in grazing dairy cows fed flaxseed-based supplement

M.A. Rahman, K.V. Almeida, D.C. Reyes, A.L. Konopoka, M.A. Arshad and A.F. Brito

University of New Hampshire, Department of Agriculture, Nutrition, and Food Systems, 129 Main St, Durham, NH 03824, USA; mdatikur.rahman@unh.edu

The effects of an extruded flaxseed-based supplement (LinPRO-R) on animal production and enteric methane emissions during the grazing season were studied using a randomized complete block design with 18 multiparous and 2 primiparous Jersey cows (128±52 DIM). Cows grazed a mixed grass-legume pasture (herbage allowance = 15 kg DM/cow daily) overnight and were fed partial total-mixed ration (pTMR) during the day. The pTMR were formulated to comprise (DM basis) 37.5% legume baleage and 62.5% of soybean meal/ground corn-based concentrate. Cows were randomly enrolled to 1 of 2 diets: (1) pasture plus pTMR (control = CTRL) or (2) pasture, pTMR, and 6% LinPRO-R (LIN). Ground corn and soybean meal were replaced with LinPro-R in LIN diet. The experiment lasted 12 weeks with 2-week covariate period and 3 sampling periods at weeks 4, 7, and 10. Two GreenFeed units were used to measure gaseous emissions throughout the study. Individual herbage intake was estimated using Cr₂O₃ and *in vitro* DM digestibility of feeds. Faecal grab samples were collected 8 times over 5 d and ruminal fluid was taken once via stomach tubing in each sampling period. Data were analysed using MIXED procedure of SAS with repeated measures over time. Cows on LIN diet were observed to have a lower herbage intake (7.52 vs 6.92 kg/d; $P<0.01$) compared with CTRL, but pTMR intake tended to be greater with feeding LIN (14.9 vs 14.5 kg/d; $P=0.07$). Intake and apparent total tract digestibilities of nutrients were not affected by treatments. Similarly, treatments had no effects on milk yield (mean=27 kg/d), and milk components. However, MUN concentration was lower ($P<0.001$) in LIN (8.38 mg/dl) than CTRL (11.0 mg/dl). No treatment effects were observed for total VFA concentration (mean=90.8 mM), and the molar proportions of acetate, propionate, butyrate, and the acetate:propionate ratio (mean=4.68). Production of CO₂ (mean=10,885 kg/d) and enteric CH₄ (mean=350 g/d), CH₄ yield (mean=15 g/kg of DMI) and CH₄ intensity (mean=10.5 g/kg of ECM) did not differ with feeding CTRL vs LIN. In summary, LinPRO-R fed at 6% diet DM did not affect production and enteric methane emissions in grazing dairy cows.

Session 74

Theatre 7

Effect of feeding brown seaweed and its extract on methane emissions and performance in dairy cattleK.D. Barnes¹, S. Huws¹, T. Yan², X. Chen², M. Hayes³ and K. Theodoridou¹*¹Queens University Belfast, School of Biological Sciences, BT9 5DL, United Kingdom, ²Agri-Food and Biosciences Institute, Large Park, BT26 6DR, United Kingdom, ³Teagasc Food Research Centre, Ashtown, D15 DY05, Ireland; kbarnes06@qub.ac.uk*

Dependent on the species, bioactive components and the dietary inclusion level, seaweed has been shown to reduce enteric methane (CH₄) emissions in ruminants. The study aim was to assess the effect of a brown seaweed species and its extract on dairy cow performance, CH₄ emissions and end-product quality. Hypothesizing that the seaweed extract would elicit a greater response due to the concentrated bioactive components. Fifteen late lactation multiparous barren Holstein-Friesian cows were evaluated in a 3 (diet) × 3 (period) Latin square design experiment with 21 days/period. The 3 groups of cows (5 cows/group) were balanced by parity, bodyweight, and average milk yield. Three total mixed ration diets each contained (dry matter; DM basis) 40% concentrates and, respectively, (1) 60% grass silage (GS) (Control), (2) 56% GS and 4% whole seaweed and (3) 56% GS and 4% seaweed extract. Gas emissions (CH₄ and hydrogen (H₂)) were recorded from day 9-14 of each period via GreenFeed. After day 15, 9 cows (3 cows/treatment) were placed in the metabolism unit individually for 6 days for digestibility measurements. Feed intake, milk production and faecal and urine outputs were recorded, and samples were collected for chemical composition analysis. No significant differences were observed for DM intake ($P=0.067$) and milk yield ($P=0.116$) between and within treatments. Dietary inclusion of seaweed and seaweed extract had no significant effect on CH₄ output in g/day ($P=0.897$), g/kg DMI ($P=0.568$) and g/kg milk ($P=0.240$). The seaweed extract tended to produce lower CH₄ results expressed as g/d and g/kg milk level. No response on H₂ output (g/day) was observed ($P=0.706$). Treatment seaweed samples need to be analysed for chemical composition, polyphenol and phlorotannin content as variations in seaweed quality could have contributed to the lack of response. Additional research needs to be carried out on the bioactive compounds involved and quantity required for consistent and substantial CH₄ reduction in ruminants. SEASOLUTIONS project. European Union's Horizon2020, under grant agreement No 696356.

Establishing conclusive links between the gastrointestinal microbiota and feed efficiency in cattle

M.M. Dycus, U. Lamichhane, C.B. Welch, K.P. Feldmann, T.D. Pringle, T.R. Callaway and J.M. Lourenco
University of Georgia, Animal and Dairy Science, 425 River Road, 30602, USA; jefao@uga.edu

The gastrointestinal tract of ruminant animals hosts a myriad of microorganisms that can ferment feedstuffs to produce energy for the host animal. The efficiency of this gastrointestinal microbial fermentation can differ between animals and impact animal productivity. Previous findings have indicated that there are associations between the host microbiota and feed efficiency; however, the scope of conclusions drawn are limited due to sample size constraints. Thus, this study was performed to strengthen the understanding regarding the link between the gastrointestinal microbiome and feed efficiency in ruminants, through utilizing a large sample size. Ruminal and faecal samples were collected from 1,480 Angus bulls located at 8 different farms in the United States. Every bull had records of performance and feed intake, which allowed calculation of their individual feed efficiency performance. The collected samples were subjected to extraction/purification and sequencing of microbial DNA in order to determine their microbial composition, evenness, richness, and diversity. As expected, the ruminal and faecal environments had distinct microbial richness, diversity, and presence of specific taxa (e.g. *Fibrobacter* and *Prevotella*). However, despite these substantial differences between the ruminal and faecal environments, both contained taxa that were significantly associated with feed efficiency, indicating that the microbiota of those two environments play important biological roles in the conversion of feedstuffs into usable products for the animal. Furthermore, it suggests that the manipulation of the gastrointestinal microbiota can be a viable approach for improving feed efficiency, and potentially decrease greenhouse gas emissions by cattle.

Session 74

Theatre 9

Variations in bulk milk urea content on dairy farms in Flanders, Belgium in 2019-2021

J. Vandicke¹, K. Goossens¹, Z. Lipkens², T. Vanblaere² and L. Vandaele¹

¹Flanders Research Institute for Agriculture, Fisheries and Food (ILVO), Scheldeweg 68, 9090 Melle, Belgium,

²Melkcontrolecentrum Vlaanderen vzw (MCC), Hagenbroeksesteenweg 167, 2500 Lier, Belgium; jonas.vandicke@ilvo.vlaanderen.be

Animal production is viewed as one of the main drivers of the nitrogen excess and eutrophication of nature reserves in Flanders, Belgium. Ammonia from manure plays a crucial role and is formed when urea in urine and urease in faeces react. Hence, lowering the urea excretion in urine can reduce ammonia emissions from manure. This can be achieved by reducing the amount of crude protein in the ration of dairy cattle. Feeding low-protein diets could therefore be a valid method for dairy farmers to prove that they are reducing ammonia emissions, if diet composition can be regularly monitored and controlled. However, today, that is not the case. Alternative ways of evaluating the protein content of the ration are therefore needed. Milk urea could be used to this end, since milk urea content is known to be largely driven by the protein content of the ration. Furthermore, milk urea content of every bulk milk collection can be analysed in Flanders by the Milk Control Centre Flanders (MCC), so data can readily be made available for the farmer. In this research, we determined the inter- and intra farm variability in bulk milk urea content on Flemish dairy farms and evaluated its potential as a predictive tool for the protein content of dairy rations. We analysed data from MCC from 1,652,470 milk collections from 3,881 Flemish dairy farms throughout 2019, 2020 and 2021. Mean bulk milk urea content over these three years was 229.6 ± 51.8 mg/l, with higher average values in summer (244.6 ± 53.1 mg/l in August) compared to winter (208.0 ± 51.9 mg/l in December), and brief peaks in milk urea content as a response to heatwaves. However, most of the variation of the milk urea content on individual farm level could not be explained by known variables such as date or temperature. We conclude that milk urea content cannot be used as a standalone predictive tool for the protein content of dairy rations. Further research will determine which additional parameters or analyses are needed to easily monitor the protein content of the ration in a cost-effective, practical and reliable manner.

Impact on environment and performance of the replacement of soybean meal in post-weaning pig dietsE. Royer¹, P. Pluk², J. De Laat², G. Binnendijk¹, K. Goris² and P. Bikker¹¹Wageningen University & Research, Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands,²Cargill Animal Nutrition, Global Innovation Center, Veilingweg 23, 5334 LD Veldriel, the Netherlands; eric.royer@wur.nl

Imported soybean meal (SBM) is more widely used in post-weaning than fattening pig feeds. A study tested the hypothesis that a more circular formulation could improve the environmental print of feed but would affect piglet performance and gut health, nutrient digestibility and nitrogen (N) and phosphorus (P) efficiency. 240 weaned pigs (6.5±0.9 kg) were allocated to 6 dietary treatments. A control diet (C) with 14% SBM was compared to diets in which SBM was totally replaced by oilseed meals, i.e. 12% sunflower meal, 12% rapeseed meal and 3% linseed meal (Oil), or legume seeds, i.e. 14% peas, 13% lupines and 13% faba beans (LS), or a mixture of equal amounts of two of these three diets (C-Oil, C-LS, Oil-LS). Diets contained 9.4 to 9.5 MJ NE/kg and 1.12 g dig lys/MJ NE and were given *ad libitum* from 7 d to 40 d after weaning. Performance and faecal consistency were registered. For treatments C, Oil and LS, faeces were collected on d 35 and 36 to determine apparent total tract digestibility (ATTD), and two piglets per pen were slaughtered at d 41 or 42 to collect contents and segments of the digestive tract. The carbon footprint (CFP) was calculated using the Nevedi-GFLI database, including land use. CFP was lower with circular diets (1,011, 778 and 867 g CO₂eq/kg for C, Oil and LS diets, respectively). Dietary treatments had no effect on growth performance and faecal consistency ($P>0.05$). The LS diet enhanced the weight of empty stomach, full caecum, and full or empty colon. Oil, LS and Oil-LS diets had lower ATTD than C diet for OM and crude protein ($P<0.001$). But LS diet had lower apparent ileal digestibility than C diet for crude protein ($P=0.03$). Non-starch polysaccharide ATTD was the highest for LS diet and the lowest for C diet ($P<0.001$). LS and Oil diets had the highest and the lowest ATTD for P and ash, respectively ($P<0.001$). N excretion per kg of gain was similar among treatments ($P>0.05$). In conclusion, the replacement of SBM by oilseed meals or legume seeds can improve the sustainability of post-weaning diets without reduction in piglet performance.

Simulating pig multiperformance in contrasted breeding systems using an individual-based modelE. Janodet^{1,2}, F. Garcia-Launay¹ and H. Gilbert²¹INRAE, PEGASE, 35590 Saint-Gilles, France, ²INRAE, GenPhySE, 31320 Auzeville-Tolosane, France; estelle.janodet@inrae.fr

Feed accounts for more than half of production costs and environmental impacts of the pig industry. The use of a greater diversity of feedstuffs, often more local but less digestible is one lever to mitigate these impacts. However, current pigs value better energy-rich and easy to digest diets. Thus, the multiperformance of different pig profiles in production systems differing for their feeding constraints should be characterized. The objective of this study is to propose a modelling approach to evaluate how different production systems affect the multiperformance of different individual pig profiles. Four contrasted systems were considered: (1) conventional system (CS) representative of standard practices in French pig farms, (2) CS excluding raw materials with high environmental impacts and including low-cost opportunity feedstuffs, (3) CS with local feedstuffs, and (4) an organic system with fodder. A dataset of 1,586 InraPorc[®] pig profiles was established from a previous trial. Feeds were formulated to cover individual nutritional requirements given the constraints of each system. Two formulation objectives were applied: a least-cost formulation, as commonly used, and a multi-objective formulation that minimizes feed environmental impacts under an economic constraint on feed price. We simulated, in each system and for each formulation objective, responses from these 1,586 pig profiles, using a previously published individual-based model of the pig fattening unit. The model provides animal performance and environmental impacts evaluated through a cradle-to-farm-gate life cycle assessment (LCA): climate change, resource use (fossils, minerals and metals), acidification, marine, freshwater and terrestrial eutrophication and land occupation. Based on these indicators, the 1,586 pigs can be ranked on their technical and environmental performances in each system, to identify which individual profiles fit best in each breeding system, and if G×E occurred. To conclude, combining system and individual level modelling provides a strategy to predict the multiperformance of pigs in a variety of systems, that could later be used to identify individual profiles adapted to each system.

Environmental impacts of substituting soybean with rapeseed or haemoglobin meal in broiler dietsV. Wilke^{1,2}, J. Gickel¹, A. Abd El-Wahab² and C. Visscher²¹University of Veterinary Medicine Hannover, Foundation, Science and Innovation for Sustainable Poultry Production (WING), Heinestraße 1, 49377 Vechta, Germany, ²University of Veterinary Medicine Hannover, Foundation, Institute of Animal Nutrition, Bischofsholer Damm 15, 30173 Hannover, Germany; julia.gickel@tiho-hannover.de

As soybean meal (SBM) shows negative impacts on the environment, a partial substitution has a benefit on the environment. In this study, 120 broilers were fed with three different diets (similar energy content) containing only SBM (32.5%) or SBM and an alternative protein source (APS) (14.5% rapeseed meal [RSM] or 4.5% haemoglobin meal [HBM]) from day 8 to 44. The initial and final body weight and feed intake was measured for the trial period. The assessment of the environmental impact of 1 t feed and 1 t carcass weight (according to the ISO 14040) was performed using the online software application Opteinics® (BASF Lampertsheim GmbH, Lampertsheim, Germany), which is based on the Global Feed LCA Institute (GFLI) database. The impact on climate change was 1.9 t CO₂ eq per t feed and was about 20% lower with a partial reduction of SBM by RSM or HSM (1.5 t CO₂ eq per t for both). A lower impact of the diets with APS was also found on eutrophication (marine/freshwater), land use and resource use. The impact of 1 t feed on acidification, eutrophication (terrestrial), particulate matter and water use was higher for the diet with RSM and lower for the diet with HBM, for ozone depletion the impact was higher for both diets with alternative protein sources (compared to SBM). The body weight of the broilers of all diets was similar at day 8 but different at day 44 (SBM: 2.8 kg; RSM: 2.9 kg; HBM: 2.5 kg). The FCR was 1.68 (SBM/HBM) and 1.71 (RSM). The impact on climate change related to carcass weight was 4.9 t per t (excluding day 1-7) and was reduced by 16% with a partial substitution of SBM by RSM or HBM. A lower impact of the meat produced with APS was also found on marine eutrophication, land use, particulate matter and resource use. The impact per t meat on acidification, eutrophication (freshwater/terrestrial) and ozone depletion was higher with an inclusion of RSM or HBM. The impact on water use per t meat was higher using the diet with HBM and lower using the diet with RSM (each compared to SBM).

Poster 13

Manipulating dietary degradable protein and starch to increase nitrogen efficiency in dairy cows

P. Piantoni, Y. Roman-Garcia, C. Canale, M. Messman and G. Schroeder

Cargill Animal Nutrition and Health, Innovation Campus, 10383, 165th Avenue Northwest, Elk River, MN 55330, USA; paola_piantoni@cargill.com

The objective of this experiment was to evaluate the effect of decreasing degradable protein (RDP) and increasing starch content as strategies to increase N efficiency (NE). Eighteen multiparous Holstein cows (51±8 kg/d milk yield; 138±78 DIM; mean ± SD) were used in a split-plot design experiment with a randomized complete block on the whole plot and a 3×3 Latin square on the sub-plot. Main plot was dietary starch level (20 and 28% of DM), and sub-plot was RDP level (8.5, 9.75, and 11% of DM). Treatment periods were 28-d long, with the last 7 d used for data collection. The starch content difference was obtained by replacing soyhulls with dry finely ground corn. Dietary CP increased with RDP and ranged from 14.2 to 16.2% of DM. RDP differences were obtained by replacing blood meal and rumen-protected amino acids with urea and soybean meal. All diets covered estimated requirements of essential amino acids. No interaction was observed between main effects for NE. Regardless of starch content, increasing RDP did not affect milk yield but 9.75% RDP decreased intake and increased feed efficiency (both $P_{\text{quad}} < 0.01$). Increasing RDP decreased NE (32.4, 31.6, and 28.0%; $P_{\text{quad}} < 0.01$) but did not affect milk protein yield. Increasing RDP linearly decreased milk fat content (3.65, 3.51, and 3.48%) and yield (1.67, 1.59, and 1.58 kg/d), and increased MUN (9.99, 11.9, and 13.9 mg/dl; all $P < 0.01$). Consequently, increasing RDP linearly decreased energy-corrected milk yield (47.1, 46.1, and 45.9 kg/d; $P = 0.03$). Regardless of RDP content, increasing dietary starch did not affect intake or energy-corrected milk yield but tended to increase milk yield ($P = 0.08$), and increased NE (32.7 vs 28.6%; both $P = 0.01$). Increasing starch decreased milk fat content (3.25 vs 3.84%) and MUN (11.3 vs 12.6 mg/dl; both $P = 0.02$) but did not affect milk fat yield or protein content and yield. The 23% decrease in RDP increased NE by 16%, and the 40% increase in starch increased NE by 14%. Therefore, decreasing RDP, while balancing for amino acids, was a more effective strategy to increase NE compared with increasing dietary starch content. Results also suggest that combining both strategies increased NE the most.

Substitution of soybean meal with canola meal in dairy cow diets: effect on enteric methane emissionC. Benchaar¹ and F. Hassanat²¹Agriculture and Agri-Food Canada, Sherbrooke R&D, 2000 rue college, Sherbrooke, QC, J1M 1Z3, Canada, ²Agriculture and Agri-Food Canada, Québec R&D, 2560 Bd Hochelaga, Québec, QC, G1V 2J3, Canada; chaouki.benchaar@agr.gc.ca

A number of studies have shown that replacing solvent-extracted soybean meal (SBM) with solvent-extracted canola meal (CM) in dairy cow diets increases dry matter intake (DMI) and milk production. However, information of such dietary changes on enteric methane (CH₄) emissions are scarce. Accordingly, this study was undertaken to determine the effects of iso-nitrogenous replacement of SBM with CM on CH₄ emissions and intensity and milk production. Sixteen multiparous lactating Holstein cows (DIM=116±23; milk yield=47.5±4.9 kg) were used in a replicated 4×4 Latin square (35-d periods; 14-d adaptation) and fed (*ad libitum*) either a control diet (0%CM) or diet supplemented with 8, 16, or 24% CM, on a dry matter (DM) basis. The forage:concentrate ratio was 52:48 (DM basis) and was similar among the experimental diets. Canola meal was included in the diet at the expense of SBM and soybean hulls, whereas the proportions of the other diet ingredients were kept the same. Methane production (respiration chambers) and milk production were determined over 5 and 7 consecutive days, respectively. Linear and quadratic contrasts (Proc MIXED; SAS 9.4) were used to determine effects of CM levels on variable responses. Significance was declared at $P \leq 0.05$. Dry matter intake increased linearly with increasing CM proportion and the increase was more pronounced for cows fed 24% CM (+1.9 kg/d) compared with cows fed 8% CM (+1.1 kg/d) or 16% CM (+1.5 kg/d) diets. Production of energy-corrected milk (ECM) increased linearly as CM proportion increased in the diet (+1.0, +1.6, and +2.2 kg/d for 8, 16 and 24% CM, respectively). Daily CH₄ emission decreased linearly with increasing CM proportion in the diet (489, 475, 463, and 461 g/d for 0, 8, 16 and 24% CM, respectively). Also, CH₄ yield (% gross energy intake), and CH₄ emission intensity (g CH₄/kg ECM) decreased linearly by up to 14 and 10%, respectively, at the highest CM dietary inclusion level. This study demonstrates that partial or full substitution of SMB with CM can successfully mitigate enteric CH₄ emission and intensity while enhancing animal productivity.

Does better circularity in livestock require a paradigm shift?A. Mottet¹ and M. Benoit²¹FAO, Viale delle Terme di Caracalla, 00153 Rome, Italy, ²INRAE, UMR Herbivores, HerbiPôle, 63122 Saint-Genès-Champagnelle, France; anne.mottet@fao.org

Livestock contribute to food security by supplying essential macro- and micro-nutrients, providing manure and draught power for agriculture, and generating income for households. But they also consume food edible by humans and graze on pastures that could be used for crop production. Livestock, especially ruminants, are often seen as poor converters of feed into food products. However, about 86% of the dry matter consumed in the global livestock sector are made of materials that are currently not eaten by humans. Livestock therefore play a key role in the bio-economy by converting forages, crop residues and agricultural by-products into high-value products and services. The production of global feed requires 2.5 billion ha of land, which is about half of the world agricultural area. Most of this area, 2 billion ha, is grassland, of which about 1.3 billion ha cannot be converted to cropland (rangeland). This means that 57% of the land used for feed production is not suitable for food production. However, the current global energy scarcity is leading to a sharp increase in its price and indirectly in the price of feed. Therefore, animal production that relies on cereals, pulses and cultivated forage is experiencing a sharp loss of competitiveness, which can lead to increased prices for milk, meat and eggs, a drop in consumption and a loss of incomes for farmers, as the increased price of outputs won't compensate the increase in input prices. To avoid this scenario, we proposed that two consequences seem unavoidable for livestock farming systems: (1) the reduction of arable land dedicated to the production of animal feed; and (2) a switch to feeding strategies based on low opportunity land and raw materials from which livestock production is most likely to benefit, i.e. low-quality resources that are difficult to harvest. This would result in a reduction in animal numbers and a redistribution of livestock in agricultural landscapes, a change in the types and traits of farm animals, an adaptation of supply chains and a rebalancing of diets. Such an evolution of livestock farming should also respond to other major challenges, such as climate change and feeding humanity.

More or better to obtain sustainable food production?H.F. Olsen¹, H. Møller², S. Samsonstuen¹, M.T. Knudsen³, L. Mogensen³ and E. Røös⁴¹NMBU, Box 5003, 1430 Ås, Norway, ²NORSUS, Stadion 4, 1671 Kråkerøy, Norway, ³AU, N. Ringgade 1, 8000 Aarhus, Denmark, ⁴SLU, Box 7070, 750 07 Uppsala, Sweden; hanne.fjordingby@nmbu.no

To ensure future food security, each country should utilize its resources to provide food to society. In current food systems, the focus is on improving the technological and biological production efficiency to produce as much food as possible to cover the increasing demand for food. Due to the risk of depleting nutrients and creating imbalance in the natural ecosystems, it is necessary to discuss the long-term effects of food production strategies. In this study, we explored three different scenarios for livestock production in Norway, which is a country with limited arable land: business as usual (BAU), maximizing the livestock production on domestic feed resources (MaxProd), and best possible utilization of domestic feed resources, including waste and by-products (BestProd). The aim was to discover how the scenarios performed in terms of use of arable land, protein production, environmental impacts including biodiversity, and resource efficiency. The scenarios were discussed with year 2040 as a time frame. MaxProd and BestProd included novel feed ingredients, such as yeast and insects, but did not allow for imported feedstuff as in BAU. An important difference between BestProd and the two others was that BestProd required using all suitable, arable land to produce plants for human consumption to reduce the feed-food competition and that BestProd also prioritized circular food production. The BAU scenario produced the largest amount of animal protein, whereas BestProd produced the lowest. In addition, the BestProd scenario had the highest climate impact due to the high share of ruminants. On the other hand, the BestProd scenario had the lowest land occupation per year but utilized most of the available biomass. Also, the land use ratio indicated that BestProd had the highest level of resource efficiency and the lowest potential loss of biodiversity. In total, we conclude that livestock production using domestically available biomass in best possible way, using livestock for recycling waste and by-products, will produce somewhat less animal protein and give a trade-off for climate change but will overall contribute to a future sustainable food production system.

Session 75

Theatre 3

Satisfying meat demand and avoiding excess manure nitrogen at the regional scale in ChinaF. Accatino¹, Y. Li² and Z. Sun²¹INRAE, AgroParisTech, Université Paris-Saclay, UMR SADAPT, 22 place de l'agronomie, 91120, France, ²Institute of Geographic Sciences and Natural Research Research, Chinese Academy of Sciences, Beijing, 100101, China, P.R.; francesco.accatino@inrae.fr

Circularity at the regional scale requires nitrogen (N) excess avoidance through crop-livestock. This could contrast with satisfying local meat demand. We aimed at: (1) classifying 261 eastern China regions according to their ability/inability to satisfy local meat demand and their deficiency/excess of manure N; (2) analysing scenarios of decreased livestock numbers. For (1) we compared meat demand (based on healthy diet recommendations) with meat production (based on livestock abundance and productivity data) and manure production (based on livestock abundance and productivity data) with manure demand (based on crop and nitrogen crop demand data). For (2) we set livestock quantities in each region to some key levels: the level meeting local meat self-sufficiency (scenario A), the level meeting local manure demand (scenario B), the level meeting local meat self-sufficiency in case manure N is not in excess, otherwise manure N excess avoidance is prioritized (scenario C). Concerning (1), our scenario showed that 15% of the analysed regions could meet meat self-sufficiency without manure N excess, however in 76% of the regions meat self-sufficiency was met but while causing manure N excess. Concerning (2) scenario C was the best performing, with 50% of the regions that could meet meat self-sufficiency (according to healthy diet recommendations) while avoiding manure N balance. This scenario achieved, at the level of the whole eastern China a global meat self-sufficiency and avoidance of N excess. Our results suggested that, while a trade-off exists between achieving meet self-sufficiency and avoiding excess of manure N, livestock is in excess in many Chinese regions and, in order to improve the allocation of livestock quantities in the regions, it is a good strategy to prioritise the avoidance of manure N excess. Improving circularity requires solutions for increasing the use of manure nitrogen as substitute of synthetic fertilizer in order to soften the trade-off. Further perspectives should also take into account the self-sufficiency of feed.

Role of livestock in the nutrient and carbon metabolism of the agri-food system of a tropical island

M. Alvanitakis¹, V. Kleinpeter¹, M. Vigne², A. Benoist³ and J. Vayssières¹

¹CIRAD, Selmet, 7 chemin de l'IRAT, 97410 Saint-Pierre, Reunion, ²CIRAD, Selmet, BP 319, 110 Antsirabe, Madagascar,

³CIRAD, BioWooEB, 40 Chem. Grand Canal, 97490 Saint-Denis, Reunion; manon.alvanitakis@cirad.fr

Increasing nutrient and carbon circularity and use efficiency is a leading topic in the search for more sustainable agri-food-waste systems (AFWS). In this study, we analyse the nitrogen (N), phosphorus (P), and carbon (C) metabolism of the AFWS in Reunion tropical Island to assess the livestock contribution to AFWS circularity, self-sufficiency, and use-efficiency. The livestock sector on Reunion Island relies heavily on imported feeds: 72, 83 and 56% of the N, P, C consumed by animals come from external sources. As a result, livestock is responsible for 36, 44 and 39% of N, P, C imports at the AFWS level. It is also responsible for 17 and 13% of respectively N & C atmospheric losses from the AFWS. On the other hand, livestock is involved in circularity as it plays a recycling supplier role. Among flows of secondary products between all sub-systems, 27, 35 and 17% of N, P and C flows come from livestock. However, this recycling is inefficient. Manure spreading is responsible for 40% of N losses from croplands to the environment. Manure application substitutes only partially the import of mineral fertilizers, which leads to nutrient surpluses at crop level (+90 kg N/ha and +40 kg P/ha) and low nutrients use efficiency of the crop sector (37 and 30% respectively for N and P). Moreover, only 36, 22 and 17% of the N, P and C contained in slaughterhouse and meat cutting wastes are recovered by the waste sector. The rest is burned or sent to landfill. Several livestock-based levers of improvement were identified, including: (1) recycling material burned or sent to landfill as feeds, bedding materials or substrates for manure co-composting; (2) limiting N losses during manure management and spreading; and (3) adjusting feed and fertiliser inputs to livestock and crop needs. Those reorganization of nutrient and carbon flows can potentially reduce the AFWS impacts on the environment. The nutrient and carbon metabolism approach will be helpful to feed a life-cycle assessment of the AFWS with and without improvement levers.

State and regional nitrogen and phosphorus balances to assess manure sheds in New York State

O.F. Godber¹, K. Workman² and Q.M. Ketterings¹

¹Cornell University, Nutrient Management Spear Program, Department of Animal Science, Ithaca, NY, 14853, USA,

²Cornell University, PRO-DAIRY, Ithaca, NY, 14853, USA; ofg6@cornell.edu

New York (NY) has a large dairy industry that produces considerable amounts of manure that is applied to cropland. This provides multiple benefits, opportunities, and challenges for attaining a climate resilient, environmentally sustainable, and economically viable agricultural sector. State and regional nitrogen (N) and phosphorus (P) balances illustrate the circularity of the NY agricultural sector, help to identify the feasibility of future improvements to reduce environmental impact, and increase the sustainability of agriculture. Here, we present N and P balances for agricultural cropland in NY, derived from crop and livestock data from the most recent (2017) United States (US) Census of Agricultural survey, and fertilizer sales data from the US Geological Survey. We present an evaluation, at the state, regional and county level, of (1) the most recent (2017) N and P balances, (2) the impact of improved nutrition on N and P excretion rates by dairy cows on N and P balances, and (3) the impact of manure application to legumes on N and P balances. Results show NY balances of 11.7-40.1 kg N/ha, and 2.6-10.8 kg P/ha, depending on the amount of legume acres that receive manure. State, regional and county-based balances reflect that manure is used as a nutrient source, offsetting N and P fertilizer use, and, with a few exceptions, there is sufficient land base to recycle manure.

Circularity in livestock production: from theory to practiceE.M. De Olde^{1,2}, O. Van Hal², A. Groenewoud² and I.J.M. De Boer²¹Wageningen Economic Research, Wageningen University & Research, P.O. Box 29703, 2502 LS The Hague, the Netherlands, ²Animal Production Systems group, Wageningen University & Research, P.O. Box 338, 6700 AA Wageningen, the Netherlands; evelien.deolde@wur.nl

Our global food system has a substantial impact on the environment through the use of natural resources, emissions to soil, air and water and the contribution to biodiversity loss. To safeguard the health of our (agro)ecosystems and avoid losses and waste, a transition towards a more circular food system has been proposed in science and policy. A recent publication presented five ecological principles for a circular bioeconomy (i.e. safeguard, avoid, prioritize, use and entropy). As such, circularity does not only imply the effective use of resources such as land, but starts with safeguarding the health of (agro)ecosystems to protect its regenerative capacity. This talk will discuss the implications of the concept of circularity and its principles for the livestock sector. For instance, how can the livestock sector contribute to healthy (agro)ecosystems and what is the impact of prioritizing biomass for human needs? The circularity concept and its principles have so far been used mostly theoretical, while (policy) pressure to measure the circularity performance of individual farms is increasing. Translating circularity to the farm level, however, raises many questions such as: What indicators can be used to gain insight into circularity at farm level? What data is available, or needed, to measure circularity? How does circularity at farm level relate to circularity at different spatial and organisational levels? Can indicators for circularity be integrated in environmental impact assessments? We will reflect on these questions using our first findings from a study on evaluating circularity in dairy farming. We will conclude this talk with some reflections on barriers and opportunities in moving towards a more circular and sustainable food system.

Session 75

Theatre 7

The perspective of young farmers on circular agriculture: definition, implementation and barriersA.G. Hoogstra, H. Geerse, I.J.M. De Boer, M.K. Van Ittersum, A.G.T. Schut, C.J.A.M. Termeer and E.M. De Olde
Wageningen University & Research, Animal production systems, Droevendaalsesteeg 4, 6708 PB Wageningen, the Netherlands; anne.hoogstra@wur.nl

Both in policy and science, the concept of circular agriculture has gained popularity as a way to improve the sustainability of agriculture. In the transition to circular agriculture, farmers and especially young farmers play a key role, however, insight into their perception of circular agriculture is lacking. Therefore, the aim of this study is to examine the perspective of young farmers in the North of the Netherlands with regard to the transition to circular agriculture. We conducted an online survey and gathered insights into their view and definition, interest in circular practices and perceived barriers with regard to circular agriculture. In this study, the focus is on dairy, mixed and arable farmers, who (co)own a farm in the provinces of Friesland, Groningen and Drenthe with a maximum age of 35 years old. In total, there were 53 respondents of which 32 arable, 16 dairy and 5 mixed farmers. The results of the survey show that young farmers vary in their perception of circular agriculture as a solution for agricultural issues in the Netherlands. This variation was also observed in their definition of circular agriculture, although there was a consensus about the themes of the recycling of nutrients in animal manure and stimulating soil vitality. The results concerning the application and interest of farm practices that are associated with circular agriculture, showed that many farmers already apply or are interested in circular farming practices. The most applied practices were precision agriculture and the production of protein crops and the most interest was for low input management of nutrients and chemicals and application of field borders. Multiple barriers were highlighted in the transition towards circular agriculture, mainly (uncertainty) regarding regulations. The insights of this paper provide valuable information for the transition to circular agriculture as it is important to offer a clear perspective for young farmers and stimulate them to adopt circular practices.

Companion modelling approach for collective nitrogen management in a French municipality*G. Martel¹, F. Garcia-Launay² and V. Souchère³**¹INRAE, UMR BAGAP, 55 rue Rabelais, 49100 Angers, France, ²INRAE, UMR PEGASE, 16, le clos, 35590 Saint-Gilles, France, ³INRAE, UMR SADAPT, Campus Agro Paris Saclay, 91120 Palaiseau, France; gilles.martel@inrae.fr*

The specialization of agriculture has led to a disruption of nutrient cycles. Many studies ask for interactions between farms at the territorial level. But the implementation of collective solutions at this level requires the involvement of a diversity of stakeholders who are not all in direct interaction. This is why we have carried out a companion modelling approach to support a municipality to think about the collective management of nitrogen, particularly from effluents. The support approach involved elected officials, advisory and support organizations, associations, cooperatives and agri-food industries and a variety of farmers. From individual interviews and a collective restitution we produced a representation of the actors, resources, dynamics and interactions necessary to talk about nitrogen management in the territory. On this topic, the stakeholders individually identify 38 types of people involved and 53 resources mobilized. Two dynamics stand out: the presence of imported nitrogenous elements in the territory and the decrease in the number of livestock in favour of cultivated surfaces on increasingly large farms. These dynamics make the stakeholders of the territory put forward the solution of the biogas production facility which can convert these inputs into digestate usable on the cultures, even if several fears around the composition of these digestates exist. Nevertheless, with the decrease in the number of animals, farms that do not use all their effluents are rare, limiting the possibilities of direct interactions between farmers and cereal growers on the territory. This work therefore highlights the importance of off-farm actors for nitrogen management at the territorial level, but it also questions the role of farmers in collective management and the resilience of these tools in the event of a decrease in livestock production. These aspects will be the objectives of the role-playing game currently being prepared, which will allow farmers and elected officials to reflect on possible options for better nitrogen management on the territory.

Historical transformation of crop-livestock integration and its drivers in a French region*R. Pedeches¹, C. Aubron², S. Bainville² and O. Philippon²**¹Université de Montpellier, 163 rue Auguste Broussonet, 34060 Montpellier, France, ²Institut Agro Montpellier, 2 place Viala, 34060 Montpellier, France; remi.pedeches@laposte.net*

The combination of crops and livestock can help reduce the negative impact of agriculture on the environment. Forage crops can be included in the rotation of non-fodder crops and play an important agronomic role, thus reducing the use of chemicals; if animals consume locally produced feed, nutrient flows can be more closed. The decline in the number of mixed crop-livestock farms and the factors behind this decline have been documented in many regions. However, some authors advocate going beyond the criterion of mixed crop-livestock farming and taking into account the functional interactions themselves. In this study, we aim at studying the recent transformations of crop-livestock interactions at the scale of a small agricultural region and at understanding their origin. To trace these interactions and their ecological roles, we had to reconstruct the overall functioning of past and present farms in a region of southwestern France. The required data were collected through 80 interviews to retired and active farmers. In 1955, most of the farms were mixed-crop-livestock farms, self-sufficient in feed and bedding, with forages included in the rotations. From 1960 onwards, the specialization of farms into livestock farms and grain farms isolated crops from livestock, which on the one hand separated forage and non-forage crops in distinct farms and on the other hand created open flows of concentrates between farms and even to beyond the region. However, crop-fodder rotations vanished on many mixed farms: indeed, some of them no longer have ruminants, but only monogastric animals. Besides, in farms with cattle, fodder and cereal crops are often produced on separate lands. We then explain these changes by the evolution of prices, policies, the development of irrigation infrastructures, and the soil and climate characteristics of the area.

Livestock: option or necessity? Changes of energy flows in an Indian village, 1950-2022C. Hemingway¹, C. Aubron¹ and M. Vigne²¹L'Institut Agro Montpellier, SELMET Research Unit, 2 Place Pierre Vialla, 34060 Montpellier, France, ²CIRAD, SELMET Research Unit, Campus international de Baillarguet ou Avenue Agropolis, 34398 Montpellier Cedex 5, France; charlotte.hemingway@supagro.fr

Since the 1950's, agriculture in India has undergone many 'revolutions'. In Anantapur, a dryland area in Southern India, the Yellow, Green and White revolutions focused on boosting the production of groundnut, rice and milk respectively. Those revolutions have not impacted farms in the same way but the role of livestock has changed substantially, modifying the circularity of energy at different levels. We combine the comparative agriculture and the territorial metabolism approaches to study the energy transition of the agriculture of a village in Southern India from the 1950's to today. For both time steps we look at changes of energy flows at farm and territorial levels, assessing the size and nature of the flows of energy (human and animal labour, gross energy of biomass and fossil energies) entering, circulating and exiting the farm and the territory. We rely on a cycling index to estimate the proportion of total internal flows among the total flows involved, and on a fossil energy consumption index to assess the dependency of farms on non-renewable external resources. Circularity of energy within farms has declined but has been reshaped at the scale of the territory. While energy flows are at both periods driven to a large extent by livestock, the nature of circularity has been modified by the use of fossil fuels. In the 1950's circularity and livestock was a *sine qua non* for agricultural production: livestock served for ploughing, lifting water for irrigation, producing food and manure. Today flows of energy are an outlet of agricultural production: livestock is no longer a necessity but rather an option for farms aiming to specialise in either milk or meat production. In the current configuration, livestock is fed partly on co-products thus fuelling the circularity of the territory. But as the cultivation of crops requires fuel and electricity, the current circularity depends on 'pulses' of external fossil energy to be maintained. We therefore show that livestock-based circularity is not always an indicator of sustainable land-use.

Session 75

Poster 11

Developing livestock-based circularities for healthy and sustainable territories: the CLiMiT projectT.T.S. Siqueira¹, J.-M. Sadaillan¹, M. Vigne², J. Veyssières¹, A. Benoist³ and M. Miralles-Bruneau¹¹Cirad – Mediterranean and Tropical Livestock Systems Unit (SELMET), Environments and Societies, 7 chemin de l'IRAT, 97410, Reunion, ²Cirad – Mediterranean and Tropical Livestock Systems Unit (SELMET), Environments and Societies, Antsirabe 110, FIFAMANOR, 319, Madagascar, ³Cirad- Biomass, Wood, Energy, Bioproducts (UPR BioWooEB), Environments and Societies, 40, chemin de Grand Canal, 97443 Saint Denis Cedex 9, Reunion; siqueira@cirad.fr

The implementation of livestock-based circularity strategies contributes to creating healthy and sustainable territories thanks to the: (1) reduction of environmental impacts through synergies in nutrient and energy flows, soil carbon storage in grasslands, organic matter recycling, the transformation of non-edible biomass in food, etc.; and (2) socio-economic development and food security by the creation of wealth and jobs. Despite the recognition of the place of livestock in sustainable development, actors seem to be sparsely or poorly equipped with tools to identify potential and to co-design circular economy projects adapted to their territories. The main scientific objective of the CLiMiT project is to develop and test a toolbox to support actors in the construction of livestock-based circularity projects considering territorial specificities and actors' preferences. Our project adopts a research-intervention approach with a transformative goal. We place the circularity paradigm as the primary vector of territorial development compatible with a reduction in greenhouse gas emissions. We propose an interdisciplinary and comprehensive 3-step approach: (1) characterizing the socio-ecological functioning of territories to better understand them; (2) modelling the different biomass and nutrient flows to assess the environmental and socio-economic impacts of the territories; (3) co-design with local stakeholders technical and organizational solutions for the implementation of circular economy projects including livestock farming.

Co-design of a scenario of biomass valorisation within a circular approach on Reunion IslandR. Youssouf^{1,2}, E. Cavillot², A.-L. Payet², T.T. Da Silva Siqueira¹ and J.-P. Choisis³¹CIRAD, 7, chemin IRAT, 97410, Saint-Pierre, France, ²ILEVA, 9, chemin Joli Fond, 97410, Saint-Pierre, France, ³INRAE, 7, chemin IRAT, 97410, Saint-Pierre, France; siqueira@cirad.fr

In outermost islands the current increase of imported agricultural input costs questions the viability of farms and of the whole agricultural sector. The need, for these territories, to be less dependent and to mobilize local resources in a circular way is rising. Nevertheless, technical and organizational lock-in makes changes difficult to achieve. From 2017 to 2020, a Research and Development project has been carried out on Reunion Island to implement a territorial approach of biomass in agriculture based on circular economy. Five case-studies were undertaken with development, agricultural training and research actors and policy makers for the co-conception of organizational biomass scenarios. This project has created a strong momentum and the co-construction of solutions. However, as in many prospective works with actors, the implementation – which is then delegated to stakeholders – is rarely applied. To overcome this pitfall, we built a new project with some of the previous actors, on the territory of a municipality, starting from the insights of two case-studies (the levers to lower manure spreading constraints and the evaluation of the interest of composting manure with green waste). After a first diagnostic phase of the territory, we carried out two kinds of actions. We first organized focus-groups with local actors to conceive an agroecological transition for the territory. Second, we set up on-farm experiments with 5 farmers to develop composting of manure mixed with green waste and to test the compost on meadows and market gardening. The transition scenario confirms the need to improve biomass management to reduce inputs, jointly with the transformation of systems toward more agroecological ones. The development of farm composts along with their use on crops and meadows were successful. But, if the project allows the production of references and learnings, we observed within the project period various dynamics of actors, more or less competing, for treating and valorising manure resources on the territory.

Poster 13

Barriers for farmers to ‘sustainabilize’ their farm: the example of nematode control managementM. Sautier¹, A. Somera², R. Rostellato^{1,3}, P. Ly¹, Y. Labrunne¹, J.M. Astruc³ and P. Jacquet⁴¹Université de Toulouse, INRAE, ENVT, GenPhySE, Chemin de Borderouge, 31320 Castanet Tolosan, France, ²Centre Départemental de l’Elevage Ovin, Quartier Ahetzia, 64130, Ordiarp, France, ³IDELE, Chemin de Borderouge, 31320 Castanet Tolosan, France, ⁴Ecole Nationale Vétérinaire de Toulouse, UMT Santé des Petits Ruminants, UMR INRAE/ENVT 1225 IHAP, 23 Chem. des Capelles, 31300 Toulouse, France; marion.sautier@inrae.fr

Current health management practices in livestock farming are not sustainable, mostly because they select pathogens resistant to treatments. Integrated health management is put forward as a way to manage trade-offs between production, animal health and the environment. But, it embeds in so few livestock farming practices that farmers do not recognize and advocate it per se. In this context, research and development is needed: (1) to identify and design sustainable livestock systems and management tools in line with integrated health management principles; and (2) to better understand adoption and innovation dynamics towards integrated health management. This presentation contributes to the latter. The aim of our study was to explore how knowledge and information circulate among farmers, and between farmers and non-farmer stakeholders around the theme of parasitism control. For this purpose, we carried out a questionnaire-based survey among 536 dairy-sheep farmers in southwestern France. We analysed knowledge networks for parasitism control by listing whom farmers talk to when dealing with parasitism control. We identified the kind of individuals likely to be contacted by farmers depending on the farming system and the farmers’ representations. Results are discussed in terms of implications for developing integrated health management programs that take into account the diversity of health management actors and farmers identities.

Benefits and limits of an organic agroforestry system associating rabbits and apple trees

D. Savietto, V. Fillon, S. Simon, E. Lhoste, M. Grillot, A. Dufils, L. Lamothe, F. Derbez, M. Fetiveau and S. Drusch
INRAE, GenPhySE, UERI, LISIS, AGIR, Ecodéveloppement, 24 Chemin de Borde Rouge, 31326, France; davi.savietto@inrae.fr

Intensive farming and animal production are facing a crisis of legitimacy due to the use of pesticides, antibiotics and the lack of respect for animal needs. In contrast, organic agriculture and agroforestry systems are models contributing to a more sustainable agriculture. Organic farming bans the use of synthetic inputs, and agroforestry combining trees and animals provides various ecosystem services, among which nutrient cycling. However, those systems are not well developed nor studied. To fill this gap, we designed an organic agroforestry system to raise a small herbivore – the rabbit – in an apple orchard (AO) and evaluated the benefits and limits of this association for both plants (weeding, fertilisation and sanitation) and animals (food, microclimate, protection against predation and welfare). We started by designing prototypes relevant to this association that were improved following the proposals of farmers made during a workshop. We obtained a functional system: mobile-pens (18 m² for 6 rabbits) placed within the apple tree rows after leaf fall. We then tested this association with 144 rabbits divided in two groups (72 in the AO and 72 in a grassland (GL) with no trees), resulting in three combinations: rabbits with apple trees, rabbits without apple trees, and apple trees without rabbits. Compared to GL, rabbits in the AO had a more propitious microclimate (thermal amplitude: 11.6 vs 13.1 °C), ingested a similar amount of grass (39 vs 36 g of dry matter/rabbit/day) and pelleted feed (147 vs 154 g/rabbit/day) and grew alike (33 vs 32 g/day). Moreover, rabbits in the AO ingested 58 g of apple/rabbit/day. There was no predation, but one rabbit died of myxomatosis at the AO. Besides the weeding service (bare ground in one week), rabbits gnawed 35 out of 215 trees, despite the presence of physical protection. This association worked well in the autumn: little orchard management, plenty of food resources and mild weather for rabbits. Data on soil fertility and rabbit hair cortisol are under analysis. Globally AO and GL improved the welfare of rabbits, as we observed behaviours (grazing, hopping, digging, etc.) not expressed in caged systems.

INOSYS livestock farming systems network: benchmarks for advisors, trainers and policy makers

P. Sarzeaud¹, J. Seegers¹, O. Dupire² and T. Charroin¹

¹French Livestock Institute, 149 Rue de Bercy, 75595 Paris Cedex 12, France, ²Chambre d'Agriculture de France, 9 Av. George V, 75008 Paris, France; patrick.sarzeaud@idele.fr

The INOSYS – French Livestock Farming Systems Network has been established during the 80s and illustrates an innovative and long term AKIS cooperation to construct technical and economic benchmarks on farming systems. This multi actor organisation is led by the IDELE and the Chambers of Agriculture. Its originality relies on the collaboration of farmers and advisors to design farming systems from the farm monitoring. It makes it possible to produce technical and economic benchmarks adapted to the systems diversity and regional contexts. In 2023, this Network hold 1100 farms monitored by more than 200 chamber- of-agriculture agents and 25 project leaders from the IDELE. It is financed and supported by public authorities and the professional agriculture bodies. Its action can be resumed in three missions: (1) observe the livestock farming systems in place in the regions; (2) identify and support innovative systems; and (3) transfer and disseminate the productions in the form of tools, methods, training and publications. Based on an operational classification, this panel is representative of the systems variety and informs about the main issues they are facing, such as sustainability, competitiveness, changes in working conditions or environmental impacts. In the context of global and competitive economy, the French Livestock Institute proposed a national method and its informatic application COUPROD, to calculate costs of production. INOSYS network is also involved in providing references to several decision tools such as CAP2er (environmental evaluation) or APIBOV (beef production monitoring). The regional and national enhancement of the Network are dedicated to different audiences: farmers, advisers, teachers (for advice or training), individuals or collectives, and local and national decision makers to measure the impact of new farming policies and lead their implementation. To enlarge the dissemination of markers and references, INOSYS network built a new web site. This platform enables visitors to consult and extract updated references covering a wide range of domain (technical, environmental, economic, social, etc.) for more than 200 farming systems models.

APIVALE scientific consortium: integrated approach for organic effluent recycling and valorisation

F. De Quelen¹, E. Jarde², C. Le Marechal³, T. Lendormi⁴, S. Menasseri⁵ and F. Beline⁶

¹INRAE Institut Agro UMR PEGASE, Saint Gilles, 35590, France, ²CNRS Université de Rennes UMR Geosciences, Rennes, 35000, France, ³ANSES, Laboratoire de Ploufragan-Plouzané-Niort, Ploufragan, 22440, France, ⁴IRDL Université Bretagne Sud, Lorient, 56100, France, ⁵INRAE Institut Agro UMR SAS, Rennes, 35000, France, ⁶INRAE UR OPAALE, Rennes, 35000, France; francine.dequelen@inrae.fr

About 400 million tons of organic waste is produced each year in France with a major contribution of animal production (300 million tons) and agroindustry (45 million tons). Agriculture is thus at the heart of organic waste recycling and valorisation (organic matter, energy, nutrients, etc.). This challenge requires the production of scientific knowledge, the development of technical or organizational innovation and a more holistic approach to better consider the possible synergies on the territories. Organic effluents are subjected to numerous biological, chemical and physical processes that modify their composition, generate emissions to the environment and finally affect the availability of nutrient to plants and soil fertility. An improved knowledge of these different processes is thus required to quantify more precisely the emissions (for environmental evaluation) as well as for their reduction (for mitigation strategies). Different research institutes located in Western France including INRAE, ANSES, CNRS, UBS, Institut Agro, Université de Rennes and ENSCR, have decided to share their skills, experimental facilities and equipment in a scientific consortium named 'APIVALE' in order to develop an integrated approach of organic effluent recycling and valorisation. The scientific consortium provides skills and facilities to perform integrated studies over the whole chain of production and valorisation of organic effluent, possibly in combination with other sources of organic waste (urban or agro-industrial).

Progress made in whole-farm nitrogen and phosphorus mass balances on New York dairy farms

O.F. Godber¹, K. Workman² and Q.M. Ketterings¹

¹Cornell University, Nutrient Management Spear Program, Department of Animal Science, Ithaca, NY 14850, USA, ²Cornell University, PRO-DAIRY, Ithaca, NY 14853, USA; ofg6@cornell.edu

The whole farm nutrient mass balance (NMB) is an assessment tool that farms can use to calculate their nitrogen (N), phosphorus (P) and potassium (K) use efficiency at the farm level. By calculating the difference in the amount of nutrients imported into and exported out of the farm in a given calendar year, the amount of nutrients remaining on the farm or lost to the environment can be estimated per unit of farmland (hectares), and per unit of output produced (a product of the farm, for example kg of milk). The balance per hectare indicates how well a farm is putting nutrients to use on that farm's land base, and the risk of losing nutrients to the environment. The balance per unit of output indicates how efficiently nutrients are being used to produce that output, and the environmental footprint of that product in terms of nutrient use. A substantial positive P and K balance per hectare indicates soil build-up and potential for nutrient loss over time. A large portion of positive N balances will be lost to the environment as N is more difficult to retain from one year to the next. Some of these losses will be nitrous oxide (N₂O), a potent greenhouse gas (GHG). Here, we show the progress made in reducing N and P balances on dairy farms in New York (NY) State between 2005 and 2020. The data indicate great improvement in P balances per unit of milk produced as well as an improvement in balance per hectare over this time period, despite an increase in animal density. The data also indicate improvements in N balances per unit of milk produced but an increase in balance per hectare due to higher animal densities in 2020 compared to 2005. Findings from a subset of 10 farms with three years of data suggest that strategies that reduce N balances also have the potential to reduce GHGs at the whole farm and product level. Work is ongoing to identify opportunities for improvements in N management.

Measuring greenhouse gas emission from pretreatment and liquid composting storage in biogas facility

G.W. Park, M. Ataallahi, N. Eska and K.H. Park

Kangwon national university, Animal life sciences, Kangwondo, Chuncheonsi, Kangwondaehakgil 1, Dept of animal life sciences 1st building Room#420, Kang, 24343, Korea, South; eskanugrahaeningtyas@gmail.com

Growing number of biogas plants in Korea has brought new assignments for making the new country-specific emissions factor to be included in national greenhouse gas inventory to quantify, monitor, and reduce methane (CH₄) and nitrous oxide (N₂O) gas emissions. The objective of this research focused on comparing the emissions between site demonstration data and the 2006 IPCC guideline. Therefore, gas measurement was the most important for quantifying the greenhouse gas emissions from biogas facility. This facility has treated 70 ton of swine manure from 20,000 heads and 30 ton of food waste per day and generate 3,000 m³ /day of biogas. In the biogas plant, swine manure and food waste were stored in pretreatment with agitation, and moving into anaerobic digester. From anaerobic digester the biogases such CH₄, CO₂, etc. were moving into biogas storage and providing gas to generator, and treated manure and food waste were moving into liquid composting storage. This research measured CH₄ and N₂O from pretreatment storage which is included slurry, and liquid composting storage. All gases in this biogas facility were vented by negative pressure from the odour treatment tower, except the generator and its blowers. Quantification of the total greenhouse gas emissions from the biogas facility was conducted on 24 hours every 2 weeks, from July to October, by using CH₄/N₂O analyser (Los Gatos Research, San Jose, CA, USA). The air inlet sample was collected from air injector to aerate for the liquid compost and external air. The air outlet sample was collected from odour treatment tower before treated by acid and base. Field demonstrated data for CH₄ and N₂O emission in biogas facility were 9,112.08±3,179.57 kg CH₄/year and 91.07±63.50 kg N₂O/year. But if methane and nitrous oxide emission were calculated by 2006 IPCC guideline Tier 2, it was 48,200 kg CH₄/year and 2,016.70 kg N₂O/year, which means respectively 5.29, 22.14 times higher than field emission data. The result concluded that the country-specific emission factor of biogas plant is necessary to produce more accurate national greenhouse gas inventory as a tool for policy-making for CH₄ and N₂O reduction.

Effect of yoghurt acid whey on quality characteristics of corn silage

I. Palamidi, V.V. Paraskeuas, I.P. Brouklogiannis, E.C. Anagnostopoulos, I. Politis, I. Hadjigeorgiou and K.C. Mountzouris

Agricultural University of Athens, Department of Animal Science, Iera odos 75, 11855 Athens, Greece; inpalamidi@aua.gr

Yogurt acid whey, a by-product of stained yogurt production, presents a serious environmental problem if left untreated, as for every 100 litres of milk used, 70 litres of yogurt acid whey are produced. Given that yogurt acid whey is rich in lactose and lactic acid, its use as a silage additive merits investigation. The aim of this study was to determine the effect of yogurt acid whey powder (YAWP) addition on nutritive, microbial and fermentation characteristics of corn silage. For this purpose, YAWP was added at 0, 2.5, 5 and 10% w/w to corn grass, in a total final weight of 7kg, which was then sieved into appropriate vacuum bags. All bags were then stored at ambient temperature (18±3 °C) for 10 weeks. Representative samples were taken at the beginning and end of ensilation and stored at -30 °C until analysed. At the end of the ensiling, dry matter, crude protein and ash were linearly increased, whereas crude fibre, neutral detergent fibre and acid detergent fibre were linearly decreased with YAWP increasing level. The pH was quadratically decreased with increasing YAWP level, with the 5% YAWP being the lowest. Concentrations of total aerobes were linearly decreased, whereas *Clostridial* counts did not differ. Acetic acid content was linearly decreased with increasing YAWP incorporation level. With increasing YAWP level, propionic acid, lactic acid and the ratio of lactic to acetic acid were increased linearly. Butyric acid content was only detected in 0 and 2.5% YAWP. Ammonia content decreased linearly by YAWP incorporation level. In conclusion, the incorporation of 5 and 10% YAWP to silage preparation improved the nutritive and fermentative characteristics of corn silage. This research has been co-financed by the European Regional Development Fund of the European Union and Greek national funds through the Operational Program Competitiveness, Entrepreneurship and Innovation, under the call RESEARCH – CREATE – INNOVATE (project code:T2EDK-00783).

How do horses perceive human emotions?

P. Jardat¹, C. Parias¹, F. Reigner², L. Calandreau¹ and L. Lansade¹

¹CNRS, IFCE, INRAE, Université de Tours, PRC, l'Orfrasière, 37380 Nouzilly, France, ²UEPAO, INRAE, l'Orfrasière, 37380 Nouzilly, France; plotine.jardat@inrae.fr

Recently, unexpected sociocognitive abilities toward humans have been discovered in domestic mammals. We will focus on horses and present recent findings on their perception of human emotions. Studies have shown that horses distinguish human facial expressions as well as vocalizations of joy and anger, and that they can recognize these emotions cross-modally; i.e. they can associate a human vocalization of joy or anger to the right facial expression. In a recent experiment, to broaden the spectrum of emotions studied, we focused on human expressions of sadness and joy. We conducted a cross-modal experiment in which horses were presented with two simultaneous soundless videos of a sad and a joyful face, while sad or joyful vocalizations were played. The results suggest that horses differentiated between the facial and vocal expressions of sadness and joy, and that they may also recognize these emotions cross-modally. Moreover, horses looked less at the sad faces than the joyful faces and seemed less aroused by sad voices than joyful faces. We conclude that emotional contagion may take place between humans and horses when the former express sadness or joy, and that it could be beneficial for horsemen and horsewomen to express joy when interacting with horses. In addition to the visual and auditory channels, we can wonder whether horses can perceive human emotions via the olfactory channel. We implemented a habituation-discrimination protocol to examine horses' ability to discriminate between human odours produced in fear vs joy contexts. Sweat odours collected on human participants watching a horror movie or comedy were presented to horses. First, odour A (from the fear or joy context) was presented twice in successive trials (habituation); then, the same odour A and a novel odour B (from the same human in the other context) were presented simultaneously (discrimination). Results show that horses discriminated between the two odours and may have separate emotional processing for each of them. Overall, these findings highlight horses' sensitivity to various human emotions via different sensory channels, which can affect the interactions between horses and their owners, riders or caretakers.

Session 76

Sensorimotor empathy in horse-human interactions: a new way to understand inter-species performance

M. Leblanc, B. Huet and J. Saury

Nantes Université, MIP, UR 4334, 25bis boulevard Guy Mollet, 44322 Nantes, France; marine.leblanc@etu.univ-nantes.fr

Inter-species performances are complex. They require a mutual understanding which highly implies the actors' body. To perform, the *écuyers*, French elite riders from Cadre noir of Saumur, and the horses both develop a disposition: sensorimotor empathy. This allows them to connect and form complex synergies. The study shows how humans and horses manage to synchronise to achieve high-level collective performances. We conducted this study with an enactivist epistemological approach, relying on the theoretical framework of the Course of action research program, which, from a phenomenological perspective, gives full place to experience. To analyse the activity of two *écuyers* who are experts in work in hand, we filmed 36 training sessions with the horses, and we confronted the *écuyers* with the videos by conducting self-confrontation interviews in order to reconstruct their course of experience. We also kept a field diary to collect ethnographic notes. To analyse the activity of the horses, we used behavioural indicators from scientific ethology in order to infer their experience. The results show that emergence of moments of mutual connection between the *écuyer* and the horse is required, to synchronise and achieve high-performance synergy. The moments of connection are characterised by pleasant sensations for the *écuyer*, which result of an intersubjective agreement between him and the horse. This latter is built in the context of a long-term relationship during which they construct a common cultural practice. It allows them to understand each other and to realise efficient synergies. Through the construction of their common cultural practice, *écuyer* and horse develop a sensorimotor empathy which is a disposition to feel, to perceive and understand the other through the body and adjust finely. The study of sensorimotor empathy helped to understand the development of a common cultural practice between the actors. This allowed them to bring together the appropriate conditions and exploit them to form complex synergies. More globally, the study of sensorimotor empathy in human-non-human interactions seems to be fruitful for understanding how two species that do not share the same 'world' manage to understand each other finely.

Rethinking horse work*R. Evans**Hogskulen for grønn utvikling, Arne Garborgsveg 22, 44340 Bryne, Norway; rhys@hgut.no*

This presentation will challenge us to rethink what we mean by 'Horse Work'. It will touch historical milestones which contributed to the traditional view that Working Horses pull heavy things. It will then examine the changing uses of horses in peoples lives and suggest some situations which equally qualify as equine work. Based upon this, it will examine some consequences of these changes for how we see, use, and heal working horses in the 21st Century.

Session 76

Theatre 4

Humans and equines: shared working conditions*V. Deneux - Le Barh^{1,2} and C. Lourd³*

¹INRAE, UMR Innovation, 2 place Pierre Viala, 34000 Montpellier, France, ²Institut Français du cheval et de l'équitation, Pôle Développement Innovation Recherches, Avenue de l'école nationale d'équitation, 49111 Saumur, France, ³Institut Français du cheval et de l'équitation, Equiressources, Le Haras du Pin, 61310 Le Pin au Haras, France; *vanina.deneux@inrae.fr*

In a context of generalisation of the watchword 'well-being': well-being and personal development, well-being at work, animal welfare, etc. Contemporary society, weighs the weight of an injunction to well-being and welfare and the equine sector is not excluded from it. In the context of work relations, the anthro-po-equine professions are all the more conducive to these reflections as they associate two different species: the human and the equine. We hypothesise that there is a link between human and equine working conditions and thus seek to show that the organisation and working conditions can be understood in a multi-factorial manner, when they are positive they are a source of fulfilment whereas they can be deleterious when they are bad. To this end, we propose to explore this questioning based on the results of two doctoral research projects, carried out between 2017 and 2021. The first one, in sociology of work, studied the life and work relationships between professionals and their animals in the different worlds of the horse. For this, the discourse of 108 semi-directive interviews was analysed. The second, in education sciences, focused on understanding the construction of professional careers in the equestrian and horse-riding sectors. This was based on the analysis of three types of sources: 1,117 curricula vitae, 226 surveys and 12 interviews. Although they come from different disciplinary fields, we obtain common results. The communication we propose is the presentation of our three main results. Firstly, we will show that the understanding of the role of organisation and working conditions on the mental and physical health of human and equine individuals depends on the individuals themselves and the geographical and economic environments. Secondly, we will show how poor working conditions have deleterious effects on both humans and equines. We will conclude with a discussion of ways of work organisation that are conducive to the fulfilment of both humans and equines.

Working horses: humanities and social sciences approachV. Deneux - *Le Barh*^{1,2}¹INRAE, UMR Innovation, 2 place Pierre Viala, 34000 Montpellier, France, ²Institut Français du cheval et de l'équitation, Pôle Développement Innovation Recherches, Route de l'école nationale d'équitation, 49111 Saumur, France; *vanina.deneux@inrae.fr*

Wherever we live, whatever our culture, we are linked to animals. There are no societies without animals, we are hybrid societies (Midgley, Lestel). In Western societies, we have been producing goods and services with domestic animals for several millennia, i.e. we are working with animals. However, the relationship of animals to work has been poorly studied. In the 19th century, the disciplinary construction of the life sciences and the humanities and social sciences established a distinction whereby animals would fall within the scope of the first, while work, which is by definition human, would be dealt with by the second. However, over the last fifteen years, we have seen the humanities and social sciences reintegrate animals into their studies and there is a desire to do sociology with animals. The Animal's Lab research group led by J. Porcher in Montpellier analyses the relationships between animals and work. Numerous fields have been conducted on dogs, elephants, horses, performing animals, and farm animals. Based on the theoretical frameworks from the labour sciences and field investigations, Animal's Lab researchers have theorised animal work, i.e. the subjective engagement of animals in work with humans. This engagement is not natural; it requires that the individuals of the species involved mobilise their senses, their intelligence and their experiences. This is learned and this requires the construction of a common language. My proposal of communication is part of this new disciplinary field. Using the case of the horse, I will present the definition and the eight key points of the theory of animal work. I will show the particularities of professions employing humans and horses compared to professions employing only humans. I will conclude the presentation by discussing the deontological and ethical issues involved in working with horses in terms of the living and working conditions of the equines.

Web based dissemination of research to support human knowledge and understanding for horse welfare

A.-L. Holgersson, K. Lagerlund and G. Gröndahl

Swedish University of Agricultural Sciences, Equine Sciences, P.O. Box 7046, 75007 Uppsala, Sweden; *anna-lena.holgersson@slu.se*

Internet today is overflowing with information and it is not easy for horse owners to find evidence-based, reliable content, based on research and proven experience. The website HästSverige ('HorseSweden'; www.hastsverige.se) is a free-to-use knowledge site in Sweden that communicates independent and objective basic knowledge as well as research and development in the field of horses. All texts are reviewed by researchers or experts from universities or well-known institutes. Through this, HästSverige offers both beginners and qualified professionals access to quality-assured, up-to-date and fact-based knowledge about horses and horse activities. The goal is to raise the level of knowledge among the hundreds of thousands of people who are in daily contact with horses in Sweden. In this way, HästSverige can contribute to better horse care and increased animal welfare. The Swedish University of Agricultural Sciences is responsible for the site and it is financed and operated in collaboration between several organizations representing researchers, university teachers, the Swedish horse sector, authorities, research financiers, sports, breeding and animal welfare. The main collaborators are the National Veterinary Institute and the Swedish Horse Industry Foundation. There are no commercial ads, branded content or integrated advertising on the site. Since its launch in 2011, over 800 pages have been published on the site. The main structure is: The horse, Diseases and injuries, The horse's environment and Horses and people. There is a special section for short basic courses and quizzes. The free program for calculating feed rations is the most visited page on the site. It uses individual variables for the horse and available feed, or default values. Business-related content, such as legislation, management and advice, is available to actors in the equestrian industry. The site has been well received with about 400,000 visitors and 600,000 sessions in 2022 and about 15,500 followers of the attached Facebook page. HästSverige has become an established and valued source of horse-related factual information, which is used by the general public as well as schools, media and veterinarians.

Comparison of ethological & physiological indicators in headshakers & control horses in riding testsL.M. Stange¹, T. Wilder¹, D. Siebler¹, J. Krieter¹ and I. Czycholl²¹Institute for Animal Breeding and Husbandry, Ohlshausenstraße 40, 24118 Kiel, Germany, ²Department of Veterinary and Animal Sciences, Grønnegårdsvej 15, 106 91 Frederiksberg, Denmark; lstange@tierzucht.uni-kiel.de

Equine headshaking syndrome (EHS) is associated with severe headshaking in absence of external stimulus, which affects horses' welfare, handling and rideability. Since EHS mainly occurs under rider, the aim of this study was to investigate different effects in standardised riding tests. It was hypothesised that riding would influence occurrence of EHS and that headshaker would express more signs of discomfort. Therefore, riding tests (n=227) were carried out on 16 headshakers and 12 corresponding control horses in order to compare physiological parameters, rein tension and ethological indicators between the two groups. Statistical analysis was performed using separate generalised linear mixed models for heart rate, rein tension as well as behaviour. In particular, the study tested for the presence of headshaking (PoHS), gait and other fixed effects depending on the model. For the study, 19 geldings and 9 mares were available, of which 19 horses were Warmbloods and nine were ponies. The average age of the headshakers was 12.1 years (control group: 14.3 years). The heart rate dataset revealed that PoHS has no significant impact on the heart rate; whereas, it is significantly influenced by gait ($P \leq 0.05$). The rein tension dataset indicated that this is not influenced by PoHS, but a meaningful influence was caused by the equipment used (saddle: $P \leq 0.05$) and environmental influences (wind: $P \leq 0.05$). The results of the behavioural parameters indicate that there is no difference between headshakers and control horses in terms of defensive reactions. Wearing a nose cover significantly reduced headshaking symptoms (head flicking: $P \leq 0.05$). In summary, no connection between the heart rate as a physiological parameter as well as rein tension and PoHS could be proven. Thus, it can be concluded that riding has a negligible effect on the EHS. Using a nose cover leads to a reduction in certain headshaking movements. This study is a first step to investigate the influence of riding on horses affected by EHS and, in general, contributes to a better understanding of idiopathic EHS.

Theatre 8

Relationship between hay botanical diversity and faecal bacterial diversity in horsesC. Omphalius¹, P. Grimm¹, V. Milojevic² and S. Julliand¹¹Lab To Field, 26 bd Dr Petitjean, 21000 Dijon, France, ²Sandgrueb-Stiftung, Sandgrueb, 8132 Egg b. Zürich, Switzerland; samy.julliand@lab-to-field.com

Greater biodiversity in ecosystems leads to greater stability. Horses grazing natural grassland with higher plant variety show a higher hindgut bacterial diversity, as compared to horses in captivity with access to poorer grazing resources. Yet if such relationship between forage and hindgut bacterial diversity is also valid for horses that only have access to hay, remains unknown. Thus, the objective of this study was to evaluate the relationship between hay botanical diversity and equine faecal microbial diversity and activity. Sixteen adult horses were included in a 2x2 Latin Square design to test 2 iso-DM, -energy, -NDF, and -protein diets during two 21 d experimental periods. The high diversity diet (HD) was composed of 100% hay from a natural meadow containing 29 different identified species, and the low diversity diet (LD) of 86% timothy and 14% alfalfa hay. Faeces was collected on d21 of each period. Bacterial composition was determined using 16S rRNA sequencing. Richness (observed OTUs), evenness (Pielou), and diversity (Shannon and inverse Simpson) indices were calculated from faecal samples. Numbers of OTUs were also categorized into 5 abundance classes (>1% of relative abundance, 0.1-1%, 0.01-0.1%, 0.005-0.01%, or <0.005%). Microbial activity was assessed through measurement of volatile fatty acids (VFA) concentrations and pH. A MIXED procedure was used to test the effect of the diet, and a Chi² test was performed to evaluate whether the proportion of each abundance class differed between diets (SAS). Microbial activity was not altered by hay botanical diversity, as faecal VFA concentrations and pH were similar with the 2 diets. Bacterial richness did not differ between diets ($P=0.164$), but the evenness and diversity indices were lower when horses were fed the HD diet ($P \leq 0.027$). The lower evenness observed with HD diet was due to the increased number of rare OTUs (between 0.005-0.01%, and <0.005% of relative abundance; $P < 0.001$) which might reflect the provision of more diverse substrates to the ecosystem. It is unknown whether this confers the horse a health benefit, and it would be interesting to study if this provides the hindgut microbiota a better resilience to stress.

Thoroughbreds in equine assisted services programmes: selection, living and working conditionsC. Neveux¹, S. Mullan², J. Hockenhu¹, J. Barker³, K. Allen¹ and M. Valencho⁴¹University of Bristol, Bristol Veterinary School, Langford, BS40 5DU, United Kingdom, ²University College Dublin, School of Veterinary Science, Belfield, Dublin 4, Ireland, ³Racing to Relate, 82 St John Street, London, EC1M 4AJN, United Kingdom, ⁴Centre INRAE Val de Loire, UMR Physiologie de la Reproduction et des Comportements (PRC-INRAE, CNRS, IFCE, Université de Tours), INRAE, 37380 Nouzilly, France; claire.neveux@bristol.ac.uk

Post-racing Thoroughbreds (TB) are often retrained for sport or leisure purposes and are increasingly being considered for equine assisted services (EAS) but have not yet been widely evaluated. To evaluate the selection criteria of EAS horses as well as their current living and working conditions, we distributed a detailed online survey aimed at EAS practitioners. In total, 129 people responded from 13 different countries. Participants provided detailed information about the 5 horses they use the most and we obtained such data on 427 EAS equids: 13.5% of TB, 77.3% of various other breeds (OB), 8.5% with unknown origins and 0.7% of donkeys. Our sample was mainly composed of geldings (TB=78.6%, OB=59.6%). The TB were significantly younger than OB (median age: TB=14yo, OB=17yo; $P<0.01$) even if the age when acquired did not differ significantly (median age: TB=OB=9yo, $P>0.05$). The three most commonly selected criteria as being important for EAS horses were: showing a good temperament, absence of kicking/biting propensity, enjoying the work. Participants declared that most of the horses participated in less than 7 EAS sessions a week (TB=97.6%, OB=80.7%). Over two third of the horses were housed in collective settings (TB=71.9%, OB=84.4%), had unrestricted access to forage (TB=77.2%, OB=67.3%) and had social contacts the majority of the time (TB=60.8%, OB=75.8%). These results move towards an understanding of the selection criteria as well as the living and working conditions of EAS horses. Some differences were highlighted between TB and OB and would need to be further investigated. The next phase of the project will compare EAS horses and TB characteristics and will involve qualitative interviews, horse personality and reactivity to human tests as well as a 12-month monitoring period.

The role of gender in the worldwide Pura Raza Español equestrian sector

M. Ripolles, A. Encina, M. Valera and M.J. Sánchez-Guerrero

Universidad de Sevilla, Animal Production, Carretera de Utrera KM, 41013, Spain; anaencmar@gmail.com

One of the least studied factors in the equestrian sector, and never carried out in a global breed, is the relevance of the role of gender in owners, riders and morphological appraisers in the Pura Raza Español (PRE) equestrian sector worldwide. The objective of this study was to evaluate the role of gender in the Pura Raza Español equestrian sector, considering: (1) the owner genders of the studs, (2) the different morphological scores and the use of the hole scale according to the appraiser gender and (3) the differences in Dressage scores according to gender of the rider. This study was carried out in 8,180 PRE studs (7,002 were run by men and 1,178 by women); 36,673 PRE appraised for its morphology (23,095 appraised by a man and 13,578 by a woman); 3,499 Dressage riders with different number of participations (1,633 were men and 1,866 were women). A descriptive analysis and comparison of means was carried out to describe the role of gender in this sector. Women run the 15.09, 12.03 and 14.69% in big, medium and small studs respectively. In the European area (leaving Spain out due to this large number of studs) women own the 68.68% of the PRE studs, while Spain, Central and South America and North America had a large predominance of men owners. In percentages, men in general use extremes more, although not in a significant way. Trot and hock lateral view were not influenced by the appraiser gender. The scale is fully used by both genders with the exception of the Ewe Neck. Men had an average of 28 participations and an active period of 3.66 ± 4.62 years and women have an average of 19.96 participations and 2.67 ± 3.48 years. The maximum active period has been 17 years in both genders. The Dressage scores obtained by men and women had not significant differences with the only exception of Submission. It had a significantly higher value for men. So, it could be concluded that women haven underrepresentation as a horse breeder in the Latin countries and acting as morphological appraisers. This is not the case when women role as Dressage rider. So, it is important to create women's networks to address their specific needs to advance in their leadership and increase their public visibility in achieving social and economic change especially in Latin countries.

Anthelmintic activity of chicory (*Cichorium intybus*) in grazing horses

J. Malsa¹, G. Sallé¹, L. Wime², J. Auclair-Ronzaud², B. Dumont³, L. Boudesocque-Delaye⁴, F. Reigner⁵, F. Guégnard¹, A. Chereau¹, D. Serreau¹ and G. Fleurance^{3,6}

¹INRAE, Université de Tours, UMR 1282 Infectiologie et Santé Publique, Nouzilly, 37380, France, ²IFCE, Plateau technique de Chamberet, Chamberet, 39170, France, ³INRAE, Université Clermont Auvergne, VetAgro Sup, UMR 1213 Herbivores, Saint-Genès-Champanelle, 63122, France, ⁴Université de Tours, Eq. 7502 Synthèse et Isolement de Molécules Bioactives, Tours, 37020, France, ⁵INRAE, EUPAO, Nouzilly, 37380, France, ⁶IFCE, Pôle développement, innovation et recherche, Saint-Genès-Champanelle, 63122, France; joshua.malsa@inrae.fr

Cyathostomins are the most prevalent parasitic nematodes of grazing horses. They are responsible for colic or diarrhoea in their hosts. After several decades of exposure to synthetic anthelmintics, they have evolved to become resistant to most compounds. In addition, the drug associated environmental side-effects question their use in the field. To face these challenges, alternative control strategies, like bioactive forages, are needed. Among these, chicory (*Cichorium intybus*, Puna II variety) is known to harbour anthelmintic compounds. We aimed to test its *in vivo* efficacy against cyathostomins. Two groups of 2-year-old infected saddle horses (n=10) grazed rotationally either: (1) a pasture sown with chicory; or (2) a mesophile grassland at the same stocking rate (2.4 LU/ha). The study took place in summer during 45 days to prevent horse reinfection. Chicory group horses mostly grazed chicory (89% of the bites) while horses of the control group grazed mainly grasses (73%) and 4% *Plantago lanceolata*, a plant with known anthelmintic properties in small ruminants. Cyathostomins egg excretion decreased in both groups throughout the experiment ($P=0.002$; average EPG falling from 2,169±802 EPG to 508±450 EPG). Accounting for this trajectory, the chicory regime was however associated with a significant 93% drop in parasite egg excretion compared to the control group, i.e. similar to the efficacy of a chemical anthelmintic drug. In addition, larval development was significantly reduced in horses grazing chicory (-39.5% between D16 and D45, $P=0.02$). *In vitro* tests are in progress to analyse the role of terpenes. The grazing of chicory (var. Puna II) by horses could thus constitute a promising strategy to reduce the use of synthetic anthelmintics.

Poster 12

Does pain condition influence the human-horse relationship?

L. Sobrero, M.G. Riva, M. Minero, A. Cafiso, A. Gazzonis and E. Dalla Costa

Università degli Studi di Milano, Dipartimento di Medicina Veterinaria e Scienze Animali (DIVAS), Via dell'Università, 6, 26900 Lodi, Italy; emanuela.dallacosta@unimi.it

Today horses are mainly considered as companions for sports and leisure activities. It is well known that being used for recreational purposes or sport competitions can predispose horses to health disorders causing pain. Pain condition can play a role in the development of behavioural problems, such as escape attempts and aggressions, that can be dangerous for both horses and riders. The aim of this study was to investigate the relationship between the presence of signs of pain and the human-horse relationship measured with 3 tests. A total of 137 adult sport and leisure horses (14±6 years), housed in 7 stables, were assessed by two trained assessors. No horses were reported to have major health issues at the moment of the evaluation. Pain was evaluated using the Horse Grimace Scale, while the quality of the H-H relationship was assessed using three tests: Avoidance Distance (AD), Voluntary Human Approach (VAA) and Forced Human approach (FHA) as described in the AWIN welfare protocol. Data were analysed with descriptive analysis and a Chi-Square test (X^2). On the assessed sample, the proportion of horses that showed signs of pain ($HGS \geq 3$) was 30.7%. During the VAA test, the proportion of horses without pain ($HGS < 3$) approaching an unknown human was significantly higher than those of horses with pain ($HGS \geq 3$), 60.7 and 23.1%, respectively ($X^2=6.234$; $P=0.044$), meaning that horses with no pain seek and enjoyed interacting with humans. No differences were found for AD and FHA tests. The results of this study confirm that pain is often under recognised in sport and leisure horses, thus leading to a possible deterioration of the human-horse relationship. Specifically, our results show that, when in pain, horses do tend to reduce positive voluntary interactions to unknown humans. Further research is suggested to investigate whether an effective pain recognition and treatment pain can also re-establish a good human-horse relationship.

Saliva steroidome and metabolome in mare during anoestrus, oestrus cycle and gestationS. Beauclercq¹, C. Douet², A. Piano³, L. Haddad³, F. Reigner⁴, P. Liere³, L. Nadal-Desbarats⁵ and G. Goudet²¹INRAE, BOA, 37380 Nouzilly, France, ²INRAE, PRC, 37380 Nouzilly, France, ³INSERM Université Paris Saclay, U1195, 94276 Kremlin Bicêtre, France, ⁴INRAE, PAO, 37380 Nouzilly, France, ⁵INSERM Université de Tours, UMR-1253 iBrain, 37000 Tours, France; ghylene.goudet@inrae.fr

Precision livestock farming using omics approach such as metabolomic and steroidomic to acquire precise and real-time data can help farmers in individual animal management and decision making. Moreover, saliva collection is a non-invasive, painless and easy sampling method. Thus, this prospective study proposes a metabolomic and steroidomic analysis in mare saliva during reproductive stages, in order to identify salivary biomarkers to detect their reproductive stage in a welfare friendly production system. Saliva samples from 6 mares were collected in anoestrus, in the follicular phase 3, 2 and 1 day before ovulation and the day when ovulation was detected, in the luteal phase 6 days after ovulation and in gestation 18 days after ovulation and insemination. Metabolome and steroidome analysis were performed by 1H-nuclear magnetic resonance spectroscopy and gas chromatography coupled to tandem mass spectrometry, respectively. We identified 59 metabolites and 25 steroids in saliva. The salivary concentrations of metabolites were significantly different between the anoestrus stage and another stage (n=11 metabolites or group of metabolites), between follicular phase and gestation (n=1), between the day of ovulation and the luteal phase (n=1), during the 4 days until ovulation (n=4). The salivary concentration of pregnenolone during gestation was significantly higher than during anoestrus or follicular phase and tended to be higher than during luteal phase. Most of the 5alpha-reduced metabolites of progesterone showed higher salivary concentrations during the luteal phase and gestation compared to anoestrus and follicular phase. These metabolites and steroids could be potential salivary biomarkers of the reproductive stage of the mare. They could allow to easily detect their reproductive stage for real-time decision making at the individual animal level. Further studies with a greater number of animals are in progress to confirm the reliability of these candidate biomarkers.

Session 77

Theatre 1

The future of genetic selection in pigs and poultryL. Verschuren¹ and P.W. Knap²¹Topigs Norsvin, P.O. Box 86, 5268 ZH Helvoirt, the Netherlands, ²Genus-PIC, Ratsteich 31, 24837 Schleswig, Germany; pieter.knap@genusplc.com

Over the past decades, the efficiency of pig and poultry production strongly increased due to improved technology for animal management, nutrition and breeding. In general, when a system becomes more efficient, it also becomes more sensitive to external and internal disturbance factors. This leads to trade-offs between animal production efficiency (with the carbon footprint as an important component) and animal welfare (with animal health as an important component). Such trade-offs must be neutralized, and this has implications for animal science: the breeding sector needs better technology to: (1) record hard-to-measure traits in the fields of greenhouse gas emission (mainly via nitrogen excretion, in monogastrics), disease resilience, physical robustness, and several types of behaviour (all of these at low cost on very large numbers of animals); (2) process that data into information that can be converted to meaningful breeding value estimates; (3) exploit metabolomics to generate biomarkers for too-hard-to-routinely-measure traits (e.g. disease tolerance); and (4) exploit genomics to generate fully annotated genome sequences with massive discovery of causal variants, to make the EBVs of point (2) more robust and more accurate. We describe a few trade-off systems that became apparent in pig production in the 1970s (carcass lean content vs meat quality), in the 1980s (growth rate vs leg soundness), and in the 2000s (litter size vs piglet survival), and the strategies that were employed to neutralize them. Coming back to the R&D needs of above, we also describe: (1) technology that is currently being developed to record physical robustness (leg soundness) and behaviour (tail biting, and maternal behaviour) in pigs; (2) a case where proper data processing can exploit routinely recorded data to quantify a resilience trait (the volatility of longitudinal individual feed intake); and (3) cases where metabolomics may play a significant role (tail biting, and boar taint).

The future of nutrition research in pigs and poultry*S. Vigers¹ and J.V. Milgen²**¹School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, ²INRA, Institut Agro, Pegase, Le Clos, 35590 Saint-Gilles, France; staffordvigers1@ucd.ie*

The pig and poultry industries have substantially improved productivity through improvements in nutrition, health and genetics. However, due to environmental, economic and social pressures there is further need for evaluation and improvement which will coincide with an increased demand to feed a global population of 9 billion in 2050. The goal therefore is to produce sustainable food from sustainable feed (and feeding) and ensure minimal trade-offs with the environmental and health aspects of production. Trade-offs means that there is not a 'win-win', but a 'win-lose' dilemma, and the decision where to win and where to lose is made by different stakeholders (e.g. legislators, producers, consumers). Nutrition is a key component of the economic feasibility with over 70% of total costs of production related to feed. An example of a trade-off between animal health and production is the ban on the use of antibiotics and ZnO. This is a 'win-win' for public health and the environment, but a 'lose-lose' for animal (gut) health and production. The environmental impact predominantly relates to nitrogen and phosphorus excretion with strategies such as reduced crude protein, increased use of synthetic amino acids and optimization of phytase rates requiring further industry integration. The future industry will require a focus on precision animal nutrition, validation of alternative feed ingredients (insects, algae, microalgae, seaweed etc), optimization of current enzymatic use and an increased usage of food waste and co-products. This precision nutrition will focus on the interaction of nutrition with animal physiology, microbiology, immunology (immunometabolism), host genetics (nutrigenomics). The tools that we need should quantify the 'win' and the 'lose' of the dilemma, so that each stakeholder can make a well-informed decision. We are now in an era that large-scale non-invasive animal monitoring is feasible and research should focus on how these tools can be used to assess health, production, and welfare. Also, for complex issues such as gut health, targeted experimental research will be required to identify the mechanisms behind promising (nutritional) levers that ensure gut health.

Session 77

Theatre 3

Economically sustainable and animal welfare friendly animal production: what is the role of research*A. Silvera¹ and H.A.M. Spoolder²**¹Svensk Fågel, Sustainability dept, Sweden, ²Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; anna.silvera@svenskfaegel.se*

The European Commission is about to publish legislative proposals to further improve the welfare of livestock. The proposals will be based on extensive scientific opinions from EFSA on the welfare requirements of various livestock species, and a number of impact assessments carried out to determine the likely consequences of any proposed new legislation. There are several areas in pig and poultry husbandry which may be addressed. For pigs it is very probable that there will be proposals on housing lactating sows and their piglets. A ban on farrowing crates will greatly improve the behavioural freedom of the sow, but it may also have implications for e.g. the cost of production, the welfare of the piglets, labour requirements and perhaps even emissions to the environment. Similarly, a ban on surgical castration of piglets also has its trade-offs: entire males may cause welfare problems when they are older, but will immune-castration be accepted by consumers? For broilers a reduction in growth rate together with lower stocking densities, are highly debated in the European Union. Focus from EFSA has been purely on animal welfare, but the interaction between genotype and environmental factors such as management and nutrition as well as the effects of a balanced breeding programme are lacking in the discussion. To make the issue even more complex and relevant in practice, environmental and economical sustainability must be added to the debate. In this 'challenge session' we will invite you to look at the trade-offs that are associated with these proposed changes, and ask you what the role of science can be in providing solutions to the deal with them.

Group discussion*K. Nilsson¹ and S. Millet²*¹Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, Box 7023, 75007, Sweden,²ILVO, Scheldeweg 68, 9090 Melle, Belgium; sam.millet@ilvo.vlaanderen.be

Session 78

Theatre 1

Farmed insects to create a circular bio-economy in the food and feed industry*A. Vilcinskas**Justus Liebig University of Giessen, Institute for Insect Biotechnology, Heinrich-Buff-Ring 26-32, 35392 Gießen, Germany; andreas.vilcinskas@agr.uni-giessen.de*

Farmed insects, such as the black soldier fly *Hermetia illucens*, are considered as a missing link for the circular bio-economy in the food and feed sector because they can mediate the industrial bioconversion of agricultural or industrial side streams into feed for aquaculture and livestock. In turn, the leftovers of farmed insects, the so-called frass (excrements, chitinous exuvia of the moulting larvae and feed leftovers), represents a valuable biofertilizer, which can replace chemical fertilizer in agriculture and vertical farming. The ability of *H. illucens* larvae both to utilize almost all organic substrates, even liquid manure, as a diet and to produce a potent biofertilizer has been attributed to their beneficial microbes in the gut, which can also mediate the detoxification of plant-derived secondary metabolites. The presentation highlights both the characterization and dynamics of the *H. illucens* gut microbiota and its prominent role for the circular bio-economy. The avenues for revenues of industrial insect farming can be expanded beyond the production of food, feed and bio-fertilizer to encompass the development of higher-added value products from the generated protein, lipid and chitin fractions. Taken together, farmed insects can help to create a sustainable and circular bio-economy in the food and feed industry.

Amino acid requirements of mealworm and black soldier fly larvaeT. Spranghers¹, A. Moradei² and M. Boudrez¹¹VIVES University of Applied Sciences, Centre of expertise for agro- and biotechnology, Wilgenstraat 32, 8800 Roeselare, Belgium, ²University of Milan, Department of Veterinary Medicine and Animal Sciences (DIVAS), Via dell'Università 6, 26900 Lodi, Italy; thomas.spranghers@vives.be

In order to achieve optimal growth and health of farm animals, a different amount/ratio of essential amino acids in the feed is necessary in each phase of life. Knowledge about which amino acids are essential and in which quantities/proportions they are best administered has already greatly advanced the pig and poultry sector and is still being generated today. For the still young, rapidly developing insect sector, this knowledge could mean a major step forward towards rearing optimization. Therefore, in this project the needs of the 2 most commercially reared insect species, namely mealworms (*Tenebrio molitor*) and black soldier fly larvae (*Hermetia illucens*, BSF), are investigated. The focus is on needs for lysine, methionine, threonine, phenylalanine and tryptophan based on indications from the literature and the needs of pigs. Semi-artificial diets based on at least 25% wheat bran (mealworm) and chicken feed/water (30/70) (BSF) (basic feed important for structure and certain micronutrients) supplemented with sugar and synthetic amino acids (a mixture of 14: the 10 essential for mammals + glutamic acid, glycine, alanine and aspartic acid) were tested. The diets were isoenergetic and isonitrogenous. Of the 5 amino acids studied, one was administered in different doses per experiment. The non-essential glutamic acid was used as a substitute at lower doses. Growth, as measured by weight gain, and survival were observed. For lysine, from a content of 0.35 g/100 g on, no extra mealworm growth was noticeable. For methionine this was from 0.13 g/100 g on. Each time more threonine was given, a significant difference could be noticed and the minimum dose appears to be 0.42 g/100 g. With tryptophan there were no differences between the different concentrations. At 0.06 g/100 g the maximum growth was already reached. Ultimately, a report will be drawn up with the formulation of standards and guidelines, with special attention to the translation of the research into practice with attention to sustainability.

Session 78

Theatre 3

Evaluation of the suitability of hemp production side-streams for the rearing of edible insectsA. Kolorizos¹, G. Baliota¹, C. Adamaki-Sotiraki¹, I. Malikentzos², C.I. Rumbos¹ and C.G. Athanassiou¹¹University of Thessaly, Lab of Entomology and Agrucultural Zoology, Phytokou str., 38446, Volos, Greece, ²Kannabio – Hemp Hellas, 110 Skoufa Str., 38334, Volos, Greece; crumbos@uth.gr

In recent years, hemp cultivation has been considerably increased across EU, as hemp can be exploited for a number of applications of the textile and the pharmaceutical industry, as well as of the food and feed sector. During hemp production, several side-streams are produced, but these materials remain largely untapped. Insects can serve as efficient bioconverters of agricultural side-streams contributing to the upcycling of these residual resources to high-value end-products (i.e. insect meal and oil). However, studies on the suitability of hemp side-streams for insect rearing are limited. Therefore, the aim of the present study was to evaluate the suitability of four by-products of hemp production as insect feed for the larvae of the yellow mealworm, *Tenebrio molitor*, the lesser mealworm, *Alphitobius diaperinus*, the superworm, *Zophobas morio*, and the black soldier fly, *Hermetia illucens*. In this regard, we studied three side-streams of the hemp seed production (*Cannabis sativa* L. var. Fedora19), i.e. cold-pressed hempseed press cake, hemp plant biomass leftovers on the field (hemp stalks, leaves and stems) and the by-product of hemp seed cleaning process (small and broken hempseeds), and one side-stream of the hemp flower bud production (*C. sativa* var. Futura75; grinded buds and leave remains, secondary stems, hempseeds). In a series of laboratory trials, early-instar larvae were fed on each of the by-products tested and larval growth parameters were recorded. Based on the results, larval growth and performance varied depending on the insect species and the by-product tested. In general, the hempseed press cake could efficiently support the larval growth and development of all species tested, as in most cases a similar to the control growth rate was recorded when larvae were fed on this by-product. These results aim to integrate two relatively new and innovative agricultural activities, i.e. insect farming and hemp production, into a sustainable, based on circular economy, farming system. This research is supported by the EU-PRIMA program project ADVAGROMED (Prima 2021 – Section 2).

Dietary fat sources impact black soldier fly larvae performance*R. Zheng, S. Karanjit and A. Hosseini**Protix, Van Konijnenburgweg 86, 4612 PL Bergen op Zoom, the Netherlands; ruilongzheng@126.com*

The use of Black soldier fly larvae (BSFL, *Hermetia illucens*) as a sustainable protein and lipid source for animal feed has gained significant momentum in recent years. Nutrition is a critical component of BSFL production, with dietary fat (F) and carbohydrates (C) serving as essential energy sources. However, the optimal balance of F and C in BSFL diets is not well understood. This study aimed to address this knowledge gap by investigating the influence of different dietary F sources on BSFL rearing. We used chemically semi-defined diets containing three different F sources: coconut oil, milk-based butter, and avocado oil. We took an integrative experimental approach to evaluate the impact of these F sources on key performance indicators in BSFL production, including bioconversion efficiency (BE), yield, and survival. Our findings revealed that the source of F influenced BSF larvae performance. Avocado oil enhanced dry yield, while coconut oil and butter were not effective when combined with high C levels. However, all F sources showed potential as replacements for C in BSFL diets without negatively affecting yield or BE when used in moderation. Our study also found that low C levels negatively impacted larval survival. Furthermore, increased levels of both C and F resulted in lower BE. Overall, this study provides new insights into the impact of different F sources on BSFL rearing and highlights potential strategies for optimizing BSFL diets commercial production.

Hermetia illucens* production parameters and the effect of dietary energy sourceE.Y. Gleeson and E. Pieterse**Stellenbosch University, Animal Sciences, Mike de Vries Building, Merriman ave, Stellenbosch Central, 7600, South Africa; 19539037@sun.ac.za*

Hermetia illucens is arguably the most extensively researched insect species in agriculture and food sciences. The larva of this species is a great candidate for the valorisation of pre-consumer food waste. The larval nutritional composition is significantly affected by a number of factors. The first factor that was known to have an influence is age. However, recent studies have identified other factors such as rearing substrate composition and environmental conditions. Based on previous work on the *H. illucens* larval nutritional requirements, the goal of formulating nutritionally balanced larval diets aimed at tailoring the larval composition to its intended use is more attainable than ever before. Although larval composition is of great importance in production, certain production parameters also have a significant influence on the success of a production system. Therefore, it is crucial to understand the effect of rearing substrate composition on production parameters of *H. illucens* larvae. This study aimed to determine the influence of dietary energy source on larval production parameters. The energy sources that were evaluated included oils i.e. sunflower and fish, and carbohydrates i.e. sucrose, fructose and corn starch. These food grade energy sources were chosen as they represent the most common energy sources found in pre-consumer waste products. The production parameters that were determined included feed conversion ratio, growth rate, and substrate reduction rate. Growth rate was unaffected by treatment diets ($P > 0.05$). This indicates that the energy source does not have an influence if the diets are formulated to supply the nutrient requirements of the animals. There were significant difference between the treatments in terms of substrate reduction rate and feed conversion ratio. The carbohydrates exhibited higher substrate reduction rates, fructose having the highest reduction rate at 72.83% ($P < 0.001$). The oils exhibited better feed conversion, fish oil treatment having the best feed conversion at 2.47 ($P < 0.001$). These results could provide parameters for the determination of optimum inclusion of a number of energy sources in larval diets, thereby optimizing production based on the chosen energy sources.

Starch digestion in *H. illucens* conversion: exploring the role of amylases from larvae and substrateJ.B. Guillaume^{1,2,3}, S. Mezdour⁴, F. Marion-Poll^{2,5}, C. Terrol¹, C. Brouzes¹ and P. Schmidely³

¹Agronutris, R&D Department, 35 blv du Libre Echange, 31650 Saint-Orens de Gameville, France, ²CNRS, IRD, Université Paris-Saclay, Laboratoire EGCE, IDEEV, 12 route 128, 91190 Gif-sur-Yvette, France, ³Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 place de l'Agronomie, 91120 Palaiseau, France, ⁴Université Paris-Saclay, INRAE, AgroParisTech, Sayfood, Campus Palaiseau, 22 place de l'Agronomie, 91120 Palaiseau, France, ⁵Université Paris-Saclay, AgroParisTech, 22 place de l'Agronomie, 91120 Palaiseau, France; jeremy.guillaume@agroparistech.fr

The capacity of black soldier fly larvae (BSFL; *Hermetia illucens*) to transform organic substrates into body proteins and lipids suitable for animal nutrition is receiving growing attention. Carbohydrate content of BSFL diet is positively related to larval growth, fat body content and adult egg production, but underlying mechanisms of feed conversion remain to be explained. Previous studies reported amylase activity in larval midgut, and it has recently been shown that BSFL were highly efficient at digesting starch. This study focused on the effect of starch content and type on BSFL amylase activity and starch Estimated Digestibility (ED). BSFL were fed on five plant-based diets with different starch contents and types, and larvae and substrates were sampled after 4, 7 and 11 days of feeding, along with initial BSFL and diets. Each sample was ground in phosphate-buffered saline with protease inhibitor and centrifuged to collect water phase. Amylase activity was assessed using the Bernfeld technique and reported to total soluble protein measured according to Bradford. For substrate samples that could contain enzymes from the plant material, microbes or larvae, BSFL amylases were detected by Western-Blot using antibodies specific to insect amylases. This approach offers insight into larval amylase regulation mechanisms and the role of extra-oral digestion of starch in BSFL conversion systems.

Session 78

Theatre 7

Investigating the nutritional requirements of black soldier fly larvae using artificial substrates

L. Broeckx, L. Frooninckx, A. Wuyts, S. Berrens, M. Van Peer and S. Van Miert

Thomas More University of Applied Sciences, RADIUS, Kleinhofstraat, 4 2440 Geel, Belgium; laurens.broeckx@thomasmore.be

Due to the rising need for alternative protein, the black soldier fly gained interest of researchers worldwide. One reason for this is the insect's remarkable efficiency at converting feed into larval biomass, rich in high-quality protein. Moreover, they are able to grow on a high variety of organic side- and waste streams, allowing local production of high-quality protein, while also valorising organic waste. Even though their remarkable plasticity towards growing on a wide range of organic substrates has been proven in many studies, optimization is still necessary to increase the sector's viability. In order to optimize the sector, one important approach is to tailor the nutritional requirements of black soldier fly larvae. By doing so, models can be developed that predict larval growth based on substrate nutrient compositions, which can help combine different organic side-streams to create a more nutritionally complete substrate for black soldier fly rearing. Therefore in this study, multiple designs were developed and tested to study the effects of macronutrient contents on the growth of black soldier fly larvae through the use of artificial substrates. Substrates were composed of casein, sunflower oil, potato starch and cellulose, which allowed precise formulation of substrates, and could reduce the background noise such as the presence of complex sugars and unbalances in amino acid profiles. In this study, a model was built, showing significant main, interaction and quadratic effects of substrate protein and fat contents. A maximal larval growth was acquired at a substrate protein content of 30.12% and a fat content of 8.75%. The effect of carbohydrates on larval growth was not significant in this study, however this could be due to poor digestibility of raw potato starch by the larvae. While larvae tend to grow best on high-protein substrates, research shows that the protein conversion efficiency is inversely proportional to substrate protein content, meaning we may need to reconsider our approach to substrate optimization if we want to balance between maximizing larval growth and improving protein conversion efficiency.

Km0 diets for black soldier fly larvae: the link between insect rearing and biogas systems

S. Bellezza Oddon, I. Biasato, Z. Loiotine, A. Resconi, C. Caimi and L. Gasco

University of Turin, Department of Agriculture, Forest and Food Sciences, Largo Paolo Braccini, 2, 10095 Grugliasco, Italy; sara.bellezzaoddon@unito.it

Energy consumption is one of the aspects that need to be considered to improve insect farming sustainability. In biogas systems part of the thermal energy is dissipated. Since black soldier fly (BSF) is reared at 28-30 °C and is able to bio-convert organic materials, the link between its farming and biogas plants could valorise the use of thermal energy, surplus of by-products (BP) for the anaerobic digestion and surrounding BP from food production. In the frame of the POWERFOOD project where a climatic room is warmed by biogas heat, this study aimed to identify the optimal BSF rearing substrates formulated using BP. Substrates were: biogas BP [BioS] (triticale, ryegrass silage, sorghum, corn mash and chopped), sugar beet BP [SB] (filtering waste, dry and liquid vinasse), beer BP [B] (brewer's spent grain and spent yeast) and milk BP [M] (milk whey). Since the BioS were km0, it was tested alone and included in all diet formulations as follows: (D1) BioS by-products, (D2) BioS + SB – except filtering waste, (D3) BioS + B, (D4) BioS + SB + B, (D5) BioS + B + M, (D6) BioS + SB + M and (D7) BioS + SB + B + M. 6-day-old larvae were reared (100 individuals/box; 6 replicates/treatment) until 5% reached the prepupae instar. At the trial end, survival rate (SR), growth rate (GR), reduction rate (RR), waste reduction index (WRI) and bioconversion efficiency corrected for residue (BER) were calculated. Data were analysed by one-way ANOVA (post-hoc: Tukey). The SR was high in all dietary treatments (>97%). Among treatments, D3 and D5 led to the best results in terms of weight ($P<0.001$). D1 larvae were lighter when compared to the other groups ($P<0.001$), with the exception of D2 and D6. D3 and D5 displayed the greatest WRI, and higher GR and BER than D1, D6 and D7 ($P<0.001$). The RR of the D1 was equal to D3 and D5, and higher when compared to the other groups ($P<0.001$). In short, diets with the B ingredients showed the best growth performance and bioconversion efficiency, with the exception of the D7 that was formulated with the highest inclusion of triticale, which is rich in fibre and may have caused reduced metabolization of nutrients.

Session 78

Theatre 9

Sugar processing by-products for black soldier fly farming: does the rearing scale matter?

I. Biasato, S. Bellezza Oddon, A. Resconi, Z. Loiotine and L. Gasco

University of Torino, Largo Paolo Braccini 2, 10095 Grugliasco (TO), Italy; ilaria.biasato@unito.it

Rearing scale may influence black soldier fly larvae (BSFL) traits, but different feeding substrates have not been tested yet. This study evaluated the effects of sugar processing by-products-based diets on performance and nutritional profile of BSFL reared in different scales. Four diets (D1-D2 [isonitrogenous, isolipidic and isoenergetic]; D3-D4 [1:1 and 1:2 as protein to carbohydrate ratios]) were tested in 3 rearing scales (4 replicate boxes/diet, constant volume [0.84 cm³]/larva and feed [0.7 g]/larva): (1) small (S; 12×12 cm, substrate height [H]: 4 cm, 686 6-day-old larvae [6-DOL]/box); (2) medium (M; 32×21 cm, substrate H: 7 cm, 5,600 6-DOL/box); and (3) large (L; 60×40 cm, substrate H: 7 cm, 20,000 6-DOL/box). Larval weight was recorded at the beginning of trial and every 4 days, and growth rate (GR), specific growth rate (SGR), feed conversion ratio (FCR), survival, bioconversion efficiency corrected for residue, reduction rate (RR), and waste reduction index (WRI) calculated at the end of larval growth (frass dry matter [DM]≥55%). Substrate pH, T and H were measured at the beginning, every 4 days, and end of trial. Larval proximate composition was analysed at the end of trial. Data were analysed by GLMM (SPSS software, $P<0.05$). D1 larvae showed higher weight, GR, SGR and WRI (along with higher substrate T) than D2 in M scale, while increased SGR and FCR – as well as decreased survival, RR and WRI – were observed in D2 larvae in S scale ($P<0.05$). Larval crude protein (CP) and ether extract (EE) contents were influenced by M and L scales only, being higher in D2 group than D1 ($P<0.001$). Differently, decreased ash was recorded in D2 larvae when reared in S and M scales, while L scale revealed higher ash in D2 group than D1 ($P>0.001$). D3 larvae displayed greater weight, SGR, survival, RR and WRI (along with greater substrate T) than D4 in M scale, with increased survival and substrate T being also highlighted in L scale ($P<0.05$). D3 larvae also showed lower DM and EE – as well as higher CP – than D4 in all the rearing scales ($P<0.001$). In conclusion, D1 and D3 led to better BSF larval performance and nutritional profile in M and L scales, attributable to the initial higher substrate H and higher substrate T achieved.

Optimization of a hatchery residues fermentation process to feed black soldier fly larvaeM. Dallaire-Lamontagne^{1,2}, G.W. Vandenberg², L. Saucier^{1,2} and M.H. Deschamps^{1,2,3}¹Institute of Nutrition and Functional Foods, 2440 Bd Hochelaga, Québec, QC, G1V0A6, Canada, ²Dép. des sciences animales, U. Laval, 2425 rue de l'Agriculture, Québec, QC, G1V0A6, Canada, ³CLEIC, <https://cleic.fsaa.ulaval.ca/>, G1V0A6, Canada; marieve.dallaire-lamontagne.1@ulaval.ca

The conventional management of hatchery residues (HR; unmarketable chicks and eggs) is associated with environmental issues and health risks. Fermenting HR could reduce the loads of pathogenic microorganisms and odours while minimizing energy costs compared to thermal rendering. Fermented HR could then be processed into animal feed through bioconversion of black soldier fly larvae (BSFL; *Hermetia illucens*), in a circular manner. Given the low sugar content of the HR, a low-cost co-product must be incorporated to optimize the fermentation. HR were thus fermented in semi-anaerobic conditions with or without the addition of a starter culture (Lacult-SAX-01; 0.3%, HR) and with supplementation of whey permeate (dry or at 55% moisture) for lactose inclusion rates of 0, 5, 15, 25 and 35% (dry matter) for 2 weeks. The pH, microbiological quality (total mesophilic aerobes, lactic acid bacteria (LAB), coliforms, *Escherichia coli*), and volatile fatty acids were measured at 0, 3, 7 and 14 days to evaluate the efficiency of the process. Fermentation of HR resulted in a maximum pH reduction (<5) after 7 days for treatments with lactose inclusion of 15-35%. The reduction in pH, the formation of lactic acid (50,6 mg/g HR) and acetic acid (7,4 mg/g HR) as well as the maintenance of LAB loads in the HR contributed to the average 5 log cfu/g reduction in coliform and *E. coli* loads for treatment at 25-35% of lactose inclusion. However, the time to reach the detection limit for these microorganisms (<1,70 log cfu/g) varied from 7 to 14 days depending on the initial contamination of the HR and the addition of a starter culture. The initial loads of LAB (>7 log cfu/g) were sufficient to initiate spontaneous fermentation of the HR. However, addition of a starter culture could still be relevant since its efficiency was demonstrated in heat pre-treated HR. This project will improve the sustainability of livestock waste management systems and provide data to support the accreditation of BSFL ingredients reared on animal co-products.

Fish side residues as a substrate for *Hermetia illucens*

M.G. Zhelezarova

NASEKOMO, Novoseltsi 174, 2100, Bulgaria; mirena.zhelezarova@nasekomo.life

Black soldier fly (BSF) is becoming the preferred insect solution to valorise non-utilized biomass from agro-industries. For fish industries, these side streams present ecological and economic benefits that the insect industry may process. However, previous studies show that high inclusion levels of aquaculture residues can have negative impacts on BSF larval development. Thus, a solution on how to efficiently include fish biomass into BSF feed to achieve significant protein yields without triggering high mortality rates and poor Feed Conversion Ratio (FCR) is needed. Understanding interactions with other raw ingredients in the recipe is also necessary. 'EcoFISHent' is a project funded by the European Union H2020 program (GA 101036428), to develop an industrial symbiosis system able to efficiently exploit fish-processing side streams and create a variety of valuable products. It involves a consortium of thirty-four parties and representatives of different sectors. NASEKOMO's mission in this project is to establish a methodology to convert such side streams into added value resources through insect bioconversion. Four diets with different saltwater fish residues inclusions were formulated in mixture with regular local raw materials and tested against benchmark recipes containing the same ingredients and proportions except for the fish ingredient being replaced by non-digestible pure cellulose. Survival rates (6-12 days old) were above 95% in all fish residues feed groups. Fish side streams diets resulted in higher weight per individual and insect biomass total yield, but lower FCR compared to their benchmarks. BSF larvae were able to feed and survive on the set of raw materials provided locally by 'Nasekomo' and mixed with aquatic animal production side-streams. High lipid concentrations in aquaculture side residues are challenging for BSF bioconversion but can be diluted in the feed with other ingredients. A variety of vitamins and sterols are also needed to satisfy nutritional requirements of the animals and need to be provided by other feed components. Substrate texture is also showed to be crucial but ultimately depends on the fish residues composition, nutritional values, and water salinity along with other ingredients characteristics and inclusions in the feed recipe.

Black soldier fly larvae production is optimized by the presence of HMTBaK. Luyt¹, G. Crielgaard¹, M. Briens², J.A. Conde-Aguilera² and M. Ceccantini²¹Entobel Ltd Company, 531a Upper Cross Street, #04-95 Hong Lim Complex, Singapore, ²Adisseo France S.A.S., 10 place du Général de Gaulle, 92160 Antony, France; mickael.briens@adisseo.com

Insects are becoming a promising source of proteins and fats for aquaculture, pet and poultry feed, and can partially replace vegetal proteins. It represents an important way to upcycle food and feed waste and decrease the carbon footprint of meat production. Still, the development of insect meal production has to be improved to have efficient and economical ways to produce insect larvae. In this study, black soldier fly (*Hermetia Illucens*) raised on food waste were tested for their efficiency on performance and cost, when a source of methionine (Hydroxy-methylthiobutanoic acid [HMTBa]) was added or not in the larvae feed. A 7-day trial starting with 1st instar black soldier fly larvae (BSFL) was run with 4 dietary treatments × 6 crate replicates: control, and control plus HMTBa at doses 0.08, 0.16 or 0.32%. The average initial weight was 2.41 mg/larvae and the larvae were equally inoculated in 12 kg of feed commonly used in Entobel production system. The HMTBa additive was added during the fermentation of feed for 3 days prior to the trial. Results: HMTBa used at 0.16 and 0.32% presented 11.9 and 10.4% significantly ($P < 0.05\%$) higher fresh larvae biomass production than control on whole period. Considering larvae biomass and feed residue on the whole period, the feed conversion of these treatments was statistically different (3.49^a; 3.14^b; 2.74^c; 2.75^d, respectively). The crude fat content of the fresh larvae was not modified by treatments containing HMTBa when compared to control (27.6; 28.9; 30.3; 29.0%, respectively). The crude protein content was not affected as well (52.7; 50.9; 48.8; 50.6%, respectively). Besides that, the cost of insect meal per treatment demonstrated to be lower by 20.3% when HMTBa was added in the larvae feed. Conclusion: the use of HMTBa brings high benefits in terms of performance and cost to produce BSFL insect proteins and fats. Further studies are necessary to confirm those effects and demonstrate the combined effect of different feed additives.

Black soldier fly larvae production is optimized by the presence of a multi-carbohydraseK. Luyt¹, G. Crielgaard¹, M. Briens², J.A. Conde-Aguilera² and M. Ceccantini²¹Entobel Ltd Company, Hong Lim Complex, #04-95 Hong Lim Complex, Singapore, ²Adisseo France S.A.S., 10 place du Général de Gaulle, 92160 Antony, France; mickael.briens@adisseo.com

Insects are becoming a promising source of proteins and fats for aquaculture, pet and poultry feed, and can partially replace vegetal proteins. It represents an important way to upcycle food and feed waste and decrease the carbon footprint of meat production. Still, the development of insect meal production must be improved to have efficient and economical ways to produce insect larvae. In this study, black soldier fly (*Hermetia Illucens*) raised on food waste were tested for their efficiency on performance and cost, when a multi-carbohydrase additive (containing xylanase [12,500 U/ml], glucanase [8,600 U/ml] and arabinofuranosidase) was added or not in the larvae feed. A 7-day trial starting with 1st instar black soldier fly larvae (BSFL) was run with 4 dietary treatments × 6 crate replicates: control, and control plus a multi-carbohydrase dose of 100, 200 or 400 ml/ton larvae feed. The average initial weight was 2.41 mg/larvae and those larvae were equally inoculated in 12 kg of feed commonly used in Entobel production system. The additive was added during the fermentation of feed for 3 days prior to the trial. Results: the treatments with multi-carbohydrase at 100 and 200 ml/ton presented 8.5 and 12.7% significantly ($P < 0.05$) better fresh larvae biomass production than control on the whole period, respectively. Considering larvae biomass and feed residue on the whole period, the feed conversion of these treatments was statistically different (3.49^a; 2.55^b; 2.26^c; 2.15^c, respectively). The fresh larvae presented just numerical increase in crude fat content for all treatments when compared to control (27.6; 33.0; 34.1; 37.0%, respectively), and no differences on the crude protein content (52.7; 47.7; 47.8; 46.7%). Besides that, the cost of insect meal per treatment demonstrated to be lower by 32% when the additive was added in the larvae feed. Conclusion: the use of multi-carbohydrases brings high benefits in terms of performance and cost to produce BSFL by the better feed conversion and fat production. Further studies are necessary to confirm those results.

Effect of water-soluble complementary feed on performance in nursery of black soldier flyL. Schneider¹, M. Brake², A. Hesecker², W. Westermeier³ and G. Dusel¹¹University of Applied Science Bingen, Department of Animal Nutrition, Berlinstraße 109, 55411 Bingen am Rhein, Germany, ²MIAVIT GmbH, Robert-Bosch-Str. 3, 49632 Essen, Germany, ³FarmInsect GmbH, Münchner Str. 10, 85232 Bergkirchen, Germany; l.schneider@th-bingen.de

The starter feed is one of the most important diets of livestock insects and especially for newly hatched black soldier fly (BSF) neonates. Proper nutrition during the starter phase is essential for adequate growth and development, which will ultimately affect the overall performance of the flock. The aim of the study was to evaluate the performance and development of BSF neonates reared in a controlled environment on an iso-nitrogenous and iso-energetic standard diet (wheat bran, chicken feed, water) with either water-soluble mineral complementary feed (WSCF1, 1%, WSCF2, 2%, WSCF3 3%) or a non-water-soluble mineral feed addition for poultry (MFP, 3%) or a control without mineral feed addition (CON). A total of 62 g BSF eggs (1 g eggs = 0.45 g neonates) were placed randomly per unit (6 replicates/treatment, 60×40×15 cm). At the end of the nursery phase the mean bodyweight of 100 larvae (BW), dry matter (DM) and total weight of 5-day-old larvae output per unit as well as total weight of larval frass was observed. The results showed that the mean BW of WSCF3- and WSCF2-fed (BW, 0.12 g/100 BSFL) larvae were nearly similar and increased by 33% ($P<0.05$) compared to CON-fed larvae (BW, 0.09 g/100 BSFL). Additionally, the DM (%) of WSCF3-fed larvae showed an 8% increase compared to MFP-fed larvae. WSCF2-fed larvae showed a 13% higher ($P<0.05$) total weight of young larvae compared to CON-fed larvae (WSCF2, 678.5 g; CON, 588.4 g). The total weight of the larval frass at the end of the nursery phase of group WSCF2 was 31% lower ($P<0.05$) than that of the CON-group (WSCF2, 1,797.3 g; CON 2,616.6 g). In conclusion, this first study demonstrates the potential of a water-soluble complementary feed on the performance and development of young BSF in the crucial pre-starter phase. Further investigations are necessary to recommend a possible efficient and sustainable preconditioning effect in BSF nursery.

Digestibility in *H. illucens* larvae: resolving faeces collection and ingesta quantification issuesJ.B. Guillaume^{1,2,3}, S. Mezour⁴, F. Marion-Poll^{2,5}, C. Terrol¹ and P. Schmidely³¹Agronutris, R&D Department, 35 bld du Libre Echange, 31650 Saint-Orens de Gameville, France, ²CNRS, IRD, Université Paris-Saclay, Laboratoire EGCE, IDEEV, 12 route 128, 91190 Gif-sur-Yvette, France, ³Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 place de l'Agronomie, 91120 Palaiseau, France, ⁴Université Paris-Saclay, INRAE, AgroParisTech, Sayfood, 22 place de l'Agronomie, 91120 Palaiseau, France, ⁵Université Paris-Saclay, AgroParisTech, 22 place de l'Agronomie, 91120 Palaiseau, France; jeremy.guillaume@agroparistech.fr

Black soldier fly larvae (BSFL; *Hermetia illucens*) are increasingly studied for their ability to convert organic substrates into body proteins and lipids that can be used for animal nutrition. Although many studies have used BSFL high weight gain to highlight their strong feed conversion efficiency, little is known about the inherent efficiency of each of the four feed conversion stages: ingestion, digestion, absorption, and metabolic utilisation. Assessing digestibility requires quantifying the amount of feed ingested and the associated faeces produced. However, this is challenging in BSFL because they feed and release excreta in the same substrate, which also hosts complex microbiota participating in digestion. This study introduced a new indicator called Estimated Digestibility (ED), defined as the difference between distributed feed and frass macronutrient weight, divided by macronutrient weight in distributed feed. The evolution of ED was assessed with increasing larval density in order to ensure complete feed ingestion and frass free from refused feed. ED was measured on a standard diet with densities from 0 to 29 larvae/cm² for dry matter (DM), starch, nitrogen, ether extract (EE), neutral detergent fibre, acid detergent fibre, acid detergent lignin, ash and energy. The results showed a sigmoidal pattern for ED of all fractions except fibres. Asymptotic ED was 80.3±1.3% (mean ± standard error) for DM, 99.0±2.3% for starch, 78.6±1.1% for nitrogen, 95.3±1.5% for EE, 58.4±1.0% for ash and 80.6±1.2% for energy. Asymptotic ED is the closest estimation of digestibility as defined in other species. It offers perspective on the understanding of BSFL digestive efficiency and could be used for diet formulation.

Black soldier fly larvae as tools for the bioconversion of sludge from wastewater treatmentsC. Ligeiro¹, I. Lopes^{1,2}, T. Ribeiro^{1,2}, I. Rehan³, K. Silvério⁴, M. De Fátima⁴ and D. Murta^{1,2}¹*Ingredient Odyssey SA, EntoGreen, Portugal*, ²*CiiEM – Centro de Investigação Interdisciplinar Egas Moniz, Campus Universitário, Portugal*, ³*Polo de Inovação da Fonte Boa, Instituto Nacional de Investigação Agrária e Veterinária, Portugal*, ⁴*Instituto Politécnico de Beja, Departamento de Tecnologias e Ciências Aplicadas, Portugal*; carolina.ligeiro@entogreen.com

The project NETA (New Strategies in Wastewater Treatment) proposes a solution for the problems related to wastewater treatments. After the wastewater treatment, a sludge is obtained and is a secondary product that must be further processed. In this study, we evaluated the bioconversion of the-derived sludge with black soldier fly larvae (BSFL). For such, 7-day-old BSFL were inoculated in plastic boxes containing a diet formulated with sludge from the treatment of 2 wastewaters: water from a dairy industry and from a general wastewater collection tank, which receives waste from toilets, slaughterhouses and animal farms. The larvae diets using sludge contained sludge, wheat bran and water (T1, with sludge from the dairy industry and T2, with sludge from the collection tank) were formulated to be isoproteic, and a control diet (CT) was formulated using wheat bran and water. All diets were balanced to a 30% DM content. The temperature of the diets and the weight of the larvae were evaluated periodically throughout the experiment. In the last day, it was possible to sift the box content and the larvae were harvested and the total larval biomass and fertilizer (frass) produced were assessed. Samples from both larvae and frass were analysed for bromatological and nutrient composition. The larvae performed well in T1 and T2, being heavier in T1 (0.893 ± 0.06 g per 10 larvae) in comparison to the CT (0.642 ± 0.04 g per 10 larvae). In addition, the larval biomass was higher in T1 as well (2.32 kg per experimental unit in comparison to 1.96 kg in CT). Production of frass was statistically higher in the treatments containing sludge. It was concluded that BSFL performed well in sludge-based diet and can be considered a viable biological tool for the bioconversion and treatment of this wastewater sludge. This study was conducted under the scope of the NETA project: POCI-01-0247- FEDER-046959 funded by PORTUGAL2020.

The upcycling of agricultural by-products through insect bioconversion can help the Mediterranean countries valorise these locally available resources for the production of animal feeds and subsequently increase the resilience of Mediterranean farming systems. In this framework, within the ADVAGROMED project, a broad spectrum of agricultural by-products that are generated in Greece, Italy, Portugal, Spain and Morocco were identified, collected and chemically characterized, as a first step towards their valorisation as diet ingredients for the two most commonly reared edible insect species, i.e. *Hermetia illucens* and *Tenebrio molitor*. Specifically, by-products of the seed cleaning process of cereals and legumes (lupin, triticale, oats, barley, peas), by-products of the cotton, rice, grape, olive and hemp production, food waste (e.g. cookies, crackers, wafer, bread), vegetable and fruit by-products (carrot, pepper, green pea, tomato, zucchini, lettuce, apple, kiwi, blueberries, melon, watermelon), as well as algae were collected and analysed. Based on the results, there was a high variability in the nutritional composition of the tested by-products. Indicatively, their protein content ranged from 0.7 to 48.3%, whereas their ether extract content varied between 0.1 and 35.0%. Similarly, variable results were obtained for their dry matter (3.6-97.9%), ash (0.3-58.8%) and fibre content (1-48.4%). As a next step, compound diets will be formulated and evaluated for the rearing of *H. illucens* and *T. molitor* based on the composition of the selected by-products and the insect nutrient requirements. This research is supported by the EU-PRIMA program project ADVAGROMED (Prima 2021–Section 2).

Multigenerational and nutritional traits of BSF reared on seaweed or selenium enriched substrates

M. Ottoboni¹, L. Ferrari¹, A. Moradei¹, F. Defilippo², P. Bonilauri² and L. Pinotti¹

¹University of Milan, Via dell'Università, 6, 26900, Lodi, Italy, ²Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna Bruno Ubertini, Via Pitagora, 2, 42124 Reggio Emilia, Italy; matteo.ottoboni@unimi.it

This study evaluated the effect of inclusion of brown algae (*Ascophyllum nodosum*) or sodium selenite in BSF growing substrate on selected insect life cycle traits and the nutritional composition of the deriving prepupae. The larvae were reared on three different substrates: (1) Gainesville diet, (CTR); (2) A. nodosum diet (AN30%), with 30% substitution of the alfalfa meal with brown algae; and (3) selenium diet (Se), based on Gainesville diet fortified with 0.3 mg/kg of sodium selenite. Eggs collected from a stable colony of BSF were placed for hatching on three experimental substrates CTR, AN30%, and Se. All experiments were carried out under dark condition, at 25 °C with 70% relative humidity, and repeated for three consecutive generations. Recorded data were: live performance (i.e. percentage of mortality in each stage, development period, larvae weight, percentage of adult emergence), and reproductive performance (i.e. number of eggs laid and percentage of hatched eggs). Rearing substrate and deriving prepupae were analysed for proximate and fatty acid composition. Mortality and larval weight did not show any difference among groups during the three-generation study. In contrast, BSF development period was lower ($P < 0.05$) in CTR than in AN30% and Se group. Further differences were observed in term of percentage of adult emergence that was higher in CTR (90.4%) and Se (90.4%) compared to AN30% (78.7%). All prepupae contained a high level of saturated fatty acids. The inclusion of seaweed in the rearing substrate did not affect the fatty acid profile in the AN30% prepupae compared to CTR and Se dietary groups. Concluding, best values for number of eggs laid and percentage of hatched eggs were observed in the case of CTR. Reproductive performance dramatically decreased in AN30%, and Se groups. Combining obtained results, BSF larvae can grow on media containing up to 30% A. nodosum or selenium with some implication for both live and reproductive performance. Further investigations are required for optimising BSF meal production for specific feed or food purposes.

Session 78

Poster 19

Bacterial biomass improves performance and antibacterial activity of black soldier fly larvae

N. N. Moghadam¹, K. Dam Nielsen¹, A. Simongiovanni² and T. Chalvon-Demersay²

¹Danish Technological Institute, Kongsvang Allé 29, 8000 Aarhus C, Denmark, ²METEX Animal Nutrition, 32 rue Guersant, 75017, France; aude.simongiovanni@metex-noovistago.com

Black soldier fly larvae (BSFL) has a great capacity to identify, inactivate, and eliminate microbial load in different sources of raw materials and to valorise them into high quality protein and oil. In this experiment, we assessed the effects of a bacterial biomass as a feed additive on the performance and antibacterial activity of BSFL. The experiment consisted of 4 diets (a control and 3 treatment diets) and performed in triplicate. The treatment diets had 2, 4 and 6% inclusion rates of the bacterial biomass which was derived from an amino acid producing bacteria. The inclusion of the bacterial biomass was done at the expense of maize gluten to reach similar protein level in all diets. The diets were used at the production stage and effects of the diets were assessed on the larval production (weight and biomass), development time, survival rate, feed conversion ratio (FCR), and activity against three different bacterial strains (*Escherichia coli*, *Staphylococcus aureus* and *Pseudomonas aeruginosa*). Overall, inclusion of the bacterial biomass had a positive effect on the BSFL weight and biomass and reduced the FCR without affecting the survival rate. Interestingly, the presence of the bacterial biomass in the BSFL diet induced the antibacterial activity of the BSFL against *E. coli* and *P. aeruginosa*. This response was more pronounced in the BSFL grown on the diet containing 4% bacterial biomass. In conclusion, inclusion of the bacterial biomass in the BSFL diet improved the larval performance in general and induced the larval activity against the two tested gram-negative bacterial strains (*E. coli* and *P. aeruginosa*). The latter finding needs to be evaluated in future studies.

Impact of zinc supply on black soldier fly larvae growth, bioconversion and microbiotaL. Frooninckx¹, L. Broeckx¹, D. Vandeweyer², C. Keil³, M. Maes³ and S. Van Miert¹¹Thomas More University of Applied Sciences, RADIUS, Kleinhoefstraat 4, 2440 Geel, Belgium, ²KU Leuven, Department of Microbial and Molecular Systems, Research Group for Insect Production, Kleinhoefstraat 4, 2440 Geel, Belgium,³Technical University of Berlin, Institute of Food Technology and Food Chemistry, Department of Food Chemistry and Toxicology, Gustav-Meyer-Allee 25, Berlin, Germany; laurens.broeckx@thomasmore.be

The larvae of the black soldier fly (BSFL), *Hermetia illucens*, can be efficiently grown on a wide range of organic residues. Moreover, BSFL are a nutritious source of protein which can be used as a feed ingredient for poultry, fish, and other livestock. Therefore it has potential to play an important role in sustainable waste management, food security, and bio-based economy. Little is known about the specific metabolic and nutritional response to alterations in trace element supply for BSFL. Zinc salts are known to improve livestock animals' immune systems and growth when fed in appropriate doses. Zinc supplementation has, however, not been well studied when it comes to food/feed-relevant insects such as BSFL. In this study, BSFL were grown on Gainesville diet and food waste spiked with three different zinc concentrations. The influence of zinc on growth, survival, bioconversion, zinc-bioaccumulation and the bacterial biota of BSFL was investigated. High zinc concentrations negatively affected growth, survival and bioconversion of BSFL. There is a clear correlation between the zinc concentration in the diets and the levels in the BSFL. Although bioconversion differs between the two diets, no difference in zinc concentration in the BSFL between the two diets was observed.

Theatre 1

Review: recent outcomes associating time to PSPB increase with pregnancy loss in dairy cows

T. Minela, A. Santos and J.R. Pursley

Michigan State University, 474 S Shaw Ln, 48824, East Lansing, USA; thainaminela@gmail.com

In the last 4 years, our laboratory has focused on understanding the role of time to increase in pregnancy specific protein B (PSPB) during early pregnancy establishment in lactating dairy cows. We utilize a daily, within-cow sampling regimen that allows us to capture PSPB increases on an individual basis. This regimen covers three important periods of embryonic development: pre-, peri- and post-attachment of the conceptus to the uterus. We utilize PSPB as a marker of conceptus viability. Characteristically, most cows have a significant PSPB increase, around d 20 (25.3%), and 21 (25%). Yet, some cows may experience a delayed increase in PSPB, on d 22 (8.7%) or later (up to d 26; 3.2%). Inarguably, an extended period to onset of increase in PSPB was associated with greater early pregnancy losses (occurring before ~d 35). Pregnancy losses totalled 76% when increase of PSPB occurred ≥ 23 d post-ovulation, 30% for cows with increase in PSPB at d 22, 12% for d 21 and 10% for ≤ 20 d post-ovulation. This phenotype is also associated with parity. Parous cows are more prone to have a later increase in PSPB than their nulliparous counterparts (nulliparous 21.1 d, primiparous 23.6 d and multiparous 24.3 d). There are three distinct patterns of PSPB profiles identified across studies. Cows with an initial PSPB increase that subsequently maintain pregnancy, cows with an initial PSPB increase that lose pregnancy by the first pregnancy diagnosis, and cows with no marked increases, thus non-pregnant cows. Cows that maintain pregnancy have greater PSPB concentrations between d 23 and 28 in comparison with cows that lose pregnancies. A more pronounced and premature increase in PSPB may be associated with greater potential for embryonic development capacity and pregnancy success. This novel way to utilize daily PSPB concentrations may provide an accurate indication of time to conceptus attachment and may be an excellent model for gaining a greater understanding of pregnancy loss in dairy cows.

Improving cow fertility by immunizing against inhibin and P4 supplementation*Z.D. Shi, F. Chen and R.H. Guo**Jiangsu Academy of Agricultural Sciences, Institute of Animal Science, 50 Zhongling Street, Xuanwu District, 210014, China, P.R.; zdshi@jaas.ac.cn*

Pursuing higher and higher milk production has led to severe decreases in dairy cow fertility that is especially prominent under hot climatic conditions. Tremendous effort has been invested to solve this problem worldwide with little success. We utilized the method of immunoneutralization of inhibin bioactivity in order to enhance ovarian development capacity by stimulating FSH secretion by the pituitary gland and enhancing follicle response to FSH. This approach has been previously shown to enhance the ovarian follicle development, oestradiol secretion and conception rate (CR) in cows subjected to Ovsynch protocol treatment. In addition, antibodies to inhibin alpha subunit treatment of the *in vitro* matured oocytes also improved oocyte maturation and the resultant pathogenic embryo development. In the latest experiments, we incorporated immunization against inhibin into the Ovsynch protocol together with supplementation of progesterone to treat the post-partum cows. In experiment 1 that was conducted under severe heat stress of July in the tropical region, CR increased from 8.1% (5/57) in the control cows to 43.9% (25/62) in the immunized animals. In experiment 2 conducted under mild heat stress of August in the temperate region, CR was increased from 26.7% (4/15) in the control cows to 64.7% (11/17) in the immunized ones. The 3rd experiment was conducted on the same farm of experiment 2 but the comfortable April, and CR was increased from 44.2% (19/43) to 71.1% (32/45) by immunization against inhibin. In experiment 2, immunization against inhibin increased blood concentration of FSH, activin A during both follicular and luteal phases, and of E2 in the follicular phase, but decreased P4 concentrations during luteal phase. However, interferon-tau concentrations in blood around the time of pregnancy recognition were doubled in the inhibin immunized cows. In conclusion, immunization against inhibin plus P4 treatment enhances ovarian follicle and the subsequent early embryo developments that help to greatly improve the conception rate to the range of 60 to 70% in Holstein dairy cows.

Session 79

Theatre 3

Characterization of sex chromosomes-linked lncRNAs in Holstein spermatozoa under stress conditions*A. Yousif, G. Thaller and M. Saeed-Zidane**Institute of Animal Breeding and Husbandry, Christian-Albrechts-University of Kiel, Animal Breeding and Genetics Group, Olshausenstraße 40, 24098 Kiel, Germany; ayousif@tierzucht.uni-kiel.de*

Long non-coding RNAs (lncRNA) are known to be involved in regulation of numerous biological processes in most types of cells studied so far including sperms. lncRNAs play a vital role during the spermatogenesis and post-fertilization stages. However, very little is known about the potential role of lncRNAs located on sex chromosomes for sperm quality and functionality under stress conditions. Therefore, the aim of this study is to investigate the genetic characteristics of X and Y chromosome-linked lncRNAs and the association of sperm-borne-lncRNAs in spermatogenesis and post-fertilization. To achieve our goals, two different groups of qualified (n=6) and non-qualified (n=6) Holstein bulls were subjected to semen collection at four different seasons. Thereafter, sperm-extracted DNA was used for genotype analysis of thymosin beta 15b lncRNA (TMSB15B) located on the Y chromosome using Sanger sequencing. The RNA level of sperm-borne lncRNAs located on sex chromosomes was analysed in all experimental semen samples collected across seasons (winter, spring, summer, and autumn). The preliminary results showed that one SNP (A/G) was found in the 350 bases upstream region of TMSB15B gene of two qualified bulls compared to bovine reference genome (NCBI). On the transcriptional level, TMSB15B lncRNA was significantly higher in the semen of qualified bulls compared with non-qualified ones. Furthermore, X inactive-specific transcript (XIST) lncRNA located on the X chromosome showed significantly higher RNA levels in non-qualified bull's semen collected in autumn compared to winter and spring. Additionally, transcript X2 was the most abundant one among the three transcripts of XIST, particularly in qualified bull's semen collected in winter and non-qualified bull's semen collected in spring. On the other hand, sperm-born lncRNA KANTR was significantly higher only in winter semen of qualified bulls. In conclusion, the sperm-borne-lncRNAs located on sex chromosomes level can have a profound prediction for pre-and post-fertilization success. Therefore, further investigations are ongoing on analysing further sperm-borne lncRNAs with the application of *in vitro* fertilization.

Inbreeding affects the freezing ability in sperm samples of Pura Raza Español stallionsZ. Peña¹, M. Valera², A. Molina¹, N. Laseca¹ and S. Demyda-Peyrás³¹Universidad de Córdoba, Campus Rabanales, 14071, Córdoba, Spain, ²Universidad de Sevilla, Utrera 2, Sevilla, Spain, ³FCV – UNLP, Calle 60 y 118, La Plata, Argentina; zahiramaria@hotmail.com

Inbreeding is a genetic condition produced by mating relatives, which affects negatively the fertility of individuals. This condition is particularly important in horses, where close-related matings are common. In this study, we analysed the effect of inbreeding on sperm quality and freezing ability (endogamic depression) of Pura Raza Español Stallions. We evaluated 720 ejaculates from 108 PRE individuals collected by natural mating on the artificial vagina. Samples were centrifugated and diluted and equilibrated for 5 min in BOTUCRIO™ extender to 50×10^6 spz/ml. In addition, a sperm aliquot was frozen following a controlled-ramp protocol. The assessment of kinetic parameters in fresh and frozen-thawed samples was performed at 5 and 60 min of incubation using a CASA analyser. The effect of inbreeding was assessed using a multivariate mixed model with REML methodology (total (MOT) and progressive (PROG) motility, VSL, VAP, VCL, ALH, and BCF), including as fixed effects age at jump, and year of birth. The inbreeding value (F) was included as a linear covariate. The variance components were estimated using the BLUPF90 software package. Results showed that the increase of inbreeding produced higher EBVs in MOT and PROG, as well as in VSL, VAP, and BCF on fresh samples. However, estimates for both motilities and BCF after 60 min of incubation were significantly lower. No effect on kinetic parameters was detected. These results agree with the hypothesis that inbreeding increases the percentage of hyperactivated spz at early stages, thus decreasing the longevity of the sperm. On the contrary, the increase in inbreeding produced a negative effect on MOT and PROG in frozen-thawed sperm which estimates were significantly lower in individuals with higher inbreeding rates. To our knowledge, this is the first attempt to model the kinetic parameters of stallion sperm from a genetic point of view. With its method, we detected and quantified a negative effect of inbreeding in kinetic parameters and freezing ability in stallions. Interestingly, similar patterns were previously reported in captive populations of wild animals, but not in livestock.

Sperm transcripts and seminal plasma metabolome reveal the regulatory mechanism of bull semen quality

W.L. Li and Y. Yu

China Agricultural University, Animal Breeding and Genetics, no.2 Yuanmingyuan WRD, China Agricultural University, 100193, Beijing, China, P.R.; yuying@cau.edu.cn

Semen quality of dairy bulls is very important for selecting excellent stud bulls. Recent studies have found that some transcripts are not only the residue of sperm maturation, but also related to semen quality. Moreover, seminal plasma can affect sperm transcriptome and further influence semen quality. However, no research has integrated sperm transcriptome and seminal plasma metabolome to analyse the molecular regulatory mechanisms of bull semen quality traits. Number of motile sperm per ejaculate (NMSPE) is an integrated trait to evaluate semen quality of stud bulls. In the present study, we selected 7 bulls with higher NMSPE ($5,698.55 \pm 945.40$ million) as group H and 7 bulls with lower NMSPE ($2,279.76 \pm 1,305.69$ million) as group L from 53 stud bulls. The differentially expressed genes (DEGs) in sperm were evaluated between the two groups (H vs L). Gene co-expression network analysis of groups H and L bulls was conducted by weighted gene co-expression network analysis (WGCNA) to screen candidate genes for NMSPE. A total of 1,099 DEGs were identified in the sperm of H and L groups. The DEGs were primarily concentrated in energy metabolism and sperm transcription. The significantly enriched KEGG pathways of the 57 differential metabolites were the aminoacyl-tRNA biosynthesis pathway and vitamin B6 metabolism pathway. The expression level of candidate gene *FBXO39* could be regarded as a reliable biomarker of bull NMSPE. We also observed that sperm cells expressed genes correlated with seminal plasma metabolites were not only located near the QTLs of reproduction-related traits, but also were enriched in the GWAS signals of sire conception rate traits. Moreover, three metabolites (mesaconic acid, 2-coumaric acid and 4-formylaminoantipyrine) might regulate *FBXO39* expression through potential pathways. These data provide new insights into the improvement of bovine semen quality traits. Funding: 2021YFD1200903, NK20221201.

Application of an oligo-based FISH method in fertility assessment of boars by chromosomal analysisW. Poisson^{1,2,3}, J. Prunier³, A. Bastien³, A. Carrier^{1,2,3}, I. Gilbert^{1,2,3} and C. Robert^{1,2,3}¹Réseau Québécois en reproduction, 3200 Rue Sicotte, Saint-Hyacinthe, QC, J2S 2M2, Canada, ²Centre de Recherche en Reproduction, Développement et Santé Intergénérationnelle, 2440, boul Hochelaga, Québec, QC, G1V 0A6, Canada,³Université Laval, 2325 Rue de l'Université, Québec, QC, G1V 0A6, Canada; william.poisson.1@ulaval.ca

Many genetic fields have benefited from the use of Fluorescence *in situ* hybridization (FISH) since its first implementation over 35 years ago. The use of vectors or flow-sorted and microdissected chromosomes are frequent means of producing FISH probes. With the improvement of oligonucleotide (oligo) production using massively parallel synthesis, these short DNA fragments become more affordable and available for use as probes for FISH experiments. Recently, we implement a new method using 207,847 oligo to evaluate chromosome integrity in pigs. Karyotyping boars before their use in artificial insemination centres is crucial since chromosomal rearrangements are recognized as a potential cause of hypoprolificity. Traditionally, karyotyping is performed using a bichrome banding pattern and requires experienced analysts for proper analysis. Alternatively, the new method called Oligo-banding produces 96 chromosomal fluorescent bands that can be analysed without prior expertise. It has been successfully used to detect and confirm four translocations and an unbalanced material addition. We also tested its versatility on other Suidae and on spermatozoa DNA. The probes generated clear banding patterns when applied to wild boar and warthog chromosomes. Hybridization on spermatozoa has shown clear signals, but analysis of translocation inheritance remains complex. Overall, the oligo-based technology generated defined patterns on chromosomes useful to evaluate genomic constitution in somatic and sperm cells with applications in fertility assessment. This project is supported by a grant from the Ministère de l'agriculture et des pêcheries du Québec, the Natural Sciences and Engineering Research Council of Canada and the Fonds de recherche du Québec – Nature et technologies.

Theatre 7

Artificial insemination success: a new trait for French dairy goats

V. Clément, A. Piacère and M. Chassier

Institut de l'Élevage, Chemin de Borde Rouge, 31320 Castanet-Tolosan, France; virginie.clement@idele.fr

Breeding scheme of French dairy goats relies on creation of genetic progress and its dissemination by frozen artificial insemination (AI). So, AI success is a major concern to increase genetic level of commercial flocks. The selection criterion is a total merit index which combines production traits (protein and fat yields and protein and fat contents), udder morphology and somatic cell counts as an indicator of udder health. Our objective was to study AI success as a new trait to select. The first step was to define the phenotype. The result of an AI is considered a success if, for a given kidding, there is a unique breeding event that coincides with the date of the AI. All AI that are not followed by a kidding are considered failures. The heritability of AI success was estimated to be 0.052 in the Saanen breed and 0.045 in the Alpine breed. Despite these low values, the genetic standard deviation is significant (9 AI points in Alpine and 11 AI points in Saanen breeds). Genome wide association studies have been conducted with Blupf90 software using genomic information from genotyped animals with the Illumina GoatSNP50 Bead Chip (800 females and 2,342 males in Saanen breed, 1,123 females and 2,937 males in Alpine breed). The two breeds were analysed separately. Analysis showed, in the Saanen breed, a zone on CHI 19 (25.6-28.4 Mb) significantly associated with AI success, with a percentage of variance explained by 20 adjacent SNP window higher than 5%. This result is consistent with previous studies that have shown that this genomic region is associated with a large number of traits as udder morphology, protein yield, buck semen production, suggesting pleiotropic effects. Finally, in order to select goats for AI success, a genomic evaluation has been implemented on this trait which has been introduced in the total merit index in January 2023. The associated weights (15% in Saanen breed and 16% in Alpine breed) make it possible to improve this new trait while continuing to progress on the other traits under selection.

The male effect as an alternative to eCG in oestrus induction and synchronization treatment in ewesN. Debus¹, G. Besche¹, S. Fréret², A. Hardy³, M.T. Pellicer-Rubio², A. Tesniere¹ and J.-B. Menassol¹¹UMR SELMET, Place Viala, 34000 Montpellier, France, ²UMR PRC, INRAE, 37380 Nouzilly, France, ³EPL La Cazotte, Route de Bournac, 12400 Saint-Affrique, France; nathalie.debus@inrae.fr

We tested if the male effect (ME) can be an alternative to eCG in oestrus induction treatment used prior to artificial insemination (AI) in ewes. Two groups of 50 Arles Merino (M) (2021) or Lacaune dairy (L) (2022) ewes were monitored during anoestrus season: (1) FGA group: ewes were treated with intra-vaginal sponges impregnated with progestagen for 14 days prior to ME; (2) C group: ewes received no hormonal treatment before ME. First, ME was performed for 14 days with 4 vasectomized rams equipped with the electronic oestrus detectors to monitor oestrus kinetics and introduced with the ewes on the day of sponge removal (D0). Then, the ewes were mated with 4 entire rams for 17 days. Progesterone was measured before FGA treatment to determine the cyclic status of the ewes prior to ME and for 11 days from D0 to characterise the ovulatory response to ME. We observed a high percentage of cyclic ewes before ME (from 46 to 74%). Most cyclic and non-cyclic ewes ovulated after ME in FGA and C groups (respectively 98 and 68% for M ewes; 98 and 63% for L ewes). The FGA treatment suppressed short cycles in response to ME (0 vs 12% for M ewes; 0 vs 6,1% for L ewes, $P<0.01$). The percentage of ewes in oestrus from D0 to D14 was higher in the FGA group than in the C group (96 vs 44% for M ewes; 96 vs 68% for L ewes; $P<0.001$). The onset of oestrus after D0 was earlier and better grouped in the FGA group (Median=34.34 h [Q1=31.08 h, Q3=43.25 h] for M ewes; 42.16 h [33.73 h, 56.85 h] for L ewes) compared to the C group (137.83 h [71.61 h, 246.74] for M ewes; 147.14 h [51.02 h, 232.35 h] for L ewes) ($P<0.001$). Our previous results showed a higher fertility rate for ewes inseminated between 0 and 35 h after the onset of oestrus. In the present study, 90% of M ewes and 68% of L ewes in the FGA group came into oestrus within a time window compatible with AI performed 53 h (M ewes) or 60 h (L ewes) after sponge removal, compared to 4% (M) and 10% (L) in the C group ($P<0.001$). The combination of ME and FGA pre-treatment is an alternative method to the use of eCG in AI protocols with a unique and fixed timing of insemination.

Session 79

Theatre 9

Circulating anti-Müllerian hormone from 5-month old Merino ewe lambs predicts first birthing rates

J. Daly, J. Kelly, K. Kind and W. Van Wettere

University of Adelaide, School of Animal and Veterinary Sciences, Roseworthy, 5371, Australia; william.vanwettere@adelaide.edu.au

Anti-Müllerian hormone (AMH) is an accurate phenotypic marker of antral follicle numbers and responsiveness to stimulation protocols in cattle and sheep. However, the relationship between pre-pubertal AMH and fertility of mature breeding females is poorly understood. Fertility at first mating and AMH has been correlated in Rasa Aragonesa and Sarda ewe lambs. The relationship between pre-pubertal AMH and the fertility of Australian Merino ewes has not yet been investigated. This study determined whether pregnancy and birthing rates of Australian Merinos following their first mating was related to plasma AMH concentration at 5 months old. At 5 months of age, a single blood sample was collected from 86 Merino ewe lambs managed under routine husbandry at a Research Centre in South Australia. At 18 months of age, ewes were housed with harnessed Merino rams for 35 days (24 hours / day). Ultrasound was used to determine pregnancy status, at an average of day 60 pregnancy. AMH levels in plasma were measured using an ovine specific AMH ELISA kit (Ansh laboratories, Texas, USA). Differences in AMH between groups of ewes that became pregnant and lambled and those that did not were determined using an ANOVA, unbalanced design (Genstat 19th Edition; VSC International). Data presented as mean $\pm$ SEM. Ewes scanned pregnant ($n=70$) had higher AMH at 5 months of age than those scanned not-pregnant ($n=16$) (2.74 ± 0.22 vs 1.64 ± 0.48 ng/ml; $P<0.05$). AMH was higher ($P<0.05$) for ewes which birthed ($n=71$) a lamb compared with those which did not ($n=15$) (2.83 ± 0.21 vs 1.26 ± 0.48 ng/ml). AMH concentrations at 5 months of age were higher ($P<0.05$) for singleton and twin-bearing ewes compared with non-lambing ewes (2.74 ± 0.23 and 3.34 ± 0.81 vs 1.26 ± 0.48 ng/ml, respectively), but similar for singleton and twin-bearing ewes. These are the first data in the Merino to demonstrate that circulating AMH concentrations at 5 months of age are higher for hoggets which produce a lamb following their first mating. This finding is consistent with previous evidence that AMH can predict fertility in Rasa Aragonesa and Sarda ewes. Ongoing studies by our group will determine the relationship between AMH at weaning and lifetime fertility and productivity of Merino ewes.

Impact of pinecone oil on reproductive performance, milk composition and serum parameters in sowsQ.Q. Zhang¹, J.H. Song¹, C.B. Lim¹, S. Biswas¹, J.S. Yoo² and I.H. Kim¹¹Dankook University, Department of Animal Resource and Science, Cheonan, 31116, Korea, South, ²Daehan feed company, 13 Bukseongpo-gil, Jung-gu, Incheon, 22300, Korea, South; 1844700948@qq.com

Pinecone oil (PO) of *Pinus koraiensis* mainly contains alpha-pinene, beta-pinene, and limonene that may ameliorate animal well-being and growth performance. This study evaluated its effects on feed intake, milk composition and yield, serum parameters, and litter growth of sows. Twenty-seven pregnant sows (parity 2 to 4) were distributed to 3 dietary treatments. The trial started on day 107 of gestation and ended on day 21 of lactation. Sows were given either a basal diet or the basal diet + 200 or 400 mg/kg PO. Each treatment contained 9 sows and each sow was considered an experimental unit. Results showed that the average daily gain and weaned weight of piglets from the sows fed 400 mg/kg PO supplements were higher ($P<0.05$) than the piglets from the control sows. Lactose content in colostrum samples and fat content in milk samples were higher ($P<0.05$) in 200 and 400 mg/kg PO-treated sows, respectively than those from the sows fed basal diet. Additionally, cortisol concentration for assessing stress in sow serum was lowered ($P<0.05$) by dietary 200 and 400 mg/kg PO on d 21 of lactation. Aspartate aminotransferase concentration in sow serum was lowered ($P<0.05$) by supplementing 400 mg/kg PO. In conclusion, supplementation of 400 mg/kg PO during late gestation and lactation contributed to greater offspring growth performance, possibly by enhanced milk quality and alleviated maternal stress.

Session 79

Poster 11

Maternal *Forsythia suspensa* extract alleviated oxidative stress and improved gut health in sows

S. Long, Z. Chen and T. He

China Agricultural University, No.2 Yuanmingyuan West Road, 100193, Beijing, China, P.R.; longshenfei@cau.edu.cn

This experiment aimed to investigate the effects of maternal *Forsythia suspensa* extract (FSE) supplementation from d 85 of gestation to lactation on alleviating oxidative stress and improving intestinal health of sows and suckling piglets. Fifty gestating sows (Landrace × Yorkshire, average parity 1.61±0.68, initial weight 199.28±37.23 kg) were selected and divided into 2 treatments, 25 sows per treatment. The trial was started from d 85 of gestation and ended on d 21 of lactation (weaning day). The treatments included the control group (corn-soybean meal basal diet; CON) and FSE group (basal diet + 100 mg/kg FSE). The results showed that compared with the CON, the litter weight gain of piglets and the apparent total tract digestibility of dry matter and organic matter in sows during lactation were increased ($P<0.05$) in FSE group. Moreover, the colostrum fat content, serum IgG and IL-10 levels of sow were increased ($P<0.05$) at weaning, while the serum MDA and weaning serum hydroxyl free radical levels of sows were reduced ($P<0.05$) at farrowing in FSE group. The serum T-AOC and GSH-Px activities of piglets were increased ($P<0.05$), while the serum hydroxyl free radicals, serum and colostrum IL-1 β level of piglets were reduced ($P<0.05$) in FSE group. Maternal dietary FSE supplementation increased the levels of SOD and CAT in duodenum ($p\leq 0.05$) and the level of GSH-Px in ileum ($P<0.05$) of piglets. Moreover, dietary FSE supplementation increased ($P<0.05$) the relative abundance of Bacilli at class level, Lactobacillus and Prevotellaceae_UCG-004 at genus level in caecal digesta of suckling piglets. In conclusion, maternal FSE supplementation from d 85 of gestation and lactation period improved the reproductive performance, milk composition, antioxidant status, immune response and gut microbial community of sow and their offsprings.

Effects of PGF2 α on luteal tissue morphology, expression of relative genes in Hu sheep

Y.Q. Liu, Y. Li, C.H. Duan and Z.P. Song

Hebei Agricultural University, Lekai Street, Baoding, 071000, China, P.R.; liuyueqin66@126.com

The purpose of this experiment was to study the effects of prostaglandin F2 α (PGF2 α) on luteal tissue morphology, expression of PGF2 α receptors and programmed necrosis-associated genes at different luteal stages in Hu sheep. Forty eight healthy ewes with similar body weight were randomly divided into 6 groups, namely the early-luteal phase experiment group and control group, the mid-luteal phase experiment group and control group, and the late-luteal phase experiment group and control group. The three experimental groups were injected with 1ml PGF2 α (0.1 mg) on day 6 (early-luteal phase), day 11 (mid-luteal phase) and day 16 (late-luteal phase), respectively. The corpus luteum tissue was collected at 3 h after each injection for gene expression detection and the morphological changes of corpus luteum. The results showed that the morphology of corpus luteum was changed after injection of PGF2 α , with inflammatory cell infiltration and apoptosis, especially at the mid-luteal phase with a higher degree of degeneration. In the early-luteal phase, injection of PGF2 α for ewes significantly reduced the expression of PGF2 α receptor A (PA) ($P<0.05$), and significantly increased the expression of PGF2 α receptor B (FPB), tumour necrosis factor receptor one (TNFR1), mixed lineage kinase domain-like protein (MLKL) ($P<0.05$), and had no effect on the expression of tumour necrosis factor α (TNF- α), tumour necrosis factor receptor one (TNFR1), and receptor interacting protein kinases three (RIPK3) ($P>0.05$). In the mid-luteal phase, injection of PGF2 α for ewes significantly up-regulated the expression of FPB, TNF- α , RIPK1 and MLKL ($P<0.05$), but has no effect on the expression of FPA, TNFR1 and RIPK3 ($P>0.05$); In the late-luteal phase, injection of PGF2 α for ewes significantly up-regulated the expression of RIPK1 ($P<0.05$), has no effect on the expression of FPA, FPB, TNF- α , TNFR1, RIPK3 and MLKL ($P>0.05$). The mRNA expression level of FPA was positively correlated with RIPK3 and TNFR1 ($P<0.05$), and the mRNA expression level of FPB was positively correlated with MLKL and TNF- α ($P<0.05$). Our findings demonstrate that PGF2 α may initiate necroptosis through the TNF- α /TNFR1 pathway by binding to its receptors FPA and FPB, and promote the degeneration of the corpus luteum.

Session 79

Poster 13

Relationship between some micronutrients in serum and their effect on the seminal quality of bullsA. Benito-Díaz¹, A.S. Sarmiento-García², M. Montañes-Foz¹, R. Bodas-Rodríguez¹ and J.J. García-García¹¹Instituto Tecnológico Agrario de Castilla y León, Subdirección de Investigación, Autovía de Castilla, 119, 47009 Valladolid, Spain, ²Universidad de Salamanca, Área de Producción Animal, Departamento de Construcción y Agronomía, C/Filiberto Fillalobos 119, 37007 Salamanca, Spain; asarmg00@usal.es

Many factors influence reproductive efficiency in beef cattle, among them, the bioavailability of micronutrients (such as vitamins and mineral traces) has been described as having an essential role in the basic motility characteristics of semen. The current research aimed to demonstrate the influence of some micronutrient serum concentrations (vitamin E, copper, and zinc) on the seminal quality of beef bulls (*Bos Taurus*). 44 seminal and serum samples from bulls of 2 through 8 years of international (Limousine, Charolais) and national (Avileña Negra Ibérica, Morucha, and Lidia) breeds which were allocated in Castilla y León and Extremadura (Spain) over 2020 were collected. The semen was collected from the electroejaculation procedure, while blood samples were drawn from the coccygeal vein. Blood samples were centrifuged, split into two aliquots, and frozen (-20 °C) until they were sent to the laboratory to determine the levels of micronutrients. Vitamin E was determined by ultra-performance liquid chromatography with a photodiode detector, while, copper and zinc concentrations were quantified by inductively coupled plasma mass spectrometry. Semen samples were analysed within two hours of the collection with CASA instruments. RStudio was used for data management and statistical analysis. Progressive motility was the most critical semen quality variable: Concentrations of copper, zinc, and vitamin E were: 67.55 $\pm$ 16.03 μ g/dl, 116.91 $\pm$ 46.02 μ g/dl, and 3.47 $\pm$ 1.73 mg/l respectively. Concerning progressive motility, the average percentage was 49,57%. A positive effect was observed ($P<0.05$) between vitamin E concentration and the sperm motility of the bull. These findings suggest that enhancing vitamin E bioavailability would be desirable to improve fertility rates in bulls.

Genetic correlations on kinetic sperm parameters in a closed population of PRE stallionsZ. Peña¹, A. Molina¹, C. Medina¹, M. Valera² and S. Demyda-Peyrás³¹Universidad de Córdoba, Campus Rabanales, 14014, Córdoba, Spain, ²Universidad de Sevilla, Utrera 1, 41005 Sevilla, Spain, ³FCV-UNLP, Calle 60 y 118 SN, 1900 La Plata, Argentina; zahiramaria@hotmail.com

Sperm quality is an important factor in horse production systems. Nowadays, computer-assisted sperm analysis (CASA) it is possible to analyse kinetic parameters which characterize the motility pattern of a given stallion. Hereby, we modelled, the genetic relationships among 5 kinetic sperm parameters and sperm motility in a closed population of Pura Raza Español stallions. The dataset included 720 ejaculates from 108 PRE individuals collected by the artificial vagina during 10 reproductive seasons in Spain. Raw samples were collected, centrifuged, and diluted to 50×106 spz/ml, and equilibrated by 5 min. Thereafter, total (MOT) and progressive (PROG) motility, and 5 kinetic parameters (VSL, VAP, VCL, ALH, and BCF) were assessed using an Androvision™ CASA analyser. EBV's for the 7 sperm traits were obtained using a multivariate REML mixed model which included age at the jump, and year of birth as fixed effects, the permanent environmental effect (PEA) and additive genetic effect (2,005 pedigree records). Inbreeding value (F) was included as a linear covariate using the BLUPF90 software package. Results showed low-to-moderate h^2 values for MOT and PROG (0.08 and 0.28), but moderate-higher estimates on kinetic traits (ranging 0.25 to 0.46). Interestingly PEA was much higher in motilities than in kinetic traits. MOT was positively correlated with velocities (~0.4) and head movement (~0.3), whereas PROG was only correlated positively with VSL (0.47) and negatively with ALH (-0.54). The genetic correlations among velocities (VAP, VSL, and VCL) were very high (ranging from 0.84 to 0.96), as well as with head movements but to a lesser extent (around 0.6). However, VSL and ALH; and VCL and BCF (0.47) correlations were lower. Finally, the correlation between both head displacement parameters was also high and positive (0.57). To our knowledge, this is the first attempt to model the genetic relationships among kinetic traits in horse sperm. However, the particularities (high relatedness and inbreeding values) and limited size of the population analysed suggest caution in extrapolate the results to further equine populations.

Gestation length in Braunvieh cows

M. Fanger, A. Burren and H. Jörg

Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences HAFL, Länggasse 85, 3052, Switzerland; melanie.fanger@students.bfh.ch

In the present study, the influence of sire breed on pregnancy duration in Braunvieh (BV) and Original Braunvieh (OB) cows was investigated. Braunvieh Schweiz provided data from 2,096,865 BV and 132,731 OB cows from 2000-2021 with 14 and 11 different sire breeds, respectively. The different sire breeds were represented as follows: Angus (AN) 20'119/780, Blue Belgian (BB) 22'630/316, Blonde d'Aquitaine (BD) 28'191/316, Brown Swiss (BS) 288'845/395, Braunvieh (BV) 1'177'947/3'159, Charolais (CH) 24'828/262, Holstein (HO) 11'718/0, Eringer (HR) 2'679/101, Jersey (JE) 2'793/0, Limousin (LM) 368'229/11'451, Original Braunvieh (OB) 96'716/114'809, Pinzgauer (PI) 5'469/168, Swiss Fleckvieh (SF) 1'938/0 and Simmentaler (SI60) 44'763/974. The relationship between gestation length and sire breed was examined using a mixed linear model. The model included fixed effects calving year and month, milk linear and quadratic, calving age linear and quadratic, number of calves born by sex and sire breed, and random effects mother, sire, and farm. The longest gestation period resulted in BV and OB cows with sire breed BD (289.7 days) and (289.9 days), respectively. This was followed by PI (289.2), OB (289.2), LM (288.4) and SI (287.8) breeds in BV cows and PI (289.3), OB (289.2), LM (288.6) and SI (288.3) in OB cows. In BV cows, the sire breed HO (282.4) and in OB cows, the sire breed AN (283.2) achieved the shortest pregnancy durations. Further, both sex and the number of calves born had an influence on pregnancy duration. For a male calf, the gestation period is longer than for a female (BV: $f=288.6$, $m=290.4$; OB: $f=289.8$, $m=291.5$). Twin births result in a slightly shorter gestation period (BV: $ff=283.6$, $mf=283.9$, $mm=285.3$; OB: $ff=284.3$, $mf=284.8$, $mm=286.0$). The results show that breeders can influence the gestation length by their selection of sire breed.

Distribution of adipokines in reproductive tract and embryonic annexes in henO.B. Bernardi^{1,2}, A.E. Estienne¹, M.R. Reverchon², A.B. Brossaud¹, C.R. Rame¹ and J.D. Dupont¹¹INRAE, UMR PRC, 37380 Nouzilly, France, ²SYSAF, UMR BOA, 37380 Nouzilly, France; ophelie.bernardi@inrae.fr

Nowadays, it is well known that adipokines, molecules secreted predominantly by white adipose tissue, have endocrine and paracrine functions involved in the regulation of many biological processes including energy metabolism, inflammation and reproduction. In mammals, it has been shown that adipokines are synthesized locally in the reproductive tract and could influence reproductive functions such as steroidogenesis. In avian species, we previously showed that chemerin is highly abundant in the albumen, compared to the yolk. Moreover, chemerin and its receptors are more expressed in the part of the oviduct called the magnum, where the albumen is formed. In addition, we observed that chemerin is expressed by allantoic and amniotic membranes and fluids during the embryo development. So in chicken, chemerin is present in the albumen, the magnum of the oviduct and expressed in embryo annexes. Here we investigated other adipokines such as adiponectin, visfatin, apelin and adipolin in the egg, the reproductive tract and embryo annexes in order to better understand their distribution and role during the embryo development. By using Western blot, RT-qPCR analysis and immunohistochemistry, we demonstrated the expression of different adipokines in the egg albumen (visfatin) and the reproductive tract (adiponectin, visfatin, apelin, adipolin). However, in case of regressive tract no adipokines were expressed suggesting a potential inhibition by steroids. We also measured the expression of adipokines in the allantoic and amniotic membranes at different embryonic days ED: 7, 9, 11, 14, 16 and 18. We showed that the amount of adipokines was dependent of the embryo development. Taken together, adipokines and their receptors are expressed in the egg, the reproductive tract and the embryonic annexes in chickens. Datas suggest an important function of these metabolic hormones during the early embryo development in *Gallus gallus domesticus*. Thus, adipokines could be used as predictive biomarkers for embryo development.

The effects of PROK 1, alone or in combination with IFN gamma on endometrial immune response in pig

S.E. Song and J. Kim

Dankook University, Animal Resources Science, 119, Dandae-ro, Dongnam-gu, Cheonan-si, Chungcheongnam-do, Republic of Korea, 31116, Korea, South; thdtjms@naver.com

Porcine endometrium undergoes fine-regulated inflammatory response during implantation as pig conceptuses secrete the pro-inflammatory cytokine interferon gamma (IFNG) and prokineticin1 (PROK1). IFNG promotes inflammatory responses in endometrium by increasing endometrial chemokines recruiting T cells and mast cells to maternal-foetal interface of pig. PROK1 acts pleiotropically as an embryonic signal mediator that regulates endometrial receptivity by increasing the expression of the genes and proteins involved in implantation. However, the underlying molecular regulatory mechanisms are not fully elucidated *in vitro*. This study investigated loading the secretory protein PROK1 into porcine endometrial cells and measured the migration of porcine peripheral blood mononuclear cells (PBMCs) toward the cytokine and PROK1 loaded endometrial cells. We also analysed the expression of T cell receptors. The results of this study demonstrate that PROK1 loaded endometrial cells increase migration of CD4⁺, CD8⁺, and CD4⁺CD8⁺ T cells in PBMCs compared to non-loaded cells. Long term exposure (24 h) to a combination of PROK1 and IFNG increased the expression of T cell co-signalling receptors including programmed cell death 1 (PDCD1), CD28, as well as chemokines CXCL9, CXCL10 and CXCL11 compared to IFNG treated alone. These results suggest that PROK1 may be critical for the establishment of pregnancy by regulating inflammatory environment and various subpopulations of T cell recruitment into the endometrium during the implantation period in pigs.

Creating a culture of openness for the responsible use of video observation in animal sciences*M.F. Giersberg and F.L.B. Meijboom**Utrecht University, Veterinary Medicine, Yalelaan 2, 3584 CM Utrecht, the Netherlands; m.f.giersberg@uu.nl*

Video observation is a popular and frequently used tool in animal behaviour and welfare research. However, in addition to the object of research, video recordings often provide unintended and unexpected information about the progress of the study, the animals or the people involved. This information can cause uncertainty in the observer when conflicting interests between animal welfare, social expectations and research integrity are weighed against each other. How should they deal with what they saw? Does for instance the welfare of the animals outweigh the privacy of the caretaker? In this study, we propose a framework which enables a culture of openness in dealing with unexpected and unintended events observed during video analysis in animal sciences. To deal with these events, the general principles of privacy and research integrity are an essential starting point. People involved in a video-based animal study need to be aware of their institutions' policies or the absence of such, for instance on consent or data confidentiality. However, in animal studies, a single focus on the prevention of privacy issues is not sufficient. That is because study animals are in a vulnerable position and depend on human care. The assumptions and responsibilities underlying such a duty of care or the expected human behaviour towards animals should therefore be made explicit in a similar way as privacy or integrity issues. Informing, educating or reminding people of these responsibilities during the planning of the study provides them with so called 'good conditions' under which to choose their behaviour. During running and reporting of the study, the risk of animal welfare and research integrity issues can be mitigated by making conflicts discussible and offering realistic opportunities on how to deal with them. A practice which is outlined and guided by conversation will prevent a mere compliance-based approach centred on checklists and decision trees. Based on this framework, we are currently developing a workshop for PhD candidates, which includes serious gaming approaches and offers room to share own experiences. With this we aim to foster reflection, co-creation and application of ethical practice.

Salivary oxytocin and lachrymal caruncle temperature as indicators of anticipation in growing pigs*G.A. Franchi¹, L.R. Moscovice², H. Telkänranta³ and L.J. Pedersen¹*

¹Aarhus University, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, ²Research institute for Farm Animal Biology (FBN), Institute of Behavioural Physiology, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, ³Arador Innovations, Kamreerintie 10, 02770 Espoo, Finland; amorimfranchi@anivet.au.dk

Conventional pigs are typically raised under intensive conditions that do not meet pigs' basic needs of behavioural expression and cognitive challenge, likely threatening their welfare. Thus, providing pigs an environment that promotes positive affective states and, consequently, positive welfare should be encouraged. Affective states and valuing of rewards can be examined through anticipation, i.e. a response to a stimulus or context based on expectations about the future. Hence, we investigated, as part of the H2020 project PIGWEB, the potential of salivary oxytocin (sOXT) and lachrymal caruncle temperature (LCT), measured by infrared thermography, as indicators of anticipatory responses in 32 conventional Yorkshire × Landrace pigs (mean ± SD body weight: 81±7 kg/pig) housed in 8 identical pens (4 pigs/pen; 3.28 m²/pig) during anticipation of either a positive (delivery of 200 g/pig of fresh straw; POS) or a negative context (straw delivery omission; NEG). Individual saliva samples were collected at -10 and +20 min and thermograms were recorded at -10, -5 and +10 min relative to the moment of conditioned stimulus presentation. Additionally, based on footage, play behaviour (locomotor-rotational, LOC; social, SOC; object, OBJ) was sampled continuously and tail posture (high; not high) was instantaneously sampled at 1-min interval, both at the individual level, from -30 to +30 min relative to the conditioned stimulus presentation moment. We found higher LCT (37.9±0.47 vs 37.3±0.47 °C; $P=0.013$) and sOXT concentration (110±7.64 vs 80±6.70 pg/ml; $P=0.002$) in POS than in NEG. No high tail was labelled in NEG, whereas 66% of pigs displayed high tail ($P<0.001$). The odds of pigs displaying OBJ were higher in POS than in NEG (OR, 95%CI: 6.7, 1.39-32.47; $P=0.015$). Additionally, pigs tended to engage more in SOC in POS than in NEG ($P=0.077$). Our results suggest thermographic LCT, sOXT, tail posture, and play behaviour have potential as non-invasive measures of anticipation and affective processing in pigs.

Pig oxidative stress model: behaviour as a potential indicator of oxidative stress in pigsR.D. Guevara^{1,2}, J.J. Pastor³, S. López-Vergé³, X. Manteca², G. Tedo³ and P. Llonch²¹AWEC Advisors S.L., Farm Animal Welfare Education Centre (FAWEC), Research Park UAB, Campus UAB, 08193, Spain, ²Universitat Autònoma de Barcelona, Department of Animal and Food Science, Edifici V, Travessera dels Turons, 08193, Spain, ³Lucta, Animal Science Innovation Division, Research Park UAB, Campus UAB, 08193, Spain; raul.guevara@awec.es

The goal of the current study was to develop a pig experimental model to investigate oxidative stress with fewer negative impacts on piglet welfare. Four independent trials (A, B, C, and D) were performed using a single intraperitoneal shot of lipopolysaccharide (immune stimulator, LPS) as an immune challenge, aiming to assess the minimal LPS dose and the most appropriate pigs' age at the oxidative challenge to trigger a measurable acute response. The challenge time and dose for each trial were the following, Trial A and B: 21 days post-weaning (p.w.) piglets (A: n=24, 6.98±1.97 kg; B: n=24, 9.20±1.09 kg) with 25 µg/kg BW of LPS; Trial C: 28 days p.w. piglets (n=24, 9.08±3.25 kg), with 25 µg/kg BW of LPS; and Trial D: 41 days p.w. piglets (n=20, 11.86±5.95 kg), with 25 µg/kg BW. The pigs were randomly allocated either to T1) Control diet + saline solution (CON), or T2) CON + LPS challenge (LPS). The oxidative response was measured through plasma glutathione peroxidase (GPx), glutathione-S-transferase (GST), superoxide dismutase (SOD), and catalase (CAT). Intestinal relative gene expression of oxidative and inflammatory markers was assessed. Faecal myeloperoxidase (MPO) activity was measured to evaluate intestinal inflammation. Illness-related behaviours (panting, prostration, trembling, and vomits) were also recorded. Plasmatic oxidative response was not consistent across the four trials even when the dose and pig age were similar (studies A & B). Pigs' individual variability may be an explanation for this outcome. Relative gene expression of inflammatory (IL10) and antioxidant (iNOS, GPx4, MnSOD, and CAT) activity detected differences between CON and LPS treatment ($P<0.05$). Behavioural observations were sensitive to the LPS dose relative to CON ($P<0.05$). These results suggested that behavioural observations may be used as a non-invasive methodology to measure the impact of oxidative stress in pigs.

Session 80

Theatre 4

Comparison of aversiveness of 8 different inert gas (mixtures) to CO₂ for stunning pigs at slaughterI. Wilk¹, J. Gelhausen², T. Friehe², T. Krebs², D. Mörlin², J. Tetens² and J. Knöll¹¹Friedrich-Loeffler-Institut, Institute for Animal Welfare and Animal Husbandry, Dörnbbergstraße 25/27, 29223 Celle, Germany, ²Georg-August-Universität Göttingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany; jonas.knoell@fli.de

Despite concerns over its aversiveness, stunning of pigs at the time of slaughter using a high concentration of CO₂ is the most common method in Europe. Inert gases and mixtures of inert gases with low concentration of CO₂ have been proposed as an alternative, but have so far not been considered market-ready due to concerns of gas stability, meat quality, costs and stunning effectiveness. As part of the project for Testing Inert Gases in order to Establish Replacements for high concentration CO₂ stunning for pigs at the time of slaughter (TIGER), experiments were conducted in a commercial Dip-Lift system using a new gassing system with residual oxygen concentrations <1%. Pigs were stunned to screen 8 different inert gas mixtures for their suitability in terms of animal welfare and meat quality. In two separate series for argon-based and nitrogen-based gas mixtures, pigs were exposed to one of four inert gas mixtures with 0, 10, 20 or 30% CO₂, or high concentration CO₂ control atmospheres. In nitrogen-based gas mixtures, argon was added with up to 30% to aid gas stability. Here we report results of the aversiveness to the gases in the induction phase. For each of the four measurement days, video sequences of the stunning procedures were randomized and cut to a new video. Aversive and other events were captured by two observers according to an ethogram. Most pigs showed an initial retreat attempt (62.5%), shortly after start of the descend of the gondola. Other aversive reactions before loss of balance were statistically significantly reduced ($P<0.05$) for all argon-based gas mixtures (7 to 21%) and for nitrogen without CO₂ (21%) compared to high concentration CO₂ (59%). Of those aversive events, hyperventilation was only observed for high concentration CO₂ (25%) and nitrogen with 30% CO₂ (15%). We conclude that all tested inert gas mixtures were beneficial with respect to reduced aversiveness in the induction phase compared to high concentration CO₂, with gas mixtures with less CO₂ showing less or shorter aversions.

Detecting onset of farrowing using CUSUM-charts based on sows' activity

T. Wilder, B. Baude and J. Krieter

Christian-Albrechts-University, Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany; twilder@tierzucht.uni-kiel.de

With the latest changes in legislation in Germany, sows are only allowed to be confined in farrowing crates for five days to prevent piglet crushing. Thus, it is important to estimate the onset of farrowing correctly to close the crate just before the farrowing and open it again after the first days to reduce negative effects on sow welfare. Monitoring the activity level of the sow, which increases about 16 to 20 h ante partum due to nest-building activities and restlessness, it is possible to estimate the onset of farrowing. However, doing this with human observation is not feasible under commercial conditions. Therefore, the activity of sows ($n=125$) was estimated using optical flow (OF, changing of pixels from one frame to the other) of video footage and cost efficient passive infrared motion sensors (PIR) during 96 h ante partum. CUSUM-charts were used to detect a change in activity separately for OF and PIR. To minimise the influence of farm staff moving in the pen, the mean activity was calculated over different time intervals (15, 30, 60 min). Afterwards, the individual activity of every sow was standardised using z-transformation $((x-\mu)/\sigma)$. Thus, every sow had a mean activity of 0 and a standard deviation of 1. This data was used in univariate one-sided CUSUM-charts. The best results of the OF were achieved with mean activity of the 60 min time interval and the combination of $h=9$ and $k=0.25$. Here, the increase in activity was correctly detected in 97% of times at a mean of 9 h 7 min (± 5 h 31 min standard deviation) before the actual farrowing. The number of false positive alarms (earlier than 24 h before farrowing) was 0.23 per sow. For the PIR, the best results were achieved with 15 min time interval and the combination of $h=1.5$ and $k=0.5$. In 91% of times increase of activity was detected at a mean of 16 h 46 min (± 7 h 11 min) before the farrowing. Here, the number of false positive alarms was 4.84 per sow. Therefore, using activity monitoring, it is possible to time the closing of the crate more precisely. However, the number of false positive alarms of the PIR motion sensor has to be improved to be of practical interest.

Session 80

Theatre 6

Impact of environmental enrichment on the behaviour and immune cell transcriptome of pregnant sowsM.M. Lopes¹, C. Clouard¹, J. Chambeaud¹, M. Brien¹, N. Villain², C. Gerard², F. Hérault¹, A. Vincent¹, I. Louveau¹, R. Resmond³, H. Jammes⁴ and E. Merlot¹*¹INRAE, PEGASE, 16 Le Clos, 35590 Saint-Gilles, France, ²Chambre Régionale d'Agriculture de Bretagne, Maurice le Lannou, 35042 Rennes, France, ³INRAE, IGEPP, La Motte au Vicomte, 35653 Le Rheu, France, ⁴INRAE, BREED, All. de Vilvert, 78352 Jouy-en-Josas, France; mariana.mescouto-lopes@inrae.fr*

The ability to assess farm animals' mood is important to evaluate their welfare, but practical assessment tools are still lacking. Human research has demonstrated a link between psychological states and the transcriptome of blood immune cells. Therefore, this study aimed to investigate whether blood immune cell transcriptome can be used to assess the animals' mood using environmental enrichment as a method to generate contrasted welfare states. Pregnant sows of mixed parities were housed in two contrasting conditions throughout gestation (0 to 105 days): a conventional system on a slatted floor (C, $n=36$) or an enriched system on accumulated straw with additional space per sow (E, $n=35$). The behaviour of multiparous sows of low (2nd and 3rd gestation; $n=29$) and high (4th gestation or higher; $n=31$) parity was observed from G99 to G104 and 14 sows per system were selected for biological sampling. Cortisol concentrations in saliva (G35 and G98), and in the hair (G98), were lower in E sows ($P<0.04$). E sows spent more time exploring the pen ($P<0.001$), less time chewing enrichment material ($P<0.001$) or exhibiting stereotypic behaviours ($P=0.04$), and had lower frequencies of agonistic behaviours ($P=0.04$). High-throughput sequencing of the blood mononuclear cell transcriptome (G98) identified only 24 differentially expressed genes (DEGs) between C and E sows (adjusted P -value <0.1 , $FC<0.8$ or >1.2). However, parity (894 DEGs) and social dominance (437 DEGs) had a greater effect, and most of the DEGs were related to innate and adaptive immunity pathways. Therefore, these results confirm that long-term environmental enrichment decreases cortisol concentration and positively influences sow behaviour. The blood transcriptome did not allow discrimination between housing conditions but it was influenced by another important factor for welfare, such as social dominance in the group.

The knowns and unknowns about feather pecking in laying hens

A. Harlander and N. Van Staaveren

University of Guelph, Animal Biosciences, Campbell Centre for the Study of Animal Welfare, Stone Road East, N1G2W1, Canada; aharland@uoguelph.ca

Feather pecking (FP), which leads to feather damage, is a behaviour commonly performed by millions of birds kept for egg-laying worldwide. It is a unique behaviour as FP is both an indicator and a cause of reduced welfare. Given its prevalence and impact to hen health, there is an urgent need to prevent FP behaviour. Ethologists have long considered FP to be reflective of frustration, arising from a lack of foraging opportunities within commercial settings. However, FP also occurs when birds are provided outdoor access, allowing them to express normal foraging behaviour, indicating additional contributing factors. This talk will summarize recent research linking FP in laying hens to the gut-microbiome-brain axis. In humans, there is an overlap between behavioural disorders, such as autism spectrum disorder, the gut microbiota and 5-HT neurotransmission between the brain and gut. Similar associations have been recently established in laying hens. Indeed, the avian serotonergic system and the amino acid precursor TRP are intimately linked to FP. Moreover, a strong desire to eat feathers, altered intestinal motility, lower gut bacterial diversity and a decreased presence of *Lactobacillaceae* has been reported in feather peckers vs non-peckers. Interestingly, the administration of *Lactobacillaceae* as a probiotic to laying hens impacted the immune system via tryptophan metabolism by reducing plasma indoleamine-pyrrole 2,3-dioxygenase activity and kynurenine concentration. More importantly, the probiotic *Lactobacillaceae* treatment prevented pecking. To conclude, the field of research to better understand FP through a neurobiological gut-brain axis lens is rich with opportunities and the potential for preventive treatment.

Session 80

Theatre 8

Lower redness of the facial skin is a marker of a positive human-hen relationshipD. Soulet¹, A. Jahoui¹, M.-C. Blache¹, B. Piégu¹, G. Lefort¹, L. Lansade¹, K. Germain², F. Lévy¹, S. Love¹, A. Bertin¹ and C. Arnould¹¹CNRS, IFCE, INRAE, Université de Tours, PRC, 37380, Nouzilly, France, ²INRAE, UE EASM, Le Magneraud, CS 40052, 17700, Surgères, France; delphine.soulet@inrae.fr

In certain mammals, facial expressions are reliable markers of the emotional state of an individual. In humans and parrots, emotional stimuli can induce a rapid change of face colour that is linked to blood flow. The aim of this study was to test whether the redness of the face in domestic hens could be used as an emotional marker in the context of the human-hen relationship. Two groups of hens (Sussex) were studied: a group habituated to a human with daily positive interaction (n=13) and a non-habituated group (n=12). Behaviour and skin colour of wattles, cheeks, ear lobes and comb were analysed from two video-recorded tests (novel environment and reactivity to human tests) conducted after 5 and 6 weeks of habituation. In the novel environment test, usually used for testing general underlying fearfulness, the hens were tested alone in an unknown environment. In the reactivity to human test, the hens were tested again in this environment but with the familiar human sitting inside. The human presence should only be stressful for the non-habituated group. As expected, the behaviour of the two groups did not differ during the novel environment test. During the reactivity to human test, the habituated hens were more relaxed than the non-habituated hens: they took their first step faster ($P=0.03$), came faster into contact with the human ($P=0.03$), explored him longer ($P=0.0003$) and displayed more comfort behaviours ($P=0.01$). Face redness differed between the two groups during only the reactivity to human test: lower redness was observed in habituated hens for 3 out of the 4 regions (wattles $P=0.01$, cheeks $P<0.0001$, ear lobes $P=0.0003$). These results show that more relaxed hens are less red, thus face redness could be a reliable marker of the quality of the human-hen relationship. As such, it could be used as a tool for human to infer the emotional state of hens and more broadly, to evaluate their welfare.

Do sheep differentiate emotional cues conveyed in human body odour?I. Larrigaldie¹, F. Damon¹, S. Mousqué^{1,2}, B. Patris¹, L. Lansade³, B. Schaal¹ and A. Destrez^{1,2}¹UMR Centre des Sciences du Goût, CNRS, Institut Agro, INRAE, Univ. Bourgogne, 9E boulevard Jeanne d'Arc, 21000 Dijon, France, ²Institut Agro, Dijon, France, 26 Bd Dr Petitjean, 21079 Dijon, France, ³UMR Physiologie de la Reproduction et des Comportements, CNRS, IFCE, INRAE, Univ. Tours, INRAE, 37380 Nouzilly, France; izia.larrigaldie@u-bourgogne.fr

Humans are significant sources of stimuli for domestic animals, especially by visual/vocal cues. Evidence that horses, dogs, and cattle do react to cues carried in human body odours is recent. Sheep perception of human visual/vocal cues has been previously reported, their reactivity to human body odor is yet to be demonstrated. We assessed whether sheep detect human odours and differentiate stressed vs non-stressed individuals. Axillary secretions were sampled from 34 students (age: 23 y, 31 ♀) before an oral examination vs a standard class, conveying stress (SO) and non-stress (nSO) odours, respectively. These samples were frozen until testing that consisted in a habituation-dishabituation procedure (n=29 sheep, age: 7-8 m, 14 ♀). An odour n°1 (habituation stimulus) was presented one minute four times at animal, then odour n°2 (dishabituation stimulus) was presented one minute once time. Sheep were either habituated with nSO and dishabituated with SO or the reverse (ability to detect and discriminate human nSO/SO). Tests were video recorded to blindly code behaviours indicating attraction, aversion or indifference (i.e. approach/withdrawal, locomotor spatiality, sniffing, ingestion, vocalization). Ewes (8.4; $P=0.038$) and rams (8.6; $P=0.037$) displayed more avoidance/stress (frequency of ears pointing backwards) when facing the dishabituation odour, but regardless of its assumed cueing of human stress. While sheep were expected to express specific different behaviours when exposed to nSO and SO, these results ultimately suggest that sheep avoid the odours of unfamiliar humans (although the discrimination of familiar/unfamiliar humans remains to be tested). Overall, further studies are required to unveil ovine olfactory performance toward humans along dimensions of familiarity and emotionality, and to provide a better understanding of subtle aspects of the human-animal relationship.

Session 80

Theatre 10

Evaluation of inter-observer reliability of dichotomous and four-level animal-based indicatorsB. Torsiello¹, M. Giammarino², L. Battaglini¹, M. Battini³, S. Mattiello³, P. Quatto⁴ and M. Renna⁵¹University of Turin, Dept. of Agricultural, Forest and Food Sciences, Largo P. Braccini 2, 10095 Grugliasco, Italy,²Asl TO3, Veterinary Service, Dept. of Prevention, Via Trento 1, 10045 Piossasco, Italy, ³University of Milan, Dept. of Agricultural and Environmental Sciences – Production, Landscape, Agroenergy, Via Celoria 2, 20133 Milano, Italy,⁴University of Milan-Bicocca, Dept. of Economics, Management and Statistics, Piazza dell'Ateneo Nuovo, 1, 20126 Milano, Italy, ⁵University of Turin, Dept. of Veterinary Sciences, Largo P. Braccini 2, 10095 Grugliasco, Italy; benedetta.torsiello@unito.it

This study focuses on the problem of assessing inter-observer reliability (IOR) in the case of dichotomous and four-level animal-based welfare indicators, using and comparing the performance of the agreement indexes available in literature. Udder asymmetry was evaluated as a dichotomous variable in 160 dairy goats by three observers (A, B and C). As four-level variables, Earposture (EP) and Eyewhite (EW) were scored by two observers from 436 photos of dairy cows during the lactating (L) and dry (D) periods. Krippendorff's α , Fleiss' K and Quatto's S were implemented to assess IOR for the dichotomous variable with three observers, while Cohen's K , K_C , K_{PABAK} , Krippendorff's α and Quatto's S were implemented to assess IOR for the four-level variables with two observers. In the case of the dichotomous variable, α and Fleiss' K were affected by the paradox effect: these indexes gave low agreement values despite a high concordance rate (P_0) ($P_{0ABC}=91\%$; α , $K=0.44$). Similarly, regarding the four-level indicators, in some cases K_{PABAK} showed the paradoxical behaviour ($P_{0EWL}=64\%$; $K_{PABAK}=0.29$; $P_{0EWD}=57\%$; $K_{PABAK}=0.14$). S index is suggested to evaluate IOR in the case of dichotomous indicators ($P_{0ABC}=91\%$; $S=0.83$). Cohen's K , α and S index are suggested to evaluate IOR in the case of four-level variables ($P_{0EPL}=79\%$; K , $\alpha=0.67$; $S=0.73$; $P_{0EPD}=83\%$; K , $\alpha=0.73$; $S=0.78$; $P_{0EWL}=64\%$; K , $S=0.53$; $\alpha=0.52$; $P_{0EWD}=57\%$; K , $\alpha=0.42$; $S=0.43$).

Social network analysis of dairy cows' group structure at the feeding trough

T. Wilder, P. Hasenpusch, A. Seidel, G. Thaller and J. Krieter

Christian-Albrechts-University, Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany; twilder@tierzucht.uni-kiel.de

As individual behaviour of social animals is always affected by behaviour of other animals, it is important to consider the group structure as well as the animal's position within this structure when analysing animal behaviour. This applies to the behaviour of group housed animals like dairy cows as well. Social network analysis is a tool which provides standardised parameters to do this. However, data acquisition of animal behaviour by human observation is very laborious and needs time to produce a sufficient data basis. Therefore, feeding troughs (animal to feeding trough ratio of 2:1) which automatically identify the cows with every visit were used to acquire data on animal behaviour, group structure and management measures. Using information on time, trough number and animal number, two types of networks were built: an undirected network of adjacent eating (NAE), in which a contact was defined as eating at adjacent troughs for at least 90 sec, and a directed network of displacement behaviour (NDB), in which a contact was defined as an animal change at one trough within 30 sec, using the succeeding cow as origin of the contact and the displaced cow as target. In NAE, cows have a greater effective degree (number of relevant contacts), if they have a greater dominance index (correlation coefficient $R=0.31$, $P<0.05$). In NDB, cows with a greater effective outdegree have a greater dominance index ($R=0.40$, $P<0.05$), while cows with a greater lactation number have a lower effective outdegree and a lower effective indegree (both $R=-0.27$, $P<0.05$), indicating less participation in displacement behaviour. Furthermore, comparing NDB at a period after the troughs were refilled with fresh feed and a control period shows higher correlation coefficients for the outdegree ($R=0.21$, $P<0.05$) than the indegree ($R=0.10$, $P<0.05$), indicating cows performing displacement behaviour tend to do this in both periods, whereas cows receiving displacement behaviour are rather randomly targeted. Combining these networks with networks based on data of an indoor positioning system, which will be done in the next step, promise new insights into group structure and behaviour of dairy cows.

Session 80

Theatre 12

Roughage and type of dispensers: what consequences on horses' feeding behaviour?

M. Roig-Pons and S. Briefe

Agroscope, SNSF, Les Longs Prés 1, 1580 Avenches, Switzerland; marie.roig-pons@agroscope.admin.ch

A great amount of hay dispensers are currently available on the market, with some of them designed to decrease speed ingestion ('slowfeeders'). This preliminary study aimed at evaluating the effect of dispenser and roughage on horses' feeding behaviour and posture. The study was divided in two experiments. (1) In 2021, we compared 3 slowfeeders (SF): HayBag (HB), HeuToy (HT) and PortaGrazer (PG) to loose hay (LOO) on the floor, the latter being traditionally considered as the gold standard. 4 Franches-Montagnes stallions housed at the SNSF were habituated to each SF during 10 days and then fed hay 3 times a day for 4 days, following a Latin square design. Horses were filmed during the first hour of their meals and 'explore', 'gather', 'bite' and 'chew' were labelled. The posture of the neck was also noted. The first video analysis revealed a difference of feeding behaviour between LOO and SF, especially in terms of bite rate ($\text{mean}(\text{nBites})_{\text{LOO}}/\text{min} = 0.8 \pm 1.1$ vs $\text{mean}(\text{nBites})_{\text{SF}}/\text{min} = 9.4 \pm 4.6$, Student-test, $P=2.2\text{e-}16$). (2) We then investigated if the feeding behaviour displayed under LOO treatment, often considered as reference, was similar to the one expressed under 'natural' conditions, namely horses grazing in pasture (PAS). To this aim, in 2022, 4 additional geldings were filmed when feeding under LOO and PAS condition. In total, 44 hours of video were analysed: (1): 32 h; (2) 12 h. The results highlighted that HT and HB decreased the ingestion speed (0.85 and 0.87 vs 1.61 kg/h for LOO), but could lead to a twisted neck position during up to 58% of the meal. In addition, horses displayed more bites resp. less chews per min under PAS (44.3 ± 10.9 , resp. 32.9 ± 6.6) compared to LOO (0.2 ± 0.3 , resp. 69.2 ± 4.8 , Wilcoxon-test, both $P=0.001$). To conclude, our experimental plan did not allow for direct comparison between PAS and SF, but results tended to show that horses express a more similar feeding behaviour between PAS and SF compared to PAS and LOO, especially for the time spent exploring and the chewing rate. The findings of this preliminary study questioned the use of loose hay as reference in many studies. An analytical study is needed to assess the influence of roughage and dispenser on horses' feeding behaviour and to discuss the use of LOO treatment as reference.

Caudectomy effect on the severity of tail lesions and abscesses' frequency in pig carcassesP. Trevisi¹, D. Luise¹, S. Viridis¹, S. Dalcanele¹ and U. Rolla²¹University of Bologna, DISTAL, Viale Fanin 46, 40126 Bologna, Italy, ²Gruppo Martini, Via Emilia 2614, 47020 Budrio di Longiano, Italy; sara.viridis3@unibo.it

The aim of this study was to evaluate the implication of the presence of the undocked tail on the prevalence and severity of tail lesions, abscess frequency and thigh defects in heavy pig carcasses at Italian slaughter. For this purpose, a total of 5,216 carcasses belonging to 45 batches were inspected in the slaughterhouse between April and September 2022. Tail lesions severity was scored from 0 to 2 according to the Welfare Quality® (2009) protocol and Lesion Score Index was calculated (LSI). Abscesses located on the thigh, spine, throat (lymph nodes), thoracic lymph node, abdomen skin, sternum/ribs, lower abdomen, navel and neck were recorded and reported as frequencies per batch. Thigh defects such as hematomas, petechiae and veins, PSE, arthritis and underweight were assessed by qualified slaughterhouse staff and reported as frequencies per batch. The LSI was higher in undocked tail pigs ($P < 0.0001$). Furthermore, a higher frequency of both thigh lesions (hematomas and petechiae) and arthritis was found in the carcasses of undocked pigs compared with docked pigs ($P < 0.0001$). No difference in any of the abscess frequencies was observed between docked or undocked carcasses. A positive correlation was observed between the increase of LSI and thigh defects such as hematomas ($r = 0.51$; $P < 0.0001$) and petechiae ($r = 0.64$; $P < 0.0001$) and the frequency of arthritis ($r = 0.56$; $P < 0.0001$). In conclusion, the absence of caudectomy appears a risk factor for the prevalence and severity of tail lesions. Although there is a correlation between tail length, thigh defects and arthritis, these two problems may be related to other risk factors. Tail length, on the other hand, did not appear to be associated with the presence of abscesses.

Session 80

Poster 14

Characterising cattle daily activity patterns using accelerometer dataS. Hu¹, A. Reverter¹, R. Arablouei², G. Bishop-Hurley¹ and A. Ingham¹¹CSIRO, Agriculture and Food, 306 Carmody Rd, St Lucia QLD 4067, Australia, ²CSIRO, Data61, 1 Technology Ct, Pullenvale QLD 4069, Australia; shuwen.hu@csiro.au

Livestock production systems have recently benefited from the adoption of automated monitoring technologies (e.g. Global Navigation Satellite Systems, inertial sensors, cameras, and microphones) facilitating the continuous surveillance of animals. In this study, cattle were fitted with a smart ear tag containing a triaxial accelerometer from which a simple measure of activity was computed. To better recognise the differences between day and night, each 24 h period was divided into 6 intervals of 4 hours. There are three-day intervals (D1, D2 and D3) and three-night intervals (N1, N2 and N3) for each day. The level of activity for each 4-hour interval was computed from the standard deviation of the accelerometer vector norm averaged over 5-minute windows. Averaged across all animals, the daily activity is 3.01×10^6 for cattle yarded overnight (environment 1, ENV1), while for free-roaming cattle (ENV2) the total daily activity is 6.15×10^6 . To characterise patterns of activity, a metric named daily differential activity (DDA) was calculated from the difference between each two intervals (e.g. D1-N1, 30 possible pairs in total). For each animal, the DDA has three components: (1) DDA_v, the maximum difference in activity for all pairs; (2) DDA_p, the pair generating DDA_v; (3) DDA_e, the information entropy (Does one pair frequently provide the highest DDA_v or is this equally spread across all pairs?). In ENV1, the mean of DDA_v is 3,086.4 and ranges from 2,378.4 to 4,598.4; while in ENV2, the mean of DDA_v is 1,087.9 and ranges from 837.5 to 1,814.1. Across all animals in both environments, we observe a strong negative correlation between DDA_v and DDA_e ($r = -0.896$) which indicates that cattle with regular behaviour (a low entropy) attain a high DDA_v. We concluded that the assessment of daily activity using the DDA metrics allows a better understanding of animal responses to different environments and, if related to performance (e.g. growth), potentially provides an indicator of animal welfare. Further, our results suggest that any approach to detect anomalies in animal behaviour based on accelerometer activity needs to be able to handle the variation observed here.

Effects of olfactory exposure to twelve essential oils on behaviour and health of cows with mastitisR. Nehme^{1,2}, C. Michelet², E. Vanbergue², O. Rampin³, S. Bouhallab¹, A. Aupiais² and L. Andennebi-Najar^{2,4}¹INRAE, Institut Agro, STLO, Rennes, 35042, France, ²IDELE Institute, Quality and Health Department, Paris, 75012, France, ³Université Paris Saclay, INRAE, AgroParisTech, PNCA, Jouy-en-Josas, 78350, France, ⁴CRSA, Sorbonne University, INSERM UMRS, Paris, 75012, France; ralph.nehme@idele.fr

Essential oils (EO) are known for their anti-bacterial, anti-inflammatory and relaxing properties. They are used nowadays by a large number of farmers and considered as promising compounds against mastitis. We have recently found that applying *Thymus capitatus* EO on the mammary gland of dairy cows through massage didn't have any effects on subclinical mastitis (SM). The aim of this study was to evaluate the effects of a scent of 12 EO belonging to different chemical families on cow's EO preference and the follow up of SM in dairy cows. 29 Holstein cows were involved in this experiment among them 19 with signs of SM. After 2 days adaptation, animals had free access (2 days) to 12 EO distributed randomly in a fenced pilot. We combined both video recording and biological sampling to study: (1) animal behaviour and preferences towards each of the 12 EO; and (2) follow the evolution of SM. Blood cortisol concentrations were also evaluated to estimate the stress level after EO's exposure. Nasal microbiota was studied from the nasal mucosa samples. For each of the healthy and SM cows, we did not observe any significant preference towards a particular EO during the whole experimentation. However, SM cows were significantly more attracted to monoterpene (MN) and monoterpenol (ML) EO's families compared to healthy ones ($P < 0.05$). Interestingly, EO with predominant ketones family were exclusively scented by the healthy cows ($P < 0.05$). For health evaluation, no statistical differences on SCC and bacteriological status in milk were highlighted at day 21 days after EO's exposure, but we did observe a significant increase in the cortisol rate in blood compared to healthy ones ($P < 0.05$). Our findings suggest that SM cows attraction to MN and ML families did not alleviate the signs of SM at day 21. Additional evaluation of the specific effects of MN and ML families on SM is needed to test different doses and other experimental conditions before any wide recommendation to farmers.

Assessment of stress in dairy cattle industry via analysis of cortisol residue in commercial milk

M. Ataollahi, G.W. Park, E. Nugrahaeningtyas, M. Dehghani, J.S. Lee and K.H. Park

Kangwon National University, College of Animal Life Sciences, Chuncheon, Gangwon, Republic of Korea, 24341, Korea, South; ataallahim@kangwon.ac.kr

Chronic stress has been a concern in dairy cattle industry with significant impact on animal health, productivity, and welfare. Cortisol is released in response to stress and there is a positive correlation between stress level and blood cortisol concentration. However, blood collection is an invasive procedure with additional effects on increasing cortisol secretion. Thus, it is essential to find less stressful procedures to measure cortisol concentration. It has been confirmed that cortisol transfers to milk and resists the high temperature during milk processing. Therefore, analysis of cortisol residue in commercial milk may be a suitable procedure to estimate the degree of stress in lactating cattle. This study was conducted to evaluate the relationship between commercial milk cortisol concentration (MCC) and temperature-humidity index (THI) at milk production date. A total of 11 commercial pasteurized and sterilized milk samples were purchased in Chuncheon, Korea with production dates from July to October in 2021. The MCC was extracted using diethyl ether and measured using enzyme immunoassay. The THI was calculated based on microclimate data from the Korea Meteorological Administration. The average of THI was 77 ± 0.8 , 75 ± 1.4 , 69 ± 1.4 , and 58 ± 1.8 , in July, August, September, and October, respectively. The average of MCC was 211.9 ± 95.1 , 173.5 ± 63.8 , 109.6 ± 53.2 , and 106.7 ± 33.7 pg/ml in July, August, September, and October, respectively. The MCC in July was higher than August, September, and October ($P < 0.05$), whereas it was lower in September and October compared with August ($P < 0.05$). Overall, monitoring cortisol residue in commercial milk can be an indicator of stress in lactating cattle in farms.

The physiological and behavioural effects of COVID-19 restrictions on lactating dairy cows

S.J. Morgan and D. Barrett

Dalhousie University, Faculty of Agriculture, Department of Animal Science and Aquaculture, 62 Cumming Drive, B2N 4H5, Bible Hill, Nova Scotia, Canada; david.barrett@dal.ca

During the height of the global pandemic, COVID-19 restrictions resulted in altered human-animal interactions with many species worldwide, which may have negatively impacted their welfare. However, few studies have assessed the impact of these restrictions on domestic animals. Thus, this study aimed to identify the impact of reduced handling and foot traffic due to the COVID-19 pandemic restrictions on the physiology and behaviour of dairy cows. Fifteen lactating dairy cows located at a research/teaching barn that saw significant changes in staff/personnel during the pandemic were used for this study. Subjects were followed from January 2021 – September 2022, through Seven COVID-19 restriction phases. As the phases progressed, cows were exposed to increasing human interactions and handling. During each phase cows were assessed for potential physiological or behavioural signs of stress. Physiological measurements included heart rate, respiration rate, and rectal temperature. Cow behaviour was assessed using cameras and a behavioural ethogram to analyse cow time budgets. Statistical analysis was carried out using a mixed model for physiological data and non-parametric Kruskal-Wallis tests for behavioural data. From Phase 1 to 7 significant decreases ($P < 0.05$) in heart rate (82.6 ± 1.6 vs 62.9 ± 4.59 beats per minute) and respiration rate (38.2 ± 1.5 vs 29.1 ± 2.1 breaths per minute) were noted in the dairy cows. No significant differences in rectal temperature or behaviours were noted among any of the restriction phases. Thus, our findings suggest that the dairy cows experienced a state of physiological stress at the onset of the pandemic, with a reduced stress response as they were re-introduced to pre-COVID-19 levels of handling and foot traffic. We therefore conclude that sudden alterations in human handling/interaction induce a state of stress in dairy cows, whereas prior experiences and gradual changes in human interaction do not invoke strong stress responses in cattle. Further studies are needed to determine what may be helpful in offsetting the stress response of dairy cows to a sudden unavoidable environmental change, or how to mitigate these changes should these situations arise again in the future.

Session 80

Poster 18

Effects of the living environment on the behaviour of rabbits

M. Fetiveau, M. Besson, V. Fillon, M. Gunia and L. Fortun-Lamothe

GenPhySe, INRAE, 24 Chemin de Borde Rouge, 31326 Castanet-Tolosan, France; laurence.lamothe@inrae.fr

Today, rabbits are mainly reared (>90%) in wired unenriched cages, which limits the behavioural repertoire of the animals. To contribute to the design of welfare-friendly systems, we compared the influence of the living environment on the behaviour of growing rabbits. Rabbits of two genetic types (control or selected for disease resistance) were distributed at weaning (35 d of age) in two contrasting rearing systems: (1) in a confined building equipped with wire cages housing 5 rabbits (0.9×0.9 m, modality 1); or (2) in a mobile house equipped with 8 roofless pens (2×1 m, modality 2) giving free access to an enriched (hay rack, straw bale shelters) grassy paddock of $1,940 \text{ m}^2$. The behaviour of the animals was assessed using scan sampling by direct observation twice a day (morning and afternoon) at 45, 56 and 66 days of age. We distinguished between locomotion (walking, pouncing, running), maintenance (browsing, eating hay or pellets, resting, gnawing), exploration (scratching, observing, training) and social interaction behaviours (side by side, nose to nose). The genetic type of the animals only influenced the very weakly expressed nose-to-nose behaviour ($P < 0.05$). Indoors, the dominant behaviour was resting (Resting: 67.8 and 56.6% vs 31.2% in pens, cages and paddock, respectively; $P < 0.001$) followed by watching (11.4 vs 3.7% and 4.4%, respectively; $P < 0.001$) and pellet ingestion (8.6 and 6.7% in cages and pens). On the contrary, the rabbits were more active on the paddock (pouncing: 8.2% on the run vs 2.1 and 0% in pens or cages; $P < 0.001$), the only place where they ran (2.2% of observations). On the course, 36% of the rabbits were observed grazing. Social interactions were frequent (18% of behaviours, of which side by side 16.7% (NS). Other behaviours (Walking, Hay eating, Gnawing or Training) were rarely observed (<5%). In conclusion, these results show that the living environment has a very strong influence on the animals' behaviour. Providing access to a grassy paddock allows rabbits to satisfy their need to graze and considerably stimulates their locomotion. It also allows a spatialization of activities, with resting inside and locomotion outside.

Behaviour test and study of sheepdogs' abilitiesB. Lasserre¹, B. Ducreux¹, M. Chassier¹, L. Joly¹, T. Le Morzadec¹, P. Cacheux¹ and C. Gilbert²¹Institut de l'Élevage, 23 Rue Jean Baldassini, 69007, France, ²Ecole Nationale Vétérinaire, 7 avenue du Général de Gaulle, 94704 Maisons-Alfort, France; boris.lasserre@idele.fr

Currently, sheepdogs' selection only relies on trial performance, in which the trainer's expertise is dominant. The objective of this study was to set up a behaviour test with a grid composed of unbiased criteria to assess the natural abilities of a sheepdog from an early age. If these criteria are heritable, a selection could be put in place. The test is composed of 2 steps: a 1-minute pre-test to let the dog familiarise with the new environment, and a 2-minute test with a fetch, the driver surrounding the flock twice and moving away from it. Each step is separated from the other by a 15-second unmoving phase. The test is conducted by a driver unknown of the dog, around 10-15 ewes, without any command. After the test, a blood sample was taken on each dog, to collect genetic information. The test was deployed in 15 French regions where 460 Border collies between 8 and 24 months old have been tested since 2019. At the end of the test, each dog is evaluated according to the phenotype considered: Not Use Value (Not VU) or Use Value (VU). A VU dog is defined as able to avoid flights, to maintain animals in a group close to human, to confront animals in a respectful way, if need be, and to provoke a movement without preying (chasing, disturbing, and biting). 23 indicators were also assessed during the test. Some focus on the dog's behaviour: fetch, movement when driver surrounding, reference to human, movement when driver walks, movement to make ewes move, biting, focusing and motivation. The other indicators focus on the ewes' reactions to the dog: mobility when fetch starts, reaction to fetch, position after 15sec unmoving, reaction when surrounded, movement when driver walks, gregarious behaviour, distance to driver walking, attempt to confront dog. The 10 first dimensions of the MCA explain 48% of VU variance. The grid correctly detects our phenotype (VU or not) with a 96% prediction rate, and ranks dogs in 10 different profiles, with a 92,5% prediction rate. 17% of tested dogs are VU, and the link between this phenotype and environmental variables was also studied. For instance, dogs under 11 months old are significantly more aggressive than older dogs ($P<0.001$).

Session 80

Poster 20

Innovative evaluation method of behavioural reactivity for 'foie gras' ducksC.M. Monestier¹, A.W. Warin¹, S.L. Lombard¹, S.L.M. Laban-Mele² and W.M. Massimino³¹Bureau Bankiva, department of R&D, 4 impasse de la fin de chêne, 21410 Gergeuil, France, ²Labeyrie Finde Foods SAS, Department of Corporate Social Responsibility, 39 route de Bayonne, 40230 Saint-Geours de Maremne, France, ³Lur Berri, Department of Innovation, R&D, Route de Sauveterre, 64120 Aiciris, France; chloe.monestier@bankiva.fr

Achieving significant advancements in farm animal welfare requires assessments that are scientifically validated. To date, the scientific literature still lacks a behavioural assessment methodology covering all animals at all rearing stages such as the overfeeding stage in 'foie gras' farms. The purpose of our study was to implement an objective measurement of behavioural responses in ducks during overfeeding. In 2021, trials were conducted in an experimental station at two separate sites and repeated four times. Behavioural and health data were recorded for 307 male mule ducks 2 h before and during overfeeding, three times throughout the duration of overfeeding. We developed a new metric conducted during overfeeding that allowed us to discriminate animal reactivity creating two behavioural indicators (struggling and overall excitement profiles) associated with the wings flapping behaviour. Ducks housed in collective cages were more excited and struggled during overfeeding more than ducks housed in pens altogether interpreted as a higher reaction to a stressful situation than ducks housed in pens ($P<0.05$). We also found that ducks housed in collective cages showed more discomfort behaviours while ducks housed in pens expressed more natural behaviours before overfeeding ($P<0.05$). The results obtained before and during overfeeding are complementary and consistent. In addition, the before overfeeding results reinforce even more those obtained with the creation of the new behavioural metrics. Moreover, as ducks express these behaviours while being handled, it is relevant to also take them into account when considering the day-to-day work conditions of farmers. Our preliminary data are encouraging in terms of reproducibility and repeatability of measurements, and we have implemented them in current trials to evaluate the individual behaviour and rearing conditions of ducks throughout overfeeding. The measured reactivity addresses the welfare of both animals and farmers, aligning with the 'one welfare' approach.

Use of scaring devices to avoid roe deer fawns getting injured or killed during mowing*J. Mačuhová, T. Wiesel and S. Thurner**Bavarian State Research Center for Agriculture, Institute for Agricultural Engineering and Animal Husbandry, Vöttinger Str. 36, 85354 Freising, Germany; juliana.macuhova@lfl.bayern.de*

Every year by forage cuts in May and June, roe deer fawns can get injured or killed during mowing. The aim of this study was to evaluate the use of scaring devices set in fields before mowing to persuade the animals to leave or not enter the fields. A query was performed using a data collection sheet (available for download from one web page for everybody applying this measure and interested in the study) during the season 2020. The goal was to obtain information such as type of used scaring devices, time of setting up and removal of scaring devices, the number of fields with scaring devices, total number of set up scaring devices on fields with scaring devices, use of other measures on fields with scaring devices, and number of fawns seen, rescued, and injured or killed during mowing. One data collection sheet should be filled in for all fields with scaring devices mowed on one day by one farmer or in one hunting ground. 171 out of 183 received data collection sheets could be evaluated. The number of fields per sheet varied between 1 to 31 (2.89 ± 3.67 ; $n=160$ (n =number of data collection sheets)). Scaring devices with light and sound signals were mainly used alone ($n=82$) or in combination with plastic bags ($n=57$). Moreover, one ($n=52$) or more ($n=26$) additional measures were applied at least at one field before mowing. 79 fawns ($n=35$) were seen running away during moving or were found during or after moving (27 of them injured or killed ($n=15$; thereof $n=6$ applying at least one and $n=8$ applying even two or more additional measures)). Unfortunately, it cannot be excluded that data regarding the number of seen and found fawns were recorded for all fields mowed at a certain term and not only for fields with scaring devices in some data sheets. Nevertheless, it can be concluded that the use of scaring devices did not prevent completely mowing death. This could be caused not only due to a possible missing effect (or incorrect effect) but also due to an improper application (not setting up the scaring devices on all mowed fields; the fawns could be already on fields without scaring devices or they moved there from fields with scaring devices).

Theatre 1

Precision feeding, recent advances for gestating sows and dairy cows*C. Gaillard, C. Ribas and M. Durand**Institut Agro, PEGASE, INRAE, 16 Le Clos, 35590, Saint Gilles, France; charlotte.gaillard@inrae.fr*

Precision feeding aims to define the right feeding strategy according to individual's nutrient requirements. Few years ago, an individual feeding strategy for gestating sows based on energy and lysine adjustment of daily supplies has been shown to reduce feed costs and environmental loads. The nutritional requirements were calculated thanks to an updated version of the InraPorc model requiring input data (i.e. sows' characteristics). A third variable to take into account during the adjustment (i.e. phosphorus requirement) is currently being added into the model and simulations are being run. More recently, on one hand the integration of the individual and daily physical activity measurements in the calculation of the energy requirements is becoming possible thanks to the development of a software able to analyse automatically and continuously the sow's postures. On the other hand, machine learning algorithms allows to predict daily nutritional requirements using only data measured by sensors or automatons. For example, energy and lysine requirements can be predicted thanks to physical activity and feeder data, respectively. Combining these data with the sows' characteristics improved the prediction accuracy. This result indicate a possible way to simplify the application of precision feeding on farm. Finally, the long term effect of a precision feeding strategy on the sows' performances is being evaluated in two different experimental farms. Concerning dairy cows, individualized feeding strategies are more complicated to set up and models or criteria to calculate precisely the individual daily requirements are not available. Preliminary experiments are taking place to determine criteria to adjust the energy of each cow's ration, at the scale of the week, by varying the amount of concentrates distributed in the automatic feeder. Furthermore, biomarkers and production variables are being screened to determine if they can be used in early lactation to predict the lactation persistency, and then adapt the feeding strategy and the reproduction timing based on the objective of the farmer and the potential of each cow. Precision feeding is therefore a burning and growing topic for farm animals, with promising results.

Individual ingestion time prediction with RGB-D cameras in beef cattle: a machine learning approach

P. Guarnido-Lopez¹, F. Ramirez-Agudelo², S. Tomozyk¹, A. Kjørvel¹, A. Carvalho¹, F. Jezegou-Bernard¹, P. Gauthier¹ and M. Benaouda¹

¹Institut AgroDijon, Université de Bourgogne, Animal production, 26 Bd Dr Petitjean, 21000, Dijon, France, ²Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 place de l'Agronomie – CS 80022, 91120, Palaiseau, France; pabloguarnido@hotmail.com

New machine learning approaches have been developed in recent years to help cattle farmers more easily and affordably measure individual dry matter intake, a key factor in overall farm efficiency and animal performance. The objective of the present work was to assess the performance of a computer vision model for classifying activities in steers and predict ingestion time (IT). For this, a total of 6 young Charolais bulls (581±37kg BW) were recorded at the same moment (meal's distribution) for 7 days. Videos (15-20 mins each) were recorded through an RGB-D camera (Intel® RealSense TMD455) at 15 frames per second. The model used for images analysis was the YOLO (V5) and the whole process entailed two steps: (1) Characterization of individual activity, where we identified animal's behaviour among 5 different activities (biting, ruminating, visiting chewing and others). A total of 530 images were randomly extracted from the videos, and the activities were manually identified using a labelling software. The images were divided into three sets for training, validation, and testing, (60, 20, and 20%, respectively). (2) The IT was determined per animal per video by summing the predicted biting and chewing times, and these predictions were compared to the actual individual ingestion time measured manually using a chronometer. Results showed a high precision of biting activity over the test images ($P=0.73$, $R=0.98$) while a lower precision in rumination ($P=0.59$, $R=0.47$). In addition, the CM showed a high ($r=0.78$) confusion between 'visiting' and 'rumination'. Then, we observed a high correlation ($r=0.92$, $P=0.001$) between predicted and measured IT. This work, shows the potential of ML models to predict accurately the IT, which may be used to help decision-making of beef cattle producers both in farm efficiency (detection of efficient individuals) and in animal's welfare (earlier disease detection).

Using image classification to estimate feed intake in weaned piglets under commercial conditions

T. Van De Putte, J. Degroote and J. Michiels

Ghent University, Department of Animal Production and Aquatic Ecology, Coupure Links 653, 9000 Ghent, Belgium; thomvdpu.vandeputte@ugent.be

Assessing feed intake in weaned piglets is critical for ensuring optimal nutrition without overconsumption, particularly during the first few days post-weaning when digestive capacity is limited. However, commercial conditions often hinder accurate assessment via computer vision due to limitations in visualizing the entire pen and identifying individual piglets. To address this challenge, we tested a simple image classifier in an experiment involving 288 pigs housed in 24 pens, monitored via camera surveillance for the first three days post-weaning. Of these pens, 12 had access to two distinct feeders: creep feed (familiar to the piglets) and the unfamiliar weaner diet, while the remaining 12 were exclusively fed the weaner diet. To create a deep learning dataset, 17,000 images were cropped around the vicinity of both feeders and classified by a human expert based on the number of eating animals, with non-nutritional feeder visits and head-lifting events excluded. Using the ResNet50 architecture as a base model, with two dense layers and a prediction layer added, the model was trained using the Tensorflow Library in Python, achieving a precision and recall of 93% each on the test dataset. Additionally, feed intake for each diet was measured daily by weighing excess feed from both feeders and compared to a daily feed index, determined by subjecting all video data to the image classification algorithm. The correlation yielded an R-squared of 0.90 (weaner diet) and 0.77 (creep feeder), indicating the algorithm provides a reliable estimate of actual daily feed intake in group-housed piglets. Further analysis revealed that eating speed increased daily, with piglets consuming at an average speed of 31 mg/s during the first 72 hours post-weaning, and spending 7% of their time eating near the end of this period. Preference for creep feed was observed when it was available, although there was no significant difference in total feed intake or total feeding time between the animals exclusively fed the weaner diet and those with access to both diets.

The value of precision feeding technologies: economic, productivity and environmental aspect

J.K. Niemi

Natural Resources Institute Finland (Luke), Kampusranta 9 C, 60320 Seinäjoki, Finland; jarkko.niemi@luke.fi

Precision livestock farming (PLF) can play an important role in making animal production economically, environmentally and socially more sustainable. In the context of feeding, PLF allows feeding animals according to their potential to utilize nutrients, thus reducing economic and environmental losses caused by insufficient or excessive feeding. While precision feeding can provide important economic and environmental benefit and enhance farm productivity, investing in precision feeding is not always economically viable. This presentation summarizes the current knowledge concerning economic, productivity and environmental aspects of precision feeding technologies in pig, poultry and cattle production. It provides examples on quantified economic costs and benefits of precision feeding especially in pig farming. Finally, it examines factors that contribute to the farmer's decision to adopt or not to adopt new precision feeding technology solutions. Besides costs and benefits themselves, these include factors such as the heterogeneity of herd and the accuracy and uncertainty of information on animal's current state of nature that is needed to determine the most preferred diet.

Session 81

Theatre 5

Precision feeding in dairy cows: what do professionals in ruminant nutrition think about it?A. Icier¹, A. Petillon-Pronk¹, J. Martin¹, E. Hertault¹, N. Gaudillière², J. Jurquet³, A. Fischer³ and Y. Le Cozler¹*¹Institut Agro Rennes-Angers, 65 rue de St-Brieuc, 35000 Rennes, France, ²Eliance, 149 rue de Bercy, 75595 Paris cedex 12, France, ³IDELE, 149 rue de Bercy, 75012 Paris, France; yannick.lecozler@agrocampus-ouest.fr*

Modern dairy farming aims at improving feed efficiency and decreasing negative environmental impacts. This can be achieved through precision feeding strategies, which consists in offering the right diet (in quantity and quality) at the right time to the right animal. However, this concept of feeding is not well-known and can have diverse definitions. A survey was performed on 50 French professionals involved in dairy cattle nutrition to identify their needs and to analyse their expectations about precision feeding. Their answers highlighted that precision feeding combined the adequate diet delivering to the requirements of the animal (8/47), the individualization of feeding (6/47), but also the need of automatic concentrate dispensers (ACD; 3/47) or robots (5/47). According to participants, the main advantages of this feeding method are to improve herd productivity (12/37), and to enhance the potential and individual performance of each cow (6/37). Among the surveyed persons, 14 claimed that precision feeding was not cost-effective whereas 10 said that it was cost effective. Complexity (6/35) and time-consumption (8/35) were two additional dis-advantages that were cited. For most professionals, adopting precision feeding should result in maximizing individual performance (12/38), improving cows' health (11/38) and improving economic profitability at the herd level (10/38). To a lower extend, the surveyed persons also expected a better feed efficiency (3/38) and reduced environmental impacts (2/38). But for most of them, adopting precision feeding must be considered farm by farm. It is concluded that different, and sometimes, opposite opinions exist between professionals working in the field of dairy cows nutrition regarding precision feeding, resulting in different expectations that need to be considered for potential development of practical tools or consultancy services in precision feeding.

Characterizing dairy cow's individual reaction to a decrease in production concentrate distributionA. Fischer¹, R. Lehuraux² and J. Jurquet¹¹Idele, 149 rue de Bercy, 75012 Paris, France, ²Institut Agro, 26 Bd Dr Petitjean, 21000 Dijon, France; julien.jurquet@idele.fr

The individual allocation of concentrates in lactating dairy cows is often based on each cow's milk production and lactation stage only, without considering the other requirements. The objective was to identify clusters of individual patterns of cow's reaction subsequently to a decrease in production concentrate distribution. The hypothesis was that the cows would offset this challenge by a combination of a decrease in net energy exported in milk (NEMilk), increase of 'basis' diet intake and body reserves mobilization. Sixty Holstein dairy cows were fed *ad libitum* with a unique basis and balanced diet distributed in individual weighing bins and supplemented individually at an electronic feeder with 4.0 kg/d/cow for 3 weeks (P4Kg) and 1.0 kg/d/cow of production concentrate the following 3 weeks (P1Kg). The first half of cows (group AdLib) had *ad libitum* access to the basis diet, whereas the second half (group Limited) had *ad libitum* access to the basis diet during P4Kg and limited access during P1Kg. This limit was set for each cow as its average intake of basis diet during P4Kg. The results highlighted that AdLib group had an average intake of 22.4 kg DM/d/cow in period P4Kg (181 MJ/d/cow) which increased by 1.4 kgDM/d/cow in period P1Kg (-8 MJ/d/cow), with a steady NEMilk for both periods of 110 MJ/d/cow. The Limited group had an average intake of 22.7 kgDM/d/cow of basis diet during both periods (173 MJ/d/cow) and produced on average 110 MJ/d/cow NEMilk during P4Kg which decreased by 7 MJ/d/cow during P1Kg. Those results show that only cows that were able to offset the decrease in concentrate distribution by an increased intake of basis diet, i.e. that had *ad libitum* access to the basis diet maintained their NEMilk. Three clusters of individual patterns were identified: cows that compensated mostly by higher intake of basis diet without decreasing their NEMilk; cows with a low or no increase in the basis diet and a decrease in NEMilk; and cows, mostly with a lower milk production, that had small changes in their performance. To have a full overview and validate those results, the next step will have to include the change in body reserves as a third lever available to each cow to adapt to the concentrate reduction.

Theatre 7

Longitudinal patterns for feeding traits in the two parental populations of the mule duckH. Chapuis¹, C. Ribas¹, H. Gilbert¹, M. Lagüe² and I. David¹¹INRAE, GenPhySE, 31326 Castanet Tolosan, France, ²INRAE, UEFG, 40280 Benquet, France; herve.chapuis@inrae.fr

In France, the mule duck contributes to more than 90% of the production of foie gras. The mule duck is the sterile hybrid obtained by crossing a Muscovy drake with a Pekin dam. Our objective was to study the dynamics of feeding behaviour traits during the growth of mule duck parental populations and ultimately evaluate if they can be used to improve their offspring foie gras production. Data were recorded on 453 Muscovy males and 740 Pekin ducks of both sexes using electronic feeders. Records were available for 5 weeks, starting from d15 in Pekin and d22 in Muscovy. Traits were computed on a daily basis as meal and feed intake (MFI and DFI), feeding time (DFT), meal duration (MD), feeding rate (FR), number of meals (NM) and body weight (BW). Traits were analysed using random regression models. The combined effects of age, batch and sex were used as fixed effects, while additive and environmental effects were fitted using Legendre polynomials of order up to 3. Daily heterogeneous residual variances were accounted for, through a structured antedependence approach. Average performances largely differed between populations: for instance, Muscovy ducks spent daily almost twice as much time feeding as Pekin ducks, while they ingested 12% less feed. However, despite these differences feeding traits exhibited similar longitudinal patterns between populations: BW, FR, DFI and MFI showed a positive trend throughout the trial in both Muscovy and Pekin populations, contrary to DFT and NM which decreased over time. In both populations, heritability estimates were low (0.10 for Pekin DFI) to moderate (0.35 for Pekin MD) at start, and increased to reach a maximum around 0.5, six to ten days later. Afterwards, in Pekin, heritabilities of feeding traits remained moderately high over time, while in Muscovy they showed a slight decrease over time (DFI, DFT, FR) or a sharp drop towards the end of the period (MFI, NM). This analysis would profitably be extended to estimate the genetic correlations of FR, DFT and MD, recently evidenced as potential selection criteria for an improved foie gras production, with the foie gras weight of mule offspring.

Models predicting methane emissions and methane conversion factor of Finnish Nordic Red dairy cowsJ.S. Adjassin^{1,2}, A. Guinguina¹, M. Eugène³ and A.R. Bayat¹¹Natural Resources Institute Finland (LUKE), Animal Nutrition, Tietotie 2C, 31600 Jokioinen, Finland, ²Laboratory of Ecology, Health, and Animal Production (LESPA), Arafat, P.O Box 123 Parakou, Benin, ³INRAE, Université Clermont Auvergne, VetAgro Sup, UMR 1213 Herbivores, 63122, Saint-Genès-Champanelle, France; josias-steve.adjassin@inrae.fr

Accurate estimates of methane (CH₄) emission factor (Y_m) are essential for greenhouse gas inventories, which can be obtained by direct measurements or model predictions. We aimed at quantifying the Y_m from Finnish Nordic Red dairy cows based on data obtained from respiration chambers and ruminal SF₆ gas tracer technique (2011-2022). Overall, 391 individual records from 13 experiments were compiled and divided randomly into a training data set (9 experiments, n=319 records) for model development and a validation data set (4 experiments, n=72 records) for model evaluation. Data were analysed using the mixed model procedure of SAS with experiment as a random effect. Root MSPE (RMSPE) and the ratio of RMSPE to standard deviation of observed values (RSR) were used to compare the models. A total of 10 and 14 linear models were developed for predicting Y_m (% of energy intake) and CH₄ emission (g/d), respectively. The predictor variables were DM intake (DMI), body weight (BW), diet composition (EE, NDF, CP, Ash, starch), energy corrected milk (ECM), milk fat and protein, organic matter digestibility and rumen acetate to propionate ratio. To avoid multicollinearity, only significant ($P < 0.05$) predictors with variance inflation factor < 10 were kept in the models. Methods of measurement were not different ($P > 0.05$) in terms of Y_m despite lower daily CH₄ emission and higher variability from SF₆ tracer technique compared to respiration chambers (446 ± 105 vs 515 ± 71.7 g/d). The average Y_m was $6.42 \pm 0.88\%$. Prediction equations based on DMI, BW, dietary EE, milk fat and AP for daily CH₄ emission performed the best (RSR=0.54 and RMSPE=8.52%). Using only BW and DMI for predicting Y_m had a low performance (RSR=0.92 and RMSPE=12.6%) and adding dietary composition variables improved the model significantly (RSR=0.71 and RMSPE=9.70%). In conclusion, accurate prediction of Y_m requires information on DMI and dietary factors such as crude fat, Ash and NDF concentrations.

Session 81

Theatre 9

Use of automated head-chamber systems as exclusive concentrate dispensers during bulls fatteningN. Lorant¹, E. Henrotte², Y. Beckers³, F. Forton⁴, A. Vanlierde¹, M. Mathot¹ and A. Mertens¹¹Walloon Agricultural Research Centre, Rue du Serpont 100, 6800 Libramont, Belgium, ²Inovéo, Chemin du Tersoit 32, 5590 Ciney, Belgium, ³Gembloux Agro-Bio Tech, Passage des Déportés 2, 5030 Gembloux, Belgium, ⁴Dumoulin SRL, Rue Bourrie 18, 5300 Seilles, Belgium; n.lorant@cra.wallonie.be

To help the beef sector to reach European climate objectives, the 'Blanc Bleu vert' project (SPW Research funding) aims at mitigating greenhouse gases emission and optimizing feed efficiency of Belgian blue bulls (BBB) through innovative feed solutions and genetic selection. In order to optimize the methane emission measurement, a trial is performed to test an exclusive use of an automated head-chamber system (AHCS) for the fattening of BBB bulls. The methodology explores the capacity to distribute the whole concentrated feed during the fattening period of BBB with AHCS and the interconnected variability and uncertainties associated to the methane measurement when the frequency of visits is increased. This research was carried out between May 2022 and August 2022 on 4 groups of 7-8 bulls, with the same concentrate/straw finishing diet. During 19 days, methane emission and ingestion of BBB, with an average live weight of 546 ± 46 kg, were monitored with AHCS. Depending on the fattening stage and weight, each bull received up to 18 feeding periods per day (840 g/visit: 15 drops/visit with 15 seconds between drop), with free access to straw. For a good measure of methane emission, only visits with a duration of more than 3 minutes were taken into account in the calculation. As expected, it is possible to feed more than 90% of a complete finishing bulls diet through the AHCS. The AHCS provided an average of 9.4 kg diet/bull/d. This daily consumption is not different from average consumption at the automatic concentrate feeding system in the previous 3 weeks (9.1 kg diet/bull/d). The dispersion coefficient related to the average daily methane emission of an animal is $3.7 \pm 1.1\%$, which corresponds to the accuracy of the device itself. To reach this precision 9.4 ± 1.6 visits/d/bull with good duration (321 ± 26 sec on average) are considered among the 9.7 ± 1.8 daily visits. With this methodology, a three week measurement allows to reach the desired accuracy to carry out the project.

On-farm nutritional supplementation to improve sows and piglets' performances: field reportP. Engler¹, G. Gemo², S. Cissé¹ and J.M. Garcia¹¹Nor-Feed SAS, 3 Rue Amedeo Avogadro, 49070 Beaucauzé, France, ²G&G Consulenza e Sviluppo, Località Brodi nr. 6, 29010 Castelvetro Piacentino (PC), Italy; sekhoul.cisse@norfeed.net

Lactation is a critical aspect of swine production for both the sow, which mobilises different body reserves to produce milk, and for the piglets, which depend on efficient transmission of essential nutrients and biological substances through the colostrum and milk. In the recent years, a particular focus has been put on the importance of colostrum in early-life management for piglets and its impact on pre-weaning mortality. Nutritional studies have showed that the use of nutritional solutions around farrowing could improve colostrum quality and beneficial nutrient transfer from the sow to the piglets. The aim of this experiment was to study the effects of supplementation with a commercial combination of standardised grape extract (SGE, Nor-Grape®, Nor-Feed, France), calcium and vitamin D on sows and piglets' performances. 80 sows of similar parity rank were randomly divided into 2 groups at their entry in nursery, a control group (CTL, n=45) and a supplemented group (SGE, n=35). The supplementation of the commercial combination was administered to the SGE group through the drinking water at a rate of 50 g/sow/day, from their entry in nursery (5-6 days pre-farrowing), until 5 days post farrowing. Litter size parameters at farrowing, after cross-fostering reorganization and at weaning (28 days) were recorded for each sow. Whilst no significant difference was observed at birth in terms of total litter size, and after cross-fostering reorganization of the litters, the supplementation tended to result in a higher level of weaned piglets in the SGE group with, on average +1.2 weaned piglet/sow (10.6 ± 0.5 vs 11.8 ± 0.5 weaned piglet/sow for the CTL and SGE group respectively, $P=0.10$). These findings are in accordance with previous ones showing that a supplementation with a SGE significantly improves colostrum quality in sows and healthier piglets. This phenomenon could thus explain the higher level of weaned piglets in sows supplemented a few days around farrowing. These results underline the importance of peri-partum management in sows and how nutritional interventions around this time can result in beneficial effects on sows and piglets performances.

Session 81

Poster 11

Effects of monosaccharides on *in vitro* NDF and starch digestibility, pH and volatile fatty acidsE. Raffrenato¹, G. Esposito² and L. Bailoni¹¹University of Padova, Department of Comparative Biomedicine and Food Science (BCA), Viale dell'Università 16, 35020 Legnaro PD, Italy, ²University of Parma, Department of Veterinary Science, Via Taglio 8, 43126 Parma, Italy; giulia.esposito@unipr.it

Sugars are known to improve NDF digestibility (NDFd) in lactating dairy cows. However, not much information is known about specific monosaccharides and inclusion levels. A study was conducted to investigate the effects of glucose, fructose, xylose and rhamnose (selected from a preliminary study) on *in vitro* NDFd, pH and VFA concentration. Oat hay (OH), alfalfa hay (AH) or a TMR were fermented with each sugar for 12 and 24 h using inclusion levels of 0 (control), 10, 15 or 20% of the NDF content of the substrates used. Fermentations were run in triplicates, across 3 runs. Bacterial communities were profiled in the *in vitro* fluids using ARISA technique. Data were analysed according to a randomized complete block design with a factorial arrangement of treatments. Each sugar was analysed separately with level, substrate and their interaction as fixed effects and run as random factor. The addition of fructose and rhamnose increased NDFd at the 15 and 20% inclusion levels ($P<0.05$), respectively, while glucose and xylose were significant at 10% of the NDF ($P=0.035$ and $P=0.022$, respectively). Overall, the sugars were more effective in increasing NDFd when added to the TMR ($P<0.05$), followed by LH and OH. Independently of the sugar and sample used, the *in vitro* system was able to maintain the pH above 6.8 ($P>0.05$). While acetic acid was variable, both propionate and butyrate were highest with 20% inclusion level for all sugars ($P<0.05$). Differences were observed in bacterial communities between the control and most of the sugar treatments. TMR showed no similarities in the bacterial communities between inclusion levels while LH had the most similarities in bacterial communities across sugars levels. Both bacterial richness and diversity were higher when glucose was added compared to the control ($P=0.0311$). This preliminary work demonstrates the potential of specific monosaccharides and the need to explore their possible effects *in vivo* on diets of dairy cows as a way of improving the rumen microenvironment.

Benefit of full matrix application for a novel phytase using a phased-dosing or fixed dosing strategyB.C. Hillen¹, S. Gilani¹, R.D. Gimenez-Rico², K.M. Venter³, P. Plumstead³ and Y. Dersjant-Li¹¹Danisco Animal Nutrition & Health, IFF, 4 Willem Einthovenstraat, 2342 BH, Oegstgeest, the Netherlands, ²Danisco Animal Nutrition & Health, IFF, Paseo de la Castellana, 149, 28046, Madrid, Spain, ³Neuro Livestock Research, Kameeldrift, Brits, South Africa; barthold-christian.hillen@iff.com

Application of full matrix for phytase including digestible phosphorus (P), calcium (Ca), sodium (Na), digestible amino acids (AA) and metabolizable energy (ME) is an important strategy to reduce feed cost and improve production benefit. This study validated the application of the full matrix for a novel consensus bacterial 6-phytase variant (PhyG) supplemented at a phased-dose or fixed dose in broilers. Ross 308 broilers were randomly assigned to 5 dietary treatments (12 replicates of 55 birds/pen). The diets were based on corn, wheat, SBM, sunflower meal and rapeseed meal, in pelleted form in 3 phases (starter, 1-10 d; grower, 10-21 d and finisher, 21-32 d). The treatments included: (1) a nutrient and energy adequate positive control (PC); (2) PC reduced in Ca, dig P, Na, dig AA and ME based on the contribution of PhyG at the specific phased-dose (NC1); (3) NC1 supplemented with PhyG at 2,000, 1,500, and 1,000 FTU/kg (NC1+PhyG) in starter, grower and finisher phase, respectively; (4) PC reduced in Ca, dig P, Na, dig AA and ME based on the contribution of PhyG at the fixed dose of 1000 FTU/kg (NC2); (5) NC2 supplemented with PhyG at 1,000 FTU/kg in all phases (NC2+PhyG). Data were analysed using JMP 16.1 and means separated by Tukey test. NC1 and NC2 decreased ($P<0.05$) 32 d BW, carcass weights, bone ash contents at d 10 and 32 and increased 1-32 d FCR vs PC. The PhyG supplementation maintained all these parameters vs PC. The estimated overall feed cost (€/kg BWG) was reduced by 7.2 and 6.8% and carbon footprint, g CO₂ eq/kg BWG was 12 and 11% lower with phased-dose and fixed dose of PhyG, respectively vs PC ($P<0.05$). In conclusion, supplementation of the novel phytase with both dosing strategies, with full matrix application maintained broiler growth performance, bone ash, carcass characteristics and resulting production benefit which could contribute to sustainable broiler production, with the phased dosing strategy being more cost effective.

Use of fodder beets in French dairy diets: farmers points of views and experimental resultsV. Brocard¹, A. Marsault¹, L. Vivenot², E. Tranvoiz³ and J. Jurquet¹¹Institut de l'Elevage, 149 rue de Bercy, 75012 Paris, France, ²Union Laitière de la Meuse, CS 20149, 55104 Verdun, France, ³Chambre d'agriculture de Bretagne, 24 route de Cuzon, 29322 Quimper, France; valerie.brocard@idele.fr

In France the use of fodder beets in diets for dairy cows is regularly questioned: new interest of producers followed by periods of oblivion. Currently 2.5% of the dairy farms are using fodder beets in average during 3 to 4 months per year, either on maize or grass silage or hay-based systems. The experience developed in 3 regions has been gathered to analyse the strengths and weaknesses of this crop. In Southwest of France, the network of farmers involved in the AccelAir program has shown the difficulties related to the crop itself and the variable yields resulting from its monitoring (seedbed, density, pesticides program, irrigation). In Eastern France, a network of dairy farmers of the ULM dairy cooperative related a positive effect of the incorporation of 2 kg DM of fodder beets on grass silage-based diets: higher productions and milk solids. To validate this impression, a trial was led during two winters in Trevarez experimental farm, Brittany (Chamber of Agriculture, Idele). 4 kg DM of fodder beets were added to a diet made of 5 kg DM of grass silage, maize silage *ad libitum* and 3.6 kg of rapeseed cakes. The cows with fodder beets decreased their intake of maize silage with a 1/1 substitution rate. No effect on fat and protein produced was noted, but the diet with the fodder beets led to a significant decrease by 1 kg of milk/cow/d. The conclusion of these 3 regional experiences does not question the quality of fodder beets to produce milk. But the efficiency seems higher on grass-based systems than on maize-based systems, notably when maize is of good quality and fed *ad libitum*. Whatever the regional background, their main asset is their capacity to secure the forage yields as their growing period takes place after the summer: they can contribute to face global warming by producing a regular, high-energy forage for lactating cows. Though, in conventional farming, their high index of pesticides use is a weakness and accounts for a high cost per hectare. In organic production, the workload related to the weed control is limiting their adoption.

Effect of wilting grass silage on milk production of dairy cows fed two concentrate protein levelsM. Grøseth^{1,2}, L. Karlsson¹, H. Steinshamn³, M. Johansen⁴, A. Kidane² and E. Prestløkken²¹Felleskjøpet Fôrutvikling, Nedre Ila 20, 7018 Trondheim, Norway, ²Norwegian University of Life Sciences, P.O. Box 5003, 1432 Ås, Norway, ³Norwegian Institute of Bioeconomy Research (NIBIO), Gunnars veg 6, 6630 Tingvoll, Norway,⁴Aarhus University, AU Viborg – Research Centre Foulum, Blichers Allé 20, 8830 Tjele, Denmark; martha.groseth@fkf.no

Increasing the protein value in grass silages for dairy cows is of interest to increase use of homegrown protein sources and reduce nitrogen (N) losses to the environment. Studies have shown that wilting of grass silage can improve the metabolizable protein (MP) value by increasing the rumen microbial protein yield (MCP) and rumen escaped feed protein. We hypothesised that feeding wilted grass silage can improve milk and milk protein production in dairy cows and reduce the need for MP, estimated as amino acids absorbed in the small intestine (AAT), in concentrate. To test this, a continuous feeding experiment with 48 early to mid-lactation Norwegian Red dairy cows, kept in a loose housing system was conducted. Treatments were first cut grass silages from round bales, harvested at early booting from a sward of timothy (*Phleum pratense*), perennial rye grass (*Lolium perenne*) and meadow fescue (*Festuca pratensis*), wilted to 260 and 417 g dry matter (DM)/kg fresh matter. The grass silage was fed *ad libitum* and supplied with 8.3 kg/d of concentrate, either low (108 g AAT/kg DM) or high (125 g AAT/kg DM) in MP concentration, in a 2×2 factorial arrangement. The experiment lasted for 11 weeks, with the 2 first weeks, where cows received same feeding, used as covariate, and the last 4 weeks were used as data collection period. Wilting reduced fermentation products, ammonia and soluble N in the grass silage, while increased residual water-soluble carbohydrates, like expected. However, there was no difference between treatments in daily silage DM intake (13.1 kg) and milk yield (30.2 kg) or milk content, but feeding high MP concentrate increased urea and uric acid in urine. No major differences were found for rumen pH, amino acids in blood plasma or purine derivatives over creatinine index, as indirect estimate for MCP. In conclusion, high silage DM and high MP in concentrate did not increase the milk production in this study.

Zootechnical performance of dairy cattle fed ensiled Italian ryegrass or winter rye

L. Vandaele, J.L. De Boever, T. Van Den Nest and K. Goossens

ILVO, Scheldeweg 68, 9090 Melle, Belgium; leen.vandaele@ilvo.vlaanderen.be

After harvest of silage maize both, winter rye (*Secale cereale* L.) (WR) and Italian ryegrass (*L. multiflorum* Lam.) (IR) are potential forage intercrops (harvest in spring) before planting new maize. WR normally results in higher dry matter (DM) and crude protein (CP) production in comparison with IR. Furthermore, WR needs less N fertilization, so that the following maize crop can receive sufficient N. However, in practice many farmers have doubts about the production capacity, feed quality and feed intake of WR harvested as forage. In this trial a parcel of 5.8 ha was split in two plots. Both IR and WR were sown on Sept 20th 2020 and mowed on April 25th, prewilted, cut and ensiled in silage bags on April 28th. The production of IR and WR was 3,924 and 2,165 kg DM per ha, respectively. The DM content of IR was higher than for WR (513 vs 368 g/kg), with 125 and 138 g CP/kg DM, 84 and 74 g DPI/kg DM and 6.73 and 5.86 MJ NE_L/kg DM, respectively. In the next year a trial was set up with 24 high producing dairy cows. Maize silage, IR or WR and pressed beet pulp (50/43/7 on DM) mixed with soybean meal (10.5% for IR, 9.2% for WR), corn meal (2% for WR) and feed urea (0.5% for IR and 0.3% for WR) were fed *ad libitum*. Both diets were supplemented with (rumen protected) soybean meal and balanced concentrates to meet 105% of the energy and protein requirements of each individual cow and to attain a rumen degraded protein balance of 180 g/d. DM intake (DMI) and milk production were registered daily, whereas milk composition was determined in the last week of each period. Intake and performance data were compared using ANOVA ($P < 0.05$). Cows achieved a higher total DMI and roughage DMI with IR (24.4±0.5 and 18.3±0.5 kg) than with WR (23.1±0.5 and 16.9±0.5 kg) ($P < 0.05$), which resulted in a trend for higher milk production for IR as compared with WR (33.2±1.0 vs 32.3±1.0 kg). Milk fat and protein content were not different. On the other hand, WR showed a higher nitrogen (32.4±0.7% for WR and 32.3±0.7% for IR) and feed efficiency (1.55±0.04 for WR and 1.48±0.04 for IR). In conclusion, unexpectedly winter rye showed a lower DM yield, a lower feed intake and trend for lower production, but showed potential in increasing feed and nitrogen efficiency in dairy cattle.

Performance of NIR spectrometry to predict amino acids content in forages*L. Bahloul¹, V. Larat¹, P. Riche² and B. Sloan³**¹Adisseo, CERN, Commentry, 03600, France, ²Adisseo, Carat, Commentry, 03600, France, ³Adisseo, NA, Alpharetta, 30022, USA; lahlou.bahloul@adisseo.com*

Near Infrared Spectroscopy (NIRS) has been used as a precise and cost-effective tool to predict chemical composition and nutritive values of ingredients. Nutrient-based feeding systems are required in ruminants to formulate more efficient, lower cost and sustainable diets. Progress towards this goal is possible with better characterization of ingredients for amino acids (AA) especially forages that are usually not analysed in feed analysis. The objective of this work was to develop NIRS calibrations to demonstrate the interest to predict individual amino acids profile in grass silages. 135 grass silages samples were collected between November 2021 and July 2022 from west and centre regions of France. The samples were dried at 70 °C for 48 h before being ground with a 1 mm sieve and further analysed for proximate parameters as well as AA. Spectra of these samples were collected from both undried and dried forms, using a DS 2500 NIR instrument from Foss, over the range 400-2,500 nm. The set of spectra was split into a calibration set of 119 samples and a test set of 16 samples. Lysine (Lys) and methionine (Met) are of utmost interest as they are usually considered the first limiting AA for milk production health and reproduction. The database represents a large variation range (CP: 13.7±3.19, Met: 0.145±0.05, Lys 0.39±0.15 as g/100 g). The NIR calibrations performed on the 1 mm ground samples using the Partial Least Squares (PLS) regression reached good predictive precision for both Lys ($R^2=0.93$, Standard Error of Prediction (SEP)=0.047 g/100 g, Ratio of percent deviation (RPD)=2.7) and Met ($R^2=0.91$, SEP=0.013 g/100 g, RPD=2.8), as well as crude protein (CP) ($R^2=0.95$, SEP=0.74 g/100 g, RPD=4.5). Interestingly, the SEP obtained with NIR calibrations surpass in precision the standard error obtained if the AA concentration is estimated by applying a fixed coefficient to the CP wet chemical analyses or NIR predictions (respectively 0.098 and 0.099 g/100 g for Lys; 0.021 and 0.023 g/100 g for Met). In conclusion, the results show the ability of NIR spectroscopy to accurately estimate AA in grass forages and its interest to move forward precise formulation of dairy rations.

Poster 17

Estimation of feed weight of dairy cows using computer vision*M. Taghavi, T. Izquierdo and I. Fodor**Wageningen University & Research, Wageningen, 6700 AH, the Netherlands; marjanah.taghavirazavizadeh@wur.nl*

Monitoring the feed intake of individual dairy cows is important for assessing not only their feed efficiency but also to detect health events. Roughage intake control bins are commonly used to measure the feed intake of individual cows in research but are not practical for commercial farms due to high costs and frequent cleaning requirements. Computer vision approaches based on deep learning algorithms are increasingly being studied as a potential solution. Our aim is to develop and validate a deep learning-based method that is scalable and affordable for commercial farms. An Intel® RealSense™ D455 depth camera was installed at the Dairy Campus research facility of Wageningen University and Research (Leeuwarden, the Netherlands). The camera was placed on a frame above a pile of feed (Total Mixed Ration), and the feed weight was measured using a digital scale with 0.1 kg accuracy. RGB-depth images of the feed were captured within a 0-20 kg range (with 0.5 kg increments) at two different vertical distances from the camera (1 m and 2.6 m), under two light conditions (morning and afternoon light) in the barn. Five different shapes were captured for each feed weight in each setup. In total, 800 RGB-depth images were collected. The images of 4 different shapes from each setup (1 m and 2.6 m in the morning and afternoon) for each weight were randomly selected for training, and the image of 1 shape per setup and weight was selected for validation. The multi-channel input models were trained using both RGB and depth images. The models consist of well-known backbones from image classification for image feature extraction, and the classification head was removed in favour of a regression head. The training and validation process was performed on the dataset for 1 m only, 2.6 m only, and a combination of both datasets. The model trained on the 1 m dataset was more accurate (expressed in mean squared error) than the one trained on 2.6 m, as expected, because the depth information is more accurate at the smaller distance of 1 meter. Prediction accuracy is continuously being improved. Further results will be presented at the conference.

The performance of cross fostered lambs from birth to weaning on commercial sheep flocks in Ireland

F.P. Campion, J. Molloy and M.G. Diskin

Teagasc, Animal & Bioscience Department, Mellows Campus, Athenry, Co. Galway, H65 R718, Ireland; francis.campion@teagasc.ie

The management and care of lambs born in large litters (>2) is often discussed and debated. Allowing ewes to rear large litters to weaning and the use of artificial milk feeders have been shown to be effective. The success of both of these systems is largely depending on flock management and can be expensive. Cross fostering is also employed by some producers whereby excess lambs are fostered to single bearing ewes with the process usually occurring once the fostering ewe is lambing. This study aimed to investigate how the performance of the fostered lamb (F) compared to the ewes own lamb (O) from birth until weaning time (14 weeks post-partum). Over three production years' ewes of mixed age and breed were performance recorded on five commercial mid-season lambing, grass based sheep flocks in Ireland. All of these flocks were enrolled in the Teagasc BETTER farm sheep programme and performance recording was done in conjunction with trained research staff. At parturition each lamb was linked to its dam and its foster dam where necessary. Lambs had their live weight recorded at birth, seven weeks and 14 weeks post-partum. The weights were used to calculate average daily (ADG). Only ewes that gave birth to a live single lamb and that had a lamb from either a triplet or quadruplet litter fostered to them were considered for the final analysis. Approximately 7% of the lambs recorded as F or O at parturition in this data set did not present for weighing at either seven or 14 weeks post-partum. Lamb ADG from birth to seven weeks post-partum differed between F lambs and O lambs (274 vs 300 g/day, ± 12.9 g/day; $P < 0.05$). However, there was no difference in ADG between F and O lambs from birth to weaning (245 vs 251 g/day, ± 10.5 g/day; $P > 0.05$) or from seven weeks to 14 weeks post-partum (229 vs 226 g/day, ± 15.1 g/day; $P > 0.05$). Live weight between F and O lambs differed at birth, seven and 14 weeks post-partum ($P < 0.05$) with F lambs being lighter at all three time points. While the ADG of the F lambs was behind the O lambs for the first seven weeks the performance was still satisfactory, particularly when the increased efficiency of a single bearing ewe rearing an additional lamb are considered.

Theatre 2

Latent factors analysis of protein profile, composition, and cheese-making traits of goat milkN. Amalfitano¹, G. Secchi¹, M. Pazzola², G.M. Vacca², M.L. Dettori², F. Tagliapietra¹, S. Schiavon¹ and G. Bittante¹¹University of Padova, DAFNAE department, Viale dell'Università 16, 35020 Legnaro, Italy, ²University of Sassari, DVM department, Via Vienna 2, 07100 Sassari, Italy; nicolo.amalfitano@unipd.it

The present study aimed to analyse the relationships between the detailed protein profile, the composition, and the cheese-making ability traits of goat milk identifying the latent factors controlling them. This study is part of the GOOD-MILK project (D.M. 9367185 – 09/12/2020) which involved the collection of at least 800 goats belonging to 6 different breeds (Camosciata delle Alpi, Saanen, Murciano-Granadina, Maltese, Sarda, and Sarda Primitiva). The detailed protein profile was obtained using the reverse-phase high-performance liquid chromatography technique (RP-HPLC). Milk composition was estimated using Fourier-transform infrared spectroscopy (FTIR) and cheese-making ability traits were obtained through a laboratory cheese-making procedure. The complete dataset was analysed for latent factors in the R environment. All the traits together yield 8 latent explanatory factors. With protein profile expressed in g/l, the first factor is the 'cheese-yield' affecting positively almost all the cheese-making traits, the fat content, and the total caseins and β -CN, and negatively the pH. The second is the 'curd firmness' factor affecting, beyond the curd firmness traits, the total casein, β -CN, and κ -CN and the recoveries of milk fat and energy in cheese. The third is the 'coagulation time' factor. The fourth is the 'udder health' factor influencing positively the lactose, the β -LG, and α -LA and negatively the somatic cells score and the NaCl. The fifth is the 'curd dynamics' factor affecting positively the curd-firming and syneresis rates and negatively the curd firmness after 30 and 45 min from rennet addition. The sixth is the 'cheese protein' factor whereas the seventh and eighth are, respectively, the ' α_{S2} -CN + κ -CN' and the ' α_{S1} -CN' factors. With protein profile expressed in % of total protein, the latent factors present some differences. This information may help to better understand the link between composition, protein profile, and cheese-making ability of goat milk.

Pyrenean wools: how improving the organisation of the upstream and downstream sectors in the massifC. Viquié¹, S. Fichot¹ and G. Brunschwig²¹Association des Chambres d'Agriculture des Pyrénées, 32 Av. du Général de Gaulle, 09000 Foix, France, ²VetAgro Sup – INRAE, UMR Herbivores, 89 avenue de l'Europe, BP 35, 63370 Lempdes, France; gilles.brunschwig@vetagro-sup.fr

For decades, the price of sheep's wool has been falling: a few years ago it was paid at around €1/kg, but now it is around €0.10/kg, a derisory sum that no longer covers shearing costs. With the closure of historic markets such as China and North Africa, the situation is deteriorating further, and in some departments the wool is not even collected on the farms and has to be stored. In several Pyrenean departments, breeders deplore a 'dramatic situation, with no solution'. In 2021, wool sector contracts were signed by several French regions and define an action plan for the next 5 years. The study presents the situation in Pyrenean chain. A cartographic inventory was carried out using regional data extractions. It provided a visual representation of the main sheep basins, and therefore of the available wool. This territorial approach was then completed by the analysis of a questionnaire sent to 2,600 farms. Focusing on breeding and shearing practices, it provides an insight into the diversity of breeding systems and practices, as well as the types of wool encountered in the Pyrenean massif. Three types of breeders can be distinguished: (1) breeders with little training in wool and who pay little attention to its cleanliness; (2) breeders who produce clean wool but do not sort it and who store it because of a lack of outlets; (3) breeders who are trained in wool sorting and who, by sorting it, value it at a higher price and are more satisfied with their situation. Furthermore, no link appears between the size and location of the farms and the outlets for their wool, especially as the strategies are varied (local craftsmen, cooperatives or private traders). This study provides an initial representation of wool production in the Pyrenees and its challenges. It contributes to the structuring of the sector, coupled with other projects carried out in parallel on the identification of artisanal initiatives or the prospecting and solicitation of French companies ready to engage in the transformation of this resource.

The Gentile di Puglia merino sheep breeds preliminary wool quality assessmentV. Landi¹, E. Ciani², G. Molina¹, R. Toppiti², F.M. Sarti³, A. D'Onghia⁴, G. Mangini⁴, F. Pilla⁵, S. Grande⁶, A. Maggolino¹ and P. De Palo¹

¹University of Bari Aldo Moro, Veterinary Medicine, SP. 62 km. 3, Valenzano (BA), 70010, Italy, ²University of Bari Aldo Moro, Department of Biosciences, Biotechnologies and Biopharmaceutics, Via Amendola 165 Bari, 70126, Italy, ³University of Perugia, Borgo XX Giugno, Perugia, 06128, Italy, ⁴ARA Puglia, Strada S. Nicola, 2, Putignano BA, 70017, Italy, ⁵University of Molise, Department of Agriculture, Environment, and Food, Via De Sanctis, Campobasso, 86100, Italy, ⁶ASSONAPA, Via XXIV Maggio, 44, Roma, 00187, Italy; vincenzo.landi@uniba.it

Wool quality assessment was carried out in the Gentile di Puglia sheep breed after more than three decades. The study was conducted on three farms in Apulia, Italy, where individual wool samples were collected from registered herds. Individual samples (100 for each herd) were collected, and the total fleece weight measured (TW). Diameter (FD) was assessed using the Fibrelux instrument both on greasy and scoured wool. The results showed that the TW ranged from the mean value of 1.54 ± 0.53 kg to 3.44 ± 0.79 for animals of 2 and 3 year more respectively. the average diameter is concentrated around 20 microns, with values between 11.3 and 28.1 (standard deviation 3.35). In greasy wool, the diameter range is between 14.82 and 31.48 (standard deviation 3.18). The average FD of the greasy wool was 23.99 ± 3.184 microns against the 20.78 ± 3.37 of the washed wool. The average washing weight yield was 0.56%, which, considering a range between 63 and 67% that is relatively low showing that there is ample room for improvement in animal management. The average FD for greasy wool for animals of 2, 3 and 4 years was 22.38 ± 1.71 , 23.35 ± 2.75 and 23.18 ± 2.61 respectively while variation coefficient was 5.87 ± 6.79 , 8.69 ± 9.88 and 8.383 ± 9.03 . These results will help to restart a selection plan for wool in this breed. Founded by the Agritech National Research Center and received funding from the European Union Next-Generation EU (PNRR) – Missione 4-2, Investimento 1.4 – D.D. 1032 17/06/2022, CN00000022). This manuscript reflects only the authors' views and opinions, neither the UE can be considered responsible for them. We thank to C. Carrino, G. Bramante and F. D'innocenzio farms for making the animals available for the collection of samples.

Using indoor and outdoor finishing systems to finish hill lambs to carcass weights between 12-16 kgM. Dolan¹, T. Boland², N. Claffey¹ and F. Campion¹¹Teagasc, Animal & Bioscience Department, Animal & Grassland Research & Innovation Centre, Mellows Campus, Athenry, Galway, H65R718, Ireland, ²University College Dublin, School of Agriculture and Food Science, Belfield, Dublin 4, D04 V1W8, Ireland; mark.dolan@teagasc.ie

Fattening lambs indoors to 12-16 kg carcass weights is widely adopted by primary hill and mountain producers in parts of Europe. Research has shown that 'light' lambs finished indoors on *ad libitum* concentrates can meet the market specifications. However, there is a paucity of information on fattening these type of lambs to 12-16 kg carcass weights on autumn pasture. The objective of the study was to examine the performance of Scottish Blackface (SBF) ram and castrate lambs when offered two dietary treatments from September to January; *ad libitum* concentrates indoors (ALC) and permanent pasture (predominantly *Lolium perenne*) outdoors supplemented with 500 g of concentrate (PP). The study was a randomised complete block design with lambs blocked by weight and balanced for sex. The experiment was carried out on two separate years with 50 ram and 50 castrate lambs allocated to each treatment each year. Lamb live weight (LW) was recorded at the start of the experiment and every fourteen days up until the point of slaughter. Ram and castrate lambs started the experiment at 23 kg LW. Ram and castrate lambs were drafted for slaughter as they reached at least 34 kg and 33 kg LW respectively with adequate fat cover. Lambs on ALC treatment had a higher average daily gain than PP lambs (189 and 124±4.1 g/day; $P<0.05$). There was no difference in carcass weights (14.9 and 15.0±0.12 kg; $P>0.05$), carcass conformation (2.8 and 2.8±0.03; $P>0.05$) or fat scores (2.8 and 2.7±0.03; $P>0.05$) while diet type also had no effect on kill out percentage (42.6 and 42.4%±0.25; $P>0.05$). The average days to slaughter was significantly lower for ALC lambs when compared to PP lambs (65 and 101±1.9 days; $P<0.05$). Results from this study show that hill bred lambs can be satisfactory slaughtered to carcass weights of between 12-16 kg from both dietary treatments. However, ALC had higher growth rates and reached the target slaughter weight significantly quicker than PP lambs which is an important consideration for these types of systems.

Session 82

Theatre 6

Influence of climatic disturbances on the lactation curve in dairy goatsA. Harnois Gremmo^{1,2}, N. Gafsi^{1,2}, F. Bidan¹, O. Martin² and L. Puillet²¹IDELE, MNE, 75595 Paris, France, ²Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 91120 Palaiseau, France; aurore.harnoisgremmo@agroparistech.fr

In the context of climate change, intensification of temperature and humidity fluctuations are inducing unquantified impacts on animal performance. The goat is described as adapted to harsh environments, however the limits of its adaptability to climatic stress are not clearly defined. The aim of this study was to investigate the relationship between lactation dynamics and climatic disturbances. This study used the daily milk production data related to 1,174 lactations from 585 goats of the experimental goat farm of INRAE MoSAR, between 2006 and 2021. The data were fitted with the Perturbed Lactation Model, which provides a theoretical-unperturbed lactation curve and characterizes the detected perturbations in the milk production time-series. Daily temperature and hygrometry data were collected at the nearest meteorological station. To explore the impact of climatic conditions, each perturbation detected was confronted with the climate conditions at the date of the perturbation and seven days prior to it. Climatic stress, cold or hot, was estimated using three indicators: a temperature accumulation and two equations of temperature humidity index. Statistical analyses were performed to evaluate if goat lactation curve perturbations were related to climatic stress indicators or to major herd management events. The results showed that for 1,174 lactations 9,010 perturbations were detected. 5.7% of these perturbations in milk production occurred on the period of reproduction (synchronization followed by artificial insemination). The climatic environment study indicated that about 25% of the perturbations occurred during cold stress periods. These results highlight the benefit of combining mathematical models with time-series data to explore animal responses to the environment, especially climatic stress. They would help to precise the thermal tolerance threshold of goats in temperate zones. Furthermore, they allow to unravel the relative effects of thermal fluctuations and other environmental factors that may alter goat metabolism, and therefore to better understand the conditions necessary to rear goats in an environment more respectful of their well-being.

Genetic parameters for fleece uniformity in AlpacasJ.P. Gutiérrez¹, A. Cruz², R. Morante², A. Burgos², N. Formoso-Rafferty³ and I. Cervantes¹¹Universidad Complutense de Madrid, Departamento de Producción Animal, 28040 Madrid, Spain, ²INCA TOPS S.A., Miguel Forga, 348, Arequipa, Peru, ³Universidad Politécnica de Madrid, Departamento de Producción A, 28040 Madrid, Spain; gutgar@ucm.es

Fiber diameter is the main selection objective and criterion in alpaca breeding programs, but it can differ across anatomic regions of the animal. Fleece uniformity is one of the requests of the textile industry. Fiber diameter is usually registered from a unique sample from the mid side of the body, and therefore fibre diameter uniformity within fleece is never taken into account, when phenotypic and genetic differences may exist for fleece uniformity in alpaca populations. The objective of this work was to estimate genetic parameters for fleece uniformity in alpacas. Fiber diameters were measured in three different locations and used as repeated records of the same animal. The dataset counted with 1,641 records of white females of Huacaya ecotype, and 1,085 animals in the pedigree file, being studied fitting a model that considers heterogeneous the residual variance of the model. The logarithm of the standard deviation of the three measures was also used as a measure of the fleece variability. Model included same effects for mean trait and its variability: the month-year of shearing, the body location and the age as covariate as systematic effects. The environmental permanent effect was included as random effect besides the residual and genetic effects. GSEVM program was used to solve the model. Shoulder location showed to be more consistent than mid side and thigh location. Age importantly affected to the residual variance leading to less uniform fleece in old animals. The additive genetic variance of the environmental variability estimate (standard error) was moderate to high, 0.43 (0.14), suggesting a considerable existence of genetic differences between individuals to select to increase fleece uniformity. Genetic correlation (standard error) of the environmental variability of the fibre diameter within fleece with the fibre diameter itself was 0.76 (0.13) indicating that fleece uniformity would be indirectly selected when reducing the fibre diameter. Therefore, and due to the cost of registering, there seems to be no need to consider uniformity as a selection criterion in alpacas breeding programs.

Session 82

Theatre 8

Farmers' competitions: stimulating new management practices by Peruvian alpaca and llama farmersE. Quina¹, T. Felix², M. Aguilar¹, G. Gutierrez², J. Candio², J. Gamarra², M. Mamani^{1,2}, A. Mejía¹ and M. Wurzinger³¹DESCOSUR-Centro de Estudios y Promoción del Desarrollo del Sur, Calle Málaga Grenet 678, Arequipa, Peru,²Universidad Nacional Agraria La Molina, Av. La Molina s/n, Lima, Peru, ³BOKU-University of Natural Resources and Life Sciences, Vienna, Gregor-Mendel-Strasse 33, 1180 Vienna, Austria; maria.wurzinger@boku.ac.at

The Puna ecoregion of the Andes is located above 3,800 masl and is a key ecoregion for the national and local economies, providing various products and ecosystem services. Most of Peru's extensive livestock farming is concentrated here. In these low-input, pasture-based systems, 4.4 million alpacas and 1.0 million llamas – autochthonous species of the Andes – are kept by about 83,000 farmers. The production level of these farms is low due to many reasons. The NGO Descosur has been co-developing mechanisms to stimulate the implementation of different management strategies with the aim of improving the management of alpacas and llamas. Descosur's area of operation is the national park 'Reserva Salinas y Aguada Blanca' in the province of Arequipa in Southern Peru. In a participatory approach, farmers' competitions were designed with local municipalities, farmers' representatives and extension workers. Since 2018 the competitions have been advertised publicly in three different districts, and interested parties could register. A jury of experts and farmers judges whether the specified measures have been implemented and to what extent. Measures that were implemented by participants were: water harvesting techniques (construction of water channels, ponds), fencing of pasture areas, sowing of improved pastures, and data collection on productive and reproductive data of animals. The five best farmers in the competition received tools and materials and were officially recognized by the Ministry of Agriculture. All other participants also received small incentives. This participatory approach was very successful as farmers showed much interest. The common design ensured that only management practices that farmers could implement were included in the competition. The winning farmers can be seen as pioneers, and their farms are models for neighbouring farmers.

YoGArt project: milk quality and oxidative status of ewes fed microalgae blend

A. Mavrommatis, P. Kyriakaki, F. Satolias and E. Tsiplakou

Agricultural University of Athens, Animal Science, Iera Odos 75, Athens, 11855, Greece; eltsiplakou@aua.gr

Enriching dairy ruminant diets with polyunsaturated fatty acids (PUFA) appears to be a sustainable strategy for improving milk's nutritional value. However, long-chain PUFAs have been recognized for their susceptibility to oxidation increasing the risk of oxidative stress emergence which in turn can activate a pro-inflammatory response. Hence, this study aims to examine the effect of microalgae blends dietary supplementation on ewes' milk quality and immune-oxidative status, assessing oxidative biomarkers and antioxidant enzymes activity along with the transcriptional profiling of immune genes from ewes' monocytes and neutrophils. Thirty-two dairy ewes at early lactation were divided into four homogeneous groups; the control group (CON) had no microalgae, the SC30 group was supplemented with 30 g *Schizochytrium* spp./ewe/day while MB30 and MB40 groups were supplemented with 30 and 40 g microalgae blend /ewe/day, respectively. Microalgae supplementation did not significantly affect milk yield while fat content has significantly reduced in MB30 ewes. In milk though, the concentration of Malondialdehyde (MDA) was decreased in the MB30 group while Protein Carbonyls (PC) were increased in MB40 compared to the MB30 group. In blood plasma, Catalase and Glutathione transferase activities were significantly increased in the MB40 group while PC was significantly reduced in the MB30 group. Regarding the immune system, the mRNA levels of TLR4 in monocytes were significantly downregulated in SC30 compared to the CON group. Additionally, IFNG, NFkB, TNFA, and CCL5 relative transcript levels tended to decrease in monocytes and neutrophils of the treated ewes. The combination of *Schizochytrium* spp. with other autotrophic algae species rich in antioxidant compounds alleviated oxidative stress induced by PUFA overload in ewes' diet.

Theatre 10

Goat AI programs based on the male effect using less or no hormones progress with suitable resultsA. Fatet¹, L. Johnson², L. Jourdain², F. Bidan³ and P. Martin⁴

¹INRAE UE1373 FERLus, Les Verrines, 86600 Lusignan, France, ²Innoval, Rue E. Tabarly, 35530 Noyal-Sur-Vilaine, France, ³Institut de l'Elevage, 42 Rue G. Morel, 49070 Beaucoz  , France, ⁴Capg  nes, 2135 Rte de Chauvigny, 86550 Mignaloux-Beauvoir, France; alice.fatet@inrae.fr

In 2021 in France, 70,648 caprine inseminations were performed (Capg  nes). In the national database, the type of preparation of the goats before artificial insemination (AI) is individually recorded for 92% of performed AI. Goat insemination in France is mainly practiced after hormonal synchronisation. However, preparation techniques with less or no hormones have been made available and advertised by the goat sector industries over the past years. This led to a sensible reduction in hormonal synchronization and a noticeable progression of the use of alternative methods based on the buck effect. Across the north-west quarter of France, where insemination cooperative Innoval performs goat AI, the proportion of AI performed after detected natural heats, buck effect (BE) or vaginal sponge and buck effect (VS-BE) preparation has grown from 6% in 2019 (n=33,870 total AI) to 15% in 2021 (n=36,076 total AI) showing hormonal synchronization is slowly decreasing. Regional practice is very diverse with a rather high adoption of less or non-hormonal techniques in Bretagne (35% of total AI), medium in Pays de la Loire (17%) and Poitou-Charente (15%) and rather low in Centre (9%; Innoval AI database). Innoval has been following closely 23 pilot breeders using BE or VS-BE preparation techniques for the past 3 years. Fertility results were quite acceptable in comparison with national fertility results after AI (58.2% in 2021 including all breeds, seasons, preparation techniques, source: Capg  nes). BE resulted in 57% fertility (n=891 AI). VS-BE preparation resulted in 59% fertility (n=1,650 AI). This study allowed identification of key steps ensuring good fertility results when using these alternative techniques: female:male ratio, well prepared males (photoperiodic treatment, sexual awakening), free interactions between males and female in the same pen, quality of heat detection, heat detection to AI interval.

Fiber characteristics of cashmere goat in MongoliaS.B. Baldan^{1,2}, M.P. Purevdorj¹, G.M. Mészáros² and J.S. Sölkner²¹Research Institute of Animal Husbandry, Animal Science Sector, Zaisan street, Khan Uul, 17024 Ulaanbaatar, Mongolia,²University of Natural Resources and Life Sciences, Institute for Livestock Sciences, Gregor-Mendel-Straße 33, 1180 Wien, Austria; johann.soelkner@boku.ac.at

Producing up to 40% of world's raw cashmere annually, Mongolian herders largely depend on cashmere goats for their livelihoods. Increased economic value led to escalated growth in the goat population posing environmental challenges in a vast pastureland. On the other hand, the intention to improve production volume brought a decline in fibre quality due to mismanaged breeding practices. This situation requires many actions to tackle environmental and productivity issues. One of them is to evaluate current production and biological resources in order to improve animal production efficiency. This paper aims to define the fibre characteristics of cashmere goats in Mongolia for their cashmere yield, fibre length, fibre diameter and cashmere content. A total of 621 goats from 14 populations were sampled for their cashmere and genetic material. Genotype was obtained by 50K goat SNP array. Sampled populations were distributed in different economic regions in the country. We intend to define the genetic structure of sampled goat populations and to study whether there is a regional difference among populations for their cashmere quality traits. Variations in cashmere production traits if observed could help to define breeding objectives for different goat populations depending on their specific quality traits. Additionally, we would examine whether there are genome-wide association signals for fibre characteristics.

Poster 12

Anco fit improves feed efficiency, milk production and milk solids in lactating ewesC. Panzuti¹, R. Breitsma² and C. Gerard¹¹ADM, Talhouet, 56250 SAINT NOLFF, France, ²ADM, Linzer Straße, 3100 St. Poelten, Austria; clemence.panzuti@adm.com

Sheep milk is an excellent source of nutrients and is mainly used for cheese production due to its high total solids content. Dietary administration of some bioactive compounds have demonstrated a positive effect on ewe milk production or composition. The aim of this study was to evaluate the dietary supplementation of Anco FIT (AF), containing bioactive substances derived from ginger, lemon balm and cinnamon, yeast components and clays, on feed efficiency, milk production and composition in dairy ewes. Eighty multiparous Lacaune ewes were allocated into two homogenous groups based on milk yield, milk protein and fat contents, lactation number, body weight and body condition score. The animals were housed in two separate pens (n=40 ewes/pen). Each animal received a standard diet consisting of forage (1/3 grass, 1/3 corn silages, 1/3 alfalfa hay) *ad libitum* (~2.3 kg dry matter (DM)/day (d)), and 1.55 kg/d as-fed concentrate composed of 0.45 kg barley, 0.60 kg dehydrated alfalfa, and 0.5 kg of an experimental concentrate without or with supplementation of AF providing 3.8 g AF/head/d. The trial lasted from 1 to 4.5 months post-partum. Milk yield, milk fat and protein were measured at the beginning of the trial and then individually every 2 weeks. Yields of milk fat, protein and solids (sum of protein and fat) were calculated. Within 2 weeks interval forage intake was measured per pen and adjusted for feed refusals. The amount of the distributed concentrate feed was recorded daily per pen. Statistical analyses were performed using Anova mixed model with R software. In comparison to the control group, the supplementation of AF ($P \leq 0.05$) increased milk production by 10% (2.1 vs 2.3 kg/d) and the yields of milk protein (135 vs 151 g/d), fat (125 vs 139 g/d), and total solids (260 vs 290 g/d) by 11, 12 and 12%, respectively. In AF group, the animals had higher ($P \leq 0.05$) forage intake + 0.2 kg DM/d and the feed efficiency was enhanced ($P \leq 0.05$) by gaining +0.03 kg milk/kg DM intake (I) and +5.3 g solids/kg DMI. The results of this study showed that AF can be used as an efficient dietary strategy to increase feed efficiency, milk production and solids in dairy ewes.

No effect of meslin flattening on dairy ewes

B. Fañca¹, A. Hardy², M. Rinn² and L. Buisson²

¹Institut de l'Élevage, 149 rue de Bercy, 75012 Paris, France, ²EPLEFPA La Cazotte, Route de Bournac, 12400 Saint-Affrique, France; barbara.fanca@idele.fr

The protein self-sufficiency of farms can be improved by producing and consuming their own concentrates. Beyond the agronomic aspect, which was not covered in this study, the objective was to evaluate the use of meslin (a grain mixture of cereals and protein crops) in the diet of dairy ewes and, in particular, the interest of distributing it after flattening. Three homogeneous groups of 40 ewes were formed. After an adaptation period, 9 milk control points were recorded for a total trial duration of 3 months. The ewes were fed with the same fodder feed ration and their supplementation varied. To accompany the decline in production, the quantities of concentrates were adjusted. At the beginning of the trial, at the start of the milking period, the Control group received the standard daily supplementation of the farm, i.e. 0.45 kg of barley, 0.5 kg of a nitrogen corrector and 0.6 kg of dehydrated alfalfa. The two Experimental groups received 0.25 kg of the commercial feed, 0.8 kg of dehydrated alfalfa and meslin equivalent to 0.3 kg of barley and 0.3 kg of peas, presented flattened or not. No significant difference in milk production or milk quality was demonstrated between the three groups. Replacing half of the corrector with the mix of grain had no effect on the quantity and quality of milk produced by the dairy ewes. Moreover, the flattening of the barley-pea mixture, representing an additional cost of about 50 euros per ton, and requiring handling and therefore time, had no positive effect on the ewes' zootechnical performance. Finally, if cereals and protein crops are produced on the farm, the part of purchased concentrates in the ration at the beginning of milking drops from 53% (Control) to 30% (Experimental). Similar results were obtained for goats on the Pradel farm (Ardèche, France) with a mixture of barley and faba beans.

Quality of cheeses made from the milk of native breeds of goats

A. Kawęcka, M. Pasternak, J. Sikora and M. Puchala

National Research Institute of Animal Production, Department of Sheep and Goat Breeding, 2 Sarego Street, 31-047 Krakow, Poland; jacek.sikora@iz.edu.pl

Goat milk and products made from it are very popular among consumers around the world and are perceived as ecological, natural, with a high content of bioactive ingredients. Many of them are made from the milk of local goat breeds, the importance of which has been growing recently. In Poland, such a breed is The Carpathian goat, typical for mountain and foothill regions, whose population is dynamically developing and is an extremely valuable element of biodiversity and potential for the development of the local market of goat milk products. The aim of this work was to study the chemical characteristics of experimental cheeses from milk of native Carpathian goat (C) in comparison to Anglonubian (A) and crossbred goats (Saannese and Alpine breed, SA). Cheese milk was obtained three times during the grazing season: in May, July, and September. In the farm's cheese factory, the milk was processed into rennet cheese according to a traditional recipe. Cheese samples were analysed for the content of dry matter, protein and fat, vitamin A and E and determination of fatty acids in fat. The obtained results indicate that the goat breed had an impact on the chemical composition of the cheeses. Cheeses from milk of SA contained the most dry matter (20.5 vs 17.5%) and vitamin A. Native breed milk (C) contained the most ash (4.6 vs 3.3-3.8%), while Anglo-Nubian (A) more total protein (20.3 vs 16.7-18.40%) than the other groups. Significant differences were found in the fatty acid profile of the cheese fat. Carpathian goat milk cheeses contained more unsaturated (UFA) than saturated (SFA) acids compared to the other groups less short-chain C8 and C10 acids than the other two groups, twice as many monounsaturated C16-1 and C18-1 acids and the CLA c9-t11 isomer. The PUFA-6/3 ratio was lower in group C, 1.4 vs 1.93-2.16 in the other groups. From the point of view of the nutritional value, the composition of the tested cheeses varied depending on the breed of goat. The cheeses from the milk of the native Carpathian breed were characterized by a more favourable profile of fatty acids, important from the point of view of human health.

The impact of live-weight and body condition score on reproductive success in ewes

P. McCarron, N. McHugh, N. Fetherstone, H. Walsh and F.M. McGovern

Teagasc, Animal and Bioscience, Animal & Grassland Research & Innovation Centre, Mellows Campus, Athenry, Co. Galway, H65 R718, Ireland; patrick.mccarron@teagasc.ie

Reproductive efficiency is deemed one of the most important traits governing overall farm productivity. In sheep production systems body condition score (BCS), which is interrelated with live-weight, is regularly monitored as a key performance indicator for benchmarking flock performance and efficiency. The objective of this study was to investigate the relationship between ewe live-weight and BCS pre-mating on a plethora of key traits associated with mating and lambing performance. A total of 2,046 data records collected from ewes (females, >18 months of age), representing two main breeds (Suffolk and Texel) over eight breeding seasons were available. Prior to mating ewe live-weight was recorded and BCS assessed, by a trained observer, using a 1 (emaciation) to 5 (over-fatness) scale, in increments of 0.5. Ewe overall conception rate and pregnancy scanned litter size were subsequently recorded within each season. At lambing the total number of lambs born, litter mortality and litter birth and pre-weaning weight were recorded. Data were analysed using linear mixed models with ewe breed, experimental group, year and ewe age included as fixed effects; animal was included as the random effect. Ewe BCS or live-weight had no effect on conception rate ($P>0.05$). Mating BCS influenced pregnancy scan rate, a 1 unit increase in BCS increasing pregnancy scan rate by 0.2 lambs ($P<0.01$). Ewes with a mating BCS of 3.5 or greater gave birth to litters 2.5% heavier when compared to ewes with a BCS of 3.0 or less ($P<0.01$). This difference increased to 5.3% in litter pre weaning live-weight. Similarly every 1 kg increase in ewe live-weight resulted in a higher pregnancy scan rate, number of lambs born and heavier litter birth weights ($P<0.05$). Additionally, ewe age at lambing had a significant effect whereby ewes aged 3 and 4 gave birth to a larger number of lambs with heavier combined litter birthweights than ewes aged 2 years ($P<0.01$). Results from this study show that both BCS and live-weight, recorded at mating, influence reproductive and lambing traits in ewes thus emphasising the importance of having ewes at BCS 3.5 or greater at mating.

Genetic parameters of medullation types in alpaca fibreA. Cruz^{1,2}, Y. Murillo¹, A. Burgos², A. Yucra², M. Quispe³, E. Quispe¹ and J.P. Gutiérrez⁴*¹Universidad Nacional Agraria de la Molina, La Molina, 15024 Lima, Peru, ²INCA TOPS S.A., Miguel Forga 348, Arequipa, Peru, ³Maxcorp, La Molina, Lima, Peru, ⁴Universidad Complutense de Madrid, Avda Puerta de hierro s/n, 28040, Spain; gutgar@ucm.es*

Alpaca fibre industry competes with other noble fibres in an international market. Improving the fibre quality is mandatory with this aim, referring to reduce the incidence of objectionable fibres. Alpaca breeding programs have been successful reducing fibre diameter (FD), but medullation seems to be greatly involved in prickling, and its reduction has been recently introduced as selection criterion in breeding programs. It has been measured by opacity using OFDA100 (optical-based fibre diameter analyser) or using projection microscopy. Fiber Med device has been recently developed, providing medullation measures, and differentiating medullation degrees. The objective of this work was to estimate the genetic parameters of medullation types and their relationship with their respective diameters in alpaca fibre. A total of 3,149 fibre samples collected between 2020 and 2022 from 1,626 alpacas aged from 1 to 16 years old were used, the total pedigree consisting of 14,457 records. Percentages of medullation types were transformed to their centre log-ratio as indicated for compositional data. The types were Strongly Medullated (SM), Continuously Medullated (CM), Uncontinuously Medullated (UM), Fragmented Medullated (FM) and No Medullated fibre (NM), with their respective diameters. A multitrait animal model was used to estimate the variance components using VCE 6.0 program. The heritabilities $\pm$ standard errors were 0.11 ± 0.01 , 0.20 ± 0.01 , 0.10 ± 0.01 , 0.18 ± 0.01 and 0.25 ± 0.01 for SM, CM, UM, FM and NM respectively and 0.10 ± 0.02 , 0.25 ± 0.02 , 0.30 ± 0.02 , 0.35 ± 0.02 , 0.27 ± 0.02 and 0.29 ± 0.03 for respective FD_SM, FD_CM, FD_UM, FD_FM and FD_NM, and global FD. Genetic correlations of medullation types with FD ranged from -0.75 (with NM) to 0.77 (with CM), obtaining moderate to low genetic correlations between medullation types and their respective diameters (from 0.01 to -0.42). The findings suggest that the reduction of FD and total percentage of medullation would perform optimal results in removing the coarsest fibers and consequently the itching.

Blood and gastrointestinal nematode profile of sheep-fed diets supplemented with fossil shell flour

O.O. Ikusika and C.T. Mpendulo

University of Fort Hare, Livestock and Pasture Science, Kings Williams Road, Ailce, 5700, South Africa; oikusika@ufh.ac.za

Fossil shell flour (FSF) is a naturally occurring fossilized atom and has recently been used as a feed additive in livestock production. Therefore, this study investigated the effects of feeding different amounts of FSF on hematobiochemical profiles and the gastrointestinal parasitic loads of Dohne Merino wethers. Twenty-four Dohne Merino wethers were randomly assigned in a completely randomized design with six wethers per treatment. The wethers were fed a basal diet, 0% FSF, basal diet +2%FSF, +4% FSF or a basal diet + 6% FSF of diet. Blood and faecal samples were collected on days 0, 25, 50, 75, and 100 of the feeding trials. The red and white blood counts increased in wethers-fed FSF-supplemented diets from day 25 to 100 compared to the control ($P<0.05$). Blood urea and serum creatinine were significantly lower in wethers with a 4% FSF diet compared to the control ($P<0.05$). Total protein concentration, bilirubin, Na, K, and glucose were within the normal range. Haemaphys and Coccidian egg count reduced in FSF-supplemented diets ($P<0.01$). Providing a diet supplemented with FSF to sheep improves hematobiochemical parameters and remarkably reduces parasite loads, especially at a 4% inclusion level.

Synchrotron FTIR microspectroscopy investigation on the sperm cryopreservation of Sanan goatS. Ponchunchoovong¹, F. Suwor¹, K. Tammanu² and S. Siri Wong²*¹Suranaree University of Technology, School of Animal Technology and Innovation, 111 University Avenue, Muang District, Nakhon Ratchasima 30000, Thailand, ²Synchrotron Light Research Institute, 111 University Avenue, Muang District, Nakhon Ratchasima 30000, Thailand; samorn@sut.ac.th*

Cryopreservation of semen and artificial insemination (AI) represent a powerful tool for livestock breeding. Several efforts have been to improve the efficiency of sperm cryopreservation in different ruminant species. However, amount of sperm still suffers considerable cryodamage, which may affect sperm quality and fertility. The success of cryopreservation depends on several factors like cooling-thawing rates, the types of extenders or cryoprotectants used to assist with the stabilization of cells during the freezing and thawing process. Although being a crucial step for Assisted Reproduction Technologies (ART) success, to date sperm selection is based only on morphology, motility, and concentration characteristics. Considering the many possible alterations, there is a great need for analytical approaches allowing more effective sperm selections. The use of Synchrotron Fourier transform infrared (FTIR) spectroscopy is an advanced and powerful optical technique for obtaining absorption spectra in the infrared region may represent an interesting possibility, being able to reveal many macromolecular changes in a single measurement in a non-destructive way. This study found that Tris base extenders with the combination of egg yolk (10%) and glycerol (5%) yielded the higher motility and viability rates compared to the other treatments, but it was lower than the commercial used (Andromed) and fresh sperm ($P<0.05$). This result was related to synchrotron FTIR study. We obtained important clues on the macromolecular changes, mainly lipid, protein modifications and nucleic acid. In our study claimed that synchrotron FTIR spectroscopy can be proposed as a new smart diagnostic tool for semen quality assessment on sperm cryopreservation of Saanen goat.

A need for knowledge on the utilisation of forage by goats according to the distribution methods*B. Fança and B. Bluet**Institut de l'Élevage, 149 rue de Bercy, 75012 Paris, France; barbara.fanca@idele.fr*

Goat farming is facing multiple constraints: economic, environmental, and societal. Feed management is among the first lever of action available for breeders to adapt. The management of feed distribution is supposed to have a strong impact on feed intake. However, there are few references as to the real impact of distribution methods on the use of forage, even though the consequences on technical and economic results and on the workload and organisation of work can be significant. The aim of this preliminary study was to measure the diversity of distribution practices and to identify the issues that farmers and their advisors are facing today. Two online surveys were therefore constructed in parallel, for livestock advisors and for farmers. 41 advisors and 119 farmers representing all the French goat sector regions and feeding systems responded and took part in the survey. A first observation is the great diversity of practices, particularly concerning the number of forage distributions ranging from 1 to 8 per day. Farmers practicing a single distribution per day or less are in the minority: 9%. However, 46% of the farmers consider the work involved in distribution to be painful, and 25% of them consider the time allocated to distribution to be not acceptable. The majority opinion of the advisors also tends to prefer 2 or 3 distributions per day, to foster the milk production. 69% of farmers distribute at least two different forages per day. However, no majority opinion emerges concerning the order of distribution of forages during the day (when they are not mixed) according to their respective qualities (feed values, fibrosity, humidity, etc.), both among farmers and advisors. The surveys distinguished the different food systems according to the nature or method of harvesting the main forages. The diversity of practices and opinions can be observed in all systems. However, systems based on hay are considered easier to manage than those on fresh grass. These results show the importance of objectivizing the consequences of different practices according to the different systems so that breeders can choose a distribution method that reconciles technical results and work organization.

Session 82

Poster 20

Changes in fattening and slaughter traits of old-type Polish merino between 2010 and 2020*M. Puchala, A. Kawęcka, J. Sikora and M. Pasternak**National Research Institute of Animal Production, Department of Sheep and Goat Breeding, 2 Sarego Street, 31-047 Kraków, Poland; michal.puchala@iz.edu.pl*

Stationary evaluation of rams based on progeny is an important element of breeding value assessment, especially in paternal (meat) herds. In addition to growth rate and feed consumption, slaughter traits are determined and analysed in stationary evaluation. The information obtained allows for accurate and objective evaluation and ongoing monitoring of traits. In further mating, it is recommended to prefer rams characterized by high values of individual traits (indices). The inspection station evaluates animals from breeding herds with a minimum of two herd rams, belonging to different breeds. At collection from the breeder, the age of individual rams should be between 56 and 75 days, and the average weight for the group should be about 18-19 kg. They are fed at will with a complete pelleted mix. A total of 36 old-type Polish Merino rams were evaluated at 209 progeny from 2010-2020 ram control stations. During the period, changes in the values of selected indicators of fattening traits were recorded. There was a marked daily gain during the fattening period from 282.84 g in 2010 to 349.18 in 2020, an increase of 18.99%. During the same period, there was a decrease in feed consumption per kg of weight gain during the fattening period by 18.18% from 4.73 kg in 2010 to 3.87 kg in 2020. The average age of fattening onset also decreased during the analysed period from 89.4 to 73.0 days in 2020, a difference of 18.38%. There was a reduction in fattening time from 83.06 to 67.39 days (a decrease of 18.86%). There was no change in the parameters of selected indicators of slaughter traits, such as cold carcass weight, slaughter yield and share of carcass cuttings in half-carcasses, while a slight increase in the proportion of meat in half-carcasses was observed from 63.22 to 64.79% (an increase of 2.42%) and a decrease in the proportion of fat in half-carcasses by 9.18%, from 15.33% in 2010 to 14.04% in 2020. During the period under review, improvements were observed in the most important fattening traits and selected slaughter traits, from the economic point of view of the highly important feed consumption and shortened fattening period.

Milk fat nutritional indices – a comparative study between retail goat and cow milkG. Papatzimos¹, P. Mitlianga², M.A. Karatzia³, Z. Basdagianni⁴ and E. Kasapidou¹¹University of Western Macedonia, Department of Agriculture, Florina, 53100, Greece, ²University of Western Macedonia, Department of Chemical Engineering, Kozani, 50100, Greece, ³Research Institute of Animal Science, HAO-Demeter, Paralimni, 58100, Greece, ⁴Aristotle University of Thessaloniki, School of Agriculture, Department of Animal production, Thessaloniki, 54124, Greece; papatzimos@hotmail.com

Milk is a nutritive food essential to people's diets throughout their lives. Lately, there is increased consumer interest in goat milk due to its health-related benefits. However, information on milk nutrient profile at retail levels is limited, whereas few studies contemporaneously compare the nutritional value of goat and cow milk. This study investigated differences in the nutritional indices related to healthy fat consumption between goat and cow retail milk produced in Greece. Samples from conventionally produced retail cow (n=48) and goat (n=48) milk were collected monthly for one year from four major food retailers. The same manufacturers produced both goat and cow milk samples. Milk fatty acid profiles were analysed by GC flame ionisation detection, and the following indices were determined: Hypocholesterolemic: hypercholesterolemic fatty acid ratio (h/H), Health Promoting Index (HPI) and Desirable Fatty acids (DFA). The h/H is a new index assessing the effect of FA composition on cholesterol. HPI is mainly used in research on dairy products such as milk and cheese. Finally, DFA represent the sum of stearic acid and unsaturated fatty acids, which are all anti-atherogenic. The latter indices are less frequently applied in evaluating the lipid nutritional quality of milk and dairy products. Differences between goat and cow milk were determined using independent t-tests. The h/H ratio was almost 0.62 in both types of milk. HPI was 0.43 and 0.82 for goat and cow milk, and the percent of DFA was almost 43 in milk from both species. There were no statistically significant differences ($P>0.05$) in all examined parameters in both types of milk. However, further research is needed to identify differences in milk fatty acid composition between seasons and between production systems. Support: 'AGROTOUR' Project (MIS 5047196), 'Reinforcement of the Research and Innovation Infrastructure', NSRF 2014-2020.

Mountain caprine milk – the higher the better?M.A. Karatzia¹, M. Amanatidis², G. Papatzimos², E. Kasapidou², P. Mitliagka² and Z. Basdagianni³¹Hellenic Agricultural Organization-DEMETER, Paralimni, 58100, Greece, ²University of Western Macedonia, Kozani, 50100, Greece, ³Aristotle University of Thessaloniki, Thessaloniki, 54124, Greece; karatzia@elgo.gr

Mountain dairy products are widely recognized as of higher quality and taste in comparison to the ones produced at the plains. The advanced quality characteristics of mountain milk originate from animals grazing in mountain pastures and meadows. As nomadic or transhumant livestock farming has been practiced for centuries in Greece, it is mainly based on highland pasture utilisation through low input goat and sheep management systems. Within this scope, a preliminary study was undertaken, to compare the chemical composition of mountain goat milk and milk produced at the plains of Western Macedonia. A total of 32 bulk goat milk samples were collected at a bi-weekly rate from two flocks during mountain transhumance from June until September (M-16 samples at 1,300 m altitude) and their stay at the plains during March-May and upon their return from the highlands in October (P-16 samples at 300 m altitude). Both farms reared Greek breed goats (*Capra prisca*). Chemical composition and total bacterial count were determined in all milk samples and results were statistically analysed using IBM SPSS v.27.0 (mean $\pm$ SD). Total solids (M-14.14 $\pm$ 1.07%; P-13.81 $\pm$ 0.48%), water (M-85.86 $\pm$ 1.07%; P-86.19 $\pm$ 0.48%), protein (M-3.91 $\pm$ 0.48%; P-3.66 $\pm$ 0.21%) and non-fat milk constituents (M-8.89 $\pm$ 0.47%; P-9.09 $\pm$ 0.19%) percentages did not differ significantly between M and P groups. Milk fat and lactose levels did not follow the aforementioned trend. The mean fat percentage in mountain milk samples was significantly higher than in plain milk samples (M-5.25 $\pm$ 0.67%; P-4.77 $\pm$ 0.38%, $P\leq 0.05$). Additionally, mean lactose level in mountain milk samples was significantly lower than in plain milk samples (M-4.15 $\pm$ 0.13%; P-4.60 $\pm$ 0.08%, $P\leq 0.05$). Total bacterial count was within the normal range in all samplings. Significantly elevated milk fat levels of mountain goat milk support a quality distinction between it and milk produced in the plains. Funding received by 'AGROTOUR' Project (MIS 5047196), 'Reinforcement of the Research and Innovation Infrastructure', NSRF 2014-2020.

Results of milk performance of Carpathian goats

J. Sikora, A. Kawęcka, M. Puchala and M. Pasternak

National Research Institute of Animal Production, Department of Sheep and Goat Breeding, 2 Sarego Street, 31-047 Krakow, Poland; jacek.sikora@iz.edu.pl

Milk is one of the basic raw materials used by humans in their diet. It is a natural food produced by mothers for their offspring. At a later age, children, adolescents and adults use the milk of other mammals to meet the body's need for protein and essential amino acids. There are many breeds of goats used for dairy purposes in Poland. Among other things, imported breeds, such as: Saanen or Alpine and domestic breeds, which are currently represented by the Carpathian breed. Carpathian goats represent a primitive breed of goats that have been present in Poland for centuries, recognized as an extinct breed at the end of the 20th century. In the years 2005-2010, at the National Research Institute of Animal Production in Balice, an attempt was made to reconstitute this breed, and in 2014 Carpathian goats were included in the genetic resources protection program. Currently, there are about 400 mother goats in the country. Since 2007, goats of this breed have been subject to milk performance control. The goat population built from scratch consisted mainly of young animals, whose milk yields were obtained in the first or second lactation – about 80%. Older goats, milked in the third and fourth lactation, they constituted a minority in the first years of the assessment, respectively 15 and 5%. In the following years, the group of older animals, assessed in higher lactations, slightly increased, however, the constant influx of young animals shaped the average level of lactation of the breed. In the first year of milk performance control, the average yield of the Carpathian goat population was 450 kg of milk, 2.8% protein, 2.9% fat. In the following years, the average milk yield was at different levels. In 2012, the average yield was 322 kg, 2.87% protein, 3.67% fat. In 2020, the average yield was 255 kg, 3.2% protein, 3.25% fat. The decrease in the level of average lactation can be explained by the introduction of young goats to evaluate milk yield and a strong emphasis on features related to the exterior of selected animals for breeding, and other features, including the level of milk production, which are omitted at this stage of breed reproduction.

Poster 24

Barley in concentrates for dairy goats – effects of alkaline and mechanical treatments

A. Martinsen¹, D. Galméus¹, H. Volden¹, K. Hove¹, M. Silberberg² and M. Eknæs¹

¹Faculty of Biosciences, Norwegian University of Life Sciences, Oluf Thesens vei 6, 1433 Ås, Norway, ²Université Clermont Auvergne, INRAE, Unité Mixte de Recherche sur les Herbivores (UMRH), Site de Theix, 63122 Saint-Genès-Champanelle, France; anita.martinsen@nmbu.no

Goat milk production in Norway is partly dependent on imported feed raw materials. Increasing the use of Norwegian cereals in commercial concentrate for goats is interesting when attempting an effective and sustainable goat milk production. We proposed to increase the use of domestic barley in pelleted concentrate feeds to goats. However, barley contains a large proportion of rapidly digestible starch. Fed in high amounts, barley will reduce ruminal pH and cause subclinical ruminal acidosis (SARA). We used processing methods like alkaline and mechanical treatments before pelleting to modify changes in ruminal pH. Nine rumen cannulated lactating goats were fed three different types of concentrates containing: (1) rolled barley treated with alkali (Alka); (2) rolled barley (Rolled); and (3) finely ground barley (Ground). The experiment was conducted as a 3×3 Latin square, with three replicates and was implemented as a dose-response experiment with three periods. Silage was fed *ad libitum* and daily concentrate rations were divided into six equal meals fed every fourth hour. Daily concentrate allowances were increased by 150 g DM every 4th day until the goats stopped eating or developed symptoms of SARA. Neither Alka barley nor mechanical treatment affected silage intake, whereas Alka barley led to lower concentrate consumption per 100 kg ECM ($P<0.01$) compared to Rolled barley. There was a higher milk yield ($P<0.01$) from the Alka barley diet compared to Rolled barley and the difference increased with increasing level of concentrate. Milk yield was not affected by mechanical treatment. Fat and protein content in milk were equal among all treatments. Ruminal pH tended to be lower ($P=0.069$) for Alka barley compared to Rolled barley, but the ratio between concentration of acetic and propionic acid was unaffected. Alka barley had a positive effect by increasing milk production on less feed. The effects of added enzymes in Alka barley and increased level of non-protein nitrogen probably resulted in improved fibre digestion.

The effect of population history, mutation and recombination on genomic selectionD. Adepoju¹, T. Klingström¹, A.M. Johansson¹, E. Rius-Vilarrasa² and M. Johnsson¹¹Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, Box 7023, 750 07 Uppsala, Sweden, ²Växa Sverige, P.O. Box 30204, 104 25 Stockholm, Sweden; martin.johnsson@slu.se

Population genetic features such as population history, mutation rate and recombination rate affect the distribution of genetic variants and their association, and thus the performance of genomic prediction. In our ongoing research on the genome dynamics of livestock breeding, we explore the effects of population history, recombination and mutation in farm animals. We have estimated the recent population history of Swedish cattle breeds (Swedish Red cattle, Swedish Mountain cattle, Fjällnära cattle, Ringamåla cattle, Bohus Polled, Väne cattle, and Swedish Red Polled), using linkage disequilibrium-based methods on both SNP chip genotypes and whole-genome sequence data. While the estimates are affected by method and data type, they consistently suggest that recent population size has been relatively large (on the order of thousands) up until the onset of systematic breeding, when it shrunk rapidly. It also suggests that efforts by breed organisations to maintain the effective population size of breeds like the Swedish Mountain cattle during the 20th century have been successful. In the case of recombination, sequence data shows the long-term effects of recombination rate on genetic diversity, in the form of a correlation between local recombination rate and the number of variants detected in whole-genome sequence data. For the effect of recombination rate on breeding, we have built a quantitative genetic simulation that includes variable recombination rate, based on real linkage maps. This model confirms that high recombination rate contributes to somewhat higher additive genetic variance in the long run, but that a higher recombination rate lowers the accuracy of genomic selection. The benefit to variance happens in the long run, but the decrease in accuracy is immediate. This suggests that, on balance, high recombination rate is not beneficial for breeding.

Session 83

Theatre 2

The detection of putative recessive lethal haplotypes in Irish sheep populationsR. McAuley¹, N. McHugh¹, T. Pabiou² and D.C. Purfield³¹Teagasc, Animal and Grassland Research Centre, Teagasc, Animal & Grassland Research Centre, Moorepark, Fermoy, Co. Cork, P61 C996, Ireland, ²Sheep Ireland, Sheep Ireland, Link Road, Ballincollig, Co. Cork, P31 D452, Ireland, ³Munster Technological University, Biological Sciences, Munster Technological University – Cork Campus, Bishopstown, Cork, T12 P928, Ireland; rory.mcauley@teagasc.ie

In livestock populations, recessive lethal alleles are a known contributor to poor reproductive performance due to embryonic death in homozygous individuals. Despite their lethal effect in the recessive form, these alleles may be maintained at high frequencies among carrier animals because of their positive pleiotropic effects on economically important traits. Although several such recessive alleles have been identified in cattle and pig populations, limited studies have been completed in sheep, and none within Irish sheep populations. Genotype data for 69,034 animals from 5 major Irish sheep breeds genotyped on a variety of panels was available for this study. Only animals and single nucleotide polymorphisms (SNPs) with a call rate >90%, and a minor allele frequency >0.01 were retained. Non-autosomal SNPs and SNPs that did not adhere to Mendelian inheritance patterns were discarded. Following imputation to medium density, 43,951 SNPs remained across 66,996 animals, which included 32,256 verified progeny-sire-dam and 2,089 verified progeny-sire-maternal grandsire trios. To identify haplotypes with homozygous deficiency, a sliding haplotype window of 10 SNPs was used to scan the genome of all genotyped animals. Haplotype lethality was determined using a chi-square test between the number of observed and expected haplotypes. Two haplotypes showed a significant deficiency of homozygote animals with expected frequency observations ranging from 80 to 88% and a carrier frequency ranging from 15 to 16%. These haplotypes were located on chromosomes 8 and 19 and found solely in the Vendeen population. Comparison of at risk-matings (between carriers) and safe matings, demonstrated that these haplotypes were associated with an increased still-birth rate ($P < 0.05$). This finding can be incorporated into Irish sheep breeding programs to avoid carrier-by-carrier matings to reduce lamb mortality.

Assessing the impact of inbreeding on mastitis and digital dermatitis in German dairy cattle*J. Mugambe**Christian-Albrechts University of Kiel, Dithmarscher Straße 9, 24113, Germany; jmugambe@tierzucht.uni-kiel.de*

Understanding the impact of inbreeding on health traits is of economic importance for dairy cattle farmers. However, there is currently no study on the impact of inbreeding on mastitis (MAS) and digital dermatitis (DD) in German Holstein dairy cattle. Here we investigated the impact of inbreeding on MAS and DD using both pedigree-based and genomic-based inbreeding estimators. Data included records of 24,489 cows with both phenotypes and genotypes. The pedigree used in the analysis comprised 819,021 animals born after 2012 with a pedigree completeness index (PCI) greater than 85% tracing 5 generations back. To investigate the effects of inbreeding depression, inbreeding coefficients from various estimators were included separately in single-trait threshold models to account for the binary nature of the health traits. For easier interpretation of results, solutions from the analyses were transformed from a liability scale to a probability scale with respect to the phenotypic incidence of 17 and 27% for MAS and DD, respectively. The mean inbreeding coefficients from all estimators ranged from -0.003 to 0.110, with negative values observed for most genomic-based methods. The probability distributions resulting from a 1% increase in inbreeding for all estimators ranged from 0.38 to 0.76 for MAS and 0.46 to 0.87 for DD. Despite the significant effect of inbreeding on both traits, inbreeding depression was larger for DD compared to MAS in German Holstein dairy cattle. Given the high economic costs associated with MAS and DD in dairy production, inbreeding can negatively impact the financial returns for dairy farmers. Thus, there is a strong motivation to regulate and manage the rate of inbreeding in dairy populations in order to minimize the incidence and spread of these diseases.

Session 83

Theatre 4

Genomic inbreeding in the Austrian Turopolje pig population*G. Mészáros¹, B. Berger², C. Draxl³ and J. Sölkner¹**¹University of Natural Resources and Life Sciences, Vienna, Gregor-Mendel-Str. 33, 1180 Vienna, Austria, ²HBLFA Raumberg-Gumpenstein, Austraße 10, 4600 Thalheim bei Wels, Austria, ³Österreichische Schweineprüfanstalt Gesellschaft mbH, Unter den Linden 1a, 2004 Streitdorf, Austria; gabor.meszaros@boku.ac.at*

The Turopolje pig is an endangered, local breed from Austria. The population was set up based on a small number of animals recovered from Croatia during the war in the early 1990ies. Due to the small number of founders and lack of further imports, the population is highly inbred. With the start of routine SNP genotyping, it was possible to set up approaches to manage the diversity of the breed. In this study we aim to assess the genomic inbreeding within the breed. The data set of Turopolje consisted of 184 animals, genotyped with custom chip with 77,122 SNPs. For comparison, pigs from all commercial breeds in Austria were used, including 82 Large White, 76 Landrace, 74 Duroc and 70 Piétrain pigs, genotyped with a Porcine 60K SNP chip. Only the common SNPs between chips were considered. The data were controlled for quality, removing SNP and individuals with more than 10% missingness. After quality control a total of 485 pigs and 54,075 autosomal SNPs remained. The genomic inbreeding was assessed based on runs of homozygosity (ROH) with the cgaTOH software, considering common ancestors up to 6 generations in the past (minimal length of ROH was 8 Mb). The average inbreeding coefficient in Turopolje was 0.18 (sd 0.06). This was similar to Duroc and Piétrain breeds (both 0.17, sd 0.04), but higher than in Landrace (0.10, sd 0.03) and Large White (0.11, sd 0.02). The variance of inbreeding levels was the highest in the Turopolje breed, ranging from 0.06 to 0.41. The genetic diversity measures have to be prioritized in the Turopolje population, with an aim to decrease overall inbreeding levels in order to maintain the viability of the breed.

A genetic diversity study of a local Belgian chicken breed using the new IMAGE SNP arrayR. Meyermans¹, W. Gorssen¹, J. Bouhuijzen Wenger¹, O. Heylen², J. Martens², S. Janssens¹ and N. Buys¹¹Center for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, Box 2472, 3001 Leuven, Belgium, ²Steunpunt Levend Erfgoed zvw, Spiegel 1, 9860 Oosterzele, Belgium; roel.meyermans@kuleuven.be

Screening for genetic diversity in livestock species breeds is important, especially for local, small populations at the risk of extinction. Moreover, recent developments have made genotyping also affordable for smaller breeds and populations. One of these new developments is the IMAGE_01 SNP genotyping array, that includes SNPs for six different species (cow, pig, sheep, chicken, horse and goat, 10K SNPs per species). This multiple species array can be a valuable addition to screen multiple breeds at once. Moreover, the array allows genotyping a small number of samples per species and combining samples where possible. In this study, we used the IMAGE genotyping array to genotype a local Belgian chicken breed, the Turkey-headed Malines (*Mechelse Kalkoenkop / Coucou de Malines à tête de dindon*). 110 DNA samples were collected for this breed, together with 29 samples from four possibly related local breeds. Genetic diversity of our local breed was examined via a principal component analysis and a F_{is} study. This revealed the breed to be closest related to the Malines chicken, and less related to the Coucou des Flandres than previously assumed. Next, an inbreeding analysis based on runs of homozygosity (F_{ROH}) and effective population size estimation was tested. Average F_{ROH} was estimated as rather high ($\pm 20\%$) and the effective population size was found to be very low (< 35). Finally, our data were matched to internationally available open access chicken genotypes, although the SNP overlap of the IMAGE array with other commercial arrays was rather low. Valuable insights on the breed composition were generated and shared with the breeders to optimize their breeding practices. Moreover, this study is the first to evaluate the genetic diversity of a Belgian chicken breed and can serve as pilot for future genetic research on local Belgian chicken breeds.

Genetic diversity in Dutch sheep breeds shaped by geography, history, use and genetic management

J.N. Hoorneman, W.J. Windig and M.A. Schoon

Centre for Genetic Resources, the Netherlands, & Livestock Research, Wageningen University & Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; noelle.hoorneman@wur.nl

The Netherlands has a rich variety of native sheep breeds from different geographic regions with different historic and present uses. Based on the number of breeding females, ten of these breeds are currently classified at risk with associated risks for high inbreeding levels. To gain more insight in the genetic structure of the Dutch sheep population, we studied the distinctiveness of the native breeds, their genetic diversity both within and between breeds, and how this diversity is shaped by geography, purpose, history and genetic management practices. Semen samples of 171 rams of 11 native Dutch sheep breeds were genotyped with the IMAGE001 10K multispecies SNP chip. Principal component analysis (PCA), population structure and phylogenetic analyses all clearly differentiated the breeds according to their historical origins and geographical distribution, except for the Texel and two Texel related breeds. Breeds bred for milk or meat production on rich grasslands in the north and west of the Netherlands, and breeds bred for grazing of nature areas and manure collection on poorer grounds in the east and south were separated in different clusters. The graphical distribution of the PCA mirrored the geographical distribution of the origin of the breeds. Within breed diversity was larger for the two breeds with largest population sizes plus the one breed, Veluwe Heathsheep, that consistently has used a breeding circle to mitigate inbreeding rates. Largest unique diversity was found for the Flevolander a breed more recently developed with the use of foreign breeds. All other breeds shared large parts of their genetic diversity with either the production breeds from rich soils or the grazing breeds from poorer soils. This study not only provides more insight in the structure of the Dutch native sheep population, but is valuable as well for assessing the effects of selection and genetic management measures. Additionally, insight in genetic diversity of the Dutch genebank collection, in contrast to the *in situ* population, can support identification of unique males in the live population to be added to the genebank collection.

Genetic diversity and population structure of the Cyprus Chios sheep and Damascus goat breeds

A.C. Dimitriou, G. Maimaris, A.N. Georgiou and G. Hadjipavlou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516, Lefkosia, Cyprus; adimitriou@ari.moa.gov.cy

Cyprus lies within a global biodiversity hotspot and it is directly threatened by climate change and hence by desertification given its geographic location at the eastern Mediterranean Sea basin. At the same time, Cyprus has the second largest population growth rate among European countries, fact that highlights the need to optimize applied primary production strategies aiming to secure food production and minimize the impact on local natural environment in a cost and time effective way. Considering the population growth and the recent registration of locally produced cheese (Halloumi) as Protected Designation of Origin, the demand of goat and sheep milk is anticipated to increase dramatically. According to constructed scenarios taking into account the current milk production on the island, goat and sheep livestock should be doubled (from ~500k to 1000k) in order to meet the expected needs. Alternatively, this goal could be fulfilled by improving the existing livestock using genetic data and modelling. For this purpose, the first high-throughput genomic data for local Cyprus sheep and goat breeds were generated by the Agricultural Research Institute (ARI), employing available SNP genotyping microarray assays. The datasets analysed included genomic data for more than 1000 animals per species, representing six farms. Estimated population metrics indicated the existence of at least four genetically distinct groups in both sheep and goat breeds, as well as an ongoing gene flow between specific farms included in our dataset. These findings are also corroborated by calculated population fixation indices in both cases. Produced data call for a more thorough, large-scale analysis including individuals from more farms aiming to describe the local livestock diversity in a comprehensive way. Towards this direction, within the framework of an EU funded project led by ARI, a significant number of farms are expected to participate in the national genetic and genomic improvement program regarding Cyprus Chios sheep and Damascus goats.

Session 83

Theatre 8

Genome-wide analysis of Greek goats with global breeds revealing population structure and diversityE. Tosiou¹, V. Tsartsianidou^{1,2}, S. Vouraki³, V. Papanikolopoulou³, L. V. Ekateriniadou⁴, E. Boukouvala⁴, I.G. Bouzalas⁴, I. Sakaridis⁴, G. Arsenos³ and A. Triantafyllidis^{1,2}

¹Aristotle University of Thessaloniki, School of Biology, University Campus, 54124 Thessaloniki, Greece, ²Center for Interdisciplinary Research and Innovation, Genomics and Epigenomics Translational Research, Balkan Center, 57001 Thessaloniki, Greece, ³Aristotle University of Thessaloniki, School of Veterinary Medicine, University Campus, 54124 Thessaloniki, Greece, ⁴Hellenic Agricultural Organization-DIMITRA, Veterinary Research Institute, Campus of Thermi, 57001 Thessaloniki, Greece; tsarvale@bio.auth.gr

Goat farming is of major importance for the Greek livestock sector, while the national herd is one of the largest in Europe, mainly consisting of Eghoria and Skopelos breeds. However, little genetic information is available, for the Skopelos breed only. We studied the genome-wide diversity and population structure of Greek goats, collectively analysed with 49 global breeds from AdaptMap project. A total of 287 goats sampled from seven indigenous Greek populations (Aridaia, Chalkidiki, Eghoria, Serres, Paggaio, Skopelos, Crossbreed) and three introduced breeds widely reared in Greece (Anglo-Nubian, Damascus and Murciano-Granadina) were genotyped using the Axiom Caprine Genotyping v2 Array. High average genetic diversity levels were estimated for Greek goats including observed and expected heterozygosity ($H_o=0.36-0.41$, $H_e=0.37-0.41$), similar to values estimated for other Mediterranean breeds. According to global-scale principal component analyses (PCA) results, most Greek populations were closely clustered and adequately differentiated from introduced and global goat breeds. Greek goats were placed closer to Turkish, Romanian and Mediterranean (Maltese sarda, Maltese, Garganica, Jonica, Rossa Mediterranea) breeds. These results contribute to the genome-wide understanding of Greek goats' population stratification, diversity and demographic history, while they provide genetic information on the downstream development of a cost-effective panel of markers for population assignment aiming to differentiate Greek from other goat breeds. A representative set of Greek goat genomes will be fully sequenced within the framework of this study, funded by the GRAEGA CHEESE project (KMP6-0083632).

Genome-wide scan for runs of homozygosity in South American camelidsS. Pallotti¹, M. Picciolini², M. Antonini³, C. Renieri⁴ and V. Napolioni¹

¹School of Biosciences and Veterinary Medicine, University of Camerino, Via Gentile III Da Varano s/n, 62032 Camerino (MC), Italy, ²SYNBIOTEC Laboratori s.r.l., Località Torre del Parco, 62032 Camerino (MC), Italy, ³Italian National Agency for New Technologies, Energy and Sustainable Development (ENEA), Centro Ricerche Casaccia, Via Anguillarese, 301, 00123 S.M. di Galeria (RM), Italy, ⁴School of Pharmacy, University of Camerino, Via Gentile III Da Varano s/n, 62032 Camerino (MC), Italy; stefano.pallotti@unicam.it

Four species of South American camelids (SAC) are distributed over the Andean high-altitude grasslands. These include 2 wild species guanacos (*Lama guanicoe*) and vicugna (*Vicugna vicugna*), and 2 domestic species, alpaca (*Vicugna pacos*) and llama (*Lama glama*) bred for meat and fibre production. The genome-wide scan for runs of homozygosity (Roh), which are contiguous lengths of homozygous segments of the genome where the two haplotypes inherited from the parents are identical, offers the possibility to unveil and compare the signatures of selection along the genome. Here, we investigated the occurrence and distribution of ROH in the four SAC species starting from whole-genome sequencing (WGS) data retrieved from public available repository and new WGS of alpacas. Sample consisted of 12 WGS from alpacas, 7 WGS from llama, 6 WGS from guanaco and 6 WGS from vicugna retrieved from NCBI. Moreover we added to our sample 7 new WGS of alpacas. The genomic variants calling was performed, then data were converted to plink files and used to perform the genome-wide scan for Roh longer than 100 kb and 500 kb. Vicugna and guanaco showed a slightly higher number of Roh longer than 100 kb than llama and alpaca. In particular, llama was the species with the lower number of Roh found. Roh longer than 500 kb were found only in alpacas genome. The inbreeding coefficient based on Roh (Froh) was low for all four species ranging from 0.04 to 0.02 and ANOVA showed no significant differences between the four species. The analysis of the overlapping Roh within the species found genomic regions which harbour candidate genes selected for fibre and body growth traits in domestic species and for local adaptation to environmental stress for both domestic and wild species.

Session 83

Theatre 10

Exploring global cattle genealogy with tree sequence

G. Mafrà Fortuna, J. Obsteter, A. Kranis and G. Gorjanc

The Roslin Institute, The University of Edinburgh, Easter Bush Campus, Midlothian, EH25 9RG, United Kingdom; g.mafrafortuna@sms.ed.ac.uk

The two cattle subspecies showcase distinct aptitudes. Acknowledging and exploring these distinctions at genomic level might be critical to improving their crosses. Two evolutionary events separate *Bos taurus* and *Bos indicus*: an ancestor split and domestication. The ancestor split occurred over 100,000 years ago. Domestication happened 10,000 and 8,500 years ago, respectively. Another 100+ years of contrasting breeding practices and environmental challenges added to the substantial differences in economic traits between subspecies. Crossing *B. taurus* and *B. indicus* is necessary for many dairy cattle systems to increase production while securing environmental resilience. Despite some boost in yield, genetic composition within admixed herds fluctuates largely. Expectedly, the genetic variation translates into noteworthy phenotypic variation. These characteristics hamper the genetic improvement of admixed populations. To overcome this issue, we require genetic evaluation methods to work across breeds but especially across subspecies. For example, methods must capture differences in genetic architecture and gene frameworks between subspecies. We propose using ancestral recombination graphs. Here we use the novel tree sequence methodology to describe cattle's genome evolution from breed differentiation to family segregation. The tree sequence succinctly encodes genealogy for each genomic region by tracking haplotype lineages in the ancestral recombination graph accounting for recombination and mutation. We inferred global cattle genealogy from 1,181 whole-genome sequences from the 1000 Bull Genome Project public data. The dataset comprised 116M SNP on 29 autosomal chromosomes, 21 *Bos taurus*, 6 *Bos indicus* breeds, and 26 admixed individuals. We inferred genealogy using the python libraries tsinfer and tsdate and analysed with tskit. The resulting tree sequences spanned 11,997,863 genome regions (local trees), 257,997,301 haplotypes (edges), and 269,727,991 mutations, all efficiently stored in 49 GB. Our results draw a detailed profile of cattle genomic evolution and the differentiation of its subspecies and breeds. The next step is applying the knowledge to improve breeding methods for admixed populations.

Which diversity measures are important for small breeds like German Black Pied Cattle (DSN)?G.A. Brockmann¹, G.B. Neumann¹, P. Korkuc¹, M.J. Wolf², K. May² and S. König²¹Humboldt-Universität zu Berlin, Albrecht Daniel Thaer-Institute, Unter den Linden 6, 10099 Berlin, Germany, ²Justus-Liebig-Universität, Institute of Animal Breeding and Genetics, Ludwigstrasse 21, 35390 Giessen, Germany; gudrun.brockmann@hu-berlin.de

DSN, a dual-purpose breed, is considered an ancestral population of Holstein, the high-yielding and most-widely used dairy breed in the world. DSN has about 2,500 herdbook animals. The breed has been replaced almost entirely because of its low milk yield, which is 2,500 kg less than in Holstein cattle. Therefore, breeding goals are improving milk production while maintaining the dual-purpose characteristics, robustness and genetic diversity. For accessing genomic peculiarities of DSN, we sequenced 304 DSN animals and developed the DSN-specific bovine DSN200k SNP chip representing 182,154 sequence variants of DSN. Using this chip and whole genome sequencing information, we investigated the diversity of DSN and performed genome-wide association analyses. DSN showed a close genetic relationship with breeds from the North Sea region. The nucleotide diversity in DSN (0.151%) was higher than in Holstein (0.147%) and other breeds. The F_{Hom} and F_{RoH} values in DSN were among the lowest. Regions with high F_{ST} between DSN and Holstein, significant XP-EHH regions, and RoH islands detected in both breeds harbour candidate genes that had been reported for milk, meat, fertility, production, and health traits, including one locus detected in DSN for endoparasite infection resistance. Using whole genome sequencing data in genome-wide association studies, we identified 13 significant genomic loci for improving milk production. The highest significance was found for MGST1 affecting milk fat content ($\log_{10}(p)=11.93$, $\text{MAF}=0.23$, $(\beta\text{MA})=0.151\%$). Key loci for protein content were regions around CSN1S1 ($\log_{10}(p)=8.47$, $\text{MAF}=0.49$, $\beta\text{MA}=0.055\%$) and GNG2 ($\log_{10}(p)=10.48$, $\text{MAF}=0.34$, $\beta\text{MA}=0.054\%$). Loci containing HTR3C, TLE4, and TNKS were suggestive for milk yield. Different from Holstein, DGAT1 was fixed (0.97) for the alanine protein variant for high milk and protein yield.

Session 83

Theatre 12

Characterisation of free-living and exotic animal species at species and individual levelM. Zorc¹, M. Cotman², A. Dovc², J. Zabavnik-Piano² and P. Dovc¹¹University of Ljubljana, Biotechnical Faculty, Department of Animal Science, Jamnikarjeva 101, 1000 Ljubljana, Slovenia,²University of Ljubljana, Veterinary Faculty, Gerbičeva 60, 1000 Ljubljana, Slovenia; peter.dovc@bf.uni-lj.si

As more and more species of wild animals are kept in captivity, including dangerous and poisonous species, there is an urgent need to regulate throughout the EU which species may be kept as pets in the future. With the amendment of the Animal Protection Act, Slovenia introduced a ban on keeping dangerous, aggressive, poisonous and difficult-to-care-for wild animal species, including endangered species. The already established methodology for identification of species (speciation), individual (individualization) and sex in various native mammal, bird and fish species represents a starting point for the development of a similar methodology for exotic animal species. Important information on DNA barcoding in a variety of animal species is available in the database BOLD (<https://www.boldsystems.org/>). For species identification purposes, mtDNA is widely used as a genetic marker (cytochrome oxidase I and D-loop region), whereas the use of STR markers, which are often conserved within taxonomic families, provides a reliable and cost-effective method for individualization. In cases where genomic data are not available, RAPD markers can be used. Recently, we have developed a methodology based on mtDNA and STR for species identification and individualization of the Hermann's tortoise (*Testudo hermani*), which is an example of an endangered species often used for commercial purposes, and a molecular test for sex determination of the Linne's two toed sloth (*Choloepus didactylus*). Molecular genetic tests allow identification of the specimen or species and can be used to determine parentage, sex, or for forensic purposes in case of animals from the prohibited species list.

Comparative analysis of heterozygosity-enriched regions in two autochthonous Italian cattle breedsG. Schiavo¹, S. Bovo¹, F. Bertolini¹, A. Ribani¹, V. Taurisano¹, S. Dall'olio¹, M. Bonacini² and L. Fontanesi¹¹University of Bologna, Department of Agricultural and Food Sciences, Division of Animal Sciences, Viale Giuseppe Fanin 46, 40127 Bologna, Italy, ²Associazione Nazionale Allevatori Bovini di Razza Reggiana (ANABORARE), Via Masaccio 11, 42124 Reggio Emilia, Italy; giuseppina.schiavo2@unibo.it

Reggiana and Modenese are autochthonous cattle breeds mainly reared in Emilia Romagna region, in the North of Italy. The production of two breed-branded Parmigiano-Reggiano cheeses assures the sustainable conservation of these cattle genetic resources. Both breeds experienced a reduction in population size in the 1980', followed by a slow recovery. Therefore, the monitoring of inbreeding and the definition of proper conservation programs are fundamental. Information derived from pedigree and from genomic regions based on runs of homozygosity had previously been evaluated for both breeds. Here, we explored Runs of Heterozygosity (ROHet), defined as regions of continuous single nucleotide polymorphisms (SNPs) with heterozygous genotype. In this work, almost two thirds of the actual population for both breeds have been genotyped with the GGP Bovine 150k SNP chip panel. ROHet were identified with the R package 'detectRuns' and ROHet islands were defined by analysing the proportion of SNPs occurring in ROHet over all genotyped cattle. The average number of ROHet in Reggiana and Modenese cattle was 14.24 ± 3.8 and 12.91 ± 3.3 , respectively. The average length of the genome covered by ROHet was $2,532.38 \pm 858$ kb in Reggiana cattle and $2,291.26 \pm 781$ kb in Modenese cattle. According to the functional annotation of the ROHet islands, these regions might have an impact on reproduction and other fitness-related traits. Results will be useful to dissect genetic mechanisms affecting breed-specific traits and define breeding and conservation programmes to further exploit these animal genetic resources. *Acknowledgements:* The research was funded by the PSRN (Programma di Sviluppo Rurale Nazionale) Dual Breeding 2 (co-funded by the European Agricultural Fund for Rural Development of the European Union and by the MASAF).

Recovering latent population stratification using ADMIXTURE and metafounders in Brown SwissC. Anglhuber¹, C. Edel¹, E.C.G. Pimentel¹, R. Emmerling¹, K.-U. Götz¹ and G. Thaller²¹Bavarian State Research Center for Agriculture, Institute for Animal Breeding, Prof. Duerrwaechter Platz 1, 85586 Grub, Germany, ²Christian-Albrechts-Universität, Institute for Animal Breeding and Husbandry, Olshausenstraße 40, 24098 Kiel, Germany; christine.anglhuber@lfl.bayern.de

Unknown pedigree information or hidden stratification within a breeding population may lead to an incomplete formulation of the conventional numerator relationship matrix (A). When such an A is combined with a genomic relationship matrix (G) in a single-step approach for genetic evaluation the inconsistency may cause bias in the resulting estimates. The objective of this study was to identify relevant stratifications within the Brown Swiss population using genomic data. Genotypes and pedigree information of European and North American Brown Swiss animals (85,249) were available for the analysis. Using ADMIXTURE, a software designed to find ancestral origins in humans, animals, and plants, we developed an iterative approach by stepwise increasing the number of potential stratifications (K) in an unsupervised manner and introducing this information into matrix A, using the Metafounder methodology. Improvements in consistency between matrix G and the resulting matrices A^T were evaluated by visual inspection of graphs from principal component analyses, by regression analysis and through the comparison of the mean and mean diagonal values of both matrices. Analyses with ADMIXTURE were initially performed on the full set of genotypes (S1). In addition, we sampled another dataset where we avoided selecting animals with close relationships (S2). Results of the regression analyses of standard A on G were -0.489, 0.780 and 0.647 for intercept, slope and fit. In the analysis of S2 our approach reached an optimum fit of 0.818 for A^T on G considering K=23, with intercept and slope being close to 0 and 1. With this optimum K practically no differences in mean and mean diagonal values between both matrices were observed. Similar improvements were found in S1 for K>7 although there was no clear optimum K. The family structure in S1 affected the ability of ADMIXTURE to detect additional stratification information beyond the information already present in A.

Genomic diversity analysis of the Swedish Landrace goat*B. Hegedüs^{1,2}, A.M. Johansson¹ and P. Bijma²*¹Swedish University of Life Sciences, Animal Breeding and Genetics, Box 7023, 750 07 Uppsala, Sweden, ²Wageningen University and Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands; bernadett.hegedus@wur.nl

There are four native goat breeds present in Sweden. However, genetic diversity in these breeds has not been investigated. This study therefore aimed to describe the population structure and the level of inbreeding in the largest Swedish goat breed, the Swedish Landrace goat. Forty-eight (48) samples from eight farms were genotyped with the Goat SNP50 Bead Chip. To study the population structure, a principal coordinate analysis (PCoA) and a Structure analysis were conducted. The level of inbreeding was investigated with three measures; observed heterozygosity, inbreeding coefficient based on runs of homozygosity (F_{ROH}) and approximated coancestry. The results from the PCoA and the Structure analysis show that there is some structuring in the population and this structure is not solely due to the geographic location of the farms. The different inbreeding measures give a similar ranking of the farms. The inbreeding level of the Swedish Landrace goat based on observed heterozygosity is comparable to that of non-island goat populations from Norway, Spain and Italy. Furthermore, a potential pattern of selection was identified on Chromosome 6, with ROH in the region of the Casein genes. Further research is needed to calculate the effective population size and the rate of inbreeding in this breed. To calculate the rate of inbreeding and the effective population size pedigree data of several generations needs to be accessible.

Session 83

Poster 16

Effect of interpopulation distance on average heterosis in crosses*A. Legarra^{1,2}, D. Gonzalez-Diequez³, A. Charcosset⁴ and Z.G. Vitezica²*¹Council on Dairy Cattle Breeding, Bowie, 20716 MD, USA, ²INRAE, UMR 1388 GenPhySE, 31326 Castanet-Tolosan, France, ³International Maize and Wheat Improvement Center, Texcoco, 56237 Texcoco, Mexico, ⁴GQE-Le Moulon, INRAE, Univ. Paris-Sud, CNRS, AgroParisTech, Université Paris-Saclay, Gif-sur-Yvette, France; zulma.vitezica@inrae.fr

Crosses between parental populations are widely used in animal and plant breeding for exploiting heterosis and complementarity. In livestock, the parental populations are not too-distant and often co-selected for traits expressed in the crosses. Assuming that the allelic frequencies differ between populations, the variance of dominance deviations (var.D) is proportional to the product of the heterozygosities of both parental populations. The distance between two populations can be expressed as Nei's distance or allele frequency correlations. We show analytically that var.D decreases as a function of distance of parental populations as far as allele frequencies are positively correlated. Heterosis (H) can be modelled as the sum of dominance deviations with non-zero expectation. Thus, we provide a general expression for the expected H as a function of genetic distance between populations. The relationship between H and genetic distance is linear. We illustrate the relationships between distance, var.D and H across two pig lines (1 and 2). Using genomic data (40,634 SNP markers) provided by Genus plc., two lines of pig showed low Nei's minimum genetic distance between them (0.07) and an allele frequency correlation of 0.55. The var.D in F1 is lower than into the parental lines. The ratio of expected H / $\sqrt{\text{var.D}}$ was 186, 185 and 241 in lines 1, 2 and the F1, respectively. These results show that the ratio is larger in crosses than in parental populations. In practice, var.D is a measure of the importance of selection within purebreds as opposed to assortative matings in crosses.

Genome of the extinct Gotland cattle breed*M. Johnsson and A.M. Johansson**Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, Box 7023, 75007 Uppsala, Sweden; anna.johansson@slu.se*

The extinct cattle breed Gotland cattle (Gotlandsko in Swedish) lived on the island of Gotland in the Baltic Sea until the beginning of the 1950s. Gotland cattle were of small size and often had yellow coat colour and big horns. We sequenced the genomes of two Gotland cattle, based on bones samples from skulls. The skulls originate from a local museum in Viklau in the middle of Gotland. DNA isolation and library preparation was performed under ancient DNA conditions at the Ancient DNA Unit at SciLifeLab, Uppsala. The depth of coverage was 2.7X and 3.3X, respectively, with a breadth of coverage of 85 and 89%. Based on coverage of the sex chromosomes, both samples appeared to be female. We detected 19 million SNPs and 2.8 million indels in the joint dataset of Gotland cattle jointly called with 47 modern Swedish cattle. In the Gotland cattle samples, 15 and 9.3% of the SNPs had missing values, which can be compared to an average missingness of 1.3% in the modern samples. In a principal component analysis, the two Gotland cattle placed the closest to Swedish Red Cattle, rather than among the southern or northern traditional breeds. In terms of the first principal component, the second closest breed was Ringamåla cattle. In terms of the second principal component, Gotland cattle samples also had similar values as the northern breed Fjällnära cattle. When performing the principal components analysis with subsets of the data as a robustness check, these qualitative patterns were preserved. In terms of mitochondrial haplotypes, the two Gotland cattle differed by one substitution. We compared them to the whole mitochondrial genomes of 30 Swedish cattle and a sample of D-loop sequences from Nordic and Baltic cattle. The Gotland cattle haplotypes were not identical to any of the other mitochondrial haplotypes, neither among the local Swedish cattle or a sample of D-loop sequences. However, they were similar to clusters of related haplotypes involving multiple other breeds, including Swedish Mountain Cattle and Swedish Red Polled. In summary, our results suggest that Gotland cattle were genetically dissimilar to the extant traditional Swedish breeds, and places it closer to the ancestors of Swedish Red cattle.

Genetic variability in Italian Mediterranean buffalo: implications for conservation and breeding*M.M. Gómez¹, R. Cimmino¹, D. Rossi¹, G. Zullo¹, G. Campanile², G. Neglia² and S. Biffani³**¹Italian National Association of Buffalo Breeders, V. Petrarca, 42-44, 81100 Caserta, Italy, ²Department of Veterinary Medicine and Animal Production Federico II University Naples, Via Federico Delpino, 1, 80137 Naples, Italy, ³National Research Council (CNR), Institute of Agricultural Biology and Biotechnology, V. Edoardo Bassini, 15, 20133 Milano, Italy; m.gomezcarpio@anasb.it*

The Italian Mediterranean Buffalo (IMB) is part of the historical and cultural heritage of Italy and its preservation is an indisputable priority. Knowing the structure of a population as well as its variability and gene flow are necessary information for setting up any selection program and for the sustainability of the population. In this study, we sought to investigate the genetic diversity and the structure of the IMB in 8 Italian geographic areas. Information from 2,441 animals genotyped with the Axiom Buffalo Genotyping Array 90K was used. The total mean values of observed and expected heterozygosity were 0.404 and 0.399, respectively. These values suggest the presence of an acceptable degree of genetic variability. The mean inbreeding coefficient (FIS) was positive in two southern areas, namely Caserta and Salerno. Incidentally, both areas have the highest buffalo population density, with 70.8 and 22.5 head per square km, respectively. Moreover, a neighbour network analysis grouped animals from those areas in the same branch, a predictable result since these areas are in geographically close relationships. On average the genetic differentiation between areas, based on the fixation index (Fst), was 2.06%. Finally, a multidimensional scaling plot analysis was performed to investigate the population structure between the 8 areas. Again, individuals from Caserta's area formed a well-defined and homogenous cluster. Results from the present study depict the current genetic structure of the IMB. Overall, no concerns can be raised as regards genetic diversity, however positive FIS values observed in two geographic areas suggest the need for correct selection and mating strategies. Acknowledgements: This research was funded by Italian Ministry of Agriculture. Project: 'BIG' Prot. N. 0215513 11/05/2021 and by Programma di ricerca per la Biosicurezza delle Aziende Bufaline- articolo 4 bis dell'OPCM n. 3634 del 21/12/2007.

A comparative genome analysis across pig breeds can help to identify putative deleterious allelesM. Ballan¹, S. Bovo¹, G. Schiavo¹, F. Bertolini¹, M. Bolner¹, M. Cappelloni², S. Tinarelli², M. Gallo² and L. Fontanesi¹¹University of Bologna, Department of Agricultural and Food Sciences, Viale G. Fanin 46, 40127 Bologna, Italy,²Associazione Nazionale Allevatori Suini, Via Nizza 53, 00198 Roma, Italy; luca.fontanesi@unibo.it

The small effective population size of many highly selected livestock breeds or nuclei can lead to an increased frequency of unfavourable and usually deleterious alleles, in particular if they are in linkage disequilibrium with other favourable QTL alleles. Animals that are homozygous for these negative alleles are, however, not observed in the adult population as the genotype is not usually compatible with a productive life. In this study, we used high density single nucleotide polymorphisms (SNPs) analysed in more than 10,000 heavy pigs belonging to three breeds (Italian Large White, Italian Landrace and Italian Duroc) and whole genome sequencing data obtained in a subset of these animals to define a comparative-across breed strategy that can identify putative deleterious alleles segregating in one or more breeds. The across-breed strategy made it possible to filter out genotyping errors and other genotyping biases that would create statistical biases in the identification of candidate genomic regions harbouring deleterious alleles. Combining this information with whole genome sequencing data, these results provided genomic markers that can be used to design targeted breeding and selection programs aimed to reduce the frequency of deleterious alleles in the Italian pig population.

The effect of recessive genetic defects on pregnancy loss in Swedish dairy cattleP. Ask-Gullstrand¹, E. Strandberg¹, R. Båge², E. Rius-Vilarrasa³ and B. Berglund¹¹Swedish University of Agricultural Sciences, Animal Breeding and Genetics, Ulls väg 26, 750 07, Uppsala, Sweden,²Swedish University of Agricultural Sciences, Clinical Sciences, Ulls väg 26, 750 07, Uppsala, Sweden, ³Växa Sverige, Ulls väg 29A, 756 51 Uppsala, Sweden; patricia.gullstrand@slu.se

The effect of carrier status of ten lethal recessive genetic defects on pregnancy maintenance was examined in Swedish dairy cattle. The genetic defects were Ayrshire haplotype 1, Ayrshire haplotype 2, *Bos taurus* autosome 12 (BTA12), *Bos taurus* autosome 23, and Brown Swiss Haplotype 2 for Red Dairy Cattle (RDC), and Holstein Haplotypes 1, 3, 4, 6, and 7 (HH1 – HH7) for Swedish Holstein (SH). The data were derived from 1,432 milk recording herds, and carrier status of genetic defects were obtained from the Nordic Cattle Genetic Evaluation. In total, 165,472 inseminations were available from 99,039 lactations from 28,473 RDC and 22,093 SH cows. Pregnancy status was defined based on pregnancy diagnosis, insemination events, calving and culling data. Pregnancy loss traits were defined as embryonic loss (1 d to 41 d after AI), foetal loss (from 42 d after AI until calving), and total pregnancy loss. Least squares means (LSM±SE, %) of pregnancy loss were estimated using linear mixed models. Effect of cow and service sire haplotype, parity (0, 1, 2, ≥3) and insemination number were considered as fixed effects, and herd by year and season of insemination, cow, service sire, and permanent environmental effect as random effects. We observed a negative effect of the ten genetic defects on pregnancy maintenance. The data permitted separate analyses of BTA12 and HH3, however, the remaining defects had too low carrier frequencies to enable further analysis. Carrier frequencies of BTA12 and HH3 were 14.1 and 4.2% in sires, and 5.6 and 4.5% in cows, respectively. The largest effect of BTA12 was in total pregnancy loss with estimates of 68.9±2.8% in at-risk matings compared with 54.8±0.7% in noncarrier matings. For HH3, the largest impact of the genetic defect was in embryonic loss with estimates of 57.5±4.7% in at-risk matings compared with 42.6±1.0% in noncarrier matings. Pregnancy loss may be reduced by avoiding at-risk matings.

EuroFAANG – an infrastructure for farmed animal genotype to phenotype research in Europe and beyond

E.L. Clark¹, E. Giuffra², A. Granados-Chapette³, M. Groenen⁴, P.W. Harrison⁵, C. Kaya³, S. Lien⁶, M. Tixier-Boichard² and C. Kuehn⁷

¹University of Edinburgh, The Roslin Institute, Edinburgh, EH25 9RG, United Kingdom, ²INRAE, AgroParisTech, Université Paris Saclay, 78352 Jouy en Josas, France, ³European Forum of Farm Animal Breeders, 1040, Brussels, Belgium, ⁴Wageningen University, 6708 PB, Wageningen, the Netherlands, ⁵EMBL European Bioinformatics Institute, Hinxton, CB10 1SD, United Kingdom, ⁶Norwegian University of Life Sciences, 1432, Ås, Norway, ⁷Research Institute for Farm Animal Biology (FBN), 18196, Dummerstorf, Germany; emily.clark@roslin.ed.ac.uk

The aim of the EuroFAANG infrastructure, which is currently in the concept development phase, is to realise the full potential of genotype to phenotype (G2P) research across species, breeds and populations of farmed animals in Europe and globally. This goal will be achieved through the following four objectives: (1) Creation of a common data structure and data access service. Creating this service for the large variety of datasets generated for farmed animals will consolidate research efforts and minimise redundancy across Europe. (2) Development, curation and biobanking of *in vitro* cellular models, for farmed animal species. A durable framework of connected biobanks, that is accessible to stakeholders across Europe, will enable scientists to use and access *in vitro* cellular models, and popularise the use of such models for G2P research. (3) Sharing and expanding capabilities in new breeding, phenotyping, and genomic technologies. Including, for example, genome editing, and artificial intelligence tools and capabilities in linking *in vitro* and *in vivo* phenotyping and exploitation of genomic data, to provide key routes to application of FAANG data. (4) Connecting with existing projects and infrastructures to consolidate G2P research in farmed animals across Europe. Links include, for example, AQUAEXCEL, PigWeb and Elixir and initiatives for linking G2P in farmed animals in the US including AG2PI and AgBioData. The EuroFAANG infrastructure concept, builds on the foundation provided by the six current H2020 EuroFAANG projects and will lead to a better alignment of the research infrastructure landscape for the advancement of excellent farmed animal science and frontier G2P research in Europe.

The H2020 GENE-SWitCH (the regulatory GENomE of SWine and CHicken: functional annotation during development) project has delivered extensive functional genomics information at three developmental stages (early and late organogenesis, newborn) for a panel of seven selected tissues. Data are publicly available (<https://projects.ensembl.org/gene-switch>); they are being processed to characterize biological switches during development and to generate the first Ensembl Regulatory Builds for the chicken (both layer and broiler) and the pig. To assess the interest of using genome annotations for precision animal breeding, two approaches were taken, coupled with dissemination and outreach activities aimed to transfer the outcomes of the project to stakeholder communities. A 'diet × epigenetic' experiment in pigs has investigated how the fibre content of the maternal diet can affect the epigenetic profiles of the liver and muscle of the offspring at the foetal and postweaning stages. In the second approach, genomic prediction models have been extended and tested to evaluate how prediction accuracy can be improved by incorporating different functional and overlapping annotations. The two next presentations will highlight the potential of this approach for swine and poultry breeding. GENE-SWitCH has received funding from the European Union's Horizon 2020 Research and Innovation Programme under the grant agreement n° 817998.

Genome-wide association studies for body weight in broilers using sequencing and SNP chip dataE. Tarsani¹, V. Riggio¹ and A. Kranis^{1,2}¹The Roslin Institute and R(D)SVS, University of Edinburgh, Easter Bush Campus, EH25 9RG, United Kingdom, ²Aviagen Ltd., Newbridge, Midlothian, EH28 8SZ, United Kingdom; etarsani@exseed.ed.ac.uk

Body weight (BW) is an economically important trait for the chicken industry. Detecting which variants affect chicken growth is of great benefit to the genetic improvement of this important agricultural species. A powerful resource for identifying trait-associated variants in genome-wide association studies (GWAS) is using whole genome sequencing (WGS) data. In this study, we used a dataset comprising of 60,558 chickens genotyped with a 50k SNP chip. These SNP genotypes were imputed to sequence level for a total of 12.8 variants with high levels of accuracy (>0.95). To evaluate the power of sequencing data, we conducted two GWAS for BW using the chip and WGS genotypes, respectively. When using the 50k SNP chip data, we obtained high genomic heritability (0.40) and identified 18 SNPs across eight autosomes (2-6, 8, 20 and 23) reaching genome-wide significance (FDR P -value<0.10) for BW. The majority of those SNPs were introns. With the use of sequencing data, results were similar to those obtained with SNP chip data. However, additional GWAS signals were found, including variants in regions harbouring functional elements for BW. The results suggest an improvement in power and precision when using WGS data. A significant increase in computational time to conduct such a large-scale WGS GWAS was noted, which can limit the number of animals to include in the study. Taken together, the present study enriched our knowledge of the genetic mechanisms regulating chicken growth traits. Next steps will focus on improving the computational tools to enable larger scale analyses to further increase the statistical power.

Theatre 4

Using methylation annotation to improve genomic prediction of gene expression in pigsB.C. Perez¹, J. De Vos², D. Crespo-Piazuello³, M.C.A.M. Bink¹, M. Ballester³, M.J. Mercat⁴, O. Madsen² and M.P.L. Calus²¹Hendrix Genetics BV, Research and Technology Center (RTC), Villa 'de Körver', Spoorstraat 69, 5831 CK, the Netherlands,²Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands,³IRTA, Animal Breeding and Genetics Program, Torre Marimon, 08140 Caldes de Montbui, Spain, ⁴IFIP, Institut du porc and Alliance R&D, B.P. 104, 35651 Le Rheu, France; bruno.perez@hendrix-genetics.com

Methylation of DNA has been linked to variation in gene expression and could be used to improve prediction of gene transcripts. Within the GENE-SWitCH project, we aimed to incorporate genome-wide methylation annotation in genomic prediction to improve predictive accuracy for gene expressions. Data comprised of whole genome sequence from 300 pigs (100 Duroc, 100 Landrace and 100 Large White). We considered 2 Kb upstream and 0.2 Kb within genes as regulatory regions and selected across all known genes the SNP placed within those regions, resulting in a panel of 65,486 SNP. Gene transcripts from 10 genes (in 3 tissues, totalizing 30 traits) measured in the same individuals were used as phenotypes. Methylation from the same tissues and two time points (30 d. post-fert. and newborn) were used to weight SNP in the genomic relationship matrix (GRM). These GRM were used in GBLUP with either including (mGBLUP) or not (GBLUP) methylation annotation, and their ability to predict gene-expression were compared using a 5-fold cross validation scheme. Fully methylated sites received a weight of 0, reflecting the assumption that those sites are not expressed. The performance of mGBLUP was quite variable across genes and tissues analysed, together with the methylation state considered as SNP weights. In general, the best mGBLUP results were obtained when methylation information came from the same tissue for which gene-expressions were predicted. Across traits, average difference in predictive accuracy between mGBLUP and GBLUP was $+2.6 \pm 3.9\%$. Although mGBLUP showed competitive predictive performance compared to GBLUP when predicting gene-expression for some genes, this pattern was not consistent across all gene-tissue combinations. GENE-SWitCH has received funding from the European Union's Horizon 2020 Research and Innovation Programme under the grant agreement n° 817998.

The path from functional annotation towards improved genomic prediction in cattle

C. Kühn

Research Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee, 18196 Dummerstorf, Germany; kuehn@fbn-dummerstorf.de

In farmed animal breeding there is still a considerable gap in understanding how the (epig)genome translates into the phenotypes of interest, particularly for complex traits. However, this knowledge is a prerequisite for precision breeding and tailored management in livestock. The EU Horizon 2020 funded BovReg project provides multiple layers of annotated functionally active genomic features in the bovine genome. Besides information obtained from FAANG core assays, also positions with significant effect on zootechnical and molecular phenotypes contributed to the improved functional annotation map. Together with a new custom transcriptome annotation, the eQTL analysis conducted with a new Nextflow-based bioinformatic pipeline highlighted previously unknown regions with potential impact on expression regulation. Finally, the functional annotation map is also complemented with regions sensitive to epigenetic modifications after environmental challenges of whole animals or embryos. All functional annotation information feeds into new models for improved genotype-to-phenotype prediction in cattle. The clustering of respective activities together with five other EU H2020-funded projects was the seed for EuroFAANG, an new EU Horizon Europe project aiming to build an infrastructure to consolidate genotype-phenotype research in farm animals in Europe. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement no. 815668.

Biology-driven genomic predictions for dry matter intake within and across breeds using WGS dataR. Bonifazi¹, G. Plastow², M. Heidaritabar², A.C. Bouwman¹, L. Chen², P. Stothard², J. Basarb², C. Li^{2,3}, Bovreg Consortium⁴ and B. Gredler-Grandl¹

¹Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands, ²Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Livestock Gentec, AB T6G 2H1 Edmonton, Canada, ³Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, AB T4L 1W1 Lacombe, Canada, ⁴<https://www.bovreg.eu/project/consortium/>, the Netherlands; renzo.bonifazi@wur.nl

Biology-driven genomic predictions incorporating functional genomic features (GF) such as expression quantitative trait loci (eQTL) have the potential to increase the accuracy of estimated genomic breeding values (GEBVs) and predicted phenotypes by accounting for casual variants underlying phenotypic variation. To this end, functional GF can be used in genomic prediction models to pre-select and weight single-nucleotide-polymorphisms (SNPs) from whole-genome-sequence data (WGS). Such prioritization can improve genomic predictions in a single and multi-breed context with lowly related animals, especially for scarcely recorded traits such as feed intake and associated traits where large datasets are not yet available. However, validation studies using real data are lacking. Hence, our aim is to validate the usage of biology-driven genomic predictions for feed efficiency within and across breeds. From the Netherlands, 4,996 Holstein-Frisian animals with dry matter intake (DMI) phenotypes and WGS imputed DNA variants are available. From Canada, more than 10,000 animals with phenotypes for DMI and WGS imputed DNA variants are available: ~3,000 for Kinsella composite and ~7,000 for commercial crossbred cattle. Significant variants for several GF (using meta-GWAS QTL, eQTL, mQTL, ChIPseq, and mobile genetic elements identified within the European Union's Horizon 2020 project BovReg) will be used to prioritize SNPs for genomic predictions. We will use a novel Bayesian approach that allows modelling multiple overlapping GF. Different scenarios in which each GF are considered separately along with SNPs from a commercial 50K panel, and where all GF are combined within and across breeds will be tested. Scenarios including GF are expected to improve the accuracy of predicted phenotypes.

Newly annotated genomic features for biology-driven genome selection: the BovReg contribution

G.C.M. Moreira¹, L. Tang¹, S. Dupont¹, M. Bhati², H. Pausch², D. Becker³, M. Salavati⁴, R. Clark⁵, E.L. Clark⁴, G. Plastow⁶, C. Kühn³, C. Charlier¹ and The Bovreg Consortium⁷

Transcriptome (mRNA, totalRNA, small-RNA and CAGE), ATAC- and ChIP-Seq (H3K4me3, H3K4me1, H3K27me3, H3K27ac and CTCF) assays were compiled in a catalogue of 129 tissue samples collected from six individuals of both sexes, different ages, kept in different environments and from three divergent dairy and beef cattle breeds/crosses. From the de novo transcriptome assembly, 43,117k gene models including ≥ 15 k potentially novel transcripts were assembled. 1,265 (638 known and 627 novel) miRNAs were detected, and for the majority, potential primary transcripts were identified. We fine mapped 51,295 transcription start sites (TSS) and 2,328 TSS-Enhancer regions shared across the three populations. On average, we identified 105,245, 28,187, 152,646, 127,855, 77,967 and 71,868 peaks ($q\text{-value} \geq 0.05$) per sample for ATAC, H3K4me3, H3K4me1, H3K27me3, H3K27ac and CTCF, respectively, covering 2.89, 1.52, 7.96, 5.16, 3.95 and 2.49% of the bovine genome on average. Regulatory regions are being characterized by virtue of epigenetic features including open chromatin regions, histone marks and transcription factor as well as, expression data from the different RNA-Seq assays compiled in the diverse catalogue of tissue samples. Moreover, using WGS data from different breeds, a catalogue of unfixed mobile genetics elements was built and a panel of tests for 727 selected insertion sites have been deployed at the public part of EuroGenomics array, widely used in European cattle breeding. The newly annotated genomic features will be used on biology-driven genomic predictions within and across different cattle breeds. The BovReg project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 815668.

AQUA-FAANG: decoding genome function to enhance genotype-to-phenotype prediction in farmed finfish

D. MacQueen¹ and S. Lien²

¹University of Edinburgh, The Roslin Institute, Easter Bush Campus, EH25 9RG, United Kingdom, ²Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Centre for Integrative Genetics (CIGENE), 1432, Ås, Norway; daniel.macqueen@roslin.ed.ac.uk

AQUA-FAANG is a European Commission funded research consortium and part of the EuroFAANG initiative. The key project objective is to deliver the first comprehensive genome functional annotations for six commercially important finfish species, namely Atlantic salmon, rainbow trout, common carp, European seabass, Gilthead seabream and turbot. To achieve this goal in support of genotype-to-phenotype prediction, extensive functional genomics datasets were generated for standardized sample types in all six species, inclusive of embryonic development, a panel of tissues from sexually immature and mature adult fish, and immune tissues/derived cells stimulated immunologically. The functional annotation data generated are thus comprehensive in terms ontogeny and of great relevance to production and welfare traits. Datasets include hundreds of RNA-Seq (mRNA-Seq and small RNA-Seq), ChIP-Seq (H3K27ac, H3K4me1, H3K4me3, H3K27me3) and ATAC-Seq libraries per species. This vast catalogue of data is currently being presented and shared on the latest genome assemblies for each species via the Ensembl Genome Browser, including annotations of regulatory elements derived from ATAC-Seq and ChIP-Seq. As of Ensembl version 109, ATAC-Seq data has been shared for several species. AQUA-FAANG data has vast applications spanning fundamental questions about fish genome biology through to practical uses in support of precision breeding. This includes fast-tracking identification and prioritization of candidate causative genetic variants overlapping regulatory elements controlling gene expression, in addition to target genes and variants for future genome editing studies. AQUA-FAANG has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 817923.

Integrating functional annotation data in genomic prediction of VNN resistance in European sea bass

S. Faggion¹, R. Mukiibi², L. Peruzza¹, M. Babbucci¹, R. Franchi¹, G. Dalla Rovere¹, S. Ferrarosso¹, D. Robledo² and L. Bargelloni¹

¹University of Padova, Department of Comparative Biomedicine and Food Science, viale dell'Università, 16, 35020, Legnaro, Italy, ²The University of Edinburgh, The Roslin Institute and Royal (Dick) School of Veterinary Studies, Easter Bush Campus, Midlothian, EH25 9RG, United Kingdom; sara.faggion@unipd.it

For the European sea bass (*Dicentrarchus labrax* L.) industry, viral nervous necrosis (VNN) is a major threat. Selective breeding to enhance disease resistance is considered a feasible approach to prevent and control mortality from VNN outbreaks; hence, one of the major goals of AQUA-FAANG is the integration of functional data to improve genomic prediction accuracy of breeding values for VNN resistance in European sea bass. 1,016 juvenile fish (body weight: 6 to 20 gr) produced in a full-factorial mating (25 sires × 25 dams) were subjected to a 29-days VNN challenge test. VNN resistance was recorded both as a binary trait and as time to death. The experimental fish were genotyped using a high-density SNP panel (~27,740 SNPs after quality control), while their parents were whole-genome sequenced and used to impute the offspring to whole-genome genotypes. Genome-wide association analyses revealed a major QTL associated with VNN resistance phenotypes on linkage group 12. A total of 528 and 578 SNP markers were identified as significantly (FDR<0.05) associated with VNN resistance as a binary trait and time to death, respectively. Using evidence from eQTLs and chromatin accessibility data, a putative causal variant was identified. SNP genotypes were used as predictors of resistance and to estimate breeding values (EBV). Genomic predictions were performed integrating prior categorizations of SNPs derived from functional information. The accuracy of the model was assessed in a cross-validation approach generating training and test sets consisting of animals of varying genetic relatedness according to the genomic relationship matrix. **Acknowledgements.** Funding: Horizon 2020 Grant n. 817923 (AQUA-FAANG). Animals used in the experiment: Valle Cà Zuliani Società Agricola srl (Italy).

GEroNIMO (Genome and Epigenome eNabled breeding in MONogastrics)

S. Lagarrigue¹, F. Pitel² and T. Zerjal³

¹Institut Agro, Rennes, 35042, France, ²INRAE, Castanet Tolosan, 31320, France, ³INRAE, Jouy-en-Josas, 78350, France; sandrine.lagarrigue@institut-agro.fr

Pig and chicken are the two main animal protein sources for human consumption in the world. To face today's challenges (climate change, socio-cultural evolution, human population growth, etc.), the GeroNIMO project is rethinking pig and chicken breeding to build more sustainable production models promoting efficient resource use, animal resilience, health, welfare, and preserving genetic diversity. Applying omics technologies, GeroNIMO contributes to improve knowledge on genome-to-phenome relationships accounting for both genetic and non-genetic mechanisms controlling traits related to production (quantity and quality), efficiency, persistency, fertility, resilience and welfare. GeroNIMO is a 5-year program that started in June 2021, involving 21 partners from 11 countries and organized in 8 work packages (WP). Four of them have objectives that contribute to the EuroFAANG mission by: (1) identifying the underlying genetics and epigenetics biological mechanisms affecting trait variation (WP1); (2) determining how changes in environment, generation, and age affect epigenetic molecular traits (WP2); (3) characterizing genetic and epigenetic diversity and propose strategies to optimize local breed conservation (WP3); (4) developing methods to improve selection strategies integrating genetic and non-genetic factors (WP4). GeroNIMO is currently generating molecular data in both species for large numbers of animals/samples including about 6,000 genotypes, 10,000 methylations (by GBS-MeDIP), and 2,000 RNAseq (mainly polyA RNA, but also small RNA and ribo depleted RNA). We already proposed a new annotation for the chicken genome by combining multiple reference annotations and providing a functional gene annotation across 47 tissues using 1,400 samples. This new atlas considers the latest release of the chicken genome assembly (GRCg7b) and gathers both associated reference annotations, 'Ensembl' integrating GENE-SWitCH data and 'NCBI-RefSeq', as well as additional FAANG and NONCODE resources. The RefSeq and Ensembl gene atlases respectively increased from 18,010 and 17,007 to 24,102 protein-coding genes and from 5,789 and 11,946 to 44,428 lncRNAs. Project funded by the European GeroNIMO programme under grant agreement N°101000236.

RUMIGEN: new breeding tools in a context of climate change

S. Mattalia¹, A. Vinet², M.P.L. Calus³, H.A. Mulder³, M.J. Carabaño⁴, C. Diaz⁴, M. Ramon⁵, S. Aguerre¹, J. Promp¹, R. Vallée¹, B.C.D. Cuyabano², D. Boichard², E. Pailhoux⁶ and J. Vandenplas³

RUMIGEN is a project financially supported by the EU that aims to develop breeding programs able of managing the trade-offs between efficient production and resilience to extreme climate conditions. RUMIGEN is designed under a multi-disciplinary approach that mixes competencies in both genetics and social sciences. The genetic approach aims to enhance genomic selection using three levers: quantitative genetics, genome editing, and epigenetics. One of the objectives of RUMIGEN is to enlarge selection criteria and to provide genomic tools to select heat tolerant dairy cows. Studies are dedicated to the definition of heat-tolerance traits based on production, reproduction and health records, as well as to the study of the trade-offs between these traits, and with those already included in selection indexes. In France, Spain and the Netherlands, performances recorded in commercial herds (i.e. milk production traits, somatic cell scores and conception rate after first AI) were combined with meteorological data obtained from the nearest weather stations, and analysed in order to measure the impact of heat stress. First results obtained for different breeds and in a large range of farming and climatic scenarios showed that the combination of both types of information was relevant at the population level. Some differences between thresholds for optimal THI were observed between countries for some traits, which could be explained by different factors (farm management, exposure to outside temperatures, mitigation practices, etc.). However a decrease was observed on all performance traits with increasing temperatures, with consistent patterns of slopes between breeds and countries. Therefore this approach appears relevant to define novel traits related to heat tolerance for different breeds and different climates.

The genetic basis of ruminant microbiomes – contribution of the HoloRuminant project

Y. Ramayo-Caldas¹, I. Mizrahi², P. Pope³, C. Creevey⁴, J.P. Sanchez¹, R. Quintanilla¹ and D. Morgavi⁵

¹IRTA, IRTA Torre Marimon, 08026, Spain, ²Ben-Gurion University of the Negev, Department of Life Sciences, Negev, Be'er-Sheva, 8443944, Israel, ³Norwegian University of Life Sciences, Faculty of Biosciences, Elizabeth Stephansens v. 15, 1430, Norway, ⁴Queen's University Belfast, School of Biological Sciences, Institute for Global Food Security, Belfast, BT9 5DL, United Kingdom, ⁵Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Saint-Genès-Champanelle, 63122, France; yulixaxis.ramayo@irta.cat

Microbiome-host interactions have profound effects on metabolic functions and physiological processes that influence growth, production efficiency, animal welfare, and the robustness of the ruminant holobiont. Interactions between the host and its microbiome are influenced by both external and host-specific factors. While the influence of the external environment has long been recognised, it has also been reported that some rumen microbes in the core microbiome are transferred from dam to offspring, with the heritability of the rumen microbiome being low to moderate. In addition, genetic variants and candidate genes associated with individual variation in microbial traits have been reported in the host ruminant genome. However, existing information is scarce, based on reduced numbers of animals and mainly focused on the rumen microbiome. In HoloRuminant, we plan to assess the host genetic influence on microbiomes by using a holistic multi-omics approach to characterise the establishment and dynamics of microbiomes from different body sites during key life events. Planned activities also include the development of an open access database (HoloR) of existing and novel data, together with a repository (HoloR tools) of standardised bioinformatics and analytical pipelines developed in the project. Hologenomic data collected at multiple meta-omics levels will then be used to explore associations between microbial functions and host phenotypes, as well as links between host genetics, microbial, and host traits. The results of the project will improve our understanding of the mechanisms driving host-microbiome interactions in ruminants and may enable the implementation of novel conservation and breeding programs from a holobiont perspective.

The effect of production systems on adipose tissue gene expression in Krškopolje pigK. Poklukar¹, M. Čandek-Potokar¹, N. Batorek-Lukač¹, M. Vrecl², G. Fazarinc² and M. Škrlep¹¹Agricultural Institute of Slovenia, Hacquetova 17, 1000 Ljubljana, Slovenia, ²Veterinary faculty, Gerbičeva 60, 1000 Ljubljana, Slovenia; meta.candek-potokar@kis.si

Krškopolje pig is a Slovenian autochthonous breed, which is characterized by lower muscularity and higher fat deposition. The breed is raised in various, mainly low-input production systems. The present study aimed to characterize the transcriptome of adipose tissue of Krškopolje pigs raised indoors (IND) and outdoors (OUT) (n=2×24). At 330 days of age, the animals were slaughtered and samples of back fat were collected. After RNA extraction, the samples were sequenced using Illumina NovaSeq. In total, sequencing yielded 66.8 million paired-end reads, with more than 92.2% of the reads uniquely assigned to the Sscrofa11.1 genome. Differential expression analysis revealed 798 genes, of which 304 were upregulated and 494 were downregulated in the OUT group compared with IND. The upregulated genes in the OUT group were involved in lipid metabolism (FASN, ME1, and SCD genes with log2FC=1.4, 1.2, and 1.1, respectively). The most interesting downregulated genes in the OUT group were involved in collagen synthesis (COL1A; log2FC=4.6), energy homeostasis (LEPR; log2FC=1.9), or triglyceride metabolism (MOGAT; log2FC=2.5). Functional enrichment analysis of downregulated genes in the OUT group revealed biological processes such as negative regulation of angiogenesis GO:0016525), collagen fibril organization (GO:0030199), and endothelial cell morphogenesis (GO:0001886). Up-regulated genes in OUT were connected with the immune response (GO:0006955). The results of the present study provide the first insights into the genetic regulation of Krškopolje pigs kept in different production systems. Session 84

Poster 14

A lncRNA gene-enriched atlas for GRCg7b chicken genome using Ensembl, RefSeq and two FAANG databasesF. Degalez^{1,2}, M. Charles¹, S. Foissac¹, H. Zhou³, D. Guan³, L. Fang⁴, C. Klopp¹, F. Lecerf^{1,2}, T. Zerjal¹, F. Pitel¹ and S. Lagarrigue^{1,2}¹INRAE, 16 Le clos, 35590 Saint-Gilles, France, ²Institut Agro, 65 rue de Saint Brieuc, 35000 Rennes, France, ³University of California Davis, Meyer Hall, 1 Shields Ave, CA95616 Davis, USA, ⁴Aarhus University, C.F. Møllers Allé 3, 8000 Aarhus C, Denmark; fabien.degalez@inrae.fr

With the release of new genome sequences, gene atlases in livestock species are steadily improving. Furthermore, genome annotations greatly vary across databases depending on data resources and bioinformatics pipelines used. These differences are particularly important for long non coding RNAs (lncRNA) compared to protein coding genes (PCG) due to their higher tissue- and stage- specificity. As previously done in 2020 for the galgal5 and GRCg6a chicken assemblies, we provide a new lncRNA-enriched atlas by considering the latest GRCg7b genome assembly. This new chicken gene atlas gathers: (1) both EMBL-EBI Ensembl/GENCODE databases which integrate GENESWITCH data and NCBI-RefSeq, considered as references; (2) 3 databases from independent projects in particular from the University of California Davis and Fr-AgENCODE based on FAANG multi-tissues resources; and (3) NONCODE, a lncRNA dedicated database. We characterized the overlap rate of gene models (max of 90% for PCGs and 39% for lncRNAs) between databases two by two and calculated concordance between gene TSS and CAGE peaks from FANTOM (max of 60% for PCGs and 40% for lncRNAs) for each database. Based on these characteristics and prioritizing the reference databases, we determined the order of gathering to maximize the quality of the final annotation. In total, the Ensembl and Refseq catalogues respectively grew from 17,007 and 18,010 to 24,102 PCGs and from 11,946 and 5,789 to 44,428 lncRNAs for a total of 78,323 genes. In addition, we provide a 'functional' gene annotation with 1,400 transcriptomes across 47 tissues and found 35,257 (79.4%) lncRNAs and 22,468 (93.2%) PCGs with an expression of TPM≥0.1. Each gene of this atlas is provided with 'genomic' and 'functional' information and the corresponding RefSeq and Ensembl gene identifiers (<http://www.fragencode.org>). Project funded by the European Union's Horizon 2020 research and innovation program under grant agreement N°101000236 and by ANR CE20 under EFFICACE program.

Effect of the Rumitech in a high-forage diet on methane production and performance of dairy cows

A. Cieslak¹, H. Huang¹, B. Nowak¹, M. Kozłowska¹, D. Lechniak², P. Pawlak², M. Szumacher-Strabel¹ and J. Dijkstra³
¹Poznań University of Life Sciences, Department of Animal Nutrition, Wolyńska 33, 60-637 Poznań, Poland, ²Poznań University of Life Sciences, Department of Genetics and Animal Breeding, Wolyńska 33, 60-637 Poznań, Poland, ³Wageningen University and Research, Animal Nutrition Group, De Elst 1, 6708 WD Wageningen, the Netherlands; adam.cieslak@up.poznan.pl

The essential oils blend Rumitech was evaluated in three experiments (*in vitro*, cannulated cows, and lactating dairy cows) to investigate its effects on methane emission, milk production, and milk composition of dairy cows. Initially, an *in vitro* study (Exp. 1; Hohenheim test) was performed; 0.35 mg of Rumitech (0.1% on diet DM basis) was supplemented to a commercial TMR (rich in brewer's grain and beet pulp; 20% of total diet DM) which corresponded to 20 g/cow per day fed to dairy cows under commercial conditions. The addition of Rumitech decreased methane yield by 6%. Based on the results of the *in vitro* experiment, two consecutive long-term (39 days) *in vivo* experiments were conducted using 4 Polish Holstein-Friesian cows fitted with rumen cannulas (Exp. 2) and 22 lactating dairy cows (Exp. 3) fed TMR (76% forage on DM basis) in a replicated 2 (diet) × 2 (period) crossover design. Methane production decreased by 10 and 8% in the groups fed the Rumitech diet compared to the control in Exp. 2 and 3, respectively. Moreover, in Exp. 3 milk yield and milk protein and lactose yield increased (by 5, 8 and 8%, respectively) in the groups fed the Rumitech diet. Sorghum hybrids as viable forage alternative to corn silage when water availability is limited

D. Duhatschek¹, J. Bell², D. Druetto³, L.F. Ferraretto⁴, K. Raver⁵, J. Goeser⁵, J. Smith¹, S. Paudyal¹, G.M. Schuenemann⁶ and J.M. Piñeiro¹

¹Department of Animal Science, Texas A&M Univ., College Station, TX, USA, ²Department of Soil and Crop Sciences, Texas A&M Univ., College Station, TX, USA, ³Richardson Seeds Ltd., Vega, TX, USA, ⁴Department of Animal & Dairy Sciences, Univ. of Wisconsin, Madison, WI, USA, ⁵Rock River Laboratory, Watertown, WI, USA, ⁶Department of Veterinary Preventive Medicine, The Ohio State Univ., Columbus, OH, USA; schuenemann.5@osu.edu

Over a third of milk produced in U.S. takes place in regions facing water scarcity challenges. Sorghum could be a viable forage alternative to corn silage when water availability is limited. Objective was to assess the effect male-sterile vs non-sterile sorghum hybrids on carbohydrates and CP. Two male-sterile (Non-BMR, F465; and BMR12, F430) and three non-sterile sorghum hybrids (non-BMR F10; BMR12, F382, and F431; Richardson Seeds) were used in a split-plot design to reduce cross-pollination. Plots were harvested 148 days after seeding with non-sterile hybrids after the hard dough stage and male-sterile hybrids 7 weeks after boot stage and harvested with a theoretical length of cut of 12 mm and roll gap setting at 2 mm. Analyses were performed using mixed linear regression models. Values are reported as percent (%) dry matter basis. Compared to non-sterile hybrids, male sterile hybrids had lower DM (28.4 and 40.8%; $P < 0.0001$). WSC was 2.5-fold higher ($18.0 \pm 0.73\%$) for the sterile hybrids compared to non-sterile ($7.21 \pm 0.63\%$), whereas starch was 2.2-fold greater for non-sterile ($28.6 \pm 0.95\%$) compared to sterile hybrids ($13.0 \pm 1.1\%$; $P < 0.0001$). Non-fibre carbohydrates were higher for non-sterile over sterile sorghum hybrids (46.2 ± 0.68 vs $39.6 \pm 0.75\%$; $P < 0.003$). Male sterile hybrids had increased aNDF ($42.3 \pm 0.59\%$) compared to non-sterile sorghum ($35.0 \pm 0.51\%$; $P < 0.0001$). CP was significantly lower for sterile compared with non-sterile hybrids (8.29 and 10.2%; $P < 0.0001$). The trade-off between WSC and starch in male-sterile sorghum hybrids is because sugars are not translocated to the grain where starch is developed as in non-sterile hybrids. These findings show that low sorghum starch digestibility can be overcome by using male-sterile sorghum hybrids that will, at least partially, compensate for the reduced starch yield by increasing water-soluble carbohydrates storage.

Feed intake and milk production of dairy cows fed with a ration with ensiled tall fescueM. Cromheeke¹, L. Vandaele¹, D. Van Wesemael¹, J. Baert¹, M. Coughnon¹, D. Reheul² and N. Peiren¹¹Flanders Research Institute for Agriculture, Fisheries and Food – ILVO, Scheldeweg 68, 9090 Melle, Belgium, ²Ghent university, Faculty of Bioscience Engineering, Department of Plants and Crops, Coupure Links 653, 9000 Gent, Belgium; maarten.cromheeke@ilvo.vlaanderen.be

Voluntary intake and digestibility of ensiled tall fescue (*Festuca arundinacea* Schreb.) is proved to be lower compared to perennial ryegrass (*Lolium perenne* L.). However, new varieties of tall fescue have been bred to improve palatability and digestibility, but there is a paucity of results on intake and animal performance trials with these new varieties. This knowledge gap inhibits adoption in practice. At the same time, there is an increased interest in tall fescue as an alternative for perennial ryegrass in North-West European dairy production because of increased frequency of periods of summer drought that jeopardizes the production of high quality forage grass. In this feeding trial we investigated differences in feed intake and milk production (MY) of dairy cows fed with a ration with ensiled tall fescue compared to (diploid and tetraploid) perennial ryegrass. We measured intake and milk production of Holstein Friesian dairy cows fed with a forage ration that was based on 1/3 of maize silage and 2/3 of ensiled (1) tall fescue (Fa), (2) perennial ryegrass diploid (Lp2) or (3) perennial ryegrass tetraploid (Lp4). Cows were randomized in 6 groups of 5 cows which subsequently received each of the three treatments using a balanced Latin-square design. Results showed a significantly lower total dry matter intake (DMI) of Fa (21.9 kg) compared to the two Lp treatments (22.8 kg Lp2 and 22.9 kg Lp4) ($P < 0.05$). This difference was related to lower roughage DMI. Fat- and protein- corrected milk (FPCM) was significantly lower for Fa in comparison with Lp2 and Lp4 (respectively 32.8, 34.6 and 35.5 kg). There were no significant differences in milk composition (fat, protein and lactose) except for milk urea. These findings confirm lower DMI and FPCM of dairy cows fed with a ration with ensiled tall fescue compared to ensiled perennial ryegrass. Similar trials will be set-up in the VLAIO KlimGras project.

Session 85

Theatre 4

Effect of supplementing live bacteria on methane production in lactating dairy cowsO. Ramirez-Garzon¹, D.G. Barber², J. Alawneh³, L. Huanle¹ and M. Soust¹¹Terragen Biotech Pty Ltd, Unit 6/39-41 Access Cres, Coolumb Beach QLD, 4573, Australia, ²DairyNEXT, Marburg, QLD, 4346, Australia, ³GCP Veterinary Consulting Ltd Pty., Brisbane, QLD, 4069, Australia; martins@terragen.com.au

Various feed supplements have been investigated to determine their association with methane (CH₄) production in dairy cattle. This longitudinal study assessed the effect of supplementing lactating dairy cows with direct-fed microbes (DFM) on CH₄ column density (ppm-m; used as a proxy for CH₄ emissions) in a commercial Australian dairy farm. A total of 150 multiparous Holstein cows were randomly selected from the main herd (n=360) based on parity (2±1 lactations) and days in milk (DIM; 127±55 DIM). The animals were randomly allocated to Group A (control; n=75) and Group B (DFM; n=75) and managed as two separate groups, housed and fed on a feed pad separately. The diet consisted of a silage-based partial mixed ration (PMR) with concentrate fed in the dairy twice daily and pasture to meet the milk production target relative to the stage of lactation. Both groups were fed the same amount of PMR once daily at 06:00 and pasture *ad libitum*. Group A (control) received the PMR ration whilst Group B (DFM) received the PMR supplemented with DFM, top-dressed using a manual sprayer. The DFM consisted of three strains of *Lactobacillus* sourced from a commercial product (Mylo, Terragen Biotech Australia). From each group, a subset of 25 Holstein cows (25 control, 25 DFM) were randomly selected and followed longitudinally throughout the study duration to measure CH₄ emissions. The subset of animals were assessed every 2-3 months (from September 2021 to January 2023) at different times of the day (00.00, 05.00, 09.00, 13.00 and 19.00) using a laser methane detector (LMD, Tokyo Gas Engineering solutions, Japan) for 5 minutes whilst restrained in a crush. There was an upward trend in CH₄ emissions across the year in both groups, which was correlated with the PMR:forage:concentrate ratio, and a significant transient reduction in CH₄ emissions ($P < 0.05$) after supplementation with the DFM that persisted for approximately 4 hours after supplementation. These findings suggest that DFM could play a role in reducing methane emissions from dairy cows.

Greenhouse gas emissions from dairy cows fed best practice diets

M. Managos¹, C. Lindahl², S. Agenäs¹, U. Sonesson³ and M. Lindberg¹

¹Swedish University of Agricultural Sciences, Department of Animal Nutrition and Management, P.O.Box, 75007 Uppsala, Sweden, ²Lantmännen Lantbruk foder, S:t Göransgatan 160A, 112 17 Stockholm, Sweden, ³Research Institute of Sweden, Sven Hultins 5, 412 58 Göteborg, Sweden; markos.managos@slu.se

During the last years, the global COVID-19 pandemic and armed conflicts have impacted, among other things, the agricultural supply chain creating uncertainty, resulting in price volatility, and affecting the availability of resources. This has highlighted that, in addition to sustainably increasing food production without exceeding the Earth's biophysical limit, it is important to consider aspects of resilience to climate change and unexpected events. This study investigated milk production and methane emissions (CH₄) from high-yielding dairy cows fed with three different concentrate mixtures with varying degrees of climate impact (CI) in the production stage. Forty-eight Swedish Holstein cows with a milk yield of 45±6.4 kg/d (mean ±SD) at the start of the experiment, blocked by parity in 2 groups, were used in a randomized complete block design with a 2-week adaptation and 7 weeks of data collection. Individual daily feed intake and milk yield were recorded, and the GreenFeed system was used for continuous measurements of CH₄. All cows received the same high-quality grass/clover silage, while three different concentrates were used in the experiment. A commercial concentrate was selected as control, and of the experimental concentrates, the first was based on by-products (BYP) where the ingredients were chosen to reduce feed-food competition, and the second was based on ingredients that can be produced domestically in Sweden. The experimental diets were formulated to have similar theoretical nutritional value as the control and the ingredients' CI was used as the optimization parameter. The sum of CH₄ emissions calculated as carbon dioxide equivalents and emissions from feed production did not differ between diets, while milk yield decreased in the group fed BYP. No difference was observed between treatment groups in the CI per kg milk or kg energy corrected milk. In conclusion, our results highlight the importance of accounting for all sources of emissions in relation to production when the CI of dairy production is evaluated.

Session 85

Theatre 6

Effects of cashew nutshell liquid on milk production and methane emission of dairy cows

R.J.F. Gaspe^{1,2}, T. Obitsu², T. Sugino², Y. Kurokawa² and Y. Kuroki²

¹Capiz State University, Agriculture, Natividad Pilar Capiz, 5804, Philippines, ²Hiroshima University, Graduate School of Integrated Sciences for Life, 1-4-4 Kagamiyama Higashi Hiroshima, 739-8528, Japan; rjunfredie@gmail.com

Cashew nutshell liquid (CNSL) contains phenolic compounds and was reported to inhibit gram-positive bacteria and increase rumen propionate concentration, thereby reducing enteric methane emissions from dairy cows. This study aimed to clarify the efficacy of CNSL in methane emissions, milk production, and rumen fermentation from lactating cows in practical condition. Ten Holstein lactating cows (BW 660±51 kg) were used in a completely randomized design with repeated measurement for a 28-day experiment in a free-stall barn with an automatic milking system. Two treatments were arranged as control (no CNSL additive, n=5) or top dressing of the additive to provide 10 g/d of CNSL (n=5) for 21 days, after 7 days of preliminary period (no addition). The average ratio of CH₄/CO₂ in respiration air during milking every 7 days was applied to predict each cow's daily methane production and methane conversion factor (MCF). Milk component and rumen VFA concentration were measured in the fourth week. *In vitro* rumen gas production was also tested using rumen fluid collected from individual cows in the fourth week. Daily dry matter intake, milk production, and methane production were not affected by the CNSL addition. However, methane production per dry matter intake and MCF tended to be lower ($P<0.15$) for the CNSL cows than those for the control cows. Especially, MCF tended to reduce by 12% in the third week compared to those in the first week in CNSL cows, but these were relatively stable in Control cows over the experimental period. Milk composition was not affected by CNSL, but ruminal total VFA concentration and acetate proportion tended to be lower ($P<0.15$) for CNSL cows. A tendency to decrease ($P<0.10$) in total gas, methane, and total VFA production was observed in the *in vitro* incubation with the rumen fluid obtained from the CNSL cows, compared to those from Control cows. These results suggest that microbial activity was slightly inhibited by top-dressing of the CNSL, thereby reducing methane production of cows in practical conditions.

***In vivo* testing of a methane-suppressing feed additive that acts by altering rumen redox potential**

C. O'Donnell¹, C. Thorn², A.C.V. Montoya¹, S. Nolan², M. McDonagh^{1,2}, E. Dunne³, F. McGovern³, R. Friel², S. Waters⁴ and V. O'Flaherty^{1,2}

Enteric methane (CH₄) emissions from livestock is a leading cause of anthropogenic greenhouse gases. A promising CH₄ mitigation strategy is anti-methanogenic feed additives. A novel mode of action for feed additives involves modulation of the rumen oxidation reduction potential (ORP) to favourably alter the rumen fermentation pathway away from methanogenesis. Prior research, using the rumen simulation technique (Rusitec) system, successfully demonstrated the potential of oxygen based additives to alter ORP and suppress methane production. The objective of this study was to evaluate the efficacy of the most promising additive tested via Rusitec (Calcium Peroxide (CaO₂)) *in vivo* using a six-week sheep trial. Sixty ewes were individually penned, housed indoors and fed a basal diet of *ad libitum* grass silage (~1.4 kg DM) and 0.4 kg barley-based concentrates. Animals were randomly assigned to one of three treatments (n=20); no additive (control), and CaO₂ supplemented at either 1.47% or 0.73% of daily DMI. Methane was measured using portable accumulation chambers (PAC) during week 6. Rumen fluid samples were extracted transoesophageally for ORP measurement, dry matter intake (DMI) was measured daily and live weight measured weekly. CaO₂ (1.47%) reduced CH₄ by 14% in terms of g/DMI ($P=0.04$) and elevated ORP by 22% ($P=0.04$). The lower CaO₂ dose had no effect on CH₄ emissions or ORP levels ($p>0.05$). Both CaO₂ treatments had no effects on DMI or live weight gain ($p>0.05$). This study represents the first *in vivo* trial of a novel ORP modulating additive demonstrating the safety and efficacy of such additives. Further optimisation on delivery mechanisms and inclusion rates to improve efficacy will be necessary for future studies.

Diurnal variation and repeatability of CO₂ production in GreenFeed studies with lactating cows

A. Guinguina^{1,2} and P. Huhtanen^{1,2}

¹Swedish University of Agricultural Sciences, Animal Nutrition and Management, Skogsmarksgränd, 901 83 Umeå, Sweden, ²Natural Resources Institute Finland, Production Systems, Tietotie 2 C, 31600 Jokioinen, Finland; abdulai.guinguina@luke.fi

Not long ago, the concept of residual CO₂ (RCO₂) was proposed as a proxy of feed efficiency using respiration chamber (RC) data from lactating dairy cows. However, the RC is costly and can reduce animal dry matter intake (DMI). The GreenFeed (GF-C-Lock, Inc., Rapid City, SD) system, an affordable and easy to use substitute to the RC can also estimate CO₂ production (g/d), which can be used to calculate RCO₂. However, due its spot-sampling nature, the reliability of the GF has been debated given the diurnal pattern and variability of animal gas production. Thus, a meta-analysis of an individual-cow data set was conducted to examine the diurnal pattern, between-cow variation, and repeatability of CO₂ production from lactating dairy cows. Data were taken from 12 (11 change-over and one continuous) studies consisting of a total of 829 cow/period observations. The experimental diets were based on grass silage with cereal grains or by-products as energy supplements, and rapeseed meal as protein supplement. Mean forage: concentrate ratio across all diets on a dry matter basis was 56:44. The diurnal pattern was determined using CO₂ production data from the continuous study. Variance components and repeatability estimates of CO₂ production were determined using data from the change-over studies with diet, period and cow within experiment as random effects in PROC MIXED of SAS. The average diurnal pattern for CO₂ production did not significantly change between feeding periods during the day. The between cow variation in CO₂ production was 9%. The repeatability estimate was also high (0.78) and practically the same as the repeatability of DMI from this dataset. Production of CO₂ was positively associated ($r=0.51$, $P<0.001$) with DMI. It is concluded that if the management of feed allotment remains constant then the diurnal pattern of CO₂ production from dairy cows will not necessarily alter with time. The high repeatability and close association between CO₂ production and DMI suggests that measurements of CO₂ made by the GF could be used to estimate feed efficiency in lactating dairy cows on-farm.

Repeatability and correlations of residual carbon dioxide and feed efficiency in Nordic Red cattle

A. Chegini, M.H. Lidauer, T. Stefanski, A.R. Bayat and E. Negussie

Natural Resources Institute Finland (Luke), Tietotie 4, 31600 Jokioinen, Finland; arash.chegini@luke.fi

Feed utilization efficiency (FE) is an important trait in dairy production and plays a significant role in reducing feed costs and lowering methane emission. One of the metrics used to measure FE in dairy cows so far is residual feed intake (RFI). This metric requires routine measurement of feed intake which is difficult and expensive. Recently, studies have found high correlation between heat and carbon dioxide (CO₂) production of cows and hence residual CO₂ could be a suitable proxy for FE in dairy cattle. Data was collected from 2 to 305 days in milk (DIM) from 46 Nordic Red dairy cows recorded for CO₂ output using two GreenFeed units and FE traits. RCO₂ and RFI were calculated by subtracting expected CO₂ production and DMI from actual CO₂ production and DMI, respectively. A bivariate model was fitted to estimate repeatability and correlations between RCO₂ and RFI traits. The models fitted included fixed effects of year-month of recording and lactation month, fixed regression (4th order Legendre plus Wilmink term) as well as random regression (1st order Legendre plus Wilmink term) for animal effect. Heterogenous residual variance considered. Repeatabilities and animal and phenotypic correlations between RCO₂ and RFI between selected DIM (DIM; 6, 36, ..., 276 and 305) were calculated. Repeatability of RCO₂ was high at the beginning of lactation (0.72 at DIM 6) and decreased around peak yield (0.27 at DIM 96) and again increased gradually towards the end of lactation. Similarly, RFI had high repeatability at the beginning (0.86 at DIM 6), however, it decreased in mid-lactation and increased towards the end of lactation. Animal correlations between RCO₂ and RFI were moderate to high on same DIM and ranged from 0.37 for DIM 96 to 0.88 at DIM 6. However, when the selected DIMs were far apart, correlations between RCO₂ and RFI were low, indicating different mechanisms controlling DMI and CO₂ exhalation at different stages of lactation. This was an initial study with 5,995 daily average records and analyses of a larger data set is needed to verify the results with higher accuracy.

Methane emission from purebred Holstein, Nordic Red and F1 crossbred cows of the two breedsA.L.F. Hellwing¹, M. Vestergaard¹ and M. Kargo²*¹Aarhus University, Campus Viborg, AU Foulum, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, ²Aarhus University, Center for quantitative genetics and genomics, C. F. Møllers Allé 3, 8000 Aarhus, Denmark; annelouise.hellwing@anivet.dk*

Results in the literature indicate that crossbred cows eat less per kg milk and are healthier than purebred cows. Would that also lead to lower methane emission per kg milk? The aim of the current experiment was to investigate methane emission of purebred Holstein, Nordic Red and F1 crossbred cows fed the same feed ration. Twenty-four cows, 8 Danish Holstein (HOL), 8 Nordic Red (RED) and 8 crossbred cows (CROSS) were used. The feed ration was made up of 34.5% maize silage, 17.4% grass-clover silage, 9.8% barley, 15.5% rapeseed cake, 10.2% rapeseed meal, 11.4% dried sugar beet pulp and 1.1% minerals and vitamins based on dry matter (DM), which is a typical ration fed to Danish dairy cows. The methane emissions were measured over three days by means of indirect calorimetry. DM intake and milk yield and composition was measured during chamber stay. The first day in the chamber was considered as an adaptation and only data from the last two days were used. Data were analysed with PROC GLM in SAS (version 9.4) with breed as the main effect. All cows were in second lactation and were 167±31 (mean ±s td) days in milk. The average weight of the cows was 670±66 kg. The DM intake (DMI) was 22.2, 19.4 and 21.3 kg for HOL, RED and CROSS, respectively ($P=0.40$). The daily methane emission did not differ between breeds and was on average 388 g/day. The methane emission was 17.9, 19.2 and 18.4 g/kg DMI for HOL, RED and CROSS, respectively ($P=0.19$). The production of energy corrected milk (ECM) differed between the breeds ($P=0.01$) where HOL yielded 35.1, RED 27.0, and CROSS 30.1 kg ECM/day during the chamber period. The CH₄ production per kg ECM was 11.5, 13.9, and 13.0 for HOL, RED and CROSS, respectively ($P=0.14$). In conclusion, it was not possible to show any breed differences in total methane production or methane per kg DMI or ECM yield when cows were fed on typical Danish feed ration.

How does a beef × dairy calving affect the dairy cow's following lactation?R.E. Espinola Alfonso¹, W.F. Fikse², M.P.L. Calus³ and E. Strandberg¹¹Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, P.O. Box 7023, 750 07 Uppsala, Sweden, ²Växa Sverige, Ulls väg 29A, 75651 Uppsala, Sweden, ³Wageningen University Research, Department of Animal Sciences, P.O. Box 338, 6700 AH Wageningen, the Netherlands; erling.strandberg@slu.se

For beef semen usage on dairy cows, much of the research has focused on the performance of the crossbred calves, yet little focus has been given to the subsequent performance of the cow itself. This study aimed to evaluate the performance of dairy cows for milk yield, fertility, and survival after giving birth to crossbred calves and compare this to the performance after giving birth to purebred dairy calves. Further, we aimed to study if the effect of a difficult calving was the same regardless of whether the calf was purebred or crossbred. Phenotypic records from 4,980,886 calving events distributed in 4,509 herds from 1997 to 2020 were collected from the Swedish milk recording system from cows of the dairy breeds Swedish Red (SR) and Swedish Holstein (SH). The data were analysed for all traits for first and later parities separately using mixed linear models, with a focus on the estimates of dam breed by sire breed combinations. Overall, milk yield was lower after mating beef × dairy compared with the purebred matings. The largest effects were found on total lactation yields and in later parities, with lower effects for earlier yields and yields in first parity. The largest decrease was about 17 kg for cumulative fat yield (corresponding to 14% of a phenotypic SD) when breeding heavy beef breed sires with purebred SR dams. For fertility traits, for most breed combinations, the effects were not large enough to be significant. Conversely, all dam-sire crossbred combinations showed significantly lower survival to the next lactation, and mostly also for last day in milk (lactation length). There was generally an unfavourable effect of a difficult calving on all traits, however, there were only some significant interactions between calving performance and dam by sire breed combination, and never in first parity. Beef × dairy difficult calvings were generally affecting performance less than corresponding difficult purebred calvings.

Extended lactation and milk yield – a randomized controlled trial in high yielding older cowsA. Hansson¹, C. Kronqvist², R. Båge³ and K. Holtenius²¹Växa, P.O. Box 30204, 10435 Stockholm, Sweden, ²Swedish University of Agricultural Sciences, Department of Animal Nutrition and Management, P.O. Box 7024, 750 07, Sweden, ³Swedish University of Agricultural Sciences, Department of Clinical Sciences, P.O. Box 7024, 750 07, Sweden; annica.hansson@slu.se

The current recommendation is that Swedish dairy herds should aim for 12.5 months calving interval. In practice, farmers are advised to strive for a voluntary waiting period (VWP) of 50 days. However recent studies have shown that primiparous cows with prolonged VWP showed improved fertility results, without negative effects on milk production. It appears to be a general opinion that older cows are less suitable than primiparous for a longer VWP due to reduced milk production and too long dry periods. However published randomized controlled studies presenting effects of delayed VWP in older cows are scarce. The aim of this study was to evaluate effects of an extended VWP on milk production in second lactation cows in herds with high milk production. Fifteen herds connected to the Swedish milk recording scheme volunteered for a randomized controlled study. Average herd milk production exceeded 10,800 kg ECM, compared with the 2018/19 national average of 10,400 kg ECM. Cows having their second calf from Dec. 2019 until Dec. 2020 were randomized to 50 days VWP (n=504) or 140 days VWP (n=481). In total 371 cows in VWP50 and 324 cows in VWP140 completed the second lactation with a third calf. Preliminary results show that the average calving interval in cows with VWP50 was 12.6 months and in VWP140 13.9 months ($P < 0.001$). Dry period was 65 days in both groups. In VWP50 average 305 days lactation yield was 12,190 kg ECM and in VWP140 12,868 ($P < 0.001$). Average daily milk yield over the lactation including the dry period was in VWP50 33.9 kg ECM and in VWP140 34.7 kg ECM ($P = 0.05$). In conclusion, these preliminary results show that second lactation cows in high yielding herds with extended lactation had higher 305 days lactation yield and tended to have higher daily milk yield over the lactation than cows with traditional calving interval. The length of the dry period was not affected by VWP.

Effect of usage BWB sire on Holstein cow performances

K. Elzinga¹, C. Schrooten¹, G. De Jong¹ and P. Duenk²

¹Cooperative CRV, Animal Evaluation Unit, Rijksweg-West 2, 6842 BD Arnhem, the Netherlands, ²Wageningen University & Research, Animal Breeding & Genomics Group, Droevendaalsesteeg 1 Building 107, 6708 PB Wageningen, the Netherlands; kirsten.elzinga@crv4all.com

Mating a Holstein Friesian (HF) dairy cow with a Belgian White Blue (BWB) sire is done as the crossbred calves are more profitable compared with calves when using a HF sire. To investigate to what extent the use of a BWB sire on a HF dam, compared with a HF sire on a HF dam, can affect the milk production and fertility of the dam in the following lactation, data was used from cows (n=268,475) in lactation 1 to 3 in the period 2016 to 2022. Cows were mated with a HF service sire as well as, in another year, a BWB service sire. Regarding production, the 305-day production of milk, fat and protein was included. Regarding fertility, number of inseminations, conception rate, non-return 56 days, calving interval, interval calving – first insemination, and interval first – last insemination was investigated. First, the effect of breed of service sire on production and fertility was studied, second the effect of the sire estimated breeding value (EBV) for calving ease was included in the model, and lastly the effect of calf characteristics (calf birth weight, calf sex, and calving ease) was studied. The use of a BWB service sire compared with a HF service sire decreased milk-, fat-, and protein production in the following lactation of the dam. HF cows mated with a HF service sire compared with a BWB service sire had better fertility in the subsequent lactation. More inseminations were needed for HF dams mated with a BWB sire and intervals between calvings and inseminations were longer. Also, conception rate for cows mated to a BWB sire was lower compared with cows mated to a HF sire. An increase in mating sire EBV for calving ease resulted in lower production and worse fertility in the following lactation. However, effects of the EBV for calving ease were low. A normal calving (class 2) resulted in the highest production and best fertility, whereas after a caesarean section (class 4) cows had the lowest production and worst fertility.

Session 85

Combined analysis: genetic and phenotypic trends in German Holstein dairy cattle

L. Hüneke¹, J. Heise¹, D. Segelke¹, S. Rensing¹ and G. Thaller²

¹IT Solutions for Animal Production (vit), Heinrich-Schröder-Weg 1, 27283 Verden (Aller), Germany, ²Christian-Albrechts-University Kiel, Institute of Animal Breeding and Husbandry, Hermann-Rodewald-Straße 6, 24118 Kiel, Germany; laura.hueneke@vit.de

Dairy cattle breeding programs have experienced drastic changes during the last 20 years, especially due to the implementation of genomic selection, which accelerated the breeding progress. In the context of intensifying discussions about animal welfare and public reports of the detrimental impact of breeding, scientifically objective information are needed. This study investigates the phenotypic and genetic trends of milk yield, longevity, calving ease, and stillbirth in the German Holstein population from the year 2000 on. Phenotypic data and breeding values of about 12 million cows were available. The means of breeding values and phenotypic values per year were calculated to analyse genetic and phenotypic trends. A parallel increase in the average breeding value and the phenotypic milk yield was observed for the milk production traits. On the other hand, the trait longevity showed clear differences in the development of phenotype and breeding value, as the strongly increasing genetic trend did not become fully visible in the phenotypic progress. This could be due to management decisions based on high replacement rates and the resulting early culling of cows due to limited space in the barn. The rates of stillbirth and calving difficulty indicated higher risk in first calving and for the birth of male calves. Nevertheless, both traits showed a declining trend over the last 20 years and incidence rates of stillbirth and calving difficulty were reduced by approximately 50%. However, the stillbirth rate was almost twice the rate of calving difficulty, which may indicate that many calves were born easily but then died for unknown reasons. The genetic trend of the calving traits only started to rise in the last 10 years, which could be caused by low weights in the selection indexes combined with low heritabilities. Moreover, it is likely that the calving traits have benefited from genomic selection. The results from this study will contribute immensely to the discussion of animal welfare in Germany.

Whole-crop maize forage preservation improvement with silage additivesI. Nikodinoska¹, E. Wambacq², G. Haesaert² and C.A. Moran³¹ Alltech European Headquarters, Summerhill Road, A86 X006, Dunboyne, Co. Meath, Ireland, ²University of Applied Sciences and Arts, Research Centre AgroFoodNature, School of Bioscience and Industrial Technology, V. Vaerwyckweg, 9000 Ghent, Belgium, ³Alltech SARL, Rue Charles Amand, Vire, 14500, France; ivana.nikodinoska@alltech.com

The efficacy of 6 silage additives on whole-crop maize preservation was examined in an ensiling trial using 2.75 t PVC microsilos. Maize was harvested at the Research Farm Bottelare (Belgium) in November 2021, at a dry matter (DM) content of 28% and chopped to 6-8 mm. The starting material contained 2.19% of water-soluble carbohydrates in the fresh material (FM) and classified as moderately difficult to ensile. The crop was inoculated with one out of 6 preparations: *Lactiplantibacillus plantarum* (LP) IMI 507026:*Pediococcus pentosaceus* (PP) IMI 507024 (50:50) at 5×10^5 cfu/g FM, LP IMI 507026:PP IMI 507024 (50:50) at 1×10^5 cfu/g FM, LP IMI 507027:PP IMI 507025 (75:25) at 5×10^5 cfu/g FM, LP IMI 507026:PP IMI 507025 (75:25) at 5×10^5 cfu/g FM + 25 mg/kg MnSO₄, LP IMI 507026:PP IMI 507025 (75:25) at 1×10^5 cfu/g FM + 25 mg/kg MnSO₄, or treated with an equal amount of water (Control-T1). Five replicates per treatment were prepared at a density of 150 kg DM/m³. Lactic acid (LA), acetic acid (AA), were determined by HPLC; ethanol was determined on an aqueous extract by NIR absorption. DM content at silo opening was determined by air drying at 60 °C and corrected for loss of volatiles during drying. The DM loss during the 100-days ensiling period at 20 °C was calculated. Crude protein and ammonia were analysed and the NH₄-N,%TN calculated as the ratio of ammonia nitrogen to total nitrogen. The pH was determined on an aqueous extract. Data were analysed according to a Mixed Effect model (Minitab v21.1) and Dunnett's post-hoc test, to compare the difference between T1 and the six inoculated treatments (T2-T7) ($P < 0.05$). All treatments significantly reduced the ethanol content compared to T1. Treatments T2, T3, T4, T6 and T7 significantly reduced the pH, whereas T3-T6 significantly increased the LA in treated forages compared to T1. Acetic acid, NH₄-N,%TN and DM losses did not significantly differ between T1 and T2-T7. These findings suggest that the homofermentative pathway was dominant, efficiently improving the silage fermentation process.

Gallic acid alleviates the negative effect of *Asparagopsis armata* on milk yield in dairy cowsR. Huang¹, P. Romero², C. Martin¹, E.M. Ungerfeld³, A. Demeter⁴, A. Belanche⁵, D.R. Yáñez-Ruiz², M. Popova¹ and D. Morgavi¹¹Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Saint-Genès Champanelle, 63122, France,²Estación Experimental del Zaidín (CSIC), Profesor Albareda 1, Granada, 18008, Spain, ³Instituto de Investigaciones Agropecuarias INIA, Centro Regional de Investigación Carillanca, Vilcún, La Araucanía, 4880000, Chile, ⁴Volta Greentech, AB Nanna Svartz väg 2-4, Solna, 17165, Sweden, ⁵Universidad de Zaragoza-CITA, Departamento de Producción Animal y Ciencia de los Alimentos, Miguel Servet 177, Zaragoza, 50013, Spain; rongcai.huang@inrae.fr

We have shown that when ruminal methanogenesis is inhibited *in vitro*, gallic acid acts as a dihydrogen acceptor and improves ruminal fermentation. In this work, we tested the effect of gallic acid and the methanogenesis inhibitor *Asparagopsis armata* on dihydrogen emissions and milk production in dairy cows. Lactating Holstein cows ($n=28$) were separated into four treatment groups as follows: CON, basal hay:concentrate diet; AS, basal diet with 0.25% *A. armata*; GA, basal diet with 0.8% gallic acid; and MIX, basal diet with 0.25% *A. armata* and 0.8% gallic acid. This study used a randomized complete block design with 6 wk of covariate and 5 wk of experimental measurements. The AS treatment decreased methane yield by 25%, increased dihydrogen emissions threefold, and reduced the acetate to propionate ratio in the rumen. In contrast, gallic acid did not affect methane or dihydrogen emissions, nor acetate or propionate molar proportions. Feed intake decreased by 10% in the AS group with a consequent decrease in milk yield of 18%. In the MIX group, feed intake was also decreased (8%), but the drop in milk yield was less severe (11%). This study confirms the antimethanogenic effect of *A. armata* but also shows a negative effect on feed intake and milk yield. While gallic acid did not decrease dihydrogen loss, it partially alleviated the negative effect of *A. armata* on milk yield.

Milk production in primiparous cows with customized voluntary waiting periodA. Edvardsson Rasmussen¹, E. Strandberg², R. Båge³, M. Åkerlind⁴, K. Holtenius¹ and C. Kronqvist¹¹Swedish University of Agricultural Sciences, Department of Animal Nutrition and Management, P.O. Box 7024, 750 07 Uppsala, Sweden, ²Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, P.O. Box 7023, 750 07 Uppsala, Sweden, ³Swedish University of Agricultural Sciences, Department of Clinical Sciences, P.O. Box 7054, 750 07 Uppsala, Sweden, ⁴Växa Sverige, P.O. Box 288, 751 05 Uppsala, Sweden; anna.edvardsson.rasmussen@slu.se

Randomized trials of extended voluntary waiting period (VWP) in primiparous cows have shown no difference in milk yield per day in the calving interval between cows with extended compared to conventional VWP. We hypothesized that individually customized VWP would improve daily milk yield. A randomized field trial in 18 commercial dairy herds was conducted. For primiparous cows calving during six months, the farmers regularly reported calving history, diseases and daily milk yields. Three criteria were used to select cows assumed to benefit from extended VWP: High genetic lactation persistency index before the start of the study (top 10%, n=41), a difficult calving and/or disease during the first month of lactation (n=59) or above average daily milk yield during day 4-33 in lactation (n=247). Cows were randomized within each criterion to an extended VWP (from 185 DIM) resulting in a 16.3 mo calving interval (ExtExt, n=174) or a conventional VWP (up to 90 DIM) resulting in a 12.4 mo calving interval (ExtConv, n=173). Cows not fulfilling any of the three criteria (ConvConv, n=183) were appointed a conventional VWP resulting in a 12.0 month calving interval. Results, including cows receiving the intended VWP and having a second calf show that 305-d yield was highest in the ExtExt group (10,383±394 kg) second highest in the ExtConv group (9,817±391 kg) and lowest in the ConvConv group (8,115±391 kg) ($P<0.01$). Milk yield per day in the calving interval was lower ($P<0.01$) in the ConvConv (22.6±1.1 kg/day) compared to the ExtConv (27.3±1.1 kg/day) and ExtExt group (27.7±1.1 kg/day), and there was no difference between the ExtConv and ExtExt groups ($P=0.63$). Cows selected for conventional or extended VWP based on calving history, diseases and daily yields produced equal average daily yield independent on VWP group.

Association of nisin and *Cymbopogon citratus* against *S. aureus* isolated from bovine mastitis

L. Castelani, T.M. Mitsunaga, L.C. Roma Jr. and L.E.F. Zadra

Institute of Animal Science and Pastures (IZ), Heitor Penteado, 56, 13380-011, Brazil; liviacastelani@gmail.com

Bovine mastitis caused by *Staphylococcus aureus* represent losses to the dairy industry and risks to consumer health. The replacement of conventional therapies by alternative biocompounds is fundamental for the sustainability of milk production. The Nisin (NS) is a bacteriocin produced by of *Lactococcus lactis* strains, and has action against several of Gram-positive bacteria species. The *Cymbopogon citratus* (CC) essential oil has anti-inflammatory and antimicrobial properties mainly due to the presence of tannins and flavonoids in its composition. The aim of this study was to evaluate the *in vitro* antibacterial activity of nisin, *C. citratus* and the NS/CC complexes against multidrug-resistant *S. aureus* (MDR) strains, isolated from bovine mastitis and belonging to an International Collection of Culture Strains (i.e. ATCC). *C. citratus* was solubilized in Mueller Hinton broth supplemented with 0.5% Tween 80, and nisin was solubilized in 0.02N HCl, decontaminated by filtration (0.45 µm). NS/CC complexes were obtained after 1 hour of interaction at 25 °C. The *in vitro* activity of the nisin, *C. citratus* and NS/CC complexes was evaluated by minimum bactericidal concentration (MBC), checkerboard method and time-kill against 27 strains of *S. aureus* exhibiting an MDR profile (aminoglycoside, B-lactam, cephalosporin, folate inhibitor, lincosamide, macrolide, quinolone, tetracycline), isolated from bovine mastitis; and *S. aureus* BAA-976TM, BAA-1026TM, MU-50. The MBC₅₀ value of nisin was 400 µg/ml, whereas the MBC₅₀ of *C. citratus* was 625 µg/ml. The MBC of the NS/CC complex was 100/156 µg/ml, and this combination was interpreted as a synergistic effect (ΣFBC≤0.5). According to time kill assay, for the NS/CC complexes, a ≥3 log₁₀ reduction (= 99.9% reduction of cfu/ml) of the ATCC BAA-976TM strain was achieved after 1 hour of interaction. The association *in vitro* of *C. citratus* and the nisin showed potential for the control of MDR *S. aureus* strains isolated from bovine mastitis. The combination of biomolecules can be useful for preventing bacterial resistance, in addition to reducing the administered dose and side effects. (Financial Support FAPESP 2018/16531-9; FAPESP 2020/09249-5).

Quick sustainability scan calculator for intensive and extensive pig farmsS. Sanz-Fernández¹, C. Reyes- Palomo¹, P. Meatquality Consortium² and V. Rodríguez-Estévez¹¹Universidad de Córdoba, Cátedra de Producción Ecológica Ecovalia-Clemente Mata, Ctra. Madrid-Cádiz km 396, 14071, Córdoba, Spain, ²Project mEATquality, Consortium, <https://meatquality.eu/>, Denmark; v22repac@uco.es

One of the main objectives of the H2020 mEATquality project is to support the development of techniques to assess the pig production sustainability, in order to improve it through the best practices and to assess the environmental, social and economic impacts of pig production. This project will assess different pig husbandry systems around Europe (80 fattening pig farms from Denmark, Italy, Poland and Spain). Thus, two quick sustainability scan calculators have been developed: one for intensive pig farms and another for extensive ones. These calculators propose each evaluation schemes, integrating the score assigned individually to a farm through the evaluation of 10 aspects related to livestock management: (1) certifications; (2) water management; (3) feed; (4) waste and residues management; (5) energy efficiency; (6) socio-economic contribution to the farm territory; (7) farm associated businesses; (8) animal management; (9) management of pastures and soil, and biodiversity; (10) stocking rate and pigs density. The last two aspects are only evaluated for extensive farms. Each of these aspects receives a score according to its importance and contributes in a different proportion to a final score, which is organized into 3 categories: environmental, social, and economic impact. The maximum achievable score in each category is 100 points. These quick scans are designed to be easily answered (yes/no), and the margin of error for over or underestimation of the contribution of some aspect is small, since the number of questions (n=62 for extensive farms; n=64 for intensive farms) is distributed among the different aspects and none force excessively the final score. With these calculators it is intended to obtain some benefits, since it is useful as a self-assessment tool for the farmers themselves, allows comparison (benchmarking) and identifies the weak points of each farm, enables participatory certification, and helps to provide confidence to consumers. This project has received funding from the European Union's Horizon 2020 research and innovation program under Grant Agreement No 101000344.

Bulk milk and farms characterization in the Parmigiano Reggiano Consortium area: the INTAQT project

M. Berton, M.A. Ramirez Mauricio, N. Amalfitano, L. Gallo, A. Cecchinato and E. Sturaro

DAFNAE-University of Padova, Viale dell'Università 16, 35020 Legnaro, Italy; marco.berton.1@unipd.it

Parmigiano Reggiano (PR) is probably the most valuable Italian cheese, produced under the regulations of a specific Consortium that supervises one of the main dairy chain in Italy. The study aimed to characterize structure, management and milk traits (milk yield, kg/d per cow -MY, protein content, % -CP, and fat content, % -FAT) of the PR-producing farms enrolled in the INTAQT project. Data originated from farm inspections (altitude zone -AZ, herd size, housing type, genetic type of cows -GT, use of total mixed rations -TMR, proportion of concentrate inclusion in the lactating cow diets -CONC) and official milk recording system (test-day MY, CP, FAT). All farms were scored for animal welfare related features (management -A, structure -B, and animal-based measure -C; 0-100 score range per category) according to the official national method for animal welfare assessment. A total of 4,558 milk records from 804 farms were considered. Altitude zone was classified as mountain and plain, GT as mostly Brown Swiss, mostly Holstein Friesian (HF+), only Holstein Friesian (HF) and local breeds, CONC into 3 classes (<25, 25-55 and >55% of the average dry matter) and welfare scores into 3 classes (mean±0.5 SDs). Test-day were grouped as seasons (SE; winter, spring, summer). Milk yield, CP and FAT were analysed with a mixed model with AZ, GT, CONC, welfare A, B, C scores and SE classes as fixed effects and farm as random one. All the fixed effects except SE were nested into farm. Farms were mostly located in the plain (77% of farms), with free-stall housing (68%), rearing HF cows (41% HF; 45% HF+) and not using TMR (44%). Lactating cows averaged 108±106 and were fed diets that included 42±8% CONC. Welfare scores A, B and C averaged 78±9, 71±10 and 79±6, respectively. Most of the fixed effects affected MY, with greater values for plain-located farms, rearing HF cows, with TMRs, high levels of CONC, scores A and C. Milk protein was affected by GT, TMR, score C and SE, whereas FAT by AZ and SE. These results could contribute to drawing interventions aiming to improve both intrinsic quality of milk destined for cheese production and extrinsic one related to environmental sustainability and animal welfare.

Bridging environmental sustainability and intrinsic quality traits of pork*M. Gagaoua, F. Gondret, F. Garcia-Launay and B. Lebret**PEGASE, INRAE, Institut Agro, 35590, Saint-Gilles, France; mohammed.gagaoua@inrae.fr*

The perceptions by consumers of fresh pork quality determine their re-purchase behaviour, which is key to the success of the pork industry. Consumers rely on intrinsic (product-related) and extrinsic (production-related) cues to form their opinions about pork. The intrinsic cues (organoleptic, technological and nutritional properties) are usually used to assess pork quality. Extrinsic cues refer to the ethical, cultural and environmental dimensions of pork production, and are becoming increasingly important to consumers who are notably seeking pork produced in sustainable and environmentally friendly practices. Notwithstanding, studies integrating environmental impacts into pork quality assessment are constrained. This work intends to address this drawback through two approaches. First, we provide an overview of the current knowledge on the expectations of consumers towards environmental sustainability of pork production with an emphasis on the gap between attitudes (expectations) and behaviours (willingness-to-purchase). Second, a proof of concept integrating environmental footprints with intrinsic qualities of meat was provided. For that, we used an experiment from farm-to-fork designed to improve intrinsic and extrinsic dimensions of pork quality. The trial included two pig genotypes (Duroc and Pietrain NN crossbreeds) and two feeding regimens: an experimental diet with extruded faba bean (national origin) as protein and extruded linseed as omega-3 fatty acid sources, while the control diet was based on oilseed meal (imported soybean, rapeseed and shelled sunflower). Raising Duroc crossbred pigs with the diet containing extruded faba bean and linseed was found as a favourable strategy to jointly improve the sensory, technological and nutritional properties of pork, while meeting the challenge of relocating protein feed resources. We further calculated and compared the environmental impacts of the four combinations of pig genotype and feeding strategy using life cycle assessment, and addressed their relationships with intrinsic meat quality traits using multivariate and clustering analyses. Incorporating environmental impacts into pork quality assessment can help promoting sustainable pork production practices and guide consumers in their purchase decisions.

Theatre 4

Improving milk intrinsic quality: considering synergies and antagonisms of farming practices*L. Rey-Cadilhac¹, A. Ferlay¹, M. Gelé², S. Léger³ and C. Laurent¹**¹UCA, INRAE, VetAgro Sup, UMR12133 Herbivores, 63122 St-Genès-Champanelle, France, ²Institut de l'Elevage, 148, rue de Bercy, 75595 Paris Cedex12, France, ³UCA, Laboratoire de Mathématiques Blaise Pascal, UMR6620-CNRS, 63178 Aubière Cedex, France; lucille.rey-cadilhac@inrae.fr*

While over the past 30 years many studies have focused on the effects of farming practices on a few milk compounds, few have considered combinations of farming practices on all compounds characterizing the intrinsic quality of milk. However, these practices could interact with each other and have antagonistic or synergistic effects on different compounds. Therefore, this study aimed to investigate the effect of combinations of farming practices on overall intrinsic quality of milk using data obtained from private farms. Ninety-nine dairy farms were visited to collect a sample of bulk tank milk and to conduct a survey on the farming practices applied to produce this milk (herd characteristics, feeding management, housing conditions, milking and milk storage conditions). The milk sample was analysed according to different compounds involved in intrinsic quality. A multi-criteria assessment was then conducted: it allows to implement about 30 indicators from the analyses carried out on milk, which, when aggregated, give scores (from 0 to 10) of the 4 dimensions (sensory, technological, nutritional and health) of the intrinsic quality and of the overall intrinsic quality. This assessment is implemented for 2 targeted products: raw milk cheese and semi-skimmed ultra-high-temperature milk. These indicator values, dimension and overall intrinsic quality scores were then predicted from combinations of farming practices using the regression tree method. Regression trees allowed to identify the combinations of practices that lead to the best indicator values, dimension and overall intrinsic quality scores, and to prioritize the importance of these practices. By comparing the trees, it was also possible to determine synergistic and antagonistic effects of farming practices among the different indicators, dimensions and targeted products. This method could be adapted to other topics such as the 'One quality' by considering both extrinsic aspects of quality in order to determine the trade-offs to be made among different quality aspects.

Imagining futures of husbandry farming: new business models for the sustainable transition?B. Smulders¹, R. Valkenburg¹ and M. Anastasi²¹Eindhoven University of Technology, Den Dolech 1, 5612 AE Eindhoven, the Netherlands, ²Cyprus Research & Innovation Center Ltd, 72, 28th Octovriou Avenue, 2414 Nicosia, Cyprus; b.smulders@tue.nl

Husbandry farming is under pressure and faces challenges, including discussions on emissions, intensive vs extensive agriculture, energy use, and health-related issues. Society at large is pressing increasingly towards sustainability, but what are potential sustainable future perspectives for husbandry farming? And what are potential business models? In this study, we support the thinking of opportunities by reimagining the future to think beyond current problems. The future is not necessarily an extrapolation of the past and present, but rather a *phenomenological* quality that allows proposing a *frame* that is discontinuous with what preceded. Future scenarios were crafted through several steps. First, a broad range of experts was interviewed, using a selection of general trends from horizon scanning reports as input. These trends were thematically coded and organized into seven dimensions – technology, users and markets, societal and environmental effects, industry and production, infrastructure, policy and regulations, and socio-cultural traditions. In the analysis of the interviews, 3-6 drivers for change per dimension were identified as signified by fault lines or missing elements from the past, discontinuities, or desires for change. Future scenarios were then constructed by creatively synthesizing the input across dimensions. This effort resulted in six images and vivid, but intentionally vague narratives that describe alternative environments for husbandry farming. The scenarios of alternative environments form the basis for reimagining value propositions. The *what-if reality* implied by the alternative value proposition allows the reconstruction of farming system elements by reinterpreting the activities, actors, artefacts, and their relations. In an interactive session, the six future scenarios will be presented during which people will be challenged to rethink their own practices, resulting in opportunities for change toward more sustainable and animal-friendly farming systems with business potential. The work presented is supported by the European Union's Horizon 2020 program under grant agreement No. 101000216 – Project Code Refarm.

Current prediction and authentication tools used and needed in EU livestock product chainsS. McLaughlin¹, F. Albert², F. Bedoin², C. Couzy², I. Legrand², A. Nicolazo De Barmon², C. Laithier², C. Manuelian³, F. Klevenhusen⁴, S. De Smet⁵, E. Sturaro⁶ and N. Scollan¹¹Queen's University Belfast, School of Biological Sciences, Institute for Global Food Security, 19 Chlorine Gardens, Stranmillis, BT9 5DL, Belfast, United Kingdom, ²IDELE, 149, rue de Bercy, 75595 Paris cedex 12, France, ³University of Barcelona, Plaça Cívica, 08193 Bellaterra, Barcelona, Spain, ⁴BfR, Max-Dohrn-Straße 8-10, 10589 Berlin, Germany, ⁵Ghent University, Coupure Links 653, 9000 Gent, Belgium, ⁶University of Padova, DAFNAE, Viale dell'Università 16, 35020 Legnaro, Italy; s.mclaughlin@qub.ac.uk

Introduction: There is a need to develop innovative and cost-effective analytical tools to enable: (1) the authentication of husbandry systems with different levels of intensification and of animal breeds and strains; and (2) the prediction of intrinsic quality traits of milk and dairy products, beef, and chicken meat. Aim: To obtain an overview of current prediction and authentication tools used and needed in European livestock product chains. Methods: Quantitative and qualitative survey administered to laboratories, processors, advisors and retailers in France, Germany, Italy, and the UK. 93 responses with 42 completed reports for all survey models. Results: Pathogen and microbiological quality analyses are widely used by the industry. Authentication methods were used most commonly to assess specific processes (e.g. meat cuts, ageing of meat, heat treatment used for milk). 56% of the sample are currently using NIR and/or MIR devices. There is great interest to develop tools and methods that rapidly assess quality using pathogens, antibiotic resistance, antibiotic residues, and shelf life as the parameters of interest. Developed tools must have the correct software and calibration to enable laboratories and companies to use such devices. The cost of equipment in terms of accessibility to end user should be considered. Conclusions: There is a growing need for novel, rapid methods to assess and authenticate product quality.

Milk quality assessment for intensive and extensive goat farming of the Skopelos breed in GreeceZ. Basdagianni¹, I. Stavropoulos¹, G. Manassis¹, C.G. Biliaderis² and I. Bossis¹¹Aristotle University of Thessaloniki, Department of Animal Production, School of Agriculture, Thessaloniki, 54124, Greece, ²Aristotle University of Thessaloniki, Department of Food Science and Technology, School of Agriculture, Thessaloniki, 54124, Greece; basdagianni@agro.auth.gr

The objective of the study was to evaluate the quality of goat milk produced in an intensive (I) and an extensive (E) farming system throughout the lactation period in the Greek Skopelos dairy goats. 938 individual milk samples from 235 goats (105 and 135, for the intensive and the extensive system respectively) were collected at 4 different lactation stages starting immediately after weaning. Milk composition (fat, protein, lactose, and total solids content), physicochemical characteristics (pH, electrical conductivity, brix value, and refractive index), fatty acid composition, somatic cells count (SCC) and total bacterial count (TBC) were measured. A mixed linear model was used to determine the effects ($P \leq 0.01$) of farming system, and lactation stage on the milk quality assessment parameters. The farming system had no significant effect on the chemical composition and physicochemical properties of milk. Farming system however, significantly affected ($P \leq 0.01$) SCC (509.02 vs 841.29 cell/ml $\times 1000$, for the I and E, respectively) and TBC (21.49 vs E:326.45 cfu $\times 1000$ for the I and E, respectively). In addition, farming system affected certain parameters of FA composition. Total unsaturated FAs were higher ($P \leq 0.01$) in the E system (27.39%) compared to the I system (21.99%). More specifically, polyunsaturated fatty acids were 3.58 and 4.24% and monounsaturated FAs were 18.41 and 23.15% for the I and the E systems, respectively. Differences in SCC and TBC between the two farming systems are probably due to milking practices and overall hygiene status. In contrast, the superior lipid profile in the extensive farming system could probably be attributed to grazing for the majority of the lactation period. This work was funded by EU (HORIZON H2020) under the 'Code Re-farm: Consumer-driven demands to reframe farming systems' (Grant No: 101000216).

Session 86

Theatre 8

Rheological evaluation of rennet-induced curdling of goat milks from different farming systemsK. Kotsiou¹, M. Andreadis¹, A. Lazaridou¹, C.G. Biliaderis¹, Z. Basdagianni², I. Bossis² and T. Moschakis¹¹Aristotle University of Thessaloniki, Department of Food Science and Technology, Thessaloniki, 541 24, Greece, ²Aristotle University of Thessaloniki, Department of Animal Production, School of Agriculture, Thessaloniki, 541 24, Greece; basdagianni@agro.auth.gr

The present study focuses on the rheological assessment of rennet-induced coagulation of milk from dairy goats of the Greek Skopelos breed. The goats were raised by either an extensive or an intensive farming system at two separate farms in Greece. The milk samples were collected after weaning. Dynamic rheological measurements were used to assess the kinetics of milk coagulation at 35 °C following the addition of rennet as well as the mechanical properties of the formed coagulum (cheese curds). The rennet coagulation time (defined as the time of the abrupt increase of storage modulus, G') of the milk samples from the extensive goat farming system was shorter than that for samples of the intensive farming system, without affecting the curd firming rate, determined by the increment of elasticity ($IE = (d\log G'/dt)_{max}$), a parameter used as a measure of the gelation rate. Curds obtained from goat milks raised by the extensive farming system exhibited higher G' 35 °C and complex viscosity (η^*) values, compared to those of the intensive system; i.e. stronger gel network structures were noted for the extensive farming system samples. The observed differences in the rheological behaviour may be ascribed mainly to differences in the compositional and/or structural characteristics of the protein components (e.g. casein fractions) content between the two groups of samples. The rheological findings make an interesting contribution to the field of animal science and cheesemaking, by demonstrating how the goat feeding system may affect the mechanical properties of rennet-coagulated cheese products. This work was funded by EU (HORIZON H2020) under the 'Code Re-farm: Consumer-driven demands to reframe farming systems' (Grant No: 101000216).

Technological tools for authentication assessment of animal products

C.L. Manuelian

Universitat Autònoma de Barcelona (UAB), G2R, Dept. Ciència Animal i dels Aliments, Facultat de Veterinària, 08193 Bellaterra (Barcelona), Spain; carmen.manuelian@uab.cat

Consumers are demanding more information on the products' origin (e.g. country, mountain areas), method of production (e.g. organic, free-range) or health benefits (e.g. low fat, rich in Calcium). However, authentication methods are needed to protect consumers' interests as labelling claims are linked with an increase in price. Traditional methods are expensive, time consuming, need skilled personnel, and require toxic solvents and reagents. Therefore, non-invasive, cost-effective, rapid, easy-to-use and environmentally friendly methods for authentication are needed. Infrared (IR) and energy-dispersive X-ray fluorescence (EDXRF) spectroscopy accomplish all these criteria. The IR produces a 'fingerprint' involving C-H, O-H and C=O chemical bonds. Benchtop devices interest is moving from gross to detailed composition and authentication. In general, individual or groups of FA present at medium-to-high concentration are more easily predicted, as well as using ground samples. Ability to predict technological, sensorial quality traits, and minerals is still limited. The ability of IR to predict minerals has been linked to their bond with organic molecules. Economic portable miniaturized IR devices have recently arrived to the market and have been tested in slaughterhouses and processed dairy products showing promising results. The main advantages are their low cost making them affordable for small-sized producers or processors. The EDXRF technique is based on an X-ray impulse which passes through the sample and to which sample minerals emit a fluorescent radiation in response. The energy of this emitted response is indicative of the mineral, and the intensity depends on the amount of each mineral in the matrix. It does not need a prior sample digestion and simultaneously quantifies minerals and trace elements. This technique application in animal-derived food is quite new, and some studies have been conducted in milk powder, fluid milk, and cheese with promising results and suggesting water interference in fluid milk. Researcher funded with a María Zambrano grant of the Spanish Ministry of Universities and the European Union-Next Generation EU.

Theatre 10

Potential of milk infrared spectroscopy to discriminate farm characteristics: the INTAQT project

M.A. Ramirez Mauricio, D. Giannuzzi, L. Gallo, M. Berton, A. Cecchinato and E. Sturaro

University of Padova, DAFNAE, Viale dell'Università 16, 35020, Legnaro, Padova, Italy; marcoaurelio.ramirezmauricio@unipd.it

The Fourier-transform infrared spectroscopy (FTIR) is one of the most developed and implemented tool for the analysis of milk chemical compounds. Besides this, FTIR can also be used to determine the fingerprint of milk for authentication purposes to certify the area of origin or the farming system in which the milk is produced. The present study, carried out within the INTAQT EU project, aimed at assessing the effectiveness of FTIR applied to bulk milk samples in discriminating dairy herds of Parmigiano Reggiano Consortium (PRC) for their structural and management characteristics. Dairy farm information included altitude zone (AZ), herd size (HS), housing type (HT), dairy cows genetic type (GT), use of total mixed rations (MR), and proportion of concentrate inclusion in the cow diets (CONC). This database was merged with milk data obtained from the official milk recording system along with FTIR spectral data of bulk milk, stored by the Breeders Association of Emilia Romagna Region lab (ARAER, Reggio Emilia, Italy) from January to August 2022. Overall data set comprised 4,610 bulk milk FTIR spectra from 940 farms, with a mean of 4.9 (± 1.1) observations per farm respectively. Each spectrum contained absorbance values at 1,060 different wavenumbers ($5,000$ to $930 \times \text{cm}^{-1}$). Quality control of spectral data involved centering and scaling, removing spectral samples using a Mahalanobis distance greater than 3 SD, and removing the water region. A Partial Least Squares Discriminant Analysis (PLS-DA) and Linear Discriminant Analysis (LDA) were fitted to estimate the probability of each observation (i.e. farm) belonging to a specific group (e.g. AZ, HS, etc.). The 60% of the data was used as training set and 40% as testing set. Finally, a prediction of the testing set was performed with both methods. PLS-DA gained an accuracy of 85, 74, 86, 82 and 95% for classifying the proportion of CONC, AZ, HT, MR and GT respectively. In the case of LDA the accuracy values obtained were 63, 73, 86, 82 and 97% respectively. These results suggest the potential of FTIR to determine the fingerprint of milk for authentication purposes in the PRC area.

A longitudinal cohort study of health and welfare status in extensively and intensively reared goats

V. Korelidou, A.I. Kalogianni and A.I. Gelasakis

Agricultural University of Athens, Department of Animal Science, Iera Odos 75, 11855 Athens, Greece; vkorelidou@aua.gr

Goats are challenged by various health and welfare issues depending on the production system and management. The objective of this study was to prospectively evaluate health and welfare status of dairy goats reared under intensive and extensive farming systems. A population of 133 and 105 purebred adult Skopelos goats, were randomly selected from a typical extensive (Farm A) and intensive farm (Farm B), respectively and were monitored during one milking period. For each individual goat, a detailed physical examination of the head, body, limbs, udder, and lymph nodes was performed by the same veterinarian every 50 days. Various health and welfare indicators were recorded using a modified protocol of AWIN (Animal Welfare Indicators). Data were analysed to estimate period prevalence, incidence rate (new cases per 1000 goat-months), and cumulative incidence. Higher prevalence, incidence rate, and cumulative incidence were observed in goats of Farm B compared to those of Farm A, with the respective values for specific conditions being as follows: (1) lameness 3.8%, 6.0, and 2.9% over 1.5%, 3.2, and 1.5%; (2) overgrown hooves 29.5%, 68.5, and 26.7% over 3.8%, 8.1, and 3.8%; (3) teeth problems 10.5%, 20.6, and 9.6% over 2.3%, 4.8, and 2.3%; and (4) swollen submandibular lymph nodes 21.9%, 56.5, and 17.2% over 5.3%, 10.1, and 3.1%. On the contrary, higher prevalence, incidence rate, and cumulative incidence were found in Farm A compared to Farm B for: (1) anaemia 48.9%, 210.9, and 46.0% over 15.2%, 13.3, and 4.3%; (2) faecal soiling 8.3%, 16.7, and 7.6% over 3.8%, 4.0, and 1.9%; (3) poor hair quality 60.9%, 64.3, and 25.7% over 49.5%, 60.5, and 26.4%; (4) swollen prefemoral lymph nodes 28.6%, 53.5, and 15.2% over 1.9%, 5.8, and 1.9%; and (5) swollen prescapular lymph nodes 25.6%, 47.2, and 13.2% over 15.2%, 29.6, and 9.2%, respectively. The results showed that health and welfare issues occur with different frequencies in intensively and extensively reared goats. Hence, it is important to further study the underlying causative agents and relevant risk factors on a case-specific basis. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 101000216.

New tool for accurate analysis of gas concentrations in barnsO. Bonilla-Manrique¹, A. Moreno-Oyervides¹, H. Moser², J.P. Wacławek², B. Lendl² and P. Martín-Mateos¹¹Universidad Carlos III de Madrid, Av. Universidad 30, 28911 Leganés, Spain, ²Technische Universität Wien, Getreidemarkt 9, 1060 Vienna, Austria; obonilla@ing.uc3m.es

Controlling the concentration of gases inside livestock buildings is essential to ensure both animal health and product quality. Compounds such as carbon dioxide and ammonia are of particular relevance, as they are produced in significant quantities by animals. The accumulation of these gases in the ambient air, which is of particular concern in the winter months when ventilation is kept to a minimum, causes significant stress on the respiratory system of the animals and has been demonstrated to affect the quality of products. There are other compounds that are also of great interest, such as, especially for ruminants, methane. Besides affecting the respiratory tract, it also provides an indication of digestibility and feed intake, and several studies indicate that methane concentration could be used to improve animal productivity and product quality. However, accurate, reliable, and real-time determination of the above-mentioned gas concentrations is currently a challenge. Several portable or fixed-location gas analyser technologies can be used today to estimate the concentration of gases inside barns. However, measuring at a single, or a few, sampling points has significant weaknesses, as it is easily affected by changes in airflow patterns and provides results that may not be representative of actual values. The main objective of the work presented here is the experimental validation of a new gas measurement tool, specifically designed for use in livestock barns. An optical system, based on molecular dispersion spectroscopy, has been designed so that an array of laser beams sweeps the barn at a height similar to that of the animals, thus providing a highly reliable and representative measurement of gases concentration to which the animals are actually exposed. This tool will make available to farmers and scientists unprecedented data that could be of great use in the challenging task of optimizing the balance of factors that ensures the maximum return from a livestock farm. The work presented was supported by the European Union's Horizon 2020 programme under grant agreement No. 101000216 – Project Code Refarm.

Implementation of husbandry practices improving quality and sustainability: a living lab approach

*E. Sturaro, C. Berri, D. Berry, R. Eppenstein, C. Laithier, A. Cartoni Mancinelli, B. Martin and F. Leiber
INTAQT Consortium, Rte de Theix, 63122 Saint-Genès-Champanelle, France; enrico.sturaro@unipd.it*

The living lab approach to innovation is receiving increasing attention also in the agricultural sector in view of the current environmental, economic, and social challenges. This contribution presents some preliminary results of INTAQT project (EU Horizon 2020), which aims to perform an in-depth multi-criteria assessment of the relationships between animal husbandry and qualities of products. In specific, this research aims to identify and implement on-farm changes in the production processes (e.g. feeding regimes, outdoor access, herd management), which are expected to improve intrinsic quality traits of the products and/or sustainability traits of the farms. A participatory approach was used to establish farmer field-groups (living labs) representative of the different geographic regions and of the main production systems involved in the project. Each farmer field group involves from 5 to 8 farms. The groups are established considering different husbandry systems according to a gradient of intensification (extensive vs intensive systems): 3 groups for dairy farms (Ireland, northern Italy and France); two groups for beef farms (Switzerland and northern Italy); two groups for poultry (France and Italy). The methodological approach is based on 5 steps: (1) tarding analytical phase: a critical analysis of trade-offs / synergies between sustainability and quality traits for each farm-field group; (2) decision phase: development of practices to improve the identified synergies / mitigate trade-offs; (3) implementation phase: implementation of practices for at least one year. During this time, 2-3 meetings of the whole farmers group on farms allow farmers discussions about their experiences, successes and drawbacks; (4) concluding analytical phase: the aim is to analyse the effects of the implementation of the practices during a last meeting in the farmer's groups and presentation of the analysis results; (5) scientific data analysis and interpretation. The first results of this approach will be presented and discussed. The ambition is to establish a network of living labs usable as pilot and demonstration enterprises regarding practice improvements for better food quality and sustainability.

Muscle proteomics towards molecular understanding of colour and water-holding biochemistry in meat

S. Yigitturk

Wageningen University & Research, Department of Agrotechnology and Food Sciences, Food Quality and Design Group, Bornse Meadows 9, 6708 WG Wageningen, P.O. Box 17, 6700 AA Wageningen, the Netherlands; seren.yigitturk@wur.nl

Poultry meat is projected to constitute 47% of the protein consumed globally from meat sources and is the primary driver of growth in meat production. The physiological and metabolic functions of the animals are influenced by many factors such as extensive husbandry practices, with consequent impact on the animal welfare and intrinsic quality of the broiler meat. However, to what extent the extensiveness of animal husbandry affects intrinsic meat quality and animal welfare still needs to be confirmed. This study, which is part of the EU-funded H2020-FNR-05 *mEATquality* project, aims to elucidate colour and water-holding biochemistry in chicken meat and clarify the function of proteomics biomarkers in the complex molecular pathways of muscle-to-meat conversion. We hypothesize that animal welfare linked to extensification factors such as genetics, diet, space availability and environmental enrichment changes the proteome of pectoralis major, leading to differences in broiler meat quality. In this project, variations in levels of structural proteins, mitochondrial enzymes, oxidative enzymes, chaperones and heat shock proteins in response to stressors would be expected to be associated with variations in colour and water-holding capacity in meat. We propose that animal welfare would change the dynamics of the aforementioned protein interactions, leading to differences in light scattering and water-holding capacity on broiler breast muscle. Final description to follow later.

Exploring YOLO deep learning model for goat detection in animal welfare and behavioural monitoring

A. Temenos, A. Voulodimos, D. Kalogeras and A. Doulamis

Institute of Communications and Computer Systems, National Technical University of Athens, Patission 42, 157 80 Athens, Greece; tasostemenos@mail.ntua.gr

In this paper, a fully automated monitoring system that detects welfare and behavioural traits in intensive farming systems is introduced. Animal health and welfare is strongly correlated with milk yield and composition, affecting dairy products' quality and safety, livestock farming trends and the dairy supply chain. Traditionally, animal monitoring is done through regular visits by veterinarians, who identify health and welfare issues based on the physical examination of the animals. However, the regular monitoring of large herds can be time-consuming and expensive for farmers. Automated procedures can detect early-stage behavioural changes and health issues (e.g. lameness) on a cost-efficient basis, without the continuous demand of an expert. You Only Look Once (YOLO) is a deep neural network capable of detecting objects in video scenes, utilizing results from a single convolutional network that predicts multiple bounding boxes and class probabilities. Its strengths are speed, accuracy, and well-generalization in real-world applications. YOLOv5 is a variation of the initial architecture that: (1) reduces number of layers; (2) reduces number of parameters; and (3) increases speed without any impact of performance. We train a YOLOv5 model to detect goats walking inside the barn, with annotated data from videos. The final dataset was split into 510 images for training, 25 for validation, and 48 for testing, after applying image processing algorithms for data augmentation (e.g. affine transformation). The proposed model achieved a 99.5% mean Average Precision. The YOLOv5 model presented in this work can detect goats inside the barn. Such detectors can be utilized for the automatic monitoring of behaviour (e.g. drinking and eating activity), and the early-stage detection of alterations in health and welfare status (e.g. lameness notification). In future work, we intend to apply tracking algorithms reading RFID tags, produce speed diagrams, and classify videos from healthy and non-healthy groups of animals. This work was funded by Code Re-farm Horizon 2020 project: 'Consumer-driven demands to reframe farming systems' (Grant No: 101000216).

The association between body condition score and the udder skin surface temperature in goats

V. Korelidou, A.I. Kalogianni and A.I. Gelasakis

Agricultural University of Athens, Department of Animal Science, Iera Odos 75, 11855 Athens, Greece; vkorelidou@aua.gr

The objective of the study was to assess the association between the body condition score (BCS) and the udder skin surface temperature (USST) in goats. For this reason, a prospective (S1) and a cross-sectional (S2) study were conducted. For the S1, 104 Skopelos goats from an intensive farm (A) were enrolled and recorded across one milking period. For the S2, 132 Skopelos goats from an extensive farm (B) and the 104 goats from farm A were studied at mid-lactation. Udder skin surface images were captured using a thermal camera (FLIR E8-XT, FLIR Systems Inc.), and the appropriate software was used to estimate the maximum and mean temperatures of teats (T1, T2), udder cleft (T3, T4), and udder halves (T5, T6), respectively. In addition, for each animal, the BCS was assessed using a 5-degree scale. Data were analysed using SPSS v26, and two linear regression models were built, with age, udder fibrosis occurrence (S1 and S2), lactation stage (S1), and farm (S2) being forced into the models as fixed effects, and the animal as random effect (S1), to estimate the effect of BCS on the USST (T1-T6). In S1, the range of means of T1, T2, T3, T4, T5, T6, and BCS were 32.9-37.3, 31.9-36.9, 36.3-38.0, 35.1-37.4, 37.1-38.4, 35.2-37.5, and 2.9-3.2 °C, respectively, while, a one-degree decrease in BCS was associated with 0.7, 0.9, and 0.6 °C increase in T3, T4, T6 ($P < 0.001$), respectively, and 0.3 °C in T5 ($P < 0.01$). In S2, mean values ($\pm$ SD) of T1, T2, T3, T4, T5, T6, and BCS were 34.2 $\pm$ 0.99, 33.0 $\pm$ 0.95, 36.8 $\pm$ 0.88, 35.2 $\pm$ 1.28, 37.6 $\pm$ 0.68, 35.6 $\pm$ 0.87, and 3.2 $\pm$ 0.33 °C, respectively, for farm A, and 35.1 $\pm$ 1.10, 34.2 $\pm$ 1.16, 37.3 $\pm$ 1.12, 35.8 $\pm$ 1.34, 37.9 $\pm$ 0.86, 36.2 $\pm$ 0.98, and 2.9 $\pm$ 0.22 °C, respectively, for farm B. In S2, a one-degree decrease in BCS was associated with 1.3 °C increase in T4 ($P < 0.001$), 0.8, 0.5, and 0.7 °C in T3, T5, and T6 ($P < 0.01$), respectively. Metabolic rhythms, and udder fat deposition are likely to be associated with the USST. However, further research to validate these findings and elucidate underlying mechanisms is warranted. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 101000216.

Leveraging the measuring and managing of livestock farms on the journey towards Net Zero*J. Gilliland**Queen's University Belfast, School of Biological Sciences, BT9 5DL Belfast, United Kingdom; john.gilliland@brookhall.org*

John Gilliland was recently appointed as a Professor of Practice at Queen's University Belfast, for his work on climate-smart farming. John started his journey on climate-smart farming on his farm back in 1988. Since then, he has participated in many different roles which have given him a breadth of knowledge which he has put to good use in accelerating livestock farmers' journey to Net Zero. Between his previous roles as a practitioner; farm leader; policy advocate; regulator; researcher; and now chair of the EIP-Agri Operational Group, ARC Zero, his hands-on experience has delivered unprecedented engagement of the farming and the agriculture policy communities. John will share some of this journey which has secured the forensic measuring of on-farm emissions and carbon stocks, resulting in the empowerment of actual farmers with their net-carbon position, allowing them to make better quality and more informed decisions, thus accelerating their journey to Net Zero. In addition, this project has delivered dynamic peer-to-peer learning and secured public policy buy-in across Northern Ireland, not just on delivering Net Zero, but also in delivering other public goods, such as food production and improved water quality.

The role of carbon sequestration in organic dehesas ruminant farms*R. Casado¹, M. Escribano¹, P. Gaspar² and A. Horrillo¹*

¹*Faculty of Veterinary Science, Department of Animal Production and Food Science, Avda. de la Universidad, s/n, 10003 Cáceres, Spain,* ²*Faculty of Agriculture, Department of Animal Production and Food Science, Avda. Adolfo Suarez, s/n, 06007 Badajoz, Spain; andreshg@unex.es*

Agri-food production must not only guarantee food security for the growing world population, but also ensure the conservation of ecosystems by avoiding overexploitation of natural resources. Therefore, one of the main objectives for the agricultural sector is to adapt its production systems to new challenges, including its contribution to the fight against climate change and the reduction of greenhouse gas (GHG) emissions. The main objective of the regional project 'MitigaDehex' (IB20070) is to analyse extensive livestock systems in Extremadura as sustainable and active production models against climate change. In this sense, one of the systems most in line with these principles are the organic ruminant farms in dehesas in the southwest of the Iberian Peninsula (Spain). The aim of this study was to calculate the balance of GHG emissions. For this purpose, life cycle assessment was used, including the calculation of the carbon footprint and carbon sequestration in two different time horizons, one at 20 years and the other at 100 years. The Carbon Footprint was performed following the IPCC 2019 guidelines and the proposed national GHG emissions inventories adapted to the characteristics of extensive livestock systems. For carbon sequestration, the livestock-manure-grassland system proposed by Petersen in 2013 was used. The functional unit used was kg of CO₂ equivalent per kilogram of live weight (FU) and also per hectare (ha). Organic meat sheep and beef cattle farms were analysed, which were differentiated according to their farming system. The carbon footprint of the sheep meat farms was 12.27 kg CO₂ eq/FU in the group 'sale lambs 18.5 to 20 kg' and 11.27 kg CO₂ eq/FU in the group 'sale lambs 20 to 23 kg'. In beef cattle, the carbon footprint was 14.92 kg CO₂ eq/ FU in calf farms and 7.04 kg CO₂ eq/ FU in yearling farms. Regarding carbon sequestration, the results show that organic farms in dehesa areas can function as true carbon sinks, since carbon sequestration through pasture and manure can offset a large part of the GHG emissions produced by livestock farming.

Estimating soil carbon sequestration gaps for ruminant systems across the globe

Y. Wang¹, I. Luotto², Y. Yigini², R. Vargas², D. Wissner³, T.P. Robinson³, U.M. Persson⁴, C. Cederberg⁴, R. Ripoll-Bosch¹, I.J.M. De Boer¹ and C.E. Van Middelaar¹

³Food and Agriculture Organization of the United Nations, Animal Production and Health Division, Vialle de Terme di Caracalla, Rome, Italy, ⁴Chalmers University of Technology, Physical Resource Theory, Department of Space, Earth & Environment, Chalmersplatsen 4, 412 96 Göteborg, Sweden; corina.vanmiddelaar@wur.nl

Soil carbon sequestration is a potential way of greenhouse gas (GHG) mitigation in livestock systems, especially for ruminants, a major contributor to methane (CH₄) emissions. The sequestration, however, is time-limited, and there are intrinsic differences between long- and short-lived GHGs, which cannot be reflected by the current widely used GHG metrics. We use GHG metric parametrization to equate the climate impact of carbon sequestration with a continuous flow of emissions, showing that one ton of carbon can offset 0.99 kg CH₄ or 35 kg nitrous oxide (N₂O) per year over 100 years. The conversion factor was applied to estimate the 'carbon sequestration gap', being defined as the difference between current and required carbon sequestration levels to offset emissions, for ruminant systems across the globe, using regional estimates of ruminant emissions and soil carbon sequestration values for grasslands. Results show that at global level, current sequestration levels are far less than the 135 gigatonnes of carbon required to offset annual emissions of CH₄ and N₂O from the ruminant sector. To effectively contribute to climate change mitigation, a combination of strategies will be required, including reduction in animal numbers and improved land use management. This study calls for critical thought regarding the approach and implications of valuing soil carbon sequestration as a means to offset the climate impact of GHG emissions by ruminant systems.

Agronomic and environmental impacts of sheep integration in cover crop management in Wallonia

N. Lorant, B. Huyghebaert and D. Stilmant

Walloon Agricultural Research Centre, Rue du Serpont 100, 6800 Libramont, Belgium; nicolas.lorant@cra.wallonie.be

Cover crops valorisation by sheep offer a new partnership between breeder and cash crop producer to support the development of the sheep sector in Wallonia, which covers only 16% of national sheep meat needs. During 2 years, in the 'SERVEAU' project (SPGE funding), 10 trials including three levels of grazing intensity (non-grazing, partial grazing and total grazing) were performed. Between 15 July and 10 September, a cover crop was sown. The grazing period extends from late October to mid-January. During the time spent on the plot, sheep destroyed 80 to 93% of the available biomass reaching an ADG of 70 g/d. To characterize the risks of nitrogen leaching, soil samples (0-30, 30-60, 60-90 cm) have been taken at different periods: cover crop sowing, after grazing, in the middle of winter and at the end of winter. According to the trials, spring crops were sown post-grazing (sugar beets, chicory, peas, beans, potatoes or corn) and their developments were followed. Soil analyses carried out at the implantation of cover crops show great variability in nitrogen residues. However, at each site, the amount of mineral nitrogen present in the soil has decreased thanks to cover crops. Soil analyses indicate a significant increase (+11 kg N/ha) in nitrogen content in the first 30 centimetres of soil following grazing, regardless of the intensity applied. This difference was no longer noticeable when the entire profile was considered (0-90 cm). Similarly, at the end of winter, there was no significant differences between the treatments. For the next spring crop, no significant differences were observed in either the emergences or the yields. Cover crops grazing could also lead to a reduction in cropping interventions for their destruction. Destruction by sheep allows the farmer to avoid a mechanical destruction, generating a gain of 384€/ha. Moreover, a breeding system combining rearing in sheepfolds and cover crop grazing makes it possible to reduce the environmental impact by 33% in kilograms of CO₂eq/kg of meat produced. This renewed interest in this practice offers several diversification opportunities within the farm but also at territorial scale.

Carbon footprint assessment of Korean native beef cattle and options to achieve net-zero emissions

R. Ibdhi¹, T. Kim², J. Byun², R. Bharanidharan³, Y. Lee⁴, S. Kang^{2,3} and K. Kim^{2,3}

¹Agroécologie, INRAE, Institut Agro, Univ. Bourgogne, Univ. Bourgogne Franche-Comté, 17 rue Sully, Dijon Cédex, 21065, France, ²Graduate School of International Agricultural Technology, Seoul National University, Pyeongchang, 25354, Korea, South, ³Institutes of Green-Bio Science and Technology, Seoul National University, Pyeongchang, 25354, Korea, South, ⁴National Institute of Animal Sciences, Rural Development Administration, Jeonju-si, 54875, Korea, South; ibidhi_ridha@hotmail.fr

In the context of global climate change, many countries are committed to achieve carbon neutrality by 2050. The carbon footprint (CF) indicator was proposed as an metric to assess greenhouse gas emissions (GHG) from beef production systems. The aims of the study were (1) to determine the CF of Korean native beef cattle (Hanwoo), and (2) to identify the major contributors to GHG emissions using life cycle assessment (LCA) method at farm-gate, expressed as a carbon dioxide equivalent (CO₂-eq) per kg live body weight (LBW). This study, based on data from a sample of 107 beef farms from nine Korean provinces. This analysis was used to identify options for mitigating GHG emissions using artificial neural networks (ANN). We generated 35 randomized scenarios of activity combinations at farm scale and evaluate associated GHG flux. The CF averaged to 8.2 CO₂-eq/kg of LBW and ranged from 3.9 to 13.8 CO₂-eq/kg of LBW. Results indicated that the largest source of GHG comes mostly from enteric fermentation (73%), followed by manure management (16%), manure and fertilizer land application (8%) and energy consumption (3%). Methane accounted for 86% of total emissions, originating from enteric fermentation and manure management. Nitrous oxide and CO₂ accounted for 11.6 and 2.8% of total GHG emissions, respectively. The modelled combination scenarios using ANN indicated that shortening the fattening period, limit the dry matter intake, coupling fattening with crop production and using organic fertilizer instead of synthetic fertilizer) seems to be the most effective strategy that can reduce the CF of Hanwoo meat by 56%. This study, suggest as well to consider the importance of soil carbon sequestration in developing GHG mitigation strategies.

Session 87

Carbon Footprint of organic beef from dairy male calves

L. Mogensen¹, T. Kristensen¹, C. Kramer², A. Munk³, P. Spleth³ and M. Vestergaard⁴

¹Aarhus University, Department of Agroecology, Blichers Alle 20, 8830, Denmark, ²Center for Frilandsdyr, Randers, DK 8940, Denmark, ³SEGES, Aarhus N, 8200, Denmark, ⁴Aarhus University, Department of Animal and Veterinary Sciences, Blichers Alle 20, 8830, Denmark; lisbeth.mogensen@agro.au.dk

Organic beef production has some challenges compared to conventional production, among other things because organic male calves in Denmark typically are raised as steers, which gives a high feed consumption per kg live weight gain and thus a high carbon footprint per kg carcass. Instead, raising organic young bulls will meet the desire, from both consumers and the political system, for organic foods with a lower carbon footprint per kg carcass. The objective was to develop new strategies for rearing organic young bulls, which consider genetic type, feeding intensity, time of year of birth, and age at slaughter with a focus on achieving the lowest possible climate impact. Ten strategies to produce organic young bulls – either pure Holstein breed or crossbred bull calves – were set up, as a combination of the time of year the calves are born, slaughter age, and feeding intensity. The effect of different production strategies was estimated by modelling. The carbon footprint per kg carcass including contribution from soil carbon changes was 32% lower for raising organic young bulls compared with that of organic steers. A strategy with high feeding intensity and slaughter at 13 months had the lowest carbon footprint per kg carcass (CF) due to the lowest feed consumption per kg LW gain and use of a high proportion (35% of DM) of concentrate. A strategy with slaughter at 17 months and high feeding intensity increased CF around 6% due to an increased feed consumption and reduction in feed conversion due to higher age at slaughter. A strategy with low feeding intensity and a slaughter at 17 months gave the highest CF. Using crossbred bull calves compared to purebred dairy bulls gave a 10-15% lower CF due to higher dressing percentage, higher carcass weight and higher growth rates.

Model to calculate the impact of interventions on the carbon footprint of dairy

A. Esselink

Trouw Nutrition, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands; allard.esselink@trouwnutrition.com

An LCA model for production of milk at farm level was developed with Pré consultants and an external expert. Goal is to quantify and compare the potential environmental impact of theoretical and actual milk production with different feeding and farming practices, such as implementation of nutritional programs, use of feed additives and manure management strategies for the respective geographical scope of the tool. The tool was developed conform ISO 14040:2006 and ISO 14044:2006 standards but also more specific guidelines, i.e. IDF (2022), PEF Guide, PEFCR of dairy products, PEFCR of animal feed. A herd dynamics model based on McLeod *et al.* is implemented to assure the number of animals born, calves for finishing and cull cows leaving the farm are in balance. Input parameters can be modified in such a way that the almost every farm situation across the globe can be described. The model can differentiate between the direct effect of an additive and the indirect effect of an intervention, like the reduction of age at first calving, which will reduce the total carbon footprint of milk. For instance, land use change, acidification, water use and eutrophication are calculated. In the application of the model, there are differences between direct effects of an additive that reduces enteric methane production and indirect effects of, for instance, a difference in milk production or animal numbers. In addition to the different global warming potential (GWP) figures, other environmental impact factors are also calculated. Using the tool, Trouw Nutrition can do an evaluation on the environmental effect of the different interventions in different situations. As an example, we took an average Dutch dairy farm, where in the model we applied the LifeStart concept. As input figures, age at first calving was reduced from 25.5 to 22.0 months, and the replacement rate from 30 to 25%. This intervention reduced the carbon footprint of the milk produced by 5%. The tool and the report written about the effect of the Trouw Nutrition solutions is externally reviewed to assure conformity with the mentioned ISO standards.

Tools to optimise the carbon footprint of milk production

D. Schwarz

FOSS Analytical A/S, Nils Foss Alle 1, 3400 Hilleroed, Denmark; das@foss.dk

It is estimated that about 14% of the total anthropogenic greenhouse gas (GHG) originates from global livestock production. Dairy farming is responsible for approximately 30% of these emissions. Dairy herd improvement (DHI) testing, meaning monthly collection and analysis of milk samples from individual cows, is broadly used for herd health, feeding, and management purposes around the globe. The objective of this study is to investigate the effect of DHI on GHG emission of dairy farms. Regular DHI results from Denmark (n=193,321) and Thuringia, Germany, (n=399,428) were available for data analysis. Mastitis is known to impair the performance of dairy cows and milk somatic cell count is used as a proxy for detection of (subclinical) mastitis. We found that the corrected (a generalized linear mixed models was applied) daily milk production of cows with 250,000 to 1,000,000 cells/ml (15% of test day results) was 3 kg and of those with >1,000,000 cells/ml (5% of test day results) was 6 kg below the production of cows with <250,000 cells/ml. These losses, in turn, translate into considerable GHG emissions, which were estimated to be 75 t of CO₂ and 78 t of CH₄ per day in Denmark alone assuming that the CO₂eq per kg milk is 1.28 kg. Such milk losses also lead to an increased GHG emission per kg of milk produced. The risk for having ketosis, a metabolic disorder in high-yielding dairy cows, can be estimated by determining milk beta-hydroxybutyrate and evident differences in milk yield between low (70% of test days) and high risk (30% of test days) cows were seen. Moreover, milk urea results provide highly valuable information on the protein content in feed and about 20% of test day results had elevated urea results indicating an oversupply of dietary protein. Milk fatty acid profiles can be used as another indicator to evaluate and optimise dairy cow feeding. In conclusion, our findings revealed that there is still potential to optimise productivity of cows and GHG emission per kg milk produced with respect to mastitis, ketosis and feeding. In this context, DHI testing programmes represent a practical and inexpensive tool for dairy farmers to manage and optimise herd health and feeding and thus productivity of their cows. This, in turn, is an essential component to achieve low GHG emission per kg of milk produced.

Evaluation of feed additives under varying diets of dairy cows on performances and enteric emissionsM.E. Uddin¹, M.R.A. Redoy¹, S. Ahmed¹, M. Bulness¹, D.H. Kleinschmit², J. Lefler³ and C. Marotz³¹South Dakota State University, SD, 57007, USA, ²Zinpro Corporation, MN, 55344, USA, ³Native Microbials Inc., CA, 92101, USA; mdelias.uddin@sdstate.edu

This abstract summarizes the effects of supplementing two feed additives, isoacids [IsoFerm (ISO); Zinpro Inc.] and a microbial product [Galaxis Frontier (GF); Native Microbials Inc.] on performances and enteric emissions. For ISO study, 64 Holsteins were used in a randomized complete block design trial (10-wk). In ISO study, cows were assigned to 1 of 4 diets (n=16; 16.5% CP, 1.29 Mcal/kg DM, and 28% NDF) with a 2×2 factorial arrangement, 2 forage level (FL) comprising 18 (LF) and 23% forage NDF (HF), without or with ISO supplementation (40 g/d). For GF study, 56 Holsteins were assigned to 1 of 2 diets in a randomized complete block design from -22 to 100 days in milk (DIM). A control diet (CON; n=29) and GF diet (CON + 5 g/d of GF; n=29), consisting of a similar basal close-up (1.29 Mcal/kg DM and 10.8% CP) and lactation diets (1.67 Mcal/kg DM and 15.3% CP) were used. Enteric methane (CH₄) was measured using GreenFeed (C-Lock Inc.). Supplementation of ISO did not affect dry matter intake (DMI) but increased milk yield (MY, 35.0 vs 30.8 kg/d; $P<0.01$) and fat-and-protein corrected milk (FPCM; 36.8 vs 33.4 kg/d; $P=0.01$) only in the HF diet. Similarly, ISO increased feed efficiency (FPCM/DMI) in the HF diet but decreased in the LF diet ($P=0.03$). Importantly, ISO decreased CH₄ intensity by 9% (9.7 vs 10.7 g/kg MY; $P=0.01$) and tended to reduce CH₄ production (332 vs 361 g/d; $P=0.07$) regardless of FL. Supplementation of GF tended to increase MY (39.7 vs 37.1 kg/d, $P=0.08$) and feed efficiency (+0.11, MY/DMI) during early (0 to 30 DIM) and mid-lactations (31 to 100 DIM), respectively. However, GF reduced plasma glucose and paraoxonase but increased BHB (0.49 vs 0.37 mmol/l; $P=0.03$), with a tendency to surge the abundance of lactate-utilizing bacteria (*Megasphaera elsdenii*) and drop the cellulolytic bacteria (*Fibrobacter succinogens*; $P=0.07$). Overall, ISO and GF enhanced the performances and efficiency of cows, while GF altered rumen bacterial abundance and ISO decreased enteric CH₄ emissions. Rumen microbiota modulation by the ISO and the potential of GF to reduce CH₄ under varying diets need to be tested.

Session 87

Theatre 10

Supplementation with a calcium peroxide additive mitigates enteric methane emissions in beef cattleE. Roskam^{1,2}, D.A. Kenny^{2,3}, V. O'Flaherty¹, A.K. Kelly³ and S.M. Waters^{1,2}¹University of Galway, School of Natural Sciences and Ryan Institute, Galway, H91TK33, Ireland, ²Teagasc Grange, Animal and Bioscience Research Department, Dunsany, Co. Meath, Ireland, ³University College Dublin, School of Agricultural and Food Science, Dublin, D04 V1W8, Ireland; emily.roskam@teagasc.ie

In Ireland, the agricultural sector is responsible for 38% of GHGs, 60% of which are methane (CH₄). Globally, GHGs need to be reduced rapidly to adhere to legally binding targets. While research into dietary supplementation with anti-methanogenic feed additives has proliferated, there are still limited products showing consistent CH₄ reductions, many of which cannot be pelleted due to sensitivity to temperature and pressure. Calcium peroxide (CaO₂) is a widely available, non-toxic, inexpensive compound, which has been shown to have anti-methanogenic effectiveness based on modulating the oxidation-reduction potential of the rumen. In this study, the effect of twice daily supplementation of CaO₂ to beef bulls on CH₄ and H₂ emissions and animal productivity was assessed. Seventy two beef bulls offered a 60:40 forage:concentrate diet were allocated silage each morning (09:00 h) and concentrates at 08:00 and 15:00 h. Following a 7 d covariate period, animals were offered 1 of 4 treatments; Control (unsupplemented), Low (1.35% CaO₂), High (2.25% CaO₂) and Pellet (High, pelleted) (n=18). All concentrates were formulated in a coarse ration, except for Pellet. CH₄ and H₂ were measured using GreenFeed systems. Data were analysed using ProcMixed, SAS 9.4. No effect on animal ADG or FCR was observed ($P>0.1$), however High reduced DMI compared to Control ($P<0.05$). All treatments reduced CH₄ emissions when expressed per day, per kg ADG and per kg DMI ($P<0.0001$). Low reduced CH₄ parameters by 17-21%. High and Pellet reduced CH₄ g/d, g/kg ADG and g/kg DMI by 28 and 27, 29 and 28, and 20 and 27% ($P<0.0001$) respectively. A 36, 35 and 32% reduction in H₂ ($P<0.0001$) was observed for Low, High and Pellet. CaO₂ can successfully endure the pelleting process and reduce CH₄ and H₂ emissions with no negative effects on animal production, making it a viable CH₄ mitigation option for pasture based systems with concentrate supplementation.

Methane emission from rosé veal calves feed a corn cob silage-based or grass silage-based ration

A.L.F. Hellwing and M. Vestergaard

Aarhus University, Campus Viborg, AU Foulum, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark; mogens.vestergaard@anivet.au.dk

The rosé veal calf production in Denmark is characterized by high daily growth rates and energy rich diets. Farmers feeding total mixed rations normally use whole-crop or corn-cob silage. However, use of grass silage-based rations has never been used in specialized rosé veal calf operations. Corn cob silage and grass silage differ considerable in starch and NDF, and this might affect the methane emission from rations based on either corn cob or grass silage. The aim of the experiment was to investigate the methane emission from rosé veal calves fed energy rich rations based on either grass silage and grains or corn cob silage and grains. Thirty-two Holstein calves were selected from a production experiment in which the calves were fed these rations from 3½ month of age. The grass silage-based ration (GB) included rolled barley, 1. cut grass silage (25-35% of dry matter) and untoasted milled fava beans, and the corn cob silage-based ration (CB) included corn-cob silage (40% of dry matter), rolled barley and rapeseed meal. Crude protein, NDF, starch, and NE were similar for the two rations. The enteric methane was measured when the calves were 8-month old by means of indirect calorimetry over three days. The data was analysed with PROC MIXED in SAS with ration as a fixed effect. The results showed that the dry matter intake did not differ between the two rations ($P=0.88$) and was on average 7.1 ± 1.1 kg (mean $\pm$ std). The average weight was 337 ± 25 kg with no difference between the two treatments. The methane emission tended to differ ($P=0.07$) with 128 g/day for GB and 112 g/day for CB. The methane emission per kg dry matter was 18.1 and 16.1 g/day for GB and CB, respectively ($P=0.14$). The methane emission per kg metabolic body size tended to differ ($P=0.07$) and was 1.63 and 1.42 g/kg BW^{0.75} for GB and CB, respectively. In conclusion, the results did not show any difference in DMI, methane emission per day or per kg dry matter intake in rosé veal calf feed either a grass silage-based or a corn cob silage-based ration with similar chemical composition.

Session 87

Theatre 12

Feeding a starch and protein binding agent for mitigating enteric methane emissions in sheepP. Prathap¹, S.S. Chauhan¹, J.J. Cottrell¹, B.J. Leury¹ and F.R. Dunshea^{1,2}¹The University of Melbourne, School of Agriculture and Food, Faculty of Science, Melbourne, VIC 3010, Australia, ²The University of Leeds, Faculty of Biological Sciences, LS2 9JT Leeds, United Kingdom; pprathap@student.unimelb.edu.au

This study investigated the effect of heat stress (HS) and wheat treated with a starch and protein binding agent (Bioprotect®) on the enteric methane (CH₄) emissions in sheep. All experimental procedures were approved (Ethics ID:1914950.1) by University of Melbourne animal ethics committee. Twenty-four one-year-old merino lambs (42.6 $\pm$ 3.6 kg) were randomly allocated to 3 dietary treatment groups that included a wheat based diet (WD), a 2% Bioprotect treated wheat-based diet (BD) and a maize based diet (MD). All diets contained 50% grain, 25% oat chaff and 25% lucerne chaff. Animals were subjected to 3 consecutive experimental periods of 1 week each. During period 1 (P1), animals were fed 1.7 $\times$ Maintenance energy (ME) level and kept under a thermoneutral environment (18-21 °C and 40-50% relative humidity; RH). During period 2 (P2) sheep fed at 1.7 $\times$ ME level were exposed to HS (28-40 °C and 30-50% RH). During period 3 (P3) sheep were fed at 2 $\times$ ME level during HS. Sheep fed BD had lower CH₄ production than WD fed sheep with MD being intermediate (25.0, 19.3, and 32.4 g/day for WD, BD, and MD respectively; $P<0.001$). Sheep showed the highest CH₄ production under thermoneutral conditions compared to during HS (28.5, 23.0 and 25.2 g/day for P1, P2, and P3 respectively; $P<0.04$). There was no significant interaction between diet and period, indicating that BD reduced CH₄ emission in sheep irrespective of controlled environmental conditions. Further, whole tract dry matter digestibility was greater for BD fed sheep followed by WD and MD fed sheep (83.0, 84.2 and 81.4% for WD, BD, and MD respectively; $P<0.001$) and was higher during P2 (82.7, 83.4 and 82.6% for P1, P2, and P3 respectively; $P<0.001$) than P1 and P3. In conclusion, sheep consuming the WD had lower CH₄ emissions than those fed MD and this was further decreased by treating the wheat component Bioprotect®. Further, the results indicate that HS exposure decreases CH₄ production in Merino sheep.

Neutralization of bovine enteric methane emission by the presence of trees in a silvopastoral system

J.R.M. Pezzopane, H.B. Brunetti, P.P.A. Oliveira, A.C.C. Bernardi, A.R. Garcia, A. Berndt, A.F. Pedroso, A.L.J. Lelis and S.R. Medeiros

Embrapa Pecuária Sudeste, Rod. Washington Luis, Km 334, 13563-970, São Carlos, Brazil; jose.pezzopane@embrapa.br

Trees in silvopastoral systems (SPS) serve as carbon sink, especially when used for lumber. Our aim was to evaluate whether carbon fixation by trees could neutralize the bovine enteric methane emission in a SPS following the Neutral Carbon Brazilian Beef (NCBB) protocol. The study was conducted at Embrapa Pecuária Sudeste, São Carlos, SP, Brazil from Dec-2017 to Feb-2019 in a SPS comprised of *Urochloa brizantha* (syn. *Brachiaria brizantha*) (Hochst ex A. Rich.) Stapf cv. BRS Piatã and *Eucaliptus urograndis* (GG100 clone). The SPS was established in 2011 spaced 15×2 m (oriented east-west) and thinned to 15×4 m in 2016. In four 3 ha modules with six paddocks each, Nellore and Canchim (5/8 Charolais + 3/8 Zebu) finishing bulls were managed under rotational stocking. The enteric methane emission was estimated by the IPCC Tier 2 equation using average live weight (ALW), average daily gain (ADG), forage digestibility and intake of each grazing cycle as inputs. Allometric equations were used to estimate tree stem biomass, using the diameter at breast height (DBH) and height of fifteen trees per paddock. The results were multiplied by 0.4549 to adjust for carbon content. The mean ALW was of 473.16 kg with ADGs ranging from 0.48 in the winter to 0.94 kg/day in the summer, resulting in an emission rate of 2.2 Mg CO₂ eq./AU/yr. The DBH and tree height at the end of the experiment were of 29.9 cm and 30.5 m, respectively, resulting in 12.7 Mg stem biomass/ha and a fixation rate of 20.9 Mg CO₂ eq./ha/yr. When considering three scenarios: all the trees (those thinned in 2016 and the remaining ones); only the trees remaining after the thinning; and only 40% of the stem volume in the second scenario as suitable to be used as lumber, the trees in the SPS neutralized the emission of enteric methane relative to 9.4, 6.7, and 2.3 AU/ha, respectively. Even in the worst scenario, the trees neutralized the emission of bovine enteric methane relative to a stocking rate above the Brazilian average. Dairy goat farms in Extremadura: carbon sources and sinks in several management systems

L. Madrid¹, M. Escribano¹, P. Gaspar² and A. Horrillo¹

¹Faculty of Veterinary Science, Department of Animal Production and Food Science, Avda. de la Universidad, s/n, 10003 Cáceres, Spain, ²Faculty of Agriculture, Department of Animal Production and Food Science, Avda. Adolfo Suárez, s/n, 06007 Badajoz, Spain; andreshg@unex.es

The fight against climate change has become a major challenge for animal food production systems due to the emission of greenhouse gases (GHG). Nowadays, society links the consumption of food of animal origin to a deterioration of the environment. This is certainly not only detrimental to food production, but all animal production systems are considered to have the same impact. This study analysed the Carbon Footprint (CF) of several management systems of goat farms in northern Extremadura. A total of seven cases were selected, grouped into three production models: intensive, semi-intensive and semi-extensive. The study is part of a regional project (MitigaDehex; IB20070) whose main objective is to analyse extensive dehesa livestock systems in Extremadura (SW Spain) as sustainable and active production models against climate change, and its specific objective is to calculate the GHG balance of these livestock production systems. The analysis was carried out using Life Cycle Assessment (LCA) and the HC was calculated following the IPCC 2019 methodology. In addition, carbon sequestration was included in this calculation, with the aim of assessing the contribution of goat farming to climate change depending on its production and feed management. The results show that enteric fermentation is the main source of on-farm emissions (50-58.9%), followed by emissions from off-farm feeding (15.9-30.71%), whose variability depends on the type of production system. In addition, there are differences among the three groups in the study, with an increase in GHG emissions per litre of milk produced (FU) linked to the intensification of livestock systems. Thus, the role of soils and their capacity to act as carbon sinks in grazing systems is relevant, showing mitigation potential with a carbon sequestration of 0.29 kg CO₂ eq./FU up to 1.9 kg CO₂ eq./FU depending on the type of farm. At present, studies that analyse the real impact of GHG emissions from livestock farming under different production models are necessary and, in particular, goat milk production is one of the most neglected.

Life cycle assessment of IntelliBond on the carbon footprint of a dairy farm

D. Brito De Araujo, K. Perryman and J.G.H.E. Bergman

Nutreco, Selko, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands; davi.araujo@selko.com

According to FAO, 14.5% of global greenhouse gas emissions are related to farming. Out of the total emissions, 58% originate directly from cows, with 42% coming from farm operations. Pressure from milk processors on farmers to reduce their carbon footprint continues to increase. Thus, a life cycle assessment accessing the impact of Selko IntelliBond trace minerals was conducted to determine its impact on the carbon footprint of dairy cattle. A meta-analysis of 11 peer reviewed studies has demonstrated that by replacing sulphate-based zinc, copper, and manganese with IntelliBond, an improvement in NDFd of 1.7% can be achieved. University research has demonstrated that each one point of difference in NDF can result in a predicted increase of Energy Corrected Milk (ECM) of 0.25-0.3 kg. These studies were then evaluated by an independent, third-party expert utilizing an ISO compliant model (ISO 14040, 14044) to predict the potential impact of IntelliBond vs sulphate trace minerals on the carbon footprint per kg of ECM. Data from this exercise indicates that a reduction of the carbon footprint of 1.5-2.0% per kg of ECM can be expected when sulphates are replaced by IntelliBond.

Poster 16

Effects of supplementation of *Asparagopsis taxiformis* as a means to mitigate methane emission

M. Angellotti, M. Lindberg, M. Ramin, S.J. Krizsan and R. Danielsson

Swedish University of Agricultural Sciences, Depart. Animal Nutrition & Management, Ulls väg 26, 753 23 Uppsala, Sweden; melania.angellotti@slu.se

Methane emissions from feed digestion in ruminants contribute significantly to anthropogenic greenhouse gas emissions globally. The red algae *Asparagopsis taxiformis* (AT) has been reported to have high potential to reduce methane emissions when fed to ruminants. AT is rich in halogenated methane analogues, such as bromoform, which is able to block the methanogenesis in the rumen, but all mechanisms and effects on animal physiology are not well understood. Hence, the aim of this study was to investigate addition of AT in dairy cow diets and evaluate the effects on enteric methane and hydrogen production, feed intake and milk production in dairy cows. Thirty cows fed a total mixed ration were blocked according to parity and days in milk and randomly assigned to one of three dietary treatment groups with different inclusion levels of AT in % of organic matter; a control group with no AT (CON), a group with 0.15% AT (LOW) and a group with 0.3% AT (HIGH) for 12 experimental weeks. Individual feed intake and milk yield were recorded automatically throughout the trial. Milk composition was determined by collecting milk samples fortnightly, enteric methane and hydrogen levels were measured continuously by the GreenFeed system. Statistical analyses were performed by using the MIXED procedure of Rstudio, treatment and experimental week was included as fixed effects and the random effect of block was used. Week was considered as repeated measurement. The results showed a significant reduction in methane production in the HIGH group by 30%, with a concomitant increase in hydrogen from the breath. However, the level of decrease in methane was not stable over time. Feed intake and energy corrected milk yield were lower in the HIGH group compared to the other two groups, which decreased by 6 and 2%, respectively. In conclusion, using AT as additive in dairy cows' feed rations allows for mitigation of enteric methane emissions, however, a reduction in feed intake with a concomitant decrease in milk production was also observed. Additional research on AT as enteric methane inhibitor is necessary since the effects appear to be dosage-dependent and change over time.

Trace element concentrations in feed ingredients: previously overlooked, now under the spotlight*M. López-Alonso**University of Santiago de Compostela, Animal Pathology, Veterinary Faculty, 27002 Lugo, Spain; marta.lopez.alonso@usc.es*

Trace minerals are part of numerous enzymes and coordinate a great number of biological processes, being essential to maintain animal health and productivity. Trace element deficiencies are very frequent worldwide. They are linked to an insufficient intake in trace elements (primary deficiencies) or to the interaction with other elements (by competitive and non-competitive mechanisms) that inhibits its absorption (secondary deficiencies). To avoid trace element deficiencies and maintain a high standard of production, diets of animals have been traditionally supplemented well above the physiological requirements, greatly overlooking the background trace element concentration of the feed materials. This was possible because rations can be formulated with large 'safety margins' so that trace element intakes generously exceed requirements without important risk for the animal health, assuming that timely supplementation of complete trace minerals was an inexpensive insurance that well worth the cost. These large safety margins even allowed to use some minerals as growth promoters: the classical example being Cu and Zn supplementation in pigs and poultry. The extensive use of these trace elements in intensive farming has led to serious environmental problems that need an urgent solution. Even representing less than 1% of total feed ingredients consumed in Europe they have a great environmental footprint, showing the highest contribution to freshwater and marine ecotoxicity and to a metal depletion due to the fact they are non-renewable resources. In times of higher production costs and changing consumer and environmental demands a tailor-made mineral supplementation is needed, what has been called precision mineral feeding, to really provide the trace elements each animal demand. Not all animals need the same trace element intakes and aspects as growth rates, stress factors (in example heat) or antibiotic-free diets should be addressed. Having in mind that quality and not only quantity of trace elements should be considered, and background concentrations of feed materials be carefully analysed, both quantitative and qualitatively, since they will be in most cases the main sources of trace elements in the animal diet.

Theatre 2

Review on native Se concentrations in feed ingredients*D. Cardoso and A. Hachemi**Adisseo, 10 Pl. du Général de Gaulle, 92160, France; denise.cardoso@adisseo.com*

This review aims to assess the amount of Se in feed ingredients and its species, that can influence the bioavailability and the metabolism in the animal. Selenium (Se) is an essential nutrient that plays a vital role in the antioxidant system of animals. In feed, the total Se concentration is recommended to be of 0.5 ppm to meet animal requirements. However, Se content of feed ingredients greatly varies depending on many different factors. Se concentration in corn and rice grown in normal and high Se areas can vary 100-500-fold. Animal by product such as fish meal can represent up 5 ppm of Se, but it known to have a low bioavailability. Indeed, average data on Se content in feedstuffs presented in various tables are not suitable for diet balancing and Se supplementation is a routine practice in commercial animal production, which is why a Se supplementation is a common practice worldwide. Selenium in feed is mainly derived from the soil, with its concentration varying significantly between 0.1 and 2 ppm. However, the bioavailability of Se for plants is largely dependent on its form rather than its total concentration. The forms of Se in soil include selenides, elemental Se, selenites, selenates, and organic Se compounds. The transfer of the selenium from soil to plant and distribution into various parts also depends on plant species; that differ markedly in their ability to incorporate Se into tissues. Se in plants exists in different forms, being the majority in the form of seleno aminoacids, such as selenomethionine (SeMet), that makes up more than half of the Se in cereal grains, grassland legumes, and soybeans. SeMet is primarily stored in the grain and the root, while lower concentrations are found in the stems and leaves. Interestingly, plants supplemented with different forms of Se metabolize Se differently. For example, selenite-supplied plants accumulate organic Se, likely SeMet, while selenate-supplied plants accumulate selenate. In summary, the Se concentration in feed will mainly depend on the Se soil concentration and its specie.

Does USEtox predicts adequately Cu and Zn ecotoxicity in soils amended with animal effluents?*E.P. Clement^{1,2}, M.N. Bravin², A. Avadi^{2,3} and E. Doelsch²**¹Ademe, 20 avenue du Grésillé BP-90406, 90406 Angers, France, ²CIRAD, Avenue Agropolis TAB-78/01, 34398 Montpellier cedex 5, France, ³ESA/INP-HB, Yamoussoukro, Cote d'Ivoire; emma.clement@cirad.fr*

Animal effluents (AE) are of interest to substitute mineral fertilizers in agriculture. They are, however, a major contributor to soil chronic copper (Cu) and zinc (Zn) contamination that are provided in animal feeds and may exert toxic effects on soil organisms and reduce soil fertility. These negative impacts question the long-term sustainability of agricultural AE recycling. To estimate the terrestrial ecotoxicity of Cu and Zn, a novel method was proposed involving the USEtox model for life cycle impact assessment. It computes the comparative toxicity potential (CTP) of trace elements via pedo-transfer functions and by decomposing it in four characterization factors: fate, availability, bioavailability and toxicity towards soil organisms. Beyond the interest of this model, its relevance in the context of AE recycling in agriculture is unknown. We empirically assessed how this model is adapted to estimate ecotoxicological impact of Cu and Zn in an AE-amended agricultural soil. A 26 day-long incubation of the soil with or without 31 AE was carried out in controlled lab conditions that mimic a field application. The AE were pig or broiler faeces, showing distinct Cu and Zn concentrations due to different feed. Initial soil properties (clay, soil organic matter, pH and Al/Fe oxides) were analysed to inform the model. Soil properties (pH, dissolved organic matter – DOM) and Cu and Zn availability in soil and soil solution, matching the CTP characterization factors, were measured at the end of the incubation in each soil-AE mixture. Empirically-determined CTPs were different by up to 1.5 log unit from the model estimations for Cu, 0.3 for Zn. The CTP variability measured after AE application in our experiment was comparable to the variability observed for world-wide soils. One explanation is the overestimation of DOM concentration and the lack of consideration of DOM binding properties in soil. Our results overall support the need to improve the model for its application to agricultural AE recycling. This will fuel our ability to assess the environmental impacts of feed trace minerals in animal productions.

Session 88

Theatre 4

Challenges in establishing the mineral composition of feed materials*G. Tran and V. Heuzé**Association française de zootechnie, 22 place de l'Agronomie CS 20040, 91123 Palaiseau Cedex, France; gilles.tran@zootechnie.fr*

Knowledge of the mineral composition of feeds is critical for livestock nutrition. Inadequate mineral supply results in performance and health problems while excess dietary minerals is detrimental to the environment. However, minerals remain secondary in feed analysis. To examine this issue, we will use the French Feed Database (FFD), which has collected since 1989 about 3 million analytical values on feed materials from laboratories. The first problem is that of data availability. Mineral analyses account for 12% of FFD data. There are fewer values for the 33 mineral elements in the FFD than there are for protein. These data are skewed toward macro minerals. Ca, P, K, Mg, Na and Cl represent 81% of the mineral data, with Ca and P each accounting for 29%. The main trace elements (Cu, Mn, Zn, Fe, S) represent 12% of mineral data, while the 22 other elements represent less than 5%. There are about 200,000 values for Ca and P while iodine is represented by only 550 values. Data are sufficient for macro minerals in major feed materials such as maize grain, but, for lesser feeds, it is common that few values are available for macro minerals, and less than 5 or none for trace elements. The second issue is that of variability. The mineral composition of feeds depends on factors such as geography, soil type, climate, and farming practices, but the range of mineral values is much greater than that of constituents like protein, with factors of ten or more between the minimum and maximum values: in maize, Ca varies from 0.1 to 2.2 g/kg DM while Mn varies from 3 to 56 mg/kg. This large variability, which can be sometimes explained by soil contamination at harvest or during storage, makes the notion of representative data much harder to assess and correlate with other factors. This problem is compounded by the lack of relations of mineral elements with other constituents, including crude ash. In conclusion, while significant numbers of data are available to establish the mineral composition of feeds, there are still gaps in knowledge that need to be addressed. The development of quicker analytical methods and the collection of more comprehensive data on the mineral composition of both traditional and novel feed materials will be crucial in improving the nutritional management of livestock.

Swiss feed database: mineral and trace element composition of feedstuffs

M. Lautrou¹, E. Manzocchi² and P. Schlegel^{1,2}

¹Agroscope, Swine Research Group, Rte de la Tioleyre 4, 1725 Posieux, Switzerland, ²Agroscope, Nutrition and Emissions Research Group, Rte de la Tioleyre 4, 1725 Posieux, Switzerland; marion.lautrou@agroscope.admin.ch

Feeding animals as close as possible to their needs has become a priority, with the idea of limiting excretions of certain elements such as copper or zinc and reducing the use of limited resources such as mineral phosphate. For this purpose, it is necessary to precisely know the animal requirements but also to properly characterize the native mineral and trace element composition of feedstuffs. It is for this second objective that the Swiss feed database is a useful tool. The Swiss Feed database gathers the chemical composition of feedstuffs used in Switzerland since the late 1980s until today. This online database presents the mineral (Ca, P, Mg, K, Na, S and Cl) and trace element (Fe, Cu, Zn, Mn, Co and Se) composition of any feedstuff analysed by Agroscope and by two private laboratories. The list of feedstuffs is large: cereal grains (barley, maize, rye, wheat, and others), cereal co-products from milling, starch industry or distillery, oil seeds and co-products, tuber and roots, milk co-products, mineral feeds and so on. In addition to the nature of the raw material, the year of production, the canton of origin and the altitude are available. These data can be used individually but are also exploited to define the Swiss reference values of each feedstuff. Then, in contrast to reference tables available in other countries, the values available for trace element are all from feedstuffs analysis and not from the literature. This Swiss feed database provides the opportunity to regularly create reference tables, according to origin or years, for the actors of the animal production field. Based on this database, we will present the evolution of the mineral and trace element composition of selected feedstuffs through years, and study the effect of their origin. Then, we will also compare these values to others reference values (from France and North America). We will also present the contribution of minerals and trace elements supplied by feedstuffs relative to the requirements of pigs.

Session 88

Theatre 6

Overview of international aquaculture feed formulation database with reference to mineral nutrition

D.P. Bureau¹, L. Manomaitis² and F.M. Damasceno³

¹University of Guelph, Dept. of Animal Biosciences, 50 Stone Rd East, N1G2W1, Guelph, Ontario, Canada, ²USSEC, SEA Aquaculture, 541 Orchard Rd, Singapore 238881, Singapore, ³Wittaya Aqua International, 1 University Avenue, Toronto, Ontario, Canada; dbureau@uoguelph.ca

The great diversity in species cultivated and culture conditions encountered in aquaculture result in a need for a great diversity of feeds of different composition. These feeds are formulated with an ever-increasing portfolio of ingredients. Cost-effective feed formulation requires accurate information on composition of ingredients and requirements of animals across their life cycle. The International Aquaculture Feed Formulation Database (IAFFD.com) is a free online open-access resource supported by USSEC (ussec.org) and Wittaya Aqua International (wittaya-aqua.ca) that helps meet the need of the industry. It is comprised of two main sub-databases: (1) Aquaculture Species Nutritional Specifications (ASNS); and (2) Feed Ingredient Composition Database (FICD). The databases are designed to be easily imported in least-cost feed formulation software. The ASNS contains detailed nutritional specifications for over 35 species at different weight ranges. Most of these nutritional specifications are generated using a nutritional modelling approach. The models and specifications are constantly updated. The FICD contains detailed information on the chemical composition for more than 700 ingredients. The information is compiled from different sources, reconciled, and regularly updated. The ASNS provides specifications for macro and micro minerals. The large number of species cultivated makes it a challenging task to develop accurate recommendations. Macro and micro-mineral composition of feed ingredients are reported in the FICD. However, information on the concentration in minerals of ingredients is often limited. There is also limited information on the digestibility and bioavailability of minerals of ingredient. This is complicated by the fact that digestibility of minerals is largely influenced by the GI physiology of animals and interactions with dietary components. Many stakeholders are involved in R&D efforts on minerals in animal nutrition and their contribution to improving the IAFFD would be highly valuable.

Mineral analysis: opportunities and limitationsP. Berzaghi¹, R. Fornaciari², M. Dorigo² and G. Cozzi¹¹University of Padua, Animal Medicine Production and Health, Viale Dell'Università 16, 35020, Italy, ²Nutristar S.p.A, Via del Paracadutista 9, 42122 Reggio Emilia, Italy; paolo.berzaghi@unipd.it

Feed and forage analysis has been traditionally limited to feed industries and large analytical laboratories. Methods of minerals analysis have been laborious and expensive and for these reasons used only when strictly necessary. The replacement of the traditional Atomic Absorption with Inductively Coupled Plasma (ICP) techniques have reduced costs and facilitated a greater use of these analysis. Yet costs and accessibility of mineral determination in feed are still limiting its wider use, particularly for forages that may have large variation in their composition. Near Infrared Spectroscopy (NIR) has gained popularity for mineral determination, because of its rapidity and very low costs and this despite the knowledge that mineral have little or not signal in the NIR spectral region. In recent years X-Ray fluorescence (XRF) has been able to greatly simplify mineral determination in feed, contributing significantly to a wider use of mineral analysis even by small feed plants and farms. As a rapid (few minutes) and non-destructive methods, XRF easily complements NIR in feed laboratories as it requires the same sample preprocessing (drying and fine grinding). XRF technique requires a calibration with a few (<20) samples for best performances and it spans from lower atomic weight of Na till heavier element like Pb. Elements under 10 ppm may not be accurately predicted by XRF and for this reason it is normally adopted for the determination of all major macro and some micro minerals (Na, Mg, Al, Si, P, S, Cl, K, Ca, Mn, Fe, Cu and Zn). Calibration for these elements in feed have great performances with R-square normally greater than 0.95 and prediction errors generally, below 5% in relative units. Low concentration is a limitation, yet mineral supplements because of their greater concentration of micro mineral can be easily monitored improving consistency during their production also for element like Se, I, or Mo that are at very low concentration in feed.

Session 88

Theatre 8

Determination of forage mineral analysis with portable X-ray Fluorescence deviceR. Balegi¹, F. Penen¹, M. Lemarchand² and A. Boudon²¹ANIMINE, 10 rue Léon Rey Grange, 74960, France, ²INRAE-Institut Agro Rennes Angers, UMR 1348 PEGASE, Saint-Gilles, France, 35650, France; rbalegi@animine.eu

Mineral supplementation of dairy herds is necessary to compensate imbalances in mineral content of many basal diets. Supplementation must be assessed as accurately as possible to avoid excessive environmental and economic losses and to allow good coverage of cow nutritional requirement. However, mineral content of forages is variable and seldom known because of high cost of reference analytical methods used in laboratories. Developing an innovative handheld analytical tool, based on X-Ray Fluorescence (XRF) technique, is an opportunity to perform more accurately mineral supplementation in a cheap and immediate way at the farm. This work aims to validate the analysis of selected minerals (Ca, P, K, Mg, Na, S, Zn, Cu, Mn, Fe and Mo) in 89 forages with a portable XRF device in comparison to inductively coupled plasma – optical emission spectrometry (ICP-OES). Twenty samples of grass, 21 of hay, 11 of haylage, 21 of maize silage and 16 samples of grass silage were collected all over Auvergne-Rhône-Alpes area in France, then dried and ground on a 0.5 mm grid. Relationship between XRF and ICP-OES methods was assessed thanks to linear regression with ICP-OES results as predicted variable. Accuracy of the relationship was given by the coefficient of determination (R^2) and mean absolute error (MAE). The correlation between the two methods results depended on the chemical element. Copper, iron and sulphur concentrations obtained by XRF and ICP-OES were correlated, with R^2 of respectively 0.70, 0.78 and 0.94 and MAE of respectively 13, 24 and 8% of the average concentrations obtained by ICP-OES. For the other minerals (Ca, P, K, Zn and Mn), R^2 ranged between 0.89 and 0.96 and MAE between 6 and 18%. For Mg, the correlation was weak ($R^2=0.02$) mainly because of XRF limit. Sodium was not detected by XRF. The XRF performance were also limited for Mo ($R^2=0.49$, MAE=61%) likely due to its very low concentration (between 0.4 and 3.7 mg/kg DM) compared with the limit of quantification of ICP-OES. Although, the portable XRF analysis showed globally promising results to quantify mineral content in forage, further analytical development is needed for magnesium, sodium and molybdenum.

A new phosphorus feeding system for the sustainability of swine and poultry production

M.P. Létourneau Montminy¹, M. Lautrou², M. Reis³, C. Couture⁴, N. Sakomura³, B. Meda⁵, C.R. Angel⁶ and A. Narcy⁵
¹Laval University, 2425 rue de l'Agriculture, G1W3C1 Quebec, Canada, ²Agroscope, Posieux, 1725 Posieux, Switzerland, ³UNESP, 14884-900, Jaboticabal, Brazil, ⁴Trouw Nutrition, Saint-Hyacinthe, J2R 1S5, Canada, ⁵INRAE, UMR BOA, Centre de Nouzilly, 37380, France, ⁶University Maryland, College Park, 20742-2311, USA; marie-pierre.letourneau@fsaa.ulaval.ca

Phosphorus (P) is essential for all types of life but the natural P cycle is disrupted. A parsimonious use of phosphate is therefore essential. This requires a P precision feeding system for livestock. A precise prediction of P availability of raw materials as well as of animal P requirements is needed. To answer this research priority, a new P feeding system combining mechanistic and empirical modelling is proposed based on apparent digestible P. This robust multicriteria approach has been developed for growing pigs and broilers. First, a mechanistic model that simulates the fate of dietary P through 3 sub-modules, digestion, soft tissue, and ash was developed. The soft tissue module simulates the growth of the protein and lipid. The ash module simulates the partitioning of absorbed calcium (Ca) and P into the bone, protein, and lipid compartments as well as urinary excretion. Then, using inversion principles, these models were adapted to predict the amount of digestible P needed to maximize P retention in soft and bone tissues. In a second step, these needs must be met by diet formulation which requires knowledge of the digestible P value of diets. In pigs, digestible P value of feedstuff are available which is not the case in broilers. Using a single P value for each feedstuff does not consider interactions with other components of the diet. To overcome this drawback, an empirical equation has been developed in pigs and broilers to quantify the impact of the different forms of dietary P, calcium (Ca) and exogenous phytases, and their interactions on digestible P. These equations predict the P digestibility based on the chemical analysis and appears more robust than a fixed value per feedstuff. Equations has been evaluated and the accuracy has been confirmed in swine with similar evaluation ongoing in broilers. This new and generic system for both species opens relevant perspectives in terms of precision feeding for P.

Session 88

Theatre 10

Phosphorus digestibility of porcine processed animal proteins (PAPs) in broiler diets

J. Van Harn and P. Bikker

Wageningen University and Research, Wageningen Livestock Research, P.O. Box 338, 6700 AH, the Netherlands; paul.bikker@wur.nl

Since 2021, EU legislation allows the use of porcine processed animal proteins (PAPs) in poultry diets. These by-products of the slaughter of pigs are a valuable source of protein, energy and minerals and their use can improve resource utilisation and circularity of poultry production. Their use requires adequate insight in digestible nutrient content since feed tables were largely based on meat and bone meal available before the feed ban, and not representative for present species-specific PAPs. Our recent studies provided insight in the digestibility of energy and amino acids but information on digestibility of phosphorus (P) and calcium (Ca) for use in poultry diets was lacking. This study was conducted to determine the pre-caecal (ileal) digestibility of P in six porcine PAPs varying in ash, Ca and P content and produced with different methods. The P content of the PAPs varied between 16 and 64 g/kg, depending on the proportion of bone in the product. At 14 days of age, 640 healthy broilers were allocated to 64 floor pens (1.2 m²) with a flexible slatted floor, and ten birds per pen. The broilers received one of ten experimental diets: a low P basal diet, a diet with mono calcium phosphate (MCP) as reference or a diet with 1.5 g P from one of six different PAPs at a constant Ca:P ratio of 1.25:1, added to the basal diet. These products reflected processing methods 1, 4 and 7 according to commission regulation (EU) 142/2011, with two method 7-products coarse and finely ground to determine the effect of particle size. At 22 days of age chyme of the terminal ileum was collected and analysed to determine pre-caecal digestibility of P and Ca. The left tibia bone of three birds per pen was collected to determine the ash, Ca and P content. Analysis of variance with pen as experimental unit was used to determine differences between treatments. The pre-caecal P-digestibility of MCP was 91%. The P-digestibility of the PAPs varied between 80 and 95%, while processing method of the PAPs and particle size did not significantly influence the pre-caecal P-digestibility and the tibia mineral content. Hence, porcine PAPs are a valuable source of nutrients with high P digestibility in poultry diets and can support circularity of food production.

Prediction of magnesium absorption in dairy cows: An update

R. Khiaosa-Ard and Q. Zebeli

University of Veterinary Medicine Vienna, Veterinaeplatz 1, 1210 Vienna, Austria; ratchaneewan.khiaosa-ard@vetmeduni.ac.at

Earlier research (e.g. Schonewille *et al.*) proposed the quantitative prediction of magnesium (Mg) absorption based on Mg intake and dietary K level. Different findings emerged in newer studies, which might be related to cow factor and feeding. We updated the database used by Schonewille *et al.* and reevaluated their predictions. In total, 21 published studies with 94 dietary treatments were included in the present analysis. Of these, 41 treatments originated from non-lactation cows and 53 from lactation cows. The dietary Mg content ranged from 0.45-17.4 g/kg DM for non-lactation cows and 1.1-6.25 g/kg DM for lactation cows and the Mg intake was 2-124 g/d and 12-120 g/d, respectively. The dietary K content ranged from 11.2-75.6 g/kg DM for non-lactation cows and 6.9-41.1 g/kg DM for lactation cows. True Mg absorption (g/d) was Mg intake – faecal Mg output + endogenous Mg secretion (which was $0.004 \times \text{BW}$). The study was included as a random factor. The evaluation showed that lactation and non-lactation cows absorb similar amounts of Mg at a given Mg intake and the average Mg absorption was 20% Mg at Mg intake ≥ 20 g/d (range 10-40%). Of the factors tested, Mg intake (g/d) and dietary K (g/kg DM) were the significant predictors for true Mg absorption (g/d) similar to the recommendation of Schonewille *et al.* However, the new data revealed that instead of treating dietary K as a quantitative predictor, categorizing it increased the accuracy of the prediction. The data suggested two different equations as follows: True Mg absorption (g/d) = $-1.927 (\pm 1.16, P=0.11) + 0.34 (\pm 0.025, P<0.001) \times \text{Mg intake (g/d)}$, when dietary K ≤ 20 g/kg DM, and = $0.154 (\pm 1.06, P=0.05) + 0.209 (\pm 0.026, P<0.001) \times \text{Mg intake (g/d)}$, when dietary K > 20 g/kg DM. The root mean square error was 2.19 and the concordance correlation coefficient (ccc) was 0.923. Estimation of the new data when using the model from Schonewille *et al.*: true Mg absorption (g/d) $3.6 + 0.2 \times \text{Mg intake (g/d)} - 0.08 \times \text{dietary K (g/kg DM)}$ resulted in a ccc of 0.854. This study refined the prediction of Mg absorption in dairy cows related to the influence of dietary K.

Se and Co balance in dairy cows: longitudinal study from late lactation to subsequent mid-lactation

J.B. Daniel and J. Martín-Tereso

Trouw Nutrition R&D, P.O. Box 299, 3800 AG, Amersfoort, the Netherlands; jean-baptiste.daniel@trouwnutrition.com

We quantitatively evaluated Se and Co balance in dairy cows from late lactation through the subsequent mid-lactation. Twelve Holstein dairy cows were housed in a tie-stall from 10 weeks before to 16 weeks after parturition. When lactating, cows were fed a total mixed ration (TMR) with 0.44 ppm Se and 0.52 ppm Co, and when dry, a TMR with 0.16 ppm Se and 0.23 ppm Co. After 2 weeks of adaptation to the facility and diet, Co and Se balances were determined at weekly intervals, by calculating the difference between total intakes and complete faecal, urinary and milk outputs, with the latter three fluxes quantified over a 48-h period. Weekly serum samples were also collected. Repeated measures mixed models were used to evaluate the effects on trace mineral balances over time. Between the dry period and week 11-16 of lactation, intakes of Se and Co increased from 2.3 to 10.7 mg/d, and from 3.1 to 12.6 mg/d, respectively. As a result, faecal Se and Co output increased from 1.7 to 6.6 mg/d, and from 3.1 to 11.3 mg/d, respectively. Apparent absorption of Se and Co were lowest during the dry period (24 and 2% respectively) as compared to lactation (32-38%, 8-12%, respectively). Milk Se concentration was highest at the end of the previous lactation (19.3 µg/l), and lowest between week 6 and 10 (15.2 µg/l). Milk Co concentration was not influenced by stage of lactation and averaged 0.36 ± 0.06 µg/l. Although urinary Co excretion was correlated to Co intake, amount excreted were negligible (from 14 to 33 µg/d). In contrast, urinary Se excretions were larger, and increased with Se intake from 0.4 to 2.9 mg/d. From late lactation to week 5, Se balance was not different from 0, but increased linearly from calving to week 16, up to 0.5 mg/d. During the dry period, Co balance did not differ from 0, but increased to 0.9-1.3 mg/d during lactation, with no effect of stage of lactation. Serum Se and Co were lowest during the dry period (0.7 and 3.9 µmol/l, respectively) and highest between week 6 and 16 (1.1 and 6.0 µmol/l, respectively). Further research is needed to elucidate if increasing Se and Co balance during lactation reflect actual body retention of Se and Co. Evaluating potential consequences on health would also be valuable.

Mineral analysis in feed using a new automated analytical method*D. Schwarz and D. Aden**FOSS Analytical A/S, Nils Foss Alle 1, 3400 Hilleroed, Denmark; das@foss.dk*

Wet-chemistry methods for mineral analysis are cumbersome and time-consuming as they are heavy on sample preparation. Hence, a high-throughput and chemical-free instrument based on Laser Induced Breakdown Spectroscopy (LIBS) has been developed. With this method, sample preparation is reduced to a minimum and total turn-around time (i.e. sample preparation and analysis) is as fast as two minutes. It is possible to analyse up to 60 samples per hour for their mineral content. Feed materials tested so far were the following: grass silage, maize silage, alfalfa/legume hay, hay, fresh grass, haylage, mixed hay, sorghum, straw, grass and clover mixture, and barley silage (whole crop silage). Macro and micro minerals in above listed feed materials were determined using classical wet-chemistry methods and the new LIBS-based method. High correlations between the two methods were found for the macro minerals calcium (Ca), magnesium (Mg), phosphorus (P), potassium (K), sodium (Na), sulphur (S) and the micro minerals aluminium (Al), boron (B), copper (Cu), iron (Fe), Manganese (Mn), Zinc (Zn). The newly developed LIBS-based method may be used complementary to existing wet-chemistry methods and open up the opportunity of cost-efficient mineral analysis of feed material. This, in turn, could help to test larger amounts of samples, thus help to better understand varying mineral contents in, e.g. grass silage, and eventually contribute to precision mineral feeding of livestock.

Poster 14

Trace mineral trends in British and Irish forages*A.H. Clarkson and N.R. Kendall**University of Nottingham, Sutton Bonington Campus, Leicestershire, LE12 5RD, United Kingdom; andrea.clarkson@nottingham.ac.uk*

Forage is the primary diet for grazing ruminants in the UK & Ireland. Problems with availability are easy to detect but trace mineral issues are harder to determine. The mineral content of forages can vary with, rainfall, soil, sward, maturity, season, and location, as well as product and fertiliser use. It is important to understand the supply of trace minerals, and their antagonists, to better refine and optimise mineral supply for animal growth, health, and production, without the risks of oversupply. This work looks at trends in trace mineral supply from forage data submitted for commercial analysis, compiling data from farms across the UK and the Republic of Ireland. UK and Irish forage sample data (n=1,453) submitted for commercial analysis (2020-2023) was used to calculate means, standard error and plot graphed data (Microsoft Excel v2301). The pooled averages for Mn, Co, Se, and Fe were typically all within or above sheep, beef, and dairy requirements (based on NRC data) across all years. However, the average Cu concentration in the UK was below the lowest requirements (<8 mg/kg DM) every year. In Ireland Cu was below this threshold in 2021 & 2022 and was below cattle requirements (<10 mg/kg DM) in 2020. Furthermore, S was above the threshold for potential copper antagonism (>2.5 g/kg DM) in 2020 & 2021 (Ireland), remaining ~2 g/kg DM the other years. Fe was consistently above the threshold (>250 mg/kg DM) for copper problems in all years except 2021 (Ireland). Mo was lowest in 2022 (Ireland) at 1.32 mg/kg DM, remained around 2 mg/kg DM (UK & Ireland) the rest of the time, but had risen to 4.31 mg/kg DM in 2023 (UK). All above the threshold for potential copper problems (>0.5 mg/kg DM). Zn was below the lowest requirements (<30 mg/kg DM) in 2021 (UK & Ireland), and 2023, remaining below dairy requirements (<40 mg/kg DM) in 2020 (UK), and 2022 (UK & Ireland). Iodine was below the lowest requirements (<0.45 mg/kg DM) in 2020 (UK), 2021 (Ireland), and 2023 (UK). Whilst there is substantial individual variation, these data suggest that grazing ruminants in the UK and Ireland would benefit from further trace mineral investigation and supplementation. The authors thank Bimeda UK & ROI for the use of their anonymised data.

Does size matter? Comparing liver sample sizes for trace element statusA.H. Clarkson¹, J. Angel² and N.R. Kendall¹¹University of Nottingham, Sutton Bonington Campus, Leicestershire, LE12 5RD, United Kingdom, ²Wern Vets, Department of Research and Innovation, Unit 11, Lon Parcwr Industrial Estate, Ruthin, Denbighshire, LL15 1NJ, United Kingdom; andrea.clarkson@nottingham.ac.uk

Liver tissue samples are valuable for defining trace mineral status in ruminants to estimate supplemental need. Liver can be used for essential trace elements such as copper, cobalt, selenium, manganese, and zinc. These minerals play important roles in reproduction and production and their deficiency or over-supply can result in compromising health conditions or death. The use of liver tissue samples provides different information to blood, providing a longer-term picture. For these elements the hepatic concentration adjusts slowly over several months compared to blood, and therefore liver concentrations allow a better understanding of changing trends and directions for informing supplemental decisions across a herd, flock, or management group. Due to the refinement of biopsy technique, liver recovery sizes are much lower (~40% less) than when the technique was first developed. The advantages of this are considerable, but it carries the risk that the smaller sample size may not provide sufficient tissue for accurate decision making. The minimum sample size of liver required for accurate representation is unclear. It is necessary to determine if there is a minimum liver tissue recovery size (from slaughter or biopsy) which can be used as a reliable indicator of trace mineral status. Three different livers >300 g were prepared into duplicate samples within four wet weight ranges; 0.04-0.14 g, 0.15-0.30 g, 0.31-0.65 g and 0.66-0.80 g. Samples were frozen then freeze-dried prior to acid-digestion and ICP-MS analysis. Data was analysed for descriptive statistics and statistical significance using GLM ANOVA with Tukey comparisons using Minitab (v.19). As expected, mineral concentration varied substantially between livers. However, there was no significant difference in trace mineral concentration between the weight ranges for Zn, Cu, Mn, Se, and Co in any of the individual livers. Indicating that the use of small size liver samples and biopsies as a measurement for hepatic concentration of trace minerals is effective in comparison to the use of larger cut liver samples.

Investigation on the variation in phosphorus of wheat bran: effect in diets of fattening pigs

R. Puntigam, P. Riesinger, A. Honig, M. Schaeffler, W. Windisch and H. Spieters

Bavarian State Research Center for Agriculture, Prof.-Dürnwächter-Platz 3, 85586, Germany; wilhelm.windisch@tum.de

Wheat (W) is the third most produced crop worldwide and the production volume increased markedly. Hence, the amount of wheat bran (WB) increased accordingly as it is a by-product of flour production. Although WB is locally processed, the high amount of phytate-bound phosphorus (P), the risk of mycotoxin contamination and its bulkiness limit the use. Especially the reduction of P in diets is an important strategy to minimise its excretion and thereof environmental pollution. Contrary it gains more interest in regard of animal welfare and reducing the competition for food between humans and pig production due to very low human-edible fraction. Since fibre and P are concentrated in the outer layers, the efficiency of the milling process is crucial for the composition of the fractions afterwards. Our hypotheses were that: (1) cultivar contribute to variation in the nutritive value of WB; (2) there is a relationship between the nutrient content in W and WB; and (3) WB is a suitable feedstuff in diets of fattening pigs. The material comprised dry milled wheat samples of eleven cultivars which were grown on three locations in Germany (3 replicates per cultivar per location; 99 W samples and 99 WB samples). Samples were analysed using the official methods of the VDLUFA. Data were analysed using the MIXED procedure and pairwise t tests of SAS (SAS Institute Inc.). The amount of WB was 220±19 g (min.: 162; max. 255 g) per kg W. Cultivar influenced CP and P content in WB ($P < 0.05$). Mean content of CP in W was 125±14 g (min.: 89; max. 153 g) and P 3.4±0.7 g (min.: 2.2; max. 4.7 g) while in WB P content was 14.1±1.5 g (min.: 11.0; max. 17.7 g) per kg DM. The P in WB was increased by 322±63% (min.: 454; max. 187%). There was no correlation between the content of CP or P in W and the content of P in WB ($r^2 < 0.01$). Based on P content (min.: 9.8; mean: 12.6; max. 15.8 g/kg) diets for fattening pigs were calculated. 5% in the starter-, 10% in grower- and 15% in finisher-period of WB with increasing amount of P resulted in mean content of P in the diets of 4.2, 4.5 and 4.8 g/kg, respectively. Diet calculated using these levels of WB (approx. 26 kg) reduced 20 kg wheat per fattening pig.

Swiss Feed Database: a closer look at minerals and trace elements in 10 years of roughage surveysE. Manzocchi¹, M. Lautrou² and P. Schlegel^{1,2}¹Agroscope, Ruminant Nutrition and Emissions, Tioleyre 4, 1725 Posieux, Switzerland, ²Agroscope, Swine Research Group, Tioleyre 4, 1725 Posieux, Switzerland; elisa.manzocchi@agroscope.admin.ch

The native mineral and trace elements supply from roughages in the basal diet of ruminants, requires full attention if a sustainable and economical supply of these nutrients is to be achieved. However, mineral and trace element concentrations in roughages need to be analysed regularly or can be retrieved from feed tables with reference values. In Switzerland, an annual survey of the quality of conserved roughages, including barn-dried and field-dried hay, as well as grass and whole-plant maize silage, has been carried out since 2012. A large proportion of all roughage samples collected on Swiss farms are analysed in two commercial laboratories for major organic nutrients and estimation of energy and protein value. At the explicit request of the farmers or extension services supplying the samples, concentrations of macro minerals (Ca, P, Mg, Na, K, S), trace minerals (Cu, Fe, Mn, Zn) and trace elements (Mo, Co, I, Se) are analysed by wet chemistry (ICP-AES/MS). All data are compiled annually in the Swiss Feed Database. Over the last 10 years the database has been expanded each year with 698 ± 77 (mean $\pm$ standard deviation), 406 ± 170 , and 108 ± 51 samples for macro minerals, trace minerals, and trace elements in hay, respectively; with 121 ± 39 , 84 ± 38 , and 10 ± 8 samples analysed for macro minerals, trace minerals and trace elements in grass silage, respectively. The database on whole-plant maize silage was increased annually by 48 ± 25 , 23 ± 16 and 6 ± 3 samples for macro minerals, trace minerals, and trace elements, respectively. Samples are geolocated to regions and altitudes, and herbage are attributed to one of seven main grassland types as declared by farmers or advisors. The data collected from this nationwide survey deliver unique, annually updated information on mineral and trace element concentrations in a large number of roughages produced on Swiss farms. Based on these data, we present trends in mineral and trace element concentrations in roughages, compare them with existing reference values, and finally show the importance of the native mineral and trace element supply from roughages in typical roughage-based dairy diets.

Mineral forage value in the INRAE feeding system for ruminantsA. Boudon¹ and G. Maxin²¹PEGASE, INRAE, Institut Agro, 35590 St-Gilles, France, ²UMR Herbivores, INRAE-VetagroSup, Univ. Clermont Auvergne, 63122 St-Genès-Champanelle, France; anne.boudon@inrae.fr

Mineral supplementation is necessary for ensuring optimal growth, health and productivity of productive ruminants for almost all diets. However, it also represents an economic cost and can induce supplementary losses of mineral elements in the environment. Thus, mineral supplementation must be adjusted as accurately as possible to insure that the total mineral supplies for animals are equivalent to their requirements. For ruminants, a significant part of the nutrient, and more specifically mineral, supplies are provided by the forages. The mineral contents of forages is highly variable, even within a farm, if we considered the evolution of plant mineral content according to the species present in the field, the meteorological conditions and the plant physiological stage. Thus, the provision of tables of forage mineral composition seems to be an interesting tool to allow a first assessment of mineral supplies allowed by the basal diet before choosing adequate supplementation. The aim of the presentation is to make a synthesis on the table of forage mineral contents backed in the INRAE feeding system and to share some perspective of evolution. The INRAE feed tables for forage is based on 740 mineral analyses in fresh forages (mainly herbage). Correlations with forage crude protein contents were used to adjust the effect of the plant physiological stage of mineral contents. For macro-element (Ca, P, Mg, Na, K, Cl and S), the effect of conservation was assessed from comparisons between fresh forages and hays and fresh forages and silages. Given that P, Ca and Mg requirements are predicted thanks to a factorial approach in absorbable amounts, true absorption coefficient are determined according to the forage family and the conservation methods according to syntheses from published data. New analytic methods could now allow cheaper and quicker mineral analyses of forage. Thus, emerging questions about these tables are to evaluate their representativeness considering the diversity of pedoclimatic context and species grown in France and to determine if their use can allow a reasonable assessment of mineral supplies allowed by the basal diets, especially for trace elements.

Minerals in cattle nutrition – meet the needs!

A.C. Honig¹, V. Inhuber², H. Spiekers¹, W. Windisch², K.-U. Götz¹, G. Strauß¹ and T. Ettle¹

¹Bavarian State Research Center for Agriculture, Prof.-Duerrwaechter-Platz 3, 85586 Poing, Germany, ²Technical University of Munich, Liesel-Beckmann-Strasse 2, 85354 Freising, Germany; wilhelm.windisch@tum.de

Adequate macro mineral supply in cattle feed ensures optimal body functions and animal growth. Feeding cattle according to their nutrient requirements is a crucial factor in reducing environmental impact. Particularly phosphorus (P) is an important issue in livestock nutrition because high P excretions can cause environmental pollution due to excessive phosphate leaching into surface water. Furthermore, P is a finite resource and its use in feed should be limited to the animals' requirements. Mineral requirements depend on the animals' physiological needs for maintenance and performance, which change during animal growth. To assess these requirements, a feeding experiment ending with a serial slaughter trial was conducted with 72 growing Fleckvieh (German Simmental) bulls. For the fattening period, bulls were randomly allocated to normal energy and high energy treatment groups fed 11.6 and 12.4 MJ ME/kg DM, respectively. Differences in the TMRs' energy concentrations were reached by varying the percentage of maize silage and concentrates. The bulls were slaughtered in five final live weight groups of 120, 200, 400, 600, and 780 kg and their entire empty bodies were analysed for their macro mineral (Ca, P, Na, K, S, Mg) concentration and accretion. Increasing the amount of concentrate and mineral supplement in the diet increased the animals' daily macro mineral intake but did not affect body mineral composition or accretion. Experimental data can be used to adjust the feeding recommendations for mineral requirements of growing Fleckvieh bulls. Comparing calculated daily P requirements and daily P intake reveals a P surplus in higher weight groups. The excess of P arose because mineral intake increased during growth, but mineral accretion declined. This was especially true for bulls in the high energy group, which showed higher P intake due to high concentrate feeding. Hence, phase feeding should be used to feed growing cattle according to their mineral requirements and to reduce P excretion and the resulting environmental impact.

Session 88

Poster 20

Ruminant feed rations rich in clay minerals may induce Zn deficiency

M. Schlattl, M. Buffler and W. Windisch

Technical University of Munich, Chair of Animal Nutrition, Liesel-Beckmann-Str. 2, 85354 Freising, Germany; wilhelm.windisch@tum.de

In ruminants, zinc (Zn) requirement is low compared to monogastric livestock and native dietary Zn contents may be sufficient at low levels of performance. But ruminants may also ingest high amounts of clay from soils via roughages, which may depress Zn bioavailability. The present study tested the potential of a total mixed ration (TMR) rich in clay to induce Zn deficiency in animals living at maintenance level. The TMR consisted of hay, alfalfa, concentrate and clay (45.9, 28.2, 14.3 and 11.2% in dry matter (DM)). Crude ash (CA) in DM was 20.5%, which is within the range of CA in grass silage. Nutritional properties of the TMR met recommendations except for Zn (27.4 ppm). The TMR was either fed as is (ZN[-]) or was added with Zn (83.1 ppm) to ensure sufficient Zn supply (ZN[+]). TMR variants were fed to eight fistulated, non-lactating dairy cows at restricted amounts (7.91 kg DM/d) according to a balanced Latin Square Design involving two time periods of each 6 weeks adaptation and 2 weeks quantitative collection of feed intake, faeces and urine, and sampling of duodenal chyme and blood. Samples were analysed for Ca, Mg, Cu, Fe, Mn, Zn, and duodenal flux was estimated via TiO₂ (0.5% in TMR). Statistics included ANOVA with animal as fixed block and dietary treatment (ZN[-], ZN[+]). Data on Ca, Mg, Cu, Fe, and Mn were not affected by Zn treatment. Compared to ZN[+], feeding ZN[-] depressed Zn intake (659 vs 216 mg/d; $P < 0.05$), and faecal Zn excretions (505 vs 254 mg/day; $P < 0.05$). Apparent digestibility dropped from 22.2 to -14.4% ($P < 0.05$) indicating a net loss of Zn from body stores when fed ZN[-]. Concomitant duodenal Zn fluxes of 324 mg/d at Zn[-] exceeded Zn intake, and indicated an Zn influx from body stores into the digestive tract. In ZN[+] duodenal Zn flux of 588 mg/d ($P < 0.05$) indicated Zn disappearance from feed towards inside the body. Plasma Zn did not markedly differ (708 vs 685 ppm, $P > 0.05$). In conclusion, the TMR rich in clay minerals seemed to bind feed zinc along the entire digestive tract and hence to negatively affected Zn bioavailability. Native dietary Zn contents were not sufficient to meet the animals' requirements of Zn. In total, dietary contaminations with clay seem to be a risk factor for Zn deficiency in ruminants.

Zn, Cu, Mn and Fe balance in dairy calves fed milk replacer or whole milk at two feeding allowances

T. Chapelain, J.B. Daniel, J.N. Wilms, L.N. Leal and J. Martín-Tereso

Trouw Nutrition R&D, P.O. Box 299, 3800 AG, Amersfoort, the Netherlands; tchapela@uoguelph.ca

Trace minerals inclusion in milk replacer (MR) largely exceed natural mineral occurrence in whole milk (WM). Our objective was to quantify trace mineral balance in calves fed either WM or MR at two feeding allowances (L: 4.5 l/d and H: 9.0 l/d) during their first 13 weeks of life. Forty-eight newborn Holstein-Friesian calves (2 ± 1.0 d of age; 45.0 ± 4.37 kg body weight) were enrolled after receiving a standardized colostrum administration. Upon arrival at the facility, calves were blocked by age and arrival date and randomly assigned to one of the four treatments. The MR was fed at 169 g/l of final product to provide the same amount of metabolizable energy as WM (3.4 MJ/l). The concentrations of zinc (Zn), copper (Cu), manganese (Mn) and iron (Fe; mg/l) in MR and WM were: 10.14 vs 4.64, 1.82 vs 0.07, 4.95 vs 0.03, and 12.19 vs 0.25, respectively. Starter feed, and straw were introduced at week 6, and calves were gradually weaned from week 6 to 10 and studied up to week 13. Complete 24 h collection of urine and faeces were performed on weeks 2, 4, 5, 7, 9, 11 and 13. All data were analysed using PROC MIXED (SAS 9.4). Preweaning, Cu, Mn and Fe, balances were higher ($P < 0.01$) for MR fed calves than WM fed calves. Increasing milk allowance increased Cu and Fe balances for calves fed MR but not for calves fed WM ($P < 0.01$). For Zn, increasing milk allowance increased Zn balance for WM calves, but decreased Zn balance for MR calves. During weaning, feeding higher milk allowance resulted in lower balances of Zn, Cu and Mn ($P < 0.01$), and Fe ($P = 0.08$). During that time, Cu balance was further reduced for WM fed calves ($P = 0.04$), whereas Zn balance was increased by feeding WM ($P < 0.01$) as compared to feeding MR. Postweaning, greater Cu ($P < 0.01$) and Fe ($P = 0.04$) balances were observed for WM vs MR-fed calves. Although trace mineral balance was lower in WM-fed calves during preweaning, no negative impacts on health and performance were observed. These results highlight the opportunity for further research to review mineral inclusion in MR.

Impact of drinking water salinity on lactating cowsA. Iritz^{1,2} and Y. Ben Meir²

¹The Robert H. Smith Faculty of Agriculture, Food, and Environment, The Hebrew University of Jerusalem, Animal Science, Herzl Street 229, 7610001 Rehovot, Israel, ²Agricultural Research Organization, Ruminant Science, 68 HaMaccabim Road, 7505101 Rishon LeZion, Israel; adi.iritz@mai.huji.ac.il

Increase use of desalinated sea water in Israel for urban, industrial and agricultural uses led to drinking water with low minerals and salts content as reflected by its electrical conductivity (EC). We measured the EC through the year and observed changes from 0.3 mS/cm to 0.9 mS/cm, depends on the precipitation. Daily free water intake (FWI) of lactating cows in the Volcani Center is circa 140 l/d. The large amount of consumed water, combined with the recent changes in the water composition, encouraged us to explore the possible effects of this on various parameters related to cow's physiology and performance. To enable the recording of the cows individual FWI and to control its minerals composition, we designed and build a systems composed of 4 individual troughs with gates allowing only designated cow to enter. Each trough were fed by 500 l water tank that was placed 4 meter higher. The tanks were filled using an irrigation robot with water and salt solution at the predetermined EC level. When the cow drank from the trough, a tap opened and water flowed from the tanks. A hydrometer was installed at the exit of each tank to record the amount and time of the water flow. Four multiparous lactating Israeli Holstein cows were offered, in a Latin square design trial, drinking water at four different EC levels: 0.4, 0.6, 0.8 and 1.0 mS/cm. Each period of the trial lasted 18 days, including 5 days of adaptation and 13 days for measurements of feed and water intake, milk yield and rumen pH. Faeces, urine and rumen fluid sampled at each period to determine digestibility, VFA content and profile, and minerals balance. Drinking water salinity affect feed intake and milk yield that was highest when cows offered water with higher EC (intake of 29.7 kg/d, 29.6 kg/d, 28.3 kg/d and 27.5 kg/d for EC of 1.0 mS/cm and 0.8 mS/cm, 0.6 mS/cm and 0.4 mS/cm respectively, $P = 0.01$ and milk yield of 47 kg/d, 45.4 kg/d, 45.4 kg/d and 44.6 kg/d for EC of 1.0 mS/cm and 0.8 mS/cm, 0.6 mS/cm and 0.4 mS/cm respectively, $P = 0.01$). Water salinity did not affect FWI that was 142 l/day.

Seasonal variation of trace essential and toxic minerals in milk and blood of dairy ewes

A. Nudda¹, M.F. Guiso¹, G. Sanna², A. Cesarani¹, M. Deroma¹, G. Pulina¹ and G. Battacone¹

¹University of Sassari, Department of Agriculture, Viale Italia 39A, 07100, Italy, ²University of Sassari, Department of Chemical, Physical, Mathematical and Natural Sciences, Via Vienna 2, 07100, Italy; battacon@uniss.it

A survey was carried out to characterize the trace essential and toxic minerals in milk and blood of Sarda dairy ewes during whole lactation. Milk samples were collected from sheep dairy farms in Sardinia (Italy) from the beginning to the end of lactation every 1.5 months. Ten animals per farms were selected. Microminerals were measured in milk, blood, and feeds samples. Minerals were determined on samples using the Inductively Coupled Plasma Optical Emission Spectrometry preceded by mineralization. Data were analysed with a linear mixed model with diet, sampling, and their interaction as fixed effects and animal as random effect. The potential of MIRS to predict the essential and toxic minerals content of sheep milk has been evaluated. Days in milk significantly affected all mineral contents. Selenium (Se), zinc (Zn) and copper (Cu) showed a peak at the beginning of lactation and then decreased during lactation. The manganese content had a peak in the spring. The lead (Pb) had a peak at the beginning of lactation and then declined, while cadmium (Cd) had the opposite pattern; at all stages of lactation the values were below the EU upper limit in milk products. The nickel (Ni) content in blood exhibited no clear pattern during lactation. The mineral contents of feeds partly explain the mineral concentrations found in milk and blood. This study provided new information on the mineral quality of milk from Sarda dairy sheep and the relationship with minerals in feeds. Moreover, this research could help to identify faster and innovative methods such as mid-infrared spectroscopy for the determination of minerals in sheep milk. Acknowledgement: This research was funded by the Autonomous Region of Sardinia SELOVIN project (CUP: J86C17000190002).

Measuring the behaviour of lambs in an isolated environment with artificial intelligence methods

B. Benet and R. Lardy

University of Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, 63122 Saint-Genest Champanelle, France; bernard.benet@inrae.fr

An experiment was conducted in an enclosed 16 m² test pen, gridded into 1 m² zones, to study the behaviour of a group of 39 lambs placed individually in the pen, for periods of 5 minutes. The aim was to study the behaviour of two groups, focusing on positioning, orientation and mobility, in order to characterise their emotional reactivity. The two groups corresponded to lambs that had previously been in an enriched environment (platforms, balls, brushes, etc.). For this study, videos were recorded for 5 days (6 hours/day). Artificial intelligence methods combined with image processing techniques were developed to automatically measure lambs' behaviour. From each 5-minute video recorded for a given lamb, the developed software first recognised the lamb and determined its position in the pen, using a GoogleNet-type neural network, with 90% accuracy, taking into account the different orientations and positions of the animal in the scene. It then automatically identified the two parts of the lamb's body (head and hindquarters). For this second step, a database of 1,500 images divided into two parts (80% for learning and 20% for testing) and annotated by experts, was used to develop an Inception-type neural network (using the Tensorflow tool in Python) that identified the front and back parts of the lamb. The success rate of this body part identification was 90%. Finally, an image processing was used to identify the orientation of the animal, in order to determine the areas in its field of vision. These operations made it possible to measure the time spent by the lambs in the different areas of the pen, to measure their mobility by looking at the speed of their movements, the evolution of their movements and their orientation over time, to identify the areas of interest of the lambs in the pen, and to make comparisons between the lambs but also between the different days for each lamb. This lamb behaviour study showed the potential of artificial intelligence to automatically analyse certain animal behaviours from video, thus facilitating behavioural analysis and extending the measurement ranges over long experimental periods.

Estimating sow posture from computer vision: influence of the sampling rate*M. Bonneau¹, J.A. Vayssade¹ and L. Canario²**¹INRAE, ASSET, Domaine Duclos, 97170 Petit-Bourg, Guadeloupe, ²INRAE, UMR1388 GenPhySE, 31326 Castanet-Tolosan, Guadeloupe; mathieu.bonneau@inrae.fr*

Advances in computer vision (CV) offer a valuable tool to monitor animal behaviour over the long term. CV tools are particularly interesting as they are non invasive and could be used to derive fine behaviour traits. On the other hands, CV quickly produces a large amount of data. This could be problematic in practice, as it implies an important organization in terms of data storage and transfer, but also for data analysis. One way to reduce the amount of generated data is the sampling rate. In this article, we were interested in estimating the daily sow activity time budget. More precisely to estimate the proportion of time the sow spent in one of these 6 postures: (1) knee; (2) sitting; (3) standing; (4) sternal; (5) udder left; and (6) udder right. The analysis was based on 23 different samples. One sample is the monitoring of a sow posture during one day. 12 different animals were considered, some of them for several days. Monitoring was done after parturition on sows kept in crate. For each sample, a reference postural time budget (PTB) was estimated from the raw camera data, at 12 frames per second. For each frame, the posture was estimated using a convolutional neural networks. Then, the PTB was also estimated using different frame rate, from one frame per second to one frame per hour. For each frame rate, the difference with the reference PTB was computed. We found that the average difference with the reference PTB was not significantly different using the lower sampling rates. On the contrary, the variance of the difference was different and increases with a decreasing sampling rate. Our data showed that using a sampling rate of 1 image every 30 seconds was sufficient to obtain less than 2% of difference with the reference PTB, with probability 95%.

Session 89

Theatre 3

Estimating pig mass in a high-density pig group during transportation*V. Bloch¹, A. Valros², C. Munsterhjelm², M. Heinonen², M. Tuominen-Brinkas², H. Koskikallio² and M. Pastell¹**¹Natural Resources Institute Luke (Finland), Latokartanonkaari 9, 00790 Helsinki, Finland, ²University of Helsinki, Research Centre for Animal Welfare, Faculty of Veterinary Medicine, Department of Production Animal, P.O. Box 57, 00014, Helsinki, Finland; victor.bloch@luke.fi*

Measuring mass of pigs would allow improved assessment of pig quality when pigs are sold as finishers. Many farms are not equipped with individual scales, hence a convenient possibility for estimation of the pig mass and its diversity can be in connection to transportation of the pigs. Usually, the pig mass is estimated with the help of 3D cameras when different factors influencing the estimation accuracy are eliminated, particularly, when a pig is separated from other pigs. However, during the transportation, the pig density is high, which causes multiple contacts and occlusions. For these conditions, a method accurately separating individual pigs and detecting their body parts must be used. In this study, a mask R-CNN model was used to extract the pig silhouette in RGBD images. The silhouette was used to define a point cloud related to the pig's back. The pig mass was estimated based on the volume calculated under the surface of the pig's back. In an experiment conducted on a commercial farm, 100 pigs were transported in four groups of 22-26 pigs. The entire group was recorded by a 3D camera installed above a door of a transportation truck in a bounded elevating platform 2×4 m². The pigs were marked and weighed before recording. The mask R-CNN was trained on 20 images including more than 400 annotated pigs. A pretrained model was trained on available datasets and used for transfer learning. Preliminary result indicated that the mass estimation based on a 3D point cloud and extraction of a pig point cloud from a dense group can be used for practical purpose on commercial farms.

Assessment of piglet maturity at birth using computer visionL. Maignel¹, R. Mailhot², A. Carrier² and P. Gagnon²¹Canadian Centre for Swine Improvement, 960 Carling avenue Building 75, K1A 0C6 Ottawa, Ontario, Canada, ²Centre de développement du porc du Québec, Tour Belle Cour, Place de la Cité, Tour Belle Cour 450, 2590, Boulevard Laurier, G1V 4M6 Quebec City, Quebec, Canada; laurence@ccsi.ca

Piglet maturity at birth is strongly linked to early survival. It can be assessed using specific morphologic characteristics, mainly based on skull dimensions and body/head proportions. Mature piglets have well developed organs at birth, especially the liver and small intestine, and more body fat, both of which are important characteristics for postnatal survival and growth. Immature piglets, also called IUGR (intra uterine growth retardation) piglets can be recognized by a specific head shape, as well as characteristic eyes and ears. Maturity scoring can be done visually after some basic training and can be assessed when piglets are weighed at birth. Developments in artificial intelligence have led to new tools such as the Pic'Let system (Neotec Vision, France) developed to classify piglets into normal/mild/severe maturity level at birth using machine learning for the classification of digital pictures of piglets' heads collected shortly after birth. A group of 692 commercial piglets born from 47 Yorkshire × Landrace sows were tracked at the Sow Research and Training Barn of the *Centre de développement du porc du Québec* (CDPQ) in Armagh, Québec. Each piglet was weighed and classified with the Pic'Let prototype within 24 hours after birth. Each animal was also assigned a subjective maturity score (0=normal/1=mildly immature/2=severely immature) at the barn, as well as a visual maturity score based on piglet digital pictures. Various body measurements were also collected including body, head and femur lengths, chest circumference and distance between the eyes. Preliminary results showed moderate concordance levels between the in-barn visual scores and Pic'Let classification (66, 59 and 34% for scores 0, 1 and 2, respectively). The accuracy increases when the comparison is made on piglets where both subjective evaluations agree (67, 80 and 83% for scores 0, 1 and 2, respectively). Overall, the Pic'Let system provided valuable information on crossbred piglets in this study, but its accuracy could be improved by expanding its reference photo bank.

Validation of new software (r-Algo) for predicting meat chemical composition from ultrasound imagesB. Ahmadi¹, T. Schwarz² and P.M. Bartlewski¹¹University of Guelph, Department of Biomedical Sciences, 50 Stone Road, Guelph N1G 2W1, Canada, ²University of Agriculture in Krakow, Department of Animal Genetics, Breeding and Ethology, 24/28 Mickiewicza Avenue, 30-059 Cracow, Poland; ahmadib@uoguelph.ca

There is no non-invasive method to accurately and repeatedly predict the proximate chemical composition and fatty acid profile of meat from observations in live animals. The objective of this study was to validate a novel computerized method of ultrasound image analysis to determine chemical composition of pectoralis major muscles in broiler chickens. Ultrasonograms of the pectoral muscles in the longitudinal and transverse plane were obtained from forty birds on the day of slaughter. All chemical constituents of muscle samples were determined with the validated and standardized laboratory techniques, and the results served as a benchmark for developing the present algorithmic estimates of chicken meat composition. An in-house developed algorithm (r-Algo) was used to normalize the ultrasonograms and to identify pixel intensity ranges for which linear correlations between mean numerical pixel values (NPV) and the content of various chemical constituents were the strongest (based on the values of correlation coefficients), using a stepwise sequestration of ultrasound bitmaps. Percentages of chemical constituents were the dependent (accepted) variables and the results of echotextural analyses (luminance or pixel intensity), carried out with a commercially available image analysis software (ImageProPlus), were the explanatory variables. The predictive regression equations were determined in thirty randomly selected algorithm-training experimental units, and their accuracy was tested in a subset of ten birds allocated to the algorithm-validation group. Significant determination coefficients were found for all chemical constituents studied, with the accuracy ranging from 62.70% (linoleic acid, transverse plane, pixel range of 141-142) to 96.65% (total hypocholesterolemic acids, longitudinal plane, pixel range of 136-150). The results of the present validation study indicate that accurate prediction of muscle chemical composition using echotextural image analyses is feasible after identifying specific pixel intensity ranges.

Coupling a sow herd model with a bioclimatic model of gestation rooms: development and evaluationE. Dubois¹, F. Garcia-Launay¹, N. Quiniou², M. Marcon², J.Y. Dourmad¹, D. Renaudeau¹ and L. Brossard¹¹PEGASE, INRAE, Institut-Agro, 35590 Saint-Gilles, France, ²IFIP, Institut du Porc, 35651 Le Rheu, France; dubois@itavi.asso.fr

Global warming and the increased frequency of heat waves intensify the risk for reproductive sows to be exposed to temperatures above their thermoneutrality zone. This affects the overall sow herd performance through feeding behaviour perturbation, reduced prolificacy, unsuccessful insemination, or increased mortality. A model was developed on Python to simulate dynamic interactions between ambient temperature in gestation rooms and individual performances of sows in the herd. Dynamics of ambient temperature result from thermal balance between heat losses (walls, air renewal) and heat sources (animals, heaters) in the room, depending on feeding management, the fan and heating systems management, walls' thickness and conductivity, and outside temperature. The model runs on an hourly time step and couples an individual-based module of herd management and feeding practices with a model of thermal balance in the room. The herd module applies discrete events associated to sow reproduction and farmer's practices. It also describes rooms with reproduction stage, number of animals and occupation time. The heat production of each sow is modelled as a function of its gestation stage, live body weight, production objectives (backfat thickness and litter size at farrowing) and diet. Data from three batches of sows were used to evaluate the model's ability to predict sows' performance and the effective ambient temperature within a gestation room. The sows' ingestion and live weight evolution were similar between observed and simulated data. Simulated temperatures were similar to the observed temperatures (mean error=0.3, 0.2 and 0.8 °C; RMSEP=0.8, 0.9 and 1.2 °C, respectively for the three batches). However, the simulated variation amplitude is larger than the observed one, especially during heat peaks. A better description of the hourly distribution of feed intake, individual activity level, and regulation rules of fan and heating systems should improve the accuracy of model predictions. The model will be integrated into a decision support tool to assess the vulnerability of swine systems to climate change.

Supervised machine learning as a tool to improve farrowing monitoring and stillborn rate in sowsC. Teixeira Costa¹, G. Boulbria¹, C. Dutertre², C. Chevance¹, T. Nicolazo¹, V. Normand¹, J. Jeusselin¹ and A. Lebreton¹¹Rezoolution, ZA de Gohélève, 56920 Noyal-Pontivy, France, ²HumanoIA, 338 route de Philondex, 64410 Cabidos, France; c.teixeira-costa@rezoolution.fr

On average, more than 60% of sows give birth to stillborn in French farms. It is an important cause of piglet mortality which continue to increase with the constant improvement of sow's prolificacy. The objective of this study was to build a predictive model of stillborn rate. This study was performed in two farrow-to-finish farms and one farrowing farm located in Brittany. In each farm, number of total born (TB), born alive (BA), stillborn piglets (S), same data at previous farrowing (TBn-1, BAn-1 and Sn-1), backfat thickness (BFT) just before farrowing and at weaning, and parity rank were added to our dataset. In total, 3,686 farrowing data were recorded. Bayesian networks as an integrated modelling approach were used for analysing stillborn rate at farrowing using BayesiaLab® software. Our results propose a hybrid model to predict the stillborn percentage during farrowing. Three significant main risk factors were retained by the model, namely, the parity rank (percentage of total mutual information: MI=64%), Sn-1 (MI=25%) and TBn-1 (MI=11%). Additionally, a fourth factor (BFT just before farrowing) was also retained for sows of parity five or more (MI=0.4%). Practically, for example, in the best conditions (i.e. low litter rank, less than 8% of stillborn and a prolificacy lower than 14 piglets at the previous farrowing), our model predicted a stillborn rate almost divided by two from 6.5% (mean risk of our dataset) to 3.5% for a sow at the next farrowing. On the opposite (i.e. older sows with a BFT<15 mm, more than 15% of stillborn and a prolificacy higher than 18 piglets at the previous farrowing), the risk would be multiplied by 2.5 from 6.5 to 15.7%. In our knowledge, it is the first study updating the Blackwell grid published in 1987. Our results highlight the impact of previous prolificacy and stillborn rate on the probability of stillborn. Moreover, the importance of backfat thickness, especially on old sows, is to be considered. These hopeful results would allow the farmer to classify sows according to their risk of give birth to stillborn and to manage them accordingly.

Use of accelerometers to predict the behaviour of growing rabbitsM. Piles¹, J.P. Sánchez¹, L. Riaboff^{2,3}, I. David⁴ and M. Mora¹¹IRTA, Torre Marimon s/n, Caldes de Montbui (Barcelona), 08140, Spain, ²VistaMilk SFI Research, Teagasc Moorepark, Fermoy, Co. Cork, P61 C996, Ireland, ³School of Computer Science, University College Dublin, Belfield, Dublin 4, D04 V1W8, Ireland, ⁴GenPhySe, Université de Toulouse, INRAE, Castanet Tolosan, France, 31320, France; miriam.piles@irta.cat

One of the challenges of precision livestock is to find tools to quantify individually the time that animals spend on each of the different activities. In this study, we propose to use accelerometers to predict the type of activity that growing rabbits are engaging at each moment. Eight rabbits (4 fed under restriction and 4 fed *ad libitum*) were equipped with an accelerometer and filmed simultaneously. A total of 4.5 hours of video were annotated, identifying 7 types of activity: eating (E), drinking (D), moving in-situ (M), walking (W), grooming (G), lying (L) and sitting (S). These types were grouped into 4 classes of activities: eating (E), drinking (D), resting (R, L+S) and general movement (GM, M+W+G). Accelerometer signals and video annotations were manually synchronized. The signal was segmented into windows of 2 seconds, in which a total of 47 features were extracted from the three axis in time and frequency domain. They included position and dispersion parameters. A total of 6,658 windows were retained. Using the training set (80%), a 3-fold cross validation was conducted to optimize the hyperparameters and to select the 20 most informative features with random forest. This algorithm was implemented to construct the prediction model with all training data given the hyperparameters previously obtained. The overall classification accuracy was 0.74. The best predicted class was E with an accuracy and a recall of 0.83 and 0.75, respectively. The worst predicted class was GM with an accuracy and a recall of 0.66 and 0.50, respectively, primarily confused with class R. These results are expected to improve by increasing data from less frequent classes synthetically and/or by annotating more images in other batches of animals. These results show that the accelerometer seems to be a suitable tool to quantify the time that rabbits devote to different daily activities. However, more data should be annotated and other algorithms are worth testing to improve predictive models.

Session 89

Theatre 9

Use of accelerometry data to detect kidding in goatsP. Gonçalves¹, M.R. Marques², A.T. Belo², A. Monteiro³ and F. Braz⁴¹Universidade de Aveiro, Campus Universitário de Santiago, 3810-193 AVEIRO, Portugal, ²Instituto Nacional de Investigação Agrária e Veterinária, Av. Professor Vaz Portugal, 2005-424 Vale de Santarém, Portugal, ³Escola Superior Agrária de Viseu, Quinta da Alagoa – Av. Dr. António Almeida Henriques, 3500-606 Viseu, Portugal, ⁴Instituto Federal Catarinense, Campus Araquari, Araquari 89245-000, Brazil; pasg@ua.pt

Kidding assistance for goats is a critical factor in reducing problems such as mother and kid mortality arising from birth complications. Creating an autonomous mechanism that allows continuous monitoring of the process would thus allow for timely human intervention. The application of Internet of Things technologies to monitor animal behaviour during kidding events, specifically through the use of wearable inertial sensors, allows for the analysis of the dynamic animal behaviour, the identification of behaviour patterns, as well as the detection of their changes. Present work consisted in the analysis of a public goat kidding dataset generated from the sensorization of 16 pregnant and two non-pregnant Charnequeira goats. The data, obtained by continuous sampling every 10 s during the experiment (day and night), include ultrasound measurements from neck to floor height, and accelerometry data measured by an accelerometer existing at the monitoring collar. It also includes the time the kiddings occurred, how many offspring they produced, and additional remarks were used to annotate the accelerometry data. A deep learning mechanism solution to identify behaviour pattern changes was created, using several concept drift mechanisms to detect and adapt the learning model to the changes in the data stream. Hourly intervals of 5, 4, 3, 2, 1, before, during, and one hour after the kidding interval, were analysed and the accuracy of kidding prediction was measured for each of the algorithms in the referred intervals. Despite the small sample size of animals and kidding events, the results obtained are very promising, especially when using the XGBoost and Random Forest algorithms, with accuracies close to 60%, revealing that the test should be continued so that new kidding events can be observed and the learning model can be improved. Future work plans include integrating the detection mechanism into a gateway to create a trial enabled with real-time kidding detector.

FTIR milk fatty acids quantification for non-invasive monitoring of rumen health in dairy cowsF. Huot¹, S. Claveau², A. Bune^{1,2}, D. Warner³, D.E. Santschi³, R. Gervais¹ and E.R. Paquet¹¹Université Laval, 2325 rue de l'université, Québec, Qc, G1V0A6, Canada, ²Agrinova, 640, rue Côté Ouest, Alma, Qc, G8B7S8, Canada, ³Lactanet, 555, boul. des Anciens-Combattants, Ste-Anne-de-Bellevue, Qc, H9X3R4, Canada; felix.huot.1@ulaval.ca

Our objective was to validate the possibility to detect subacute ruminal acidosis (SARA) from milk FTIR fatty acids (FA) and machine learning. For the prediction of SARA, a total of 562 milk samples (67 Holstein cows, 7 Canadian farms) were used. Every milk sample was associated with its corresponding SARA classification (SARA-positive if the cow spent 300 minutes or more with a reticuloruminal pH under 6.0 or SARA-negative otherwise). Data were split into a training and a validation set consisting of 70 and 30% of animals, respectively. Partial least square models were validated using 3 cross-validation (CV) scenarios: (1) completely random; (2) individual cow allocated to either training or test sets; (3) individual farm allocated to either training or test sets. We also tested 3 sets of predictors: (1) Milk major components, namely fat, protein, lactose, MUN, and SCC (MMC); (2) Milk FA composition (MFA); and (3) MMC coupled with MFA (MCFA). Area under the ROC curve (AUC) was used to evaluate model performance. The effect of the set of predictors was assessed using a mixed model and higher AUC were obtained for both FA and MCFA models ($P<0.01$), suggesting that milk FA provided essential information to the models. We then evaluated models on the validation set and compared the performance of the CV scenarios. Training models on the completely random CV led to the lowest prediction performance on new data ($P<0.01$). Thus, using different animals/farms in the CV is of importance for a better performance evaluation. Overall, the best predictions were obtained when test and training sets were selected based on individual cows and with MCFA predictors (CV-AUC=0.75; Validation-AUC=0.65). Milk FTIR FA quantification enables monitoring of SARA on commercial farms with moderate performance.

Theatre 11

Optimizing breeding performance through algorithmic approaches to maximize meat quality in livestockJ. Albechaalany^{1,2}, M.P. Ellies-Oury^{1,2}, J.F. Hocquette², C. Berri³ and J. Saracco⁴¹Bordeaux Science Agro, 1, cours du Général de Gaulle, CS 40201, 33170 Gradignan Cedex, France, ²INRAE, UMR1213, Theix, 63122, France, ³INRAE, UMR BOA, 37380 Nouzilly, France, ⁴INIRIA, IMB, 33400 Talence, France; john.albechaalany@agro-bordeaux.fr

Consumers are now increasingly aware of the impact of meat production on animal welfare and the environment. Simultaneously, there has been a decline in meat consumption and a demand for high-quality meat (in terms of sensory as well as nutritional quality). This study aims to propose a methodological approach that uses breeding practices to estimate meat quality, aiming to achieve optimal quality and meet consumer demand. To achieve this goal, we have developed an updated version of NSGA-II (Non-dominated Sorting Genetic Algorithm II). This algorithm generates a set of candidate solutions, selects the best individuals based on their fitness, and applies genetic operators such as crossover and mutation to generate new offspring. The decision space is defined by the variables X related to the management of breeding practices, while the objective space Y represents the variables related to the sensory and/or nutritional quality of the meat to optimize. To ensure accuracy and precision, the fitness value of each objective is assessed using a multiple linear regression model. An AIC (Akaike Information Criterion) approach is then mobilized to select the most relevant model for each objective. Once a new population is evaluated using the selected models, the Pareto front approach is utilized to identify the non-dominant variables in the multi-objective space. In order to prevent the algorithm from getting trapped in local maximum scenarios, a crowding distance method is employed to maintain population variability and to ultimately reach the global maximum. With this approach, we can generate the best breeding practices for each breed/type of animal and optimize quality. Using the hypervolume approach, we can compare the different optimum front scenarios and recommend, for example, the best breed according to the objectives. In conclusion, this study presents an updated methodological approach for estimating meat quality using breeding practices, which has the potential to improve meat quality and meet consumer demands.

Detection of multiple feeding behaviours in calves using noseband and accelerometer sensors

S. Addo, K.A. Zipp, M. Safari, F. Freytag and U. Knierim

University of Kassel, Faculty of Organic Agricultural Sciences, Nordbahnhofstr. 1a, 37213 Witzenhausen, Germany; sowah.addo@uni-kassel.de

Behavioural activities provide a valuable source of information for accessing animal health and welfare. However, gathering such information through direct personal observation is laborious, which makes the use of digital tools a viable alternative. The current study aimed at investigating suckling, feeding and ruminating behaviours of calves using a combination of noseband and accelerometer sensor variables. Ten calves were fitted, each with a ruminating halter containing an accelerometer at the cheek, and a noseband to measure acceleration and pressure, respectively, over a three-day period. Additionally, direct observational data on the various behaviours lasting about ten hours were concurrently recorded. Eighteen features were generated from the raw sensor data for five different epoch length categories (1 s, 5 s, 10 s, 30 s and 60 s). A sixth epoch category was defined by combining the afore-mentioned epoch lengths. Finally, different machine learning algorithms including random forest (RF), classification and regression tree (CART) and conditional inference tree (ctree) were applied to each epoch category to simultaneously predict suckling, feeding and ruminating events. Using 70% of each dataset for training and the remaining as test set, preliminary results on two animals showed very high accuracies for the mixed epoch dataset: 99.7% (RF), 97.8% (ctree) and 85% (CART), while the 60 s epoch dataset had the lowest, being 72% (CART). From the mixed epochs, the estimates of sensitivity, specificity and precision for all behaviours were above 95% considering RF and ctree. Features including the variance in pressure and movement intensity at 60 s intervals proved to be very important in our prediction models. Our findings have a potential for studying changes in feeding behaviours and welfare of calves undergoing natural weaning.

Numerical detection of productive anomalies induced by heat stress in dairy cows

M. Bovo, M. Ceccarelli, C. Giannone, S. Benni, P. Tassinari and D. Torreggiani

University of Bologna, Department of Agricultural and Food Sciences, Viale Giuseppe Fanin 48, 40127, Italy; marco.bovo@unibo.it

Since dairy cattle are in an intensive housing system for most of their lives, facilities have a significant impact on the animals' welfare. Despite the growing interest in finding new animal housing and equipment management strategies for reducing impacts, and the interesting results mostly concerning the daily production data, there are lack of studies investigating the factors that can lead to productive anomalies. On the other hand, the use of automatic milking robots, milking parlours, collars and pedometers allows the precise monitoring of dairy cows, providing farmers with real time information. In this context, the early detection of production anomalies is fundamental for animal health and safety. In this work, two numerical methods for detecting daily milk production anomalies are presented and applied to three different farms selected as case studies. The methods described in this paper provide a numerical procedure having the scope of detecting milk yield anomalies. Both the algorithms presented hereinafter are based on statistical calculations and take as input daily resting time and daily milk yield recorded respectively by the pedometers worn by the cows and by the automatic milking system of the barns. The first method take into consideration two indicators, namely the Difference in Relative Production (DRP) and the Daily Rest time (DR). DRP is defined as the relative difference in daily milk yield between real-time data of a single animal and a baseline curve considered as an ideal trend. An anomaly (i.e. a deviation from the normal value) is determined, for a single cow, for a specific day, if two conditions on DRP and DR are contemporary verified. In the second method, starting from the Wood function, maybe the most famous model to fit the production of the cow in dependence of day in milk, the concept of reliability of robust statistics has been introduced in order to obtain, for each animal, a more solid and realistic lactation curve since not affected by outlier values.

Using existing slaughterhouse data to assist detection of boar taint*B. Callens¹, M. Aluwé¹, R. Klont², M. Bouwknecht² and J. Maselyne¹**¹ILVO, Burg Van Gansberghelaan 92 bus 1, 9820 Merelbeke, Belgium, ²Vion Food Group, Boseind 15, 5281 RM Boxtel, the Netherlands; jarissa.maselyne@ilvo.vlaanderen.be*

This study aimed to investigate whether existing slaughter data could be used to identify pig carcasses or batches with (a high risk of) boar taint presence. The human nose method is currently used for this purpose as an instrumental method is lacking, but it is labour-intensive and requires close follow-up. The dataset analysed consisted of more than one million records of entire male pigs collected by Vion over a period of 28 months. The data contains carcass quality statistics like muscle- and fat thickness and lean meat percentage determined by a fibre optic probe, as well as the estimated weight and yield of the different meat cuts determined by the Frontmatec Autofom III. Furthermore, waiting time of the pigs in the slaughterhouse, month of slaughter and the cold carcass weight were included. Principle Component Analysis was used to exclude some outliers. Ten-fold cross-validation was used for the results, and z-score normalisation was applied. A Random Under Sampling Boosting Tree Ensemble model was used to handle the imbalanced data (only around 3.1% boar taint), resulting in an accuracy of 59.5%. Other machine learning methods (including XGB, various SVM, Trees, KNN, ANN, Naïve Bayes, Discriminants) achieved higher accuracy on the majority class (no boar taint), but failed to classify the minority class of boar taint present. A balanced dataset was created by randomly sampling the majority class, but the accuracy remained low even for the best performing balanced models (58-59%). When these balanced models were applied on the full dataset, accuracy was similar (57-59%). Variable importance was determined using local model-specific and model-agnostic methods but the results were not consistent. Overall, it does not seem possible to create a practical working model to identify pig carcasses or batches with a higher risk of boar taint using existing slaughter data alone. Additional data from other sources such as the farm might be needed to create a better performing risk assessment model, as boar taint is a multi-factorial problem. A dedicated boar taint sensor would also be a huge step forward for automation.

Session 89

Poster 15

Evaluation of SARA risk prediction models based on non-invasive measurements in dairy cows*V. Leroux, C. Jaffres, A. Budan and N. Rollet**Neolait, Cargill Animal Nutrition, Voie de la ville Louze, 22120 Yffiniac, France; vincent_leroux@cargill.com*

The subacute ruminal acidosis (SARA) is an energy metabolism disorder affecting frequently dairy cows. The measurement of this disorder is difficult to evaluate in farms. The objective of this study is to define the prediction performance of different multiparametric models based on non-invasive measurements to predict SARA in dairy cows. The accuracy of 12 multiparametric prediction models of SARA was evaluated using data coming from 65 articles published in peer review journals, where SARA was evaluated according to specific pH thresholds. The efficiency of the prediction of SARA (EF) ranged from 50 to 81%. The sensitivity and the specificity of the best model were respectively 83 and 80%. The EF reached 85% when three prediction models were combined, with a sensitivity of 78% and a specificity of 89%. One out of 12 models and a combination of 3 of them, all based on faecal pH, milk urea, DMI and fat milk/protein milk were able to predict in a simple and non-invasive way SARA in dairy farms with an efficiency higher than 80%.

Use of linear data for characterization and selection of sport horses with highest genetic potentialK.F. Stock¹, A. Hahn², I. Worke¹ and W. Schulze-Schleppinghoff²¹IT Solutions for Animal Production (vit), Heinrich-Schroeder-Weg 1, 27283 Verden, Germany, ²Oldenburger Pferdezuchtverband e.V., Grafenhorststrasse 5, 49377 Vechta, Germany; friederike.katharina.stock@vit.de

Routine linear profiling and genetic evaluation for linear traits is giving access to detailed information on the individual horse and its genetics regarding conformation, gaits and jumping. Previous studies have indicated the suitability of genetic linear profiles for selecting horses for performance in riding sport, with generally minor role of conformation and particular value of distinct aspects of gaits for dressage and several linear jumping traits for show jumping. The aim of this study was to quantify the possible impact of strong focus on top sport performance on development towards extremes and risk of overemphasis of certain traits. Analyses were performed for the mare population of the Oldenburg studbooks OL and OS and based on phenotypic data and estimated breeding values (EBVs) for 46 linear traits included in the routine genetic evaluation and on EBVs for sport traits, using rank-based (R) and summarizing (highest level achieved, L) trait definitions for reflecting dressage (D) and show jumping (J) competition performance. Mares were categorized depending on whether or not they belonged to the 10% (25%) with the highest sport EBVs, followed by statistical analyses of these categories vs linear trait phenotypes and EBVs using SAS software. Only mares with sport EBV reliability $\geq 30\%$ were considered ($n=2,873$ for DL to $n=5,187$ for JR), and inclusion criterion of own phenotypic data and/or at least two progeny with phenotypic data for the linear traits reduced the studied mare sample to $n=1,084$ (JL) to $2,737$ (DR). Analyses of variance revealed that ranking among the mares with highest sport EBV significantly increased the probability of extreme linear trait EBV with discipline-specific pattern (all gait and few conformation aspects for D, jumping aspects for J). On the phenotypic level, more extreme values were rarely found in the mares and their progeny, and none of the category differences reaching significance indicated strong shifts towards extreme trait expressions which may harm long-term functional integrity. The use of linear data for continued monitoring is recommended.

Session 90

Theatre 2

Effect of mitochondrial genetic variability on performance of endurance horsesA. Ricard^{1,2}, S. Dhorne-Pollet², C. Morgenthaler², J. Speke Katende², C. Robert^{2,3} and E. Barrey²¹Institut Français du Cheval et de L'Equitation, Pole développement, innovation et recherche, 61310 Exmes, France,²Université Paris-Saclay, AgroParisTech, INRAE, GABI, 78350 Jouy-en-Josas, France, ³Ecole Nationale Vétérinaire d'Alfort, 7 Avenue du Général de Gaulle, 94700 Maisons-Alfort, France; anne.ricard@inra.fr

Endurance races in horse require a high level of aerobic energy production to fulfil the demand of the cardio-respiratory system and skeletal muscles. At the cellular level, the mitochondrial respiratory chain (RC) performs ATP synthesis via the phosphorylation oxidative pathway. We performed mtDNA sequencing followed by SNP calling and GWAS analysis on 434 horses (Arabian 83.4% and Anglo-Arabian 9.6%) descended from 232 sires with an average family size of 1.8 descendants per sire. The endurance performances were measured by two traits: average speed and status at the arrival (finishing or not). Among 1,268 SNP detected with some heteroplasmy, 458 were finally used after selection with minimum calling frequency of 85% and minimum minor allele frequency of 2.3%. The GWAS analysis was performed using a mixed animal model to estimate the SNP allele effects (up to 4 copies) on the two performances corrected for fixed effects (age, sex and race). Random polygenic effect was included in the model using pedigree information (5,382 ancestors). ASREML software was used. The model could detect a total of 15 SNP significantly associated (raw P -value < 0.01) to the performance traits. Seven SNP were significantly associated with both average speed and status at the arrival. In these cases, the reference allele was frequent ($\geq 89\%$) and its effect was favourable on both traits (from +0.30 to +0.64 in phenotypic standard deviation unit). Five SNP were significantly associated with average speed with the same configuration: reference allele frequent ($> 92\%$) and favourable (+0.40 to +0.49). Three SNP were significantly associated with status at the arrival, with high reference allele frequency ($\geq 93\%$) and favourable effect of reference allele for one SNP (+0.45) and unfavourable for two SNPs (-0.39 and -0.45).

Early life jumping traits' potential as proxy for jumping performance in Belgian Warmblood horses

L. Chapard, R. Meyermans, W. Gorssen, N. Buys and S. Janssens

Center for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, Box 2472, 3001 Leuven, Belgium; lea.chapard@kuleuven.be

The breeding goal of most Warmblood studbooks is to breed successful show jumpers. However, competition results are only available rather late in life (horses start competing at 6 years old on average). Moreover, performance in competitions was shown to be lowly heritable. To improve the breeding practice, having good proxy phenotypes that are available from an early age on and can be used to indirectly select on the trait of interest would be of interest for studbooks. In this study, we investigated the potential use of early life jumping traits as proxy for later success in competitions in Belgian Warmblood horses. Therefore, we studied 2,280 free jumping and 1,768 jumping under saddle records on 2,170 and 1,588 horses and eleven early life jumping traits assessed during young horses contests: scope, take-off (power/quickness), technique of forelegs, technique of back, technique of haunches, attitude (willingness), care, stride length, impulsion, elasticity and balance. These traits were scored by trained assessors on a 9-point scale. Additionally, almost 675,000 national show jumping competition records on 26,351 horses and more than 80,000 horses in the pedigree were used in this study. Later success in competitions was expressed as 'adjusted fence height' which combines fence height and ranking in competitions. Genetic correlations between early life jumping traits and adjusted fence height were estimated using bivariate animal models. They were moderate to high (from 0.40 for attitude (willingness) assessed freely and under saddle to 0.65 for scope assessed freely). These results show that early life jumping traits provide valuable information for the target trait (success in competitions) and could help achieving more genetic progress in the Belgian Warmblood populations by including early life jumping traits in their breeding program.

Genetic covariance components of conformation, movement and athleticism traits in Irish Sport Horses

J.L. Doyle¹, S. Egan¹ and A.G. Fahey²

¹Horse Sport Ireland, Naas, Co. Kildare, W91 TK7N, Ireland, ²University College Dublin, School of Agriculture and Food Science, Dublin 4, D04 V1W8, Ireland; jdoyle@horsesportireland.ie

Conformation, movement, and athleticism traits have been routinely captured on Irish Sport Horses (ISH) via linear profiling at studbook inspections of mares and stallions since 2010. The scoring system used in the ISH studbook is derived from the linear descriptive system that was first introduced by the Dutch Warmblood studbook in 1989 and has since been widely used as inspiration for other warmblood studbooks. Genetic parameters of linear descriptive traits have been extensively researched in continental warmbloods but, no such research has been conducted in the ISH population. Therefore, the objective of the present study was to estimate the genetic parameters of the linear scored conformation, movement, and athleticism (jumping) traits in the ISH and to determine their suitability for inclusion in a national genetic evaluation for sport horses. A total of 37 linear scored traits on 2,129 ISH were included in the analysis. Data were analysed using an animal linear mixed model that included the fixed effects of sex of the horse, age at scoring, the year of scoring, and the chairperson of the inspection panel that scored the horse. The heritability estimates for the conformation traits ranged from 0.03 (standard error (SE)=0.04) for length of croup to 0.23 (SE=0.06) for head-neck connection and shape of feet. The lowest heritability estimate within the movement traits was for walk correctness (0.09; SE=0.04) while heritability estimates for the rest of the traits within this group ranged from 0.23 (SE=0.06) for canter balance to 0.40 (SE=0.07) for trot length of stride. Scope (0.31; SE=0.07) had the highest heritability of the athleticism traits while attitude (0.02; SE=0.04) had the lowest heritability of these traits. Overall, the genetic correlations among the traits were in the same direction as the phenotypic correlations among the same traits but were generally stronger in magnitude. In general, the strongest genetic correlations were found among the movement traits and the athleticism traits. Results of the present study may be used for future genetic evaluations in the ISH population.

Start status in Swedish Warmblood horses

Y. Blom, S. Eriksson and Å. Gelinder Viklund

Swedish University of Agricultural Sciences, Dept. of Animal Breeding and Genetics, P.O. Box 7023, 75007, Sweden; asa.gelinder.viklund@slu.se

The breeding goal for the Swedish Warmblood horse (SWB) is to produce internationally competitive horses in dressage and show jumping. In the current genetic evaluation, lifetime accumulated points is used as measure of competition performance. Points are given to the 25% best horses in each competition. There is a preselection of horses that enter competition, and some competing horses never receive points. The aim of this study was to analyse the all-or-none trait start status in competition for possible use in genetic evaluation. Since 2007, all started horses in competitions are recorded. The studied population was restricted to SWB horses born between 2003 and 2018 that had the possibility to compete during the period from 2007 until 2022. Horses were categorized into disciplines according to their sire's and grandsire's discipline category. In total, 23,125 jumping (J) horses and 14,470 dressage (D) horses were studied separately. Information on start status in show jumping or dressage, lifetime accumulated points, assessed gaits and jumping traits from young horse test (YHT) and riding horse test (RHT) were available. The genetic analyses were performed with BLUP animal models. For J horses, 12,837 (55.5%) had competed in show jumping, whereof 9,413 (73.3%) had received points. Out of the competing J horses, 43.1% had also assessment from YHT (4,208) and/or RHT (1,905). For D horses, 4,964 (34.3%) had competed in dressage, whereof 2,722 (54.8%) had received point. About 55% of the competing D horses also had assessment from YHT (2,408) and/or RHT (997). The heritability for start status in show jumping was estimated to 0.30 on the observable 0/1-scale and 0.47 when transformed to the underlying continuous scale. For start status in dressage the corresponding heritability estimates were 0.20 and 0.34. Genetic correlations were strong between start status in show jumping and jumping traits at YHT and RHT (0.78-0.93) and moderate to strong between start status in dressage and gait traits at YHT and RHT (0.46-0.88). The genetic correlations between start status and accumulated lifetime point were strong, 0.93 for show jumping and 0.86 for dressage. We conclude that start status has potential to be used in the genetic evaluation.

Session 90

Theatre 6

Genetic analysis of the precocity potential in trotting races of Spanish Trotter Horses

M. Ripollés-Lobo, D.I. Perdomo-González, M.D. Gómez, M. Ligero and M. Valera

Universidad Sevilla, Agronomy, Ctra.Utrera km 1, 41005 Sevilla, Spain; marriplob@alum.us.es

Precocity is a quality that is sought after in all racehorses in order to obtain better results in the short term, as there is a perceived better opportunity for return on training costs in prize money. The Spanish Trotter Horse (STH) can be considered as a composite of the main World trotter populations. In the STH, a strong selection for sport performance in trotting races is underway. So far, the potential of horses for training and early participation in trotting races has not been evaluated from a genetic point of view. The aim of this paper is to study the precocity in trotting races of STH, estimating the genetic parameters of different variables: (1) age at first placed race (position 1, 2 or 3); (2) percentage of races placed in five years of life; (3) number of races needed for the animal to reach the first placed race. For this purpose, we used 176,137 racing records from 4,947 horses during the five-year period from the birth of each animal. All the known ancestors of the recorded animals were included in the pedigree file (11,488 horses), making sure that at least four generations were included. The genetic parameters were estimated using Gibbs90+ modules of BLUPF90 package software. The genetic model of variable 1, included race time as covariate and gender (2 classes), type of race (2 classes), distance meters (3 classes), racecourse (4 classes), and race earnings (3 classes) as fixed effects. The model of variable 2, included number of races in 5 years and age at first race as covariate, and gender (2 classes), total earnings in 5 years/number of races placed, year of birth of the horse (7 classes) as fixed effects. The model of variable 3 included age at first placed race minus age at first race participated as covariable and gender (2 classes) and age at the first race placed (3 classes) as fixed effects. The estimates of heritability were 0.14 ± 0.030 for variable 1, 0.32 ± 0.037 for variable 2 and 0.08 ± 0.023 for variable 3. The precocity evaluated through these new criteria, is a predictive tool for selection of horses for early racing performance and for informing training decisions.

Is the ability to race barefoot a heritable trait in Standardbred trotters?

P. Berglund¹, S. Andonov¹, A. Jansson², T. Lundqvist³, C. Olsson³, E. Strandberg¹ and S. Eriksson¹

¹Swedish University of Agricultural Sciences, Dept. of Animal Breeding and Genetics, P.O. Box 7023, 75007 Uppsala, Sweden, ²Swedish University of Agricultural Sciences, Dept. of Anatomy, Physiology and Biochemistry, P.O. Box 7011, 75007 Uppsala, Sweden, ³Swedish Trotting Association, P.O. Box 20151, 16102 Bromma, Sweden; paulina.berglund@slu.se

Racing barefoot is a common practice to increase speed of the horse in trotting races. By removing all four shoes or only the hind shoes at races, the horse does not only run faster, but the risk of gallop and disqualification also increases. Not all horses have sufficient hoof quality to race barefoot, and the hind hooves are often the limiting factor. Therefore, the aim of this study was to investigate the possibilities to select for the ability to race barefoot, as an indirect measurement of hoof quality in Swedish Standardbred trotters by estimating heritability. The data contained recordings of shoeing information from Swedish trotting races from the years 2005-2022. Only races in the period from March 1 to November 30 were included, because barefoot racing is not allowed during winter. Only horses that had started at least 10 races in the studied period and with at least one race with barefoot hind hooves were included in the study. In total 546,492 observations of 19,261 horses born 2002-2018 and raced at 3-10 years of age were included. Ability to race barefoot was defined as relative frequency of races with unshod hind hooves. This figure increased by birth years from 0.27 in 2002 to 0.31 in 2018. A univariate mixed linear animal model with sex and year of birth as fixed effects was analysed with the BLUPF90 suites of programmes using REML to estimate variance components. Heritability of 0.21 ± 0.02 was estimated. Further studies using repeated observations are needed to verify the genetic contribution to the ability to race barefoot and genetic correlations to the traits used in today's genetic evaluation. In conclusion, these preliminary results show that there exists a genetic variation in ability to race with barefoot hind hooves.

Session 90

Theatre 8

Searching for genomic regions associated with conformation traits in the Pura Raza Español horse

N. Laseca¹, C. Ziadi¹, D.I. Perdomo-González², M. Valera², P. Azor³, S. Demyda-Peyrás¹ and A. Molina¹

¹University of Cordoba, Department of Genetics, Campus de Rabanales. N-IV, km 396, 14014 Córdoba, Spain, ²University of Seville, Department of Agronomía, ETSIA, 41013 Seville, Spain, ³Asociación Nacional de Criadores de Caballo de Pura Raza Española, ANCCE, Edificio Indotorre, 41012 Seville, Spain; ge2lagan@uco.es

Conformation is of great importance in equine breeds like Pura Raza Español (PRE) horse, not only because it reflects the horse's appearance, but also because it is related to its functionality, especially classical dressage in this breed. The aim of the study was to identify markers associated with 5 zoometric measurements (scapular-ischial length (SiL), length of back (LB), dorsal-sternal diameter (DsD), thoracic perimeter (TP), perimeter of anterior cannon bone (PACB)), of the 50 zoometric measurements analysed in the PRE horse. For this, a mixed model was implemented using the ssREML animal methodology with the BLUPF90+ package. In addition to the animal effect, sex, age, coat colour, and country of origin of the animal were included as fixed effects. A total of 7,152 horses from 1,615 studs from 6 countries were included. From them, 2,916 horses were genotyped with 61,271 SNPs. The relationship matrix included ancestors up to the 5th generation with 41,889 animals. The average molecular relatedness between the genotyped animals was 0.073 and the genealogical relatedness between the animals with records and the genotyped animals was 0.029. Our results showed 562, 27, 49, 168, and 70 significant SNPs associated with SiL, LB, DsD, TP, and PACB, respectively ($P < 10^{-6}$). Furthermore, 17 common significant markers were found for all traits, of which 14 SNPs were located on chromosome 3 and 3 SNPs on chromosome 17. In conclusion, although more studies are required to increase the number of animals and the number of zoometric measurements analysed, our findings indicate that genomic markers associated with conformational traits are located on regions of chromosomes 3 and 17.

Successful genotype imputation from medium to high density in Belgian Warmblood horsesL. Chapard¹, R. Meyermans¹, W. Gorssen¹, B. Van Mol², F. Pille², N. Buys¹ and S. Janssens¹¹Center for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, Box 2472, 3001 Leuven, Belgium, ²Ghent University, Faculty of Veterinary Medicine, Department of Large Animal Surgery, Anaesthesia and Orthopaedics, Salisburylaan 133, 9820 Merelbeke, Belgium; lea.chapard@kuleuven.be

Genotype imputation is a method that infers unobserved genotypes in a sample of individuals using a reference population. Genotype imputation permits increasing the density of available genotypes within a population and combining genotypes from different density SNP arrays and can therefore improve the power of genomic studies. Here, we investigate the feasibility of genotype imputation from medium to high density SNP arrays in Belgian Warmblood horses. 628 horses were genotyped during the course of 3 projects using the Affymetrix Axiom Equine 670K. SNP positions were updated from EquCab 2.0 to EquCab 3.0 and common variants between the three projects (74%) were kept for further analysis. Quality control (QC) was performed on the 31 autosomes and the 628 horses with PLINK v1.9 and consisted of removing individuals with a call-rate ≤ 0.95 , outlying heterozygosity and duplicated individuals and SNPs with a call-rate ≤ 0.95 , minor allele frequency ≤ 0.02 and Hardy-Weinberg equilibrium ≤ 0.00001 . 616 horses and 416,143 SNPs were retained after QC. Haplotype phasing and genotype imputation were performed using Beagle 5.1. A cross-validation scheme was used to assess imputation accuracy for the GGP 70K array. The dataset was randomly divided five times into two sets: a reference set (75% of the horses) and a validation set (25% of the horses). Complete genotypes were retained for horses in the reference set whereas only 52,454 common SNPs between the 670K array and the GGP Equine 70K were kept for horses in the validation set. Imputation accuracy (correlation between true and inferred genotype) was calculated for each horse. Imputation accuracies were high and ranged from 0.93 to 0.98 with a mean value of 0.97. These results show that a reference population of 616 horses can be used for genotype imputation in Belgian Warmblood horses. This opens perspectives to routinely genotype at 70K and impute with this reference population in order to aid in the ongoing and future genomic research in Warmbloods.

Session 90

Theatre 10

Inbreeding in the Belgian equine warmblood population: current degree and evolutionB. Van Mol^{1,2}, H. Hubrechts², R. Meyermans², L. Chapard², W. Gorssens², M. Oosterlinck¹, N. Buys², F. Pille¹ and S. Janssens²¹Ghent University, Department of Large Animal Surgery, Anaesthesia and Orthopaedics, Faculty of Veterinary Medicine, Salisburylaan 133, 9820 Merelbeke, Belgium, ²Center for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, Box 2472, 3001 Leuven, Belgium; bram.vanmol@ugent.be

A tremendous evolution has taken place in the field of equine reproduction during the past decade. Advanced reproduction techniques, such as ovum pick up combined with intracytoplasmic sperm injection and embryo transfer, have become more and more routine procedures in warmblood breeding. These techniques allow 'popular' mares to produce multiple foals per year via surrogate mares. The latter evolution and the impression that only a limited number of popular stallions are preferred by the equine breeders due to strong selection, could generate a fast-paced increase in autozygosity. Consequently, research is needed to assess the current levels of inbreeding in the equine warmblood population and to map the evolution of inbreeding. In this study we estimated the level of inbreeding of the Belgian warmblood population by analysing the HD genotypes (670K, Affymetrix) of over 700 horses by runs of homozygosity (ROH). Horses of the study sample were born in the period 2001-2020 and were divided in 2 time-windows to compute the evolution in the genomic inbreeding coefficient (F_{ROH}). We assessed the F_{ROH} at both the population and the individual level using PLINK. We examined the number and length of ROH to determine the evolution of inbreeding and studied ROH islands to achieve insights in signatures of positive selection. Furthermore, we quantified the genetic diversity by calculating the effective population size (N_e) of the Belgian equine warmblood population. The analyses so far showed restricted recent inbreeding ($F_{ROH} \pm 2\%$) and quite extensive old inbreeding ($F_{ROH} \pm 18\%$). N_e is ± 90 , which means the population is at risk ($N_e < 100$). The final goal of this study is to give equine breeders insights on the inbreeding that occurs in this population and as such help them re-think and adjust their mating choices.

Population structure assessment using genome wide molecular information in Martina Franca donkeyV. Landi¹, E. Ciani² and P. De Palo¹¹University of Bari Aldo Moro, Veterinary Medicine, SP. 62 per Casamassima km. 3, Valenzano (BA), 70010, Italy,²University of Bari Aldo Moro, Department of Biosciences, Biotechnologies and Biopharmaceutics, Via Amendola 165/a Bari, 70126, Italy; vincenzo.landi@uniba.it

The Martina Franca donkey is indigenous to the region of Puglia in southern Italy. It is a medium-sized animal that is renowned for its strength, stamina, and tame temperament. These donkeys are primarily used for agricultural purposes, as they are well adapted to the stony land of the region. The history of the Martina Franca donkey can be traced back to the Roman Empire, where they were used for transportation and agriculture. The breed continued to thrive throughout the Middle Ages, and by the 17th century, they had become a prized possession of the local nobility. However, with the advent of modern mechanization, the demand for donkeys declined, and the breed was almost lost during the decade of '70- '80. Recently, a renewed interest in both meat-derived products and their use in tourism and onotherapy practices, but above all the use of milk as a nutraceutical food for infants and to produce cosmetics has made possible a new increase in the number of animals raised but in the absence of a structured selective plan. To analyse the population structure and compare the pedigree inbreeding data with those obtained from molecular data we analysed 100 samples from 10 farms in the Puglia region using the ddRAD Seq technique. 41,796 genotyped loci were obtained, and finally 28,347 passing the frequency and missingness filters. The call rate for SNPs shows more than 90% of the markers have values greater than 95%. The observed heterozygosity for SNPs is 0.26 ± 0.16 and that for individual is 0.23 ± 0.018 . The results relating to the genetic distances and to the assignment with the Admixture software show how the Farm of the Apulia region (a conservation nucleus) is confirmed as a point of dispersion of breeding animals. The analysis of linkage disequilibrium decay shows some herds, with very low levels in the range 0.4 and 0.6. The divergence of some groups of animals could however be due to exotic genetic introgression phenomena (with other Italian or Spanish breeds) but also the presence of very different genetic lines interesting from a conservation point of view.

Session 90

Theatre 12

Unravelling genomic regions with transmission ratio distortion in horseN. Laseca¹, A. Cánovas², M. Valera³, S. Id-Lahoucine⁴, D.I. Perdomo-González³, P.A.S. Fonseca⁵, S. Demyda-Peyrás¹ and A. Molina¹¹University of Cordoba, Department of Genetics, N-IV, km 396, 14014, Córdoba, Spain, ²Center of Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, ³University of Sevilla, Department of Agronomía, ETSIA, Sevilla, Spain, ⁴Scotland's Rural College, Department of Animal and Veterinary Science, Easter Bush, United Kingdom, ⁵University of Leon, Department of Animal Production, Leon, Spain; ge2lagan@uco.es

Transmission ratio distortion (TRD, or the deviation from the expected Mendelian inheritance) can be due to multiple biological mechanisms affecting gametogenesis, embryo development and postnatal viability. The TRD analysis estimates the frequency with which heterozygous parents transmit each of their two different alleles at a locus. The TRD was characterized across the Pura Raza Español horse genome with a SNP-by-SNP approach using 277 genotyped horses in trios (offspring-stallion-mare) including 554,634 SNPs, by a genotypic and allelic parameterization using TRDscan v.2.0 software. Evidence of TRD was found for 166 SNPs. Among them, 38, 76 and 63 SNPs exhibited overall, stallion- and mare-TRD, respectively. Moreover, among the SNPs identified by the genotypic TRD model, 5 presented additive TRD effect, 3 dominance TRD effect and 3 SNPs showed both additive and dominance TRD. A total of 790 functional candidate genes were annotated in allelic- and genotypic-TRD regions. Functional analyses revealed significant functional categories related to spermatogenesis, gametogenesis, oocyte division, embryonic development, and hormonal activity. Among them, 26 candidate genes were identified playing an important role in fertility and reproductive processes. Twenty-one were associated with allelic TRD (*FGF8*, *CXCL12*, *EPHA2*, *PRLH*, *STAT6*, *SPIRE1*, *NOS2*, *RELA*, *PDPK1*, *GCG*, *CDC25B*, *PDGFB*, *PPARA*, *NTF3*, *CATSPER1*, *PRSS21*, *BAG6*, *KCNU1*, *DDX17*, *MSH5* and *PRNP*) and 6 with genotypic TRD (*HORMAD1*, *YTHDC2*, *HSPA1L*, *EHMT2*, *BAG6* and *ASTL*). Interestingly, the *BAG6* gene encompassed a region with allelic-and genotypic-TRD. To our knowledge, this is the most extensive study performed to evaluate from a genomic perspective the presence of alleles and functional candidate genes with transmission ratio distortion in horse.

Microsatellite-based detection of transmission ratio distortion in the Pura Raza Española horseD.I. Perdomo-González¹, S. Id-Lahoucine², A. Molina³, A. Cánovas⁴, N. Laseca³, P.J. Azor⁵ and M. Valera¹¹Universidad de Sevilla, Ctra Utrera km1, 41005 Sevilla, Spain, ²Scotland's Rural College, Easter Bush, EH25 9RG Midlothian, United Kingdom, ³Universidad de Córdoba, Ctra.Madrid-Cádiz, Km.396, 14071 Córdoba, Spain, ⁴Center of Genetic Improvement of Livestock, University of Guelph, N1G 2W1 Guelph, Canada, ⁵Real Asociación Nacional de Criadores de Caballos de Pura Raza Española, Av. del Reino Unido, 41012 Sevilla, Spain; dperdomo@us.es

Transmission ratio distortion (TRD) is a genetic phenomenon widely demonstrated in most livestock species, which occurs when certain alleles/genotypes are over- or under-represented in the offspring. It can be caused by a variety of factors: embryonic lethality, gamete viability, genomic imprinting, or inbreeding depression. Although there is ample evidence that the expected Mendelian inheritance is altered in certain molecular markers in horses, the TRD has not yet been investigated. A total of 126,394 trios (offspring-stallion-mare) of Pura Raza Española horses genotyped by a set of 17 neutral microsatellite markers have been analysed. The number of alleles available for each marker ranged from 13 to 18, thus a total number of 268 alleles were investigated. The TRDscan software was used with the biallelic procedure to investigate the inheritance of each allele separately. After completing the analysis, a total of 12 alleles (out of 11 microsatellites) were identified with decisive evidence for genotypic TRD; 3 with additive and 9 with heterosis patterns. In addition, 19 alleles (out of 10 microsatellites) were identified displaying allelic TRD. Among them, 14 were parent-nonspecific and 5 were stallion-mare specific TRD. A total of 24 positional candidate genes were annotated within those genomic regions with signals of TRD. Functional analysis using the annotated genes identified molecular functions and biological processes related to cholesterol metabolism and homeostasis which results in unspecific symptoms of reduced growth, fertility, and health. TRD results show the significant impact on the inheritance of certain genetic traits in horses. Further analysis and validation are needed to better understand the TRD impact before the potential implementation in the horse breeding program strategies.

Session 90

Poster 14

Estimation of the genetic parameters for temperament in Haflinger horsesT.H. Zanon¹, B. Fürst Waltl², S. Gruber¹ and M. Gaulty¹¹Free University of Bolzano, Piazza Università 5, 39100, Italy, ²University of Natural Resources and Life Sciences (BOKU), Gregor-Mendel-Straße 33/II, 1180, Austria; thomas.zanon@unibz.it

From the literature, there are indications that the personality and temperament of a horse are sufficiently genetically determined. This background motivated continued collecting of phenotypic information on the temperament in the South Tyrolean Haflinger horses to have it for marketing purpose and to possibly estimate genetic parameters on a long-term basis. The latter may open the possibility to include temperament traits in the breeding program. Therefore, the aim of the present study was to consider for the very first-time phenotypic information from multi-year character testing for estimating genetic parameters for temperament in Haflinger horses. For the present study, data from character testing of 210 South Tyrolean Haflinger mares between 2019 and 2021 were considered. A multivariate estimation of heritabilities (h^2) and genetic correlations (r) was carried out for the criteria 'Interest', 'Activity' and 'Excitement'. In addition, univariate and bivariate estimation runs were also performed. Heritability for the behavioural trait Interest was lowest with 0.07 and a standard error of ± 0.04 . For the other two criteria, Activity and Excitement, h^2 was 0.19 ± 0.05 and 0.21 ± 0.04 , respectively. The genetic correlation between Interest and Activity and between Interest and Excitement was in both cases negative with -0.52 and -0.61, respectively, while the genetic correlation between Excitement and Activity was positive (0.99). Although the quality of the phenotypic performance data collected during the character testing was good, the restricted number of animals limited the accuracy of the estimated genetic parameters. As next step, a continuation of the collection of phenotypic temperament performance on mares and possibly also on stallions is crucial for increasing the robustness of the data and therefore, improve the accuracy in heritability estimation.

Estimation of the genetic propensity to suffer hock osteochondrosis in Pura Raza Española horsesM. Ripollés¹, A. Molina², M. Novales³, C. Ziadi², E. Hernández³ and M. Valera¹¹Universidad Sevilla, Ctra Utrera, 41005 Sevilla, Spain, ²Universidad Córdoba, Genética, Rabanales, 14014 Córdoba, Spain, ³Universidad Córdoba, Medicina y Cirugía Animal, Rabanales, 14014 Córdoba, Spain; marriplob@alum.us.es

Osteochondrosis (OC) is a Developmental Orthopaedic Disease caused by an imbalance in bone metabolism that weakens the bone structure. It can cause pain, swelling or lameness. It has importance in most sporting breeds, including the Pura Raza Española horse (PRE). The hock OC in PRE horses has been evaluated at the level of 2 zones in both limbs, left and right (Eict: Intermediate eminence of tibial cochlea, Llta: Lateral trochlea of talus) in 3,053 horses. The clinical veterinary hospital of University of Cordoba performed the clinical diagnosis of the digital radiographs. Prevalence of 13.33% was determined for hock OC, being the highest prevalence in Eict_Right (6.58%) and the lowest in Llta_Right (1.97%). Two genetic approaches have been used for the estimation of the genetic propensity to suffer OC of the hock: (1) by a threshold model (absence/presence of OC); (2) by Bayesian lineal model (using OC grades: a linear scale from 0 (absence) to 3 (maximum grade)). Both at the general level and at the level of each of the zones and extremities (right and left) using different genetic models: (1) threshold model (absence/presence of hock OC); (2) Bayesian lineal model (using OC grades: 0,1,2,3); with a pedigree of 12,032 animals. The model to estimate the heritability (h^2) of hock OC included as fixed effects: age at radiological diagnosis, gender, coat colour, and size of the breeder's stud farm. Genetic parameters were estimated using different modules of BLUPF90 package software. The h^2 for presence/absence of hock OC, independent of location, was 0.28 ± 0.112 in model 1 and 0.03 ± 0.018 in model 2. Estimates for different locations, ranged from 0.19 ± 0.131 (Llta_Right) to 0.21 ± 0.124 (Eict_Left) for model 1 and ranged from 0.01 ± 0.007 (Llta_Left) to 0.05 ± 0.025 (Eict_Right) for model 2. The best results were obtained by Threshold Model. It would be necessary to increase the animals examined, but both prevalence and h^2 (depending on the methodology used) are similar to those found in other equine breed. These results imply that selection against OC is possible and genetic risk of offspring could be reduced.

Session 90

Genetic characterization of white facial marking in Pura Raza Español horses depending on coat colour

A.E. Martínez, M.J. Sánchez Guerrero, A. López, M. Ligeró and M. Valera Córdoba

Universidad de Sevilla, Ciencias Agroforestales, Carretera de Utrera km 1, 41031, Sevilla, España., Spain; anaencmar1@alum.us.es

White facial markings are a relatively common horse coat characteristic of the Pura Raza Español horses (PRE) population. These white facial markings in horses are the result of a local lack of melanocytes in the skin. The aim of this study was to calculate the within-breed prevalence of white facial markings in a representative population sample of PRE and determine its prevalence depending on the coat colour and the other environmental effects (year of birth, sex, birth stud geographical area and inbreeding coefficient). The appearance of white facial markings has been classified into 5 score: 0 no white facial markings, 1 small white marking on the forehead, 2 big white markings in the forehead, 3 white markings on front-nose and 4 white markings all over the head. A total of 27,374 Pura Raza Español horses were analysed. Of this PRE population, a total of 64.91% had no white facial markings and 35.09% had white facial markings. Genetic parameters were estimated using a Bayesian procedure with the BLUPF90 software. Systematic effects were included in the model according to significant results in analyses of variance (Generalized Non-Linear Model (GLZ)): year of birth, sex, birth stud geographical area and inbreeding coefficient. The pedigree information included a minimum of 4 generations (74,675 horses). Heritability of white facial marking ranged from 0.687 (chestnut, bay, and grey in the dichotomic heterogeneity model) to 0.348 (chestnut population in the linear heterogeneity model). It has been demonstrated that factors (such as the coat colour but also year of birth, sex, birth stud geographical area and inbreeding coefficient) were significant. Our results showed that white facial markings were more prevalent in inbred chestnut males born in Europe (including Spain). The additive genetic base of white facial markings in PRE, which presents moderate to high heritability, shows that the prevalence of this horse coat characteristic could be effectively managed by genetic selection.

Climate effects on foaling event: genotype-by-environment interactions in horse fertilityC. Sartori¹, E. Mancin¹, G. Gomez-Proto¹, B. Tuliozi² and R. Mantovani¹¹University of Padova, Dept. of Agronomy Food Natural resources Animals and Environment, Viale dell'Università 16, 35020 Legnaro (PD), Italy, ²Duke University, 080 Duke University Road, Durham, NC 27708, USA; roberto.mantovani@unipd.it

Horses are a species with a low reproductive capacity, in which fertility is influenced by many environmental and management factors, often difficult to disentangle from individual effects like inbreeding (F) and individual additive genetic value. Few estimations of genetic parameters have been performed, and literature on the possible impact of genotype-by-environment interactions (G×E) is lacking. This study aimed to estimate genetic parameters for horse fertility and investigate the G×E on the trait using climate data. The study subject was the local Italian Heavy Draught Horse breed, and target trait was the individual outcome of the mating (or foaling event): 1 was successful foaling event and 0 no successful foaling (e.g. absence of pregnancy, abortion). The time lag between two parities was also considered. Data over 30 years of more than 22,600 foaling events were considered for about 3,350 mares and joined with individual F computed from the stud book. Multiple combinations of environmental units (EU) were realized for studs in the same geographical area and rearing system (stable, feral or semi-feral), and included in a traditional animal model (M1) with age at foaling, F, permanent environment and additive genetic effects. Then, climate information of the studs' municipalities were obtained from the NASA's Climate Data Services and referred to the time in which mares conceived (about 1 month around the date of conceiving). Temperature-humidity index (THI) was calculated and included as environmental covariate in a single-step reaction norm model (M2) updating M1. About 84% of data were successful foaling events. Heritability (h²) estimates varied from 0.11 to 0.14 on liability scale (0.05 to 0.06 on observed scale). Results from M2 showed that part of the phenotypic covariance was due to G×E, and h² changed consequently. Some re-ranking occurred between individual breeding values under M1 and M2. Results suggest the importance of accounting for climate information and G×E in genetic evaluation of horse breeds, typically reared under a variety of environments and management conditions.

Theatre 1

Impact of raw and digested pig manure on ammonia volatilization after land applicationF.M.W. Hickmann^{1,2,3,4}, R. Rajagopal⁴, N. Bertrand³, I. Andretta², M.-P. Létourneau-Montminy¹ and D. Pelster³¹Université Laval, 2325 Rue de l'Université, G1V 0A6, Québec, Canada, ²Universidade Federal do Rio Grande do Sul, Av. Bento Gonçalves, 91540-000, Porto Alegre, Brazil, ³Quebec Research and Development Center, Agriculture and Agri-Food Canada, 2560 Bd Hochelaga, G1V 2J3, Quebec, Canada, ⁴Sherbrooke Research and Development Center, Agriculture and Agri-Food Canada, 2000 College Street, J1M 0C8, Sherbrooke, Canada; felipe-mathias.weber-hickmann.1@ulaval.ca

Improved pig manure management practices can mitigate the environmental impacts of pig production by reducing nitrogen (N) losses such as ammonia (NH₃) volatilization. Anaerobic digestion (AD) is a promising technology for transforming pig manure into bio-based fertilizers (i.e. digestate). However, little is known about the impact of such technology on NH₃ volatilization after land application with manure that differs in terms of N content. Thus, this study aimed to evaluate the NH₃ volatilization after land application of raw and digested pig manure from animals fed different low-protein diets. Different N concentrations of raw pig manure (6,600 and 6,100 mg/kg) and digested manure (4,000 and 3,200 mg/kg) were tested. In a temperature-controlled room (25±1 °C), 16 cylinders (4 treatments × 4 replicates) with sandy loam soil were assigned to a 2×2 factorial design: factor 1 (raw or digestate) and factor 2 (control or low N). In each cylinder, manure was applied on soil surface to reach the 160 kg N/ha recommendation for corn. Data were analysed with PROC mixed and comparison of means through the Tukey test (SAS software). Differences in raw and digested pig manure began to be observed 4 h after land application (29.05 vs 102.25 mg N-NH₃/h). Overall, applying digested manure has three times more NH₃ volatilization than the raw manure application throughout all periods analysed (4 h, 24 h, 1 week, 2 weeks, and 3 weeks after land application; P<0.001). On the other hand, there was no effect of N level in any period (P=0.624). These results show some trade-offs of AD that increases NH₃ volatilization given the N organic form after digestion. Moreover, differences in N concentrations were not enough to affect NH₃ volatilization as manure was applied to reach the same recommended application rate.

Influence of housing manure management on ammonia emissions from broiler and laying hen productionsE. Caron¹, P. Le Bras² and M. Hassouna³¹ITAVI – Institut Technique de l'Aviculture, Rue Maurice le Lannou, 35000 Rennes, France, ²IFIP – Institut du Porc, La Motte au Vicomte, 35650 Le Rheu, France, ³INRAe UMR SAS, 65 rue de Saint Brieuc, 35000 Rennes, France; caron@itavi.asso.fr

In France, poultry productions contribute for about 0.06% of national greenhouse gases emissions and 6.3% of national ammonia (NH₃) emissions (CITEPA, 2022). The emissions come from the different steps of manure management on farm and vary in function of the breeding practices, the manure management inside the building and climate conditions. Nowadays there is a need of more accurate emissions factors (EFs) for different kind of purposes. This study aims to refine national EFs for broiler and laying hen productions according to different housing manure managements by using all data collected in the ELFE (ELevage et Facteurs d'Emissions, i.e. livestock and emission factors) database. ELFE structure was built in 2017 and permits an exhaustive description of the publications through 979 variables for the housing. Emission values have been converted into references units (kg NH₃-N/place/year) by using data given in the corresponding papers. In January 2022, the database contains 1,027 emissions values from 106 publications for the housing. About 50% of the values relate to the NH₃ compound (551), and 97% of the values refer to broilers and laying hens. After the cleaning process and the conversion to reference units, 25% of NH₃ values was deleted. Within the analysis, the type of floor has been selected as an influential variable. Several EFs are given, one for each technical itinerary. The number of emission values decreases according to the complexity of the technical itinerary. Standard deviation is computed for each value, to assess the accuracy of the result. These values take into account publications from the USA for more than a half of the database and experimental results, from experimental facilities with specific breeding conditions. This has to be interpreted within the results. A comparison to international references like the EMEP guideline has also been done. The limits of the study were the small number of literature references for the poultry sector and the lack of information describing the experiments.

Session 91

Theatre 3

NH₃, N₂O and CH₄ emission from piggeries: comparison of several manure management techniques

N. Guingand and P. Le Bras

IFIP Institut du Porc, La motte au vicomte, 35651, France; nadine.guingand@ifip.asso.fr

In France, the contribution of the pig farming to national emissions is 8% for ammonia (NH₃), 7% for nitrous oxide (N₂O) and 9% for methane (CH₄). Although low, this contribution will have to be drastically reduced in the foreseeable future to limit pig production impact on climate change and answer to social expectations. Housing is the first step in the emission process. Building design and practices such as manure management can affect emissions from building but also from storage and land application. The aim of this study is to compare different manure management techniques within the building on NH₃, N₂O and CH₄ emissions. The comparison is based on the use of the database called ELFE described by Vigan *et al.* This database gathers emission factors available in the literature but also metadata concerning breeding conditions and measurement methodology. In December 2022, 2,116 NH₃, N₂O and CH₄ emission factors of pig buildings published from 22 countries between 1964 and 2022 are collected in the database. Emission factors of sows, post-weaning piglets and growing-finishing pigs are established for four different manure management techniques: storage in the pit under animal, frequent gravity evacuation, manure collection in water, flushing and V-scraper. The comparison of emissions factors is discussed and argued in relation with the advantages and limits of each technique both in terms of implementation and relative effectiveness on each gas. Because French piggeries are mostly old, technical constraints can become a real obstacle to the deployment of a national policy to reduce gas emission from piggeries.

Feeding pigs with low-protein diets: impact of pig manure nitrogen content on biogas productionF.M.W. Hickmann^{1,2,3}, I. Andretta³, L. Cappelaere², B. Goyette¹, M.-P. Létourneau-Montminy² and R. Rajagopal¹¹Agriculture and Agri-Food Canada, Sherbrooke, J1M 1Z7, Quebec, Canada, ²Université Laval, Département des Sciences Animales, 2325 Rue de l'Université, G1V 0A6, Québec, Canada, ³Universidade Federal do Rio Grande do Sul, Department of Animal Science, Av. Bento Gonçalves, 91540-000, Porto Alegre, Brazil; felipe-mathias.weber-hickmann.1@ulaval.ca

Lowering dietary crude protein levels is a nutritional strategy recognized to decrease both nitrogen (N) excretion and the use of feed ingredients with high environmental impacts. Improved pig manure management practices can further mitigate the environmental impacts associated with pig production towards carbon neutrality and net-zero emissions. Anaerobic digestion (AD) is a promising technology for transforming pig manure into energy as biogas and into bio-based fertilizers (i.e. digestate from AD). However, little is known about the effects of pig manure N content on AD. Thus, this study aimed to evaluate the impact of pig manure N content on biogas production through the AD of manure from pigs fed low-protein diets. Three pig manure N concentrations were tested: T₁ = 5,873, T₂ = 5,421, and T₃ = 5,149 total Kjeldahl nitrogen (TKN, mg/l). Throughout 5 fed-batch cycles (25±4 days/cycle), biogas production and its composition (CH₄, CO₂, and H₂S) were measured. In a temperature-controlled room (20±1 °C), 6 digesters (3 treatments × 2 replicates) were operated as single-stage reactors to digest pig slurry (mixture of urine and faeces, TS: 5.6%) inoculated with a liquid inoculum (TS: 2.3%) to improve manure-microbe interactions. Data were analysed as repeated measures with PROC mixed and comparison of means through the Tukey test (SAS software). Decreasing pig manure N content showed a tendency to reduce biogas (-20% in T₃ vs T₁; P-value=0.078) and methane (-22% in T₃ vs T₁; P-value=0.0578) production per cycle. Regarding biogas composition, CH₄/biogas and CH₄/CO₂ decreased with N content (-3 and -4% in T₃ vs T₁; P<0.01). These results suggest that a reduction in pig manure N content reduces biogas production and its quality (ratio of CH₄ to CO₂). This latter parameter is important for biogas efficiency; thus, reducing crude protein levels in pig diets may affect biogas production in AD.

Session 91

Theatre 5

A tool to reduce worker exposure from ammonia and particles in swine and poultry housingN. Guingand¹, S. Lagadec², K. Amin², D. Bellanger³, A.L. Boulestreau-Boulay³, C. Delaquerze⁴, C. Depoudent², L. Gabriel³, E. Koulete³, V. Le Gall⁴, P. Lecorquille⁵, L. Leroux³, G. Manac'h⁶, S. Roffi² and M. Brouard, 49105 Angers, France, ⁴MSA 49, Rue C. Lacreteille, 49070 Beaucozéz, France, ⁵MSA Armorique, Rue de Paimpont, 22025 Saint Brieuc, France, ⁶Porc Armor Evolution, Impasse Monge, 22600 Loudéac, France; nadine.guingand@ifip.asso.fr

Air quality inside pig and poultry housing is already known to be concentrated in ammonia and particles. Regular exposure is associated with a high prevalence of respiratory dysfunctions and pathologies such as chronic bronchitis or asthma. The aim of the project is to develop an assessment tool to (1) allow workers to evaluate the air quality inside buildings, (2) promote the implantation of techniques to prevent the risk of exposure and (3) advise workers on the existence/use of personal protective equipment (PPE). For the first step, a questionnaire grouping technical aspects, working organisation and health history of workers has been elaborated by the partners. A group of 24 farmers (pig and poultry) has been formed to be directly implicated in the test of the self-diagnostic tool. Visits and collection of data will be completed in summer 2023. The next steps are the elaboration of fact sheets highlighting the different ways of reduction of gas and particles inside building and the different type of PPE with a focus on strengths and weaknesses. After having collected data on PPE available in the market, a study will be conducted on their assessment on the ground directly by farmers and people working in the experimental farms of partners. Results of this step will be the base of exchange between partners and manufacturers for the improvement of one or two PPE. In relation with a previous work done on best practices to reduce ammonia and particles, a multi-criteria evaluation grid on mitigation techniques to reduce gas and particles has been built. The writing of fact sheets in progress and contacts have been already taken with manufacturers of PPE. First results are available on www.qualiair.chambres-agriculture.fr.

Methodological redesign of the poultry mass-balance excretion and variability of nitrogen excretion

V. Blazy, E. Caron, D.D. Djenontin-Agossou and Y. Guyot

ITAVI, The French Technical Institute for Poultry, environment division, rue Maurice le Lannou, 35000 Rennes, France; blazy@itavi.asso.fr

Nowadays the excretion levels are an essential indicator for the administration, the farmers and their advisors. Excretion values are used in environmental assessment and to dimension land spreading plans. The industrial emission directive defines best available technics associated total nitrogen (N) excreted and annual excretion monitoring for different poultry productions. This monitoring can be carried out by using manure analysis or mass balance calculation based on feed intakes and animal performance. Based on daily mass balance computation, a new excretion calculation methodology is developed in this study. It considers the feeding program (with the different nutrients levels for each diet) during the rearing period. Calculation is based on the generation of a posteriori growth, feed intake and mortality dynamics from users zootechnical data and references curves for a given poultry production. Thus, with help of deposition values, excretion dynamics can be simulated for 6 elements (including N), and so a more accurate balance-sheet can be computed on the rearing span. The methodological redesign tends to make the excretion computation tool more readable and conceptually more accurate. Computing the mass-balance at daily scale allows the user a better understanding of how each input data affects the final excretion results. In parallel, a quantification of N excretion variability is carried out for laying hens production (as example). For that purpose, a sensitivity analysis has been performed for each data input on the mass balance results. The data input having the most influence on the excretion value is the flow of ingested feed. Then, this is the mass of egg production with the slaughter weight. Finally the growing span and the mortality have a very poor influence. Thus, mass-balances simulations including interquartile and extreme ranges of feed consumption and egg production can roughly allow assessing the variability of the laying hens N excretion. Results indicated that based on average performances, laying hens excreted 912 gN/ animal. Interquartile and extreme ranges respectively corresponded to excretion results of 814-1057 and 786-1153 gN/ animal.

Box 57, 00014 University of Helsinki, Finland, ⁸Wageningen University & Research, De Elst 1, 6708 WD Wageningen, the Netherlands; antonia.ruckli@bfn.ch

Husbandry aspects intended to improve animal welfare (AW) such as bedding or access to an outdoor run are currently financially supported through AW labels in several countries. At the same time, they may impact the environment through possible changes in feed efficiency and manure management. Therefore, we compared farms differing in AW relevant husbandry aspects regarding pig welfare, global warming (GWP), acidification potential (AP), fresh water (FEP) and marine (MEP) eutrophication potential. We collected data on 50 farms with growing-finishing pigs in seven European countries: NOBED (31 farms without bedding and outdoor run), BED (11 farms with bedding only) and BEDOUT (8 farms with bedding and outdoor run). Pigs in NOBED farms manipulated enrichment (e.g. straw, objects) less, pen fixtures more and showed more oral stereotypies than on BED and BEDOUT farms. AP of BEDOUT and BED farms was significantly higher (67.1 ± 7.5 , 73.5 ± 6.3 g SO₂-eq/kg BMNG) compared to NOBED farms (44.3 ± 3.8 , $P=0.002$) due to higher ammonia emissions allocated to solid manure. BEDOUT farms had higher MEP than NOBED farms (BEDOUT: 36.6 ± 5.0 , BED: 25.1 ± 4.3 , NOBED: 19.0 ± 2.6 g N-eq/kg BMNG, $P=0.035$). GWP and FEP did not differ, probably due to large variability within farm systems regarding feed composition and -conversion. Nevertheless, the large variation within farm systems suggests that the trade-off may be minimised, e.g. through manure management (frequent cleaning) and feed composition (protein adjustment).

Reduction of protein and potassium to improve welfare and environmental footprint in broilersT. De Rauglaudre^{1,2,3}, B. Méda², W. Lambert⁴, S. Fournel¹ and M.P. Létourneau-Montminy³¹Université Laval, Département des sols et de génie agroalimentaire, Québec, G1V 0A6, Canada, ²INRAE, BOA, Nouzilly, 37380, France, ³Université Laval, Département des sciences animales, Québec, G1V 0A6, Canada, ⁴METEX Animal Nutrition, Paris, 75017, France; theophane.de-rauglaudre.1@ulaval.ca

A proper management of litter moisture management is important to limit nitrogen (N) volatilization and footprint lesions. In broilers, it is known that both dietary crude protein (CP) and electrolyte balance (DEB) influence water intake, and consequently litter moisture. Since soybean meal (SBM) is rich in potassium (K), reducing CP in feed also reduces K intake, and thus DEB. The objective of this study was therefore to dissociate the effects of reducing CP and K on water intake, total water excretion, and N balance. For this purpose, three experimental treatments were tested, a control diet (C; CP=20.5%; DEB=224 mEq/kg), a low CP diet (LCP; CP=17.5%; DEB=145 mEq/kg), and a low CP diet supplemented with K carbonate (LCP+K; CP=17.7%; DEB=224 mEq/kg) to bring back DEB to the level of C. The three diets were iso energy (AMEn=3,050 kcal) and SID lysine (9.5 g/kg), and feed-grade amino acids (AA) have been used to reach indispensable AA requirements. At 20 days of age, 72 Ross 308 male were randomly allocated to 18 cages of 4 birds each. After 7 days of adaptation to the experimental diets, total excreta, feed and water consumption were measured daily per cage for 3 days and a representative sample of excreta was collected. In comparison to C, only LCP treatment have an effect on water intake (-31%; $P<0.01$), water excretion (-39%; $P<0.001$), humidity of excreta (-9%; $P<0.001$), and water:feed ratio (-21%; $P<0.01$). Comparatively to C treatment, N excretion was reduced by 34% ($P<0.001$) and 30% ($P<0.001$) for LCP and LCP+K treatments respectively, while the N retention efficiency was increased by 6% ($P<0.05$) and 11% ($P<0.001$). Only simultaneous reduction of DEB and CP affected water intake and water excreted, while the effect of CP alone was not significant. As expected, N balance was only impacted by the CP. Thus, decreasing K and CP together is an effective strategy to reduce N excreted, water intake and improve litter DM which will lead to a reduction in both N volatility and pododermatitis.

Session 91

Theatre 9

Effects of reducing protein content in broiler diets on environmental impactsJ. Gickel¹, V. Wilke^{1,2}, C. Ullrich² and C. Visscher²¹University of Veterinary Medicine Hannover, Foundation, Science and Innovation for Sustainable Poultry Production (WING), Heinestraße 1, 49377 Vechta, Germany, ²University of Veterinary Medicine Hannover, Foundation, Institute of Animal Nutrition, Bischofsholer Damm 15, 30173, Germany; julia.gickel@tiho-hannover.de

The use of extracted soybean meal (SBM) is resulting in a higher carbon footprint of poultry production in Europe. Therefore, efforts are being made to reduce the amounts in the diets. Moreover, generally lower contents of crude protein (CP) and the use of certain amino acids in the diets might reduce negative environmental impacts, too. In this study, 360 day-old broilers, where divided in four treatment groups, kept for 35 days and fed diets (starter/grower/finisher) containing different amounts of CP/added amino acids (CPC [control]: 22.2%/20.5%/19.9%; CP-1: 21.5%/19.4%/19.2%; CP-2: 20.2%/ 18.6%/ 18.1%; CP-3: 19.2%/17.7%/17.0%). Starter and grower phase lasted 7 days each, followed by 21 days finisher phase; performance parameters were measured weekly. The assessment of the environmental impact per t carcass weight (according to ISO 14040) was performed using the online software application Opteinics® (BASF Lampertsheim GmbH, Germany), based on the Global Feed LCA Institute (GFLI) database. In week 1 and 2 body weight (BW) was similar between CPC, CP-1 and CP-2, while the BW of CP-3 was lower. At the end of the trial CP-2 showed the highest BW followed by CP-1, CPC and CP-3. No significant differences were found regarding the feed conversion ratio (FCR). Highest values occurred for CP-3 (week 1-4) and CPC (week 5). The impact on climate change throughout the production (related to carcass weight) was 4.4 t per t for CPC and could be reduced by 6% (CP-1), 8% (CP-3) and 12% (CP-2). For CP-2, the lowest environmental impact of the production was also found in the following categories: eutrophication (marine/freshwater), land use, particulate matter and use of resources and water. The impact on acidification and eutrophication (terrestrial) showed the highest reduction for CP-3. The impact on ozone depletion was reduced for CP-1 but higher for CP-2 and CP-3 (compared to CPC). The results showed that the highest CP-reduction did not result in the lowest environmental impact for all categories mainly due to a lower efficiency of the production.

Effect of reduced-crude protein diets on performance, meat yield, and nitrogen production in broilerC. Gayrard¹, T. Wise², J.D. Davis², J.C. De Paula Dorigam¹, V.D. Naranjo¹ and W.A. Dozier, Iii²¹Evonik Nutrition & Care GmbH, Animal nutrition, Hanau, Germany, ²Auburn University, 36849, Alabama, USA; cecile.gayrard@evonik.com

The impact of feeding reduced crude protein (CP) diets to 1,500 Ross × Ross 708 male broilers while providing adequate essential amino acid concentrations, on growth performance, nitrogen concentrations, mortality rate and carcass characteristics was examined from 1 to 33 d of age. Broilers were randomly distributed into 60 floor pens (25 birds/pen) and fed 1 of 6 dietary treatments (10 pens/treatment) varying in CP content. Diet 1 (control) was supplemented with DL-Met, L-Lys, and L-Thr and contained 23.0, 19.8, 18.9% CP in the starter (1-14 d of age), grower (15-25 d of age), and finisher (26-33 d of age) periods respectively. Additional L-Val, Gly, L-Ile, L-Arg, and L-Trp were sequentially supplemented in the order of limitation respective of diets 2 through 6. Dietary CP was reduced from diets 1 to 6 to 20.0, 17.4, and 16.7% in the starter, grower and finisher periods, respectively. Broilers fed diets 2 to 6 had similar average daily gain (65 g/d, *P*-values ranging 0.10 to 0.99) and feed intake (86.4 g/d, *P*=0.22) compared with broilers fed the control diet. There was no treatment effect on feed conversion ratio (FCR) except for the lowest CP-diet which was significantly higher than all other treatments (1.45 vs 1.41 to 1.43; *P*<0.05). Dietary treatments did not affect carcass traits (*P*-values ranging 0.11 to 0.60). The mortality rate was low (1.5%) and not impacted by the treatments (*P*=0.31). Nitrogen intake (*P*<0.001) was decreased in the low CP-diet 6 vs the control diet. The N excretion values were compared using a direct and an indirect methods, and decreased from diet 1 to 6 by 32% (*P*<0.001) when using the indirect method. With both methods, N excretion per kg of meat was reduced (*P*=0.046 vs *P*<0.001) from diet 1 to 6. Nitrogen utilization was improved from 65.5 to 73.5% (*P*<0.001) from diet 1 to 6 (indirect method) while it was not affected (76.5%) with the direct method (*P*=0.89). Results from this study indicated that the supplementation of amino acids from DL-Met up to L-Trp allowed reduction of dietary CP content without depressing growth rate and meat yield of broilers from 1 to 33 d of age while reducing Nitrogen meat excretions emission values.

Session 91

Theatre 11

Effect of reducing dietary protein content on performance and environmental impact of pig productionE. Gonzalo¹, A. Simongiovanni¹, C. De Cuyper², B. Ampe², M. Aluwe², W. Lambert¹ and S. Millet²¹METEX Animal Nutrition, 32 rue Guersant, 75017 Paris, France, ²ILVO, Animal Sciences, Scheldeweg 68, 9090 Melle, Belgium; enrique.gonzalo@metex-noovistago.com

The objective of the present trial was to study the effect of a decrease in dietary crude protein (CP) content on the growth performance, carcass quality, nitrogen efficiency and global warming potential (GWP) in fattening pigs. Thus, 288 pigs were distributed in 48 pens of 6 animals (male-female parity) during three feeding phases: 10-15 (phase 1), 15-20 (phase 2) and 20 weeks of age – slaughter (phase 3). Six dietary treatments tested a reduction in CP (RCP). The SID Lys/CP levels were kept stable between the feeding phases at 5.4, 5.7, 6.0, 6.3, 6.7 and 7.1%, respectively for T1 to T6 treatments: dietary CP varied from 17.4 to 13.2% in phase 1, 15.9 to 12.1% in phase 2, and 14.2 to 10.9% in phase 3, with SID Lys levels of 9.4, 8.6 and 7.7%, for phase 1, 2 and 3, respectively. Essential amino acid (AA) levels in relation to lysine were maintained. Pen was the experimental unit. Over the entire period, RCP had no effect on average daily feed intake and carcass yield. In contrast, RCP with SID Lys/CP≥6.3% degraded average daily gain (825±36 g/d in T1 vs 730±36 g/d in T6) and feed conversion ratio (2.33±0.06 in T1 vs 2.60±0.15 in T6) (*P*<0.001). Carcass characteristics were maintained up to SID Lys/CP≤6.7%. Nitrogen efficiency increased linearly from 43.6±1.1% (T1) to 51.8±2.9% (T6). The effect on GWP (kg CO₂eq/kg BW gain with AA from Europe or China) showed a significant interaction between treatment and AA origin (*P*<0.001). The GWP calculated with European AA decreased from T1 to T6 (1.45±0.04 vs 1.29±0.07 kg CO₂eq/kg BW gain), while results with Chinese AA increased from T1 to T6 (1.51±0.04 vs 1.82±0.11 kg CO₂eq/kg BW gain). This was due to high values for GWP for Chinese compared to European AA in the dataset used (Agrisalyse 3.1), as a result of differences in the production process. It can be concluded that reducing the dietary CP level while maintaining pig performance is possible up to a SID Lys/CP level of 6%. This RCP is accompanied by a beneficial effect on GWP when using AA of European origin.

Impact of genotype×feed-interactions in nitrogen- and phosphorus-reduced ration on of fattening pigsC. Große-Brinkhaus¹, B. Bonhoff¹, I. Brinke¹, E. Jonas², S. Kehraus¹, K.H. Südekum¹ and E. Tholen¹¹University of Bonn, Institute of Animal Science, Endenicher Allee 15, 53115 Bonn, Germany, ²Association for Bioeconomy Research (FBF), Adenauerallee 174, 53113 Bonn, Germany; cgro@itw.uni-bonn.de

Strict governmental regulations for the distribution of manure coupled with high production costs lead lowered nitrogen (N) and phosphorus (P) reduced concentrations in diets for growing pigs. This feeding strategy requires high availability of nutrients in diets ingredients, and efficient nutrient utilization by pigs. It is assumed that the genotype of an animal is the reason for variation in adaptability to dietary changes, potentially leading to a re-ranking of genotypes: a genotype×feed-interaction (G×F). Two trials were conducted to assess the effects of lowered dietary N and P concentrations on N and P excretion and to investigate the existence of G×F. In total, 900 pigs (♂ and ♀) of Pietrain × crossbred sows, and 1000 Landrace boars were divided into one of two feeding groups, the control- or low protein/P-group before fattening phase. Animals were tested for performance in a 3- or a 2-phase *ad libitum* growth period until 115 kg. A subset of 200 pigs of each line were kept individually in order to collect faeces samples after diet change and to determine the digestibility and excretion in faeces (ex_{fe}) of N and P. Blood samples were collected from 100 pigs to estimate urinary N excretion (ex_{ur}). First results revealed a h^2 ranging from 0 for P ex_{fe} to 0.56 for N ex_{ur} . For all traits the effect of sire×feeding group was below 0.15. Although the influence of the sire and the interaction group was not significant, sire rank correlations of 0.27 for N- and 0.07 for P ex_{fe} indicate the existence of a G×F. The results of the present study provide further evidence for the existence of G×F in diets with lowered N and P concentrations for growing pigs. In addition, possible consequences on bone composition and density due to lowered nutrient concentrations and the observed interindividual variability of digestibility values will be investigated. These studies are funded by the Ministry of Environment, Agriculture, Nature and Consumer Protection of North Rhine-Westphalia and by the German Government's Special Purpose Fund held at Landwirtschaftliche Rentenbank (FKZ 28-RZ-3.104).

Session 91

Theatre 13

Pig performance, carcass composition and meat quality can be maintained with high CP reductionL. Cappelaere^{1,2}, F. Garcia-Launay¹, W. Lambert³, A. Simongiovanni³ and M.-P. Létourneau-Montminy²¹PEGASE, INRAE, Institut Agro, 16 le Clos, 35590 Saint Gilles, France, ²Université Laval, Département des sciences animales, rue de l'agriculture, G1V 0A6 Québec, Canada, ³METEX Animal Nutrition, 32 rue Guersant, 75017 Paris, France; lea.cappelaere.1@ulaval.ca

Low crude protein (CP) diets reduce nitrogen (N) born environmental impacts in pig production. Newly available feed-grade amino acids allow to reduce dietary CP to seldom tested levels, with balanced diets. The objective of this trial was to test the effect on growth performance, N balance, carcass composition and meat quality of CP reduction permitted by L-Ile and L-His supplementation. Twenty-four pens of 3 barrows and 3 gilts were fed *ad libitum* one of three soybean meal-corn based dietary treatments. Control CP levels in the four feeding phases (25-50 kg, 50-80 kg, 80-100 kg and 100-135 kg) were 180, 161, 143 and 126 g/kg. Treatments were 12 and 24 g/kg CP reductions, in all phases. Bodyweight (BW) gain and feed intake (FI) were recorded for each phase. Body composition was analysed by two-photon X-ray absorptiometry (DXA) in one pig per pen at the beginning and end of the trial. Carcass parameters were measured at the slaughterhouse for all pigs. Longissimus dorsi samples were taken for meat quality analysis 24 h after slaughter for two pigs per pen. A general linear model was used to test the effect of CP reduction. Dietary CP did not affect FI (2.86 vs 2.93 vs 2.93±0.12 kg/d, $P=0.34$), BW gain (1.18 vs 1.19 vs 1.16±0.04 kg/d, $P=0.42$), or feed conversion ratio (2.73 vs 2.81 vs 2.76±0.10, $P=0.11$). N intake was linearly decreased by 6.7% between treatments and N excretion by 11% ($P<0.001$). N efficiency was linearly improved by 2.8 percentage points between treatments ($P<0.001$). Carcass composition was not affected: DXA fat (20 kg; $P=0.91$) and lean (56 kg; $P=0.44$) deposition, carcass weight (109 kg, $P=0.39$), muscle depth (67 mm, $P=0.13$), backfat thickness (21 mm, $P=0.93$) and meat percentage (59.9%, $P=0.87$). Meat colour, intramuscular fat and pH at 24 h were not affected ($P>0.1$) but drip loss tended to increase ($P=0.054$) with CP reduction. In this trial, a 24 g/kg CP reduction efficiently decreased N excretion while maintaining performance and carcass and meat quality.

Alpha mannan polysaccharide supplement increase growth performance and reduce gas emission in pigJ.H. Song¹, C.B. Lim¹, M.D.M. Hossain¹, S. Biswas¹, J.S. Yoo², I.H. Kim¹ and Q.Q. Zhang¹¹Dankook University, Department of Animal Resource and Science, Cheonan, 31116, Korea, South, ²Daehan feed company, 13 Bukseongpo-gil, Jung-gu, Incheon, 22300, Korea, South; thdwnsh@naver.com

The objective of this study was to evaluate the effects of supplementing α -mannan polysaccharides to the diet of weaning pigs on their growth performance, apparent nutrient digestibility, faecal microbiota, faecal score, and faecal gas emission. A total of 160 crossbred weaning pigs [(Yorkshire $\times$ Landrace) $\times$ Duroc, 28 days old] were randomly assigned to four groups based on their initial body weight (7.70 ± 1.27). The experimental period was 42 days (Phase 1: week 1; Phase 2: weeks 2-3; Phase 3: weeks 4-6). Dietary treatments consisted of pigs receiving basal diet without α -mannan polysaccharides as the control group and treatment groups consisted of pigs fed basal diet supplemented with 0.1, 0.2, 0.3% α -mannan polysaccharides respectively. The addition of α -mannan polysaccharide resulted in a linear increase ($P < 0.05$) in daily gain over Weeks 1, 3, and throughout the trial. Supplementation of α -mannan polysaccharide to the diet of weaned pigs led to a linear increase in the gain to feed ratio. There was a linear spike in dry matter digestibility ($P < 0.05$) in piglets that had been fed a diet with α -mannan polysaccharide. The bacteria count in the faeces of weaned pigs was not affected by the addition of α -mannan polysaccharide to their diet. The faecal score was not significantly affected. H_2S and total mercaptan levels have been demonstrated to linearly decrease ($P < 0.10$) with increasing amounts of mannan in the diet of weaned pigs. The addition of α -mannan polysaccharide in the diet of weaning pig could be beneficial to enhance the daily gain and gain to feed ratio and, improved the dry matter digestibility and decreased faecal H_2S and total mercaptan gas emission.

Characteristic of odour substances from broiler farms

S.Y. Seo, J.S. Park, S.Y. Park and M.W. Jung

National Institute of Animal Science, Animal Environment Division, #1500, Kongjwipatjiwi-ro, Ison-myeon, Wanju-gun, Jeollabuk-do, 55365, Korea, South; seosi@korea.kr

An increase in meat consumption led to the growth of the livestock industry. However, with growth of the livestock industry, it brings increase of livestock manure and complaints of odour. Even this situation, so far odour research mostly has been conducted on swine farm. For study how to reduce livestock odour, we should evaluate odour of other species like dairy cow, beef cattle and poultry. The main aim of this study was to evaluate odour from broiler farms and find main odour substances of broiler farms. The measurements were performed by investigating complex odour and the concentration of ammonia, acetaldehyde, volatile fatty acids (acetic acid, propionic acid, n-butyric acid, i-valeric acid, n-valeric acid) and evaluating odour activity value (OAV). Sampling point was in front of ventilation fan of the broiler farm and sampling was started at one week after all in. Four times, once a week, of sampling was conducted and samples were brought to lab to measure concentration by Gas Chromatography. OAV was calculated with minimum detection concentration. The result showed that ammonia and other VFAs were increased with time. Ammonia was 0.15 ppm at 1st week, 1.10 ppm, 1.37 ppm, 4.00 ppm. However, complex odour dilution factor and concentration of acetaldehydes were decreased by time. Acetaldehydes was 0.33 ppm, 0.12 ppm, 0.07 ppm and last week was 0.01 ppm. The highest OAV was acetaldehydes (66.26), and propionaldehydes (32.45), ammonia (16.55), trimethylamine (7.16), n-butyric acid (1.29) follow. It seems acetaldehydes is main odour substance which affect complex odour most and as broiler grows, the ammonia and VFAs are getting more emission.

Environmental assessment of layer-type male chicks breeding

E. Dubois and M. Quentin

ITAVI, environment, 7 rue du Faubourg Poissonnière, 75009 Paris, France; dubois@itavi.asso.fr

Since 2022, due to ethical concerns, French legislation prohibited the culling of layer-type male chicks after hatching. In order to deal with this prohibition, three methods can be applied. The first one is *in ovo* sexing, resulting in the culling of male eggs before hatching. A second one is the selective breeding of layer-type male chicks. The third method is the use of dual-purpose breeds, selected for balanced performances in meat and egg productions. Since the genetic selection of current poultry breeds has led to a negative correlation between meat and egg production performances, layer-type male or male from dual-purpose breeds have variable growth performances and a different environmental impact. Thus, this study aimed to assess the environmental impact of male chicks breeding, using life cycle assessment (LCA) method from cradle to slaughterhouse. A trial was set up to evaluate the meat production performances of two different layer genetics (Lohmann Brown, H&N SuperNick White) and one dual-purpose breed (Hendrix ISA-DUAL) compared to a meat-type slow growing breed (Hubbard JA S757N) used in French 'label-rouge' production. Each genetic type was raised at two different market targets: cockerel or broiler, with an objective live-weight at slaughter of respectively 850 to 1000 g or 1,800 to 2,200 g. The results of this study were carried out through eight LCA scenarios, one for each genetic at each growth stage. The functional unit is kg of carcass weight. The indicators assessed will be climate change, land use, acidification, water use and eutrophication. Indicators will be compared for each scenario in order to quantify the environmental burden of alternatives to the culling of layer-type male chicks. The environmental impact is expected to be higher for broilers than for cockerels, with longer growth duration and higher feed conversion ratio. Breeding male chicks of layer-type has a higher environmental impact than conventional broilers. These results could help the poultry sector to find environmental, economic and technical compromises to face an ethical challenge related to the prohibition of layer-type male chicks' culling. Further environmental assessment of the couple male chicks and laying hens will be led for the layer-type and dual purpose breeds, in order to assess their global impact.

Session 92

Theatre 1

Milk metabolites differ with feed efficiency during early lactation but not during feed restrictionJ. Pires¹, T. Larsen², S. Bes¹, I. Constant¹, D. Roux³, M. Tourret¹, A. De La Torre¹, I. Ortigues-Marty¹, F. Blanc¹ and I. Cassar-Malek¹¹INRAE, UCA, VetAgro Sup, UMRH, Theix, 63122, France, ²Aarhus University, D. Animal Sci., Tjele, 8830, Denmark,³INRAE, UE1414 Herbipôle, Theix, 63122, France; jose.pires@inrae.fr

The objective was to study associations among indicators of feed efficiency and selected milk metabolites during early lactation, and in response to experimental feed restriction (FR) for the discovery of non-invasive proxies. 28 cows divergent in phenotypic residual feed intake (RFI; positive or negative) were selected, each RFI group composed of 14 Holstein and 14 Montbéliarde cows. Energy balance (EB) and conversion efficiency (ECE; NE_L secreted/intake) were calculated. Early lactation RFI (RFI_{earlylact}) was measured during the first 10 wks of lactation. Starting at 87 ± 9 DIM, cows underwent four 4-day periods of FR to meet 50% of individual energy requirements (FR1-FR4). Mid-lactation RFI (RFI_{midlact}) was measured during 5 wks following FR4, as described (doi.org/10.1016/j.ansci.2022.07.181). Milk isocitrate, glucose, glucose-6-phosphate, malate, glutamate and free amino groups (NH₂-groups) were measured on wk 1, 2, 3, 4, 6 and 8, and daily during FR1 only. Data was analysed using mixed models with repeated measures, and spearman correlations. RFI_{earlylact} ranged from -0.44 to -2.39 for negative RFI_{earlylact} (i.e. more efficient), and from 0.42 to 2.34 kg DMI/d for positive RFI_{earlylact} groups. Early lactation ECE was higher, whereas EB, plasma glucose, milk glucose, NH₂-groups and glutamate were lower for the negative RFI_{earlylact} group. Average early lactation milk glutamate and NH₂-groups from wk1 to 8 were correlated with RFI_{earlylact} ($r = 0.44$ and 0.41), but not with RFI_{midlact}. No milk metabolite RFI group differences were observed during FR1. Weekly EB was positively correlated with milk glucose and malate ($r = 0.30$ and 0.32), and negatively correlated with milk isocitrate and NH₂-groups ($r = -0.25$ and -0.17), and the inverse correlations were observed for ECE. RFI_{earlylact} associations with plasma glucose, milk glucose, NH₂-groups and glutamate during early lactation may reflect in prioritization of nutrients towards milk secretion in more efficient cows. Conversely, these effects may be due to the lower EB experienced by cows with negative RFI_{earlylact}.

Dairy cow inflammatory status is modulated by physiological stage and feed restriction

C. Delavaud¹, A. De La Torre¹, D. Durand¹, S. Bes¹, D. Roux², A. Thomas¹, M. Turret¹, I. Ortigues-Marty¹, I. Cassar-Malek¹, M. Bonnet¹ and J. Pires¹

¹INRAE, UCA, VetAgro Sup, UMR Herbivores, Theix, 63122 Saint-Genès-Champanelle, France, ²INRAE, U1414 Herbipole, Theix, 63122 Saint-Genès-Champanelle, France; carole.delavaud@inrae.fr

In dairy cows, the transition period is characterized by an altered inflammatory status (IS) whose physiological origin has not been clarified. The objectives were to describe the IS around parturition, and to evaluate the effects of feed restriction (FR) after peak lactation, in order to evaluate effects of DMI on IS separately from physiological changes of transition period. Fourteen Holstein and 14 Montbéliarde multiparous cows were studied from weeks -4 to +23 of lactation. Starting at 87±9 DIM, cows underwent four 4-day periods of FR to meet 50% of individual net energy requirements (FR1 wk12, FR2 wk14, FR3 wk15, FR4 wk16). Dry matter intake was measured, and blood samples were collected from coccygeal vessels before am feeding on weeks -3 (wk-3), 2 (wk+2), 12 (wk+12) and 22 (wk+22) of lactation. Two samples were collected on days 0 (i.e. before) and 4 of FR1 wk12. Plasma was stored at -80 °C and the IS was assessed by analysis of a panel of chemokines, pro and anti-inflammatory cytokines (IL-1α, IL-6, IL-8, IL-10, MCP-1, MIP-1β, TNFα and VEGFα; Milliplex^R Bovine; BCYT1-33K-10, Merck, DE). Antioxidant capacity was assessed by FRAP assay and lipomobilization by plasma NEFA. Data were analysed using mixed models and repeated measures with cow as random effect. For Holstein and Montbéliarde cows, IL-1α, IL-10, MCP-1, IL-6 and MIP-1β were significantly lower on wk+2 compared to wk-3 and remained steady over the course of lactation. IL-8 concentration was higher on wk+2 compared with wk-3, whereas VEGFα declined on d0-wk+12 and wk+22 compared with wk-3 and +2. IL-8, TNFα and VEGFα were higher in Holstein than Montbéliarde cows. The 4-day FR1 significantly decreased IL-10, MCP-1 and MIP-1β concentrations. Plasma FRAP was negatively correlated with NEFA (r=-0.40), and decreased with FR. The cytokines measured were not correlated with either plasma FRAP or NEFA. To conclude, the lactation stage modulates IS in dairy cows, and short FR after lactation peak does not seem to cause inflammation despite lipomobilization and altered redox state.

Session 92

Theatre 3

Energy balance clusters in relation to metabolic and inflammatory status and disease in dairy cows

J. Ma¹, A. Kok¹, R. Bruckmaier², E. Burgers¹, R. Goselink¹, J. Gross², T. Lam³, A. Minuti⁴, E. Saccenti¹, E. Trevisi⁴ and A. Van Knegsel¹

¹Wageningen University & Research, De Elst 1, Wageningen, the Netherlands, ²University of Bern, Bremgartenstrasse 109a, Bern, Switzerland, ³Utrecht University, Yalelaan 7, Utrecht, the Netherlands, ⁴Università Cattolica del Sacro Cuore, Via Emilia Parmense 84, Piacenza, Italy; ariette.vanknegsel@wur.nl

The early lactation period in dairy cows is characterized by complex interactions among energy balance (EB), disease and alterations in metabolic and inflammatory status. The objective of this study was to evaluate relationships between EB, disease, metabolic and inflammatory status in dairy cows in early lactation. Holstein-Friesian dairy cows (n=154) were selected and monitored for disease treatments during week 1 to 6 in lactation. Weekly EB was calculated and plasma samples were analysed for metabolic and inflammatory variables. First, cows were clustered based on time profiles of EB (SP: stable positive; MN: mild negative; IN: intermediate negative; SN: severe negative). Cluster of EB was related to plasma non-esterified fatty acids and β-hydroxybutyrate concentration. Cows in SN cluster had a higher milk yield, lower dry matter intake, and lower insulin concentration compared with cows in SP cluster, and lower glucose and IGF-1 concentration compared with cows in SP and MN cluster. Cows in SN cluster tended to have a higher concentration of ceruloplasmin compared with cows in SP cluster. Second, cows were grouped based on disease treatments (CHP: cows with treatment for clinical health problem including endometritis, fever, clinical mastitis or retained placenta; OHP: cows with no CHP but treatment for other health problem; NHP: cows with no treatments). Energy balance was not different among disease groups. The CHP cows had lower albumin and paraoxonase concentration and a higher haptoglobin concentration compared with OHP and NHP cows. In week 1 after calving, NHP cows had a higher concentration of glucose, insulin and IGF-1 concentration compared with OHP and CHP cows. Overall, EB time profiles were associated with metabolic status of dairy cows in early lactation, but limitedly related with inflammatory status. Inflammatory status was related to disease events in early lactation.

Effects of parity on metabolism, redox status and cytokines in early lactating dairy cows

A. Corset^{1,2}, A. Boudon², A. Remot³, S. Philau², P. Poton², O. Dhumez², B. Graulet⁴, P. Germon³ and M. Boutinaud²
¹Biodevas Laboratoires, ZA de L'Épine, 72460 Savigné-l'Évêque, France, ²INRAE-Institut Agro Rennes Angers, UMR 1348 PEGASE, 16 Le Clos, 35590 Saint Gilles, France, ³INRAE-Université de Tours, UMR 1282 ISP, Centre de recherche Val de Loire, 37380 Nouzilly, France, ⁴INRAE-VetAgro Sup, UMR Herbivores, Theix, 63122 Saint-Gènes-Champanelle, France; marion.boutinaud@inrae.fr

In dairy cows during early lactation, inflammation and oxidative stress can occur and lead to a risk of cell damages and may be related to the metabolic status. Our objective was to investigate the influence of parity on the metabolic, redox status and immunity of dairy cows. Fifteen Holstein cows were classified into four groups according to calving date with 7 primiparous and 8 multiparous cows. Blood samples were collected 3 weeks before calving and 4, 8 and 12 weeks postpartum and after calving milk was sampled at the same times. Plasma metabolic and redox status markers were analysed by spectrophotometry. In leucocytes collected from milk, the expression of genes coding for antioxidant enzymes were analysed by RTqPCR. Plasma cytokines were analysed after an *ex vivo* challenge of whole-blood cells with or without heat-killed *Escherichia coli*. Data were analysed with a mixed model including parity, week, and their interaction as fixed effects, and cow as a random effect. As expected, milk production was higher in multiparous than in primiparous cows. Plasma non-esterified fatty acids and β -hydroxybutyrate were higher in multiparous than in primiparous respectively at the 2nd and the 4th weeks of lactation, whereas glucose was lower. Multiparous cows have higher d-ROM at 8 weeks in plasma, higher GPX activity in erythrocytes at 4 weeks, and higher Sod1 expression levels at 4 weeks in milk leucocytes. Associated with these results, multiparous cows had a higher level of vitamin E but lower plasma concentrations of cytokines CXCL10, CCL2, IL1 α and IFN γ . After *E. coli* challenge, at the 3rd week before and the 8th week after calving, the immunity of multiparous cows would be less effective with lower IL1 α and TNF α . The increased energy metabolism is accompanied by an increase in the antioxidant response to resolve redox balance, and by a probably less effective immunity in multiparous compared with primiparous cows.

Session 92

Theatre 5

Tissue distribution and pharmacological characterization of bovine free fatty acids-sensing GPCRs

T.C. Michelotti¹, M. Bonnet¹, V. Lamothe², S. Bes¹ and G. Durand^{1,2}

¹INRAE, INRAE, Université Clermont Auvergne, Vetagro Sup, UMRH, 63122 Saint-Genès-Champanelle, France, ²Bordeaux Sciences Agro, 1, cours du général de Gaulle, 33175 Gradignan Cedex, France; tainara.michelotti@inrae.fr

More than just an energy source, free fatty acids (FFAs) are signalling molecules known to affect metabolic functions, such as regulation of systemic energy homeostasis and immune response. FFAs mediate their action through the interaction with different receptors: PPAR nuclear receptor, glucocorticoid receptor, and FFA receptors (FFARs). Recently discovered, FFARs have been well studied in humans and mice, although their characterization in bovine species is currently scarce. Therefore, our objective is to characterize 5 bovine FFARs (FFAR1 to 4, and GPR84) in regards of tissue distribution and pharmacological properties. Samples from 6 tissues [liver, ileum, rectum, spleen, longissimus thoracis (LT), and perirenal adipose tissue (PRAT)] were collected from 16 Charolais bulls (16-18 months old) at slaughter. Total RNA was extracted and FFARs' gene expression was assessed by RT-qPCR. Results show that *FFAR1*, *FFAR2*, *FFAR3*, and *GPR84* were expressed in all studied tissues, while *FFAR4* expression was restricted to ileum, rectum, and PRAT. Furthermore, in order to unravel the mode of action of FFAs at the level of the different bovine FFARs, we are conducting *in vitro* experiments using HEK293A cells. Cells are transfected to individually express the 5 bovine FFARs. Through bioluminescence resonance energy transfer (BRET) assay, pharmacological properties of the FFARs (e.g. G protein selectivity, G protein dependent and β -arrestin-dependent signalling) are assessed in response to a broad range of FFAs. Preliminary results show that FFAR1 and FFAR2 are coupled to G-protein subunits $G\alpha_{q1}$ and $G\alpha_{i/o}$, and present β -arrestin2 recruitment. While FFAR1 is activated by medium and long chain FFAs, FFAR2 is activated exclusively by short chain FFAs. Overall, we believe that results from the *in vitro* experiments, aligned with tissue expression data, could reveal novel information regarding FFA effects in bovine metabolism, which might affect animal production, adaptation to physiological conditions, or development of metabolic disorders.

Maternal nutrition carry-over effects on beef cow colostrum but not on milk fatty acid compositionN. Escalera-Moreno¹, B. Serrano-Pérez¹, E. Molina¹, L. López De Armentia², A. Sanz² and J. Álvarez-Rodríguez¹¹University of Lleida, Lleida, 25198, Spain, ²CITA de Aragón-IA2, Zaragoza, 50059, Spain; javier.alvarez@udl.cat

Prepartum nutrition (60 vs 100% their energy requirements during 3 months before calving, LOW vs HIGH) effects on beef cow colostrum and milk fatty acids (FA) profile were evaluated (n=80 cows, half from Parda de Montaña and Pirenaica beef breeds). The postpartum cows were fed 100% their energy requirements (0.7% of total FA, 37.1% C18:2 n-6, 29.8% C16:0, 12.9% c9-C18:1, 9.7% 18:3 n-3). Colostrum was manually milked <12 h post-partum and milk was machine milked by oxytocin technique at week 3 post-partum. Samples were freeze-dried, and FA were analysed by gas chromatography using C11:0 as internal standard and reference standards to compare identified peaks. In colostrum, de novo synthesized saturated FA (SFA) (C4:0 to C15:0) content were lower in LOW than in HIGH fed cows (17.73 vs 21.31±0.41%, $P<0.001$) whereas odd-chain SFA were higher in LOW than in HIGH fed cows (1.98 vs 1.77±0.04%, $P<0.001$). Desaturase index was higher in LOW than in HIGH fed cows ($P<0.001$), leading to greater total trans- and cis-monounsaturated FA (MUFA) in LOW than in HIGH cows (2.05 vs 1.51±0.07%, 26.32 vs 21.35±0.52%, $P<0.001$). Polyunsaturated FA (PUFA) n-3 were higher in LOW than in HIGH cows (2.26 vs 1.96±0.08%, $P<0.001$), mainly as a result of greater C18:3 n-3, whereas PUFA n-6 did not differ across groups ($P>0.05$). Likewise, colostrum rumenic acid content was higher in LOW than in HIGH cows (0.97 vs 0.71±0.031%, $P<0.001$). The c9-C18:1/C15:0 ratio, which is a proxy of negative energy balance, was higher in LOW than in HIGH cows (27.8 vs 20.4±0.99, $P<0.001$). However, total FA in colostrum did not differ across pre-partum feeding levels (4.64±0.52%, $P>0.05$). Subsequently, there were no differences between treatments in any milk FA group, except in total PUFA n-3, that were lower in LOW than in HIGH cows (0.85 vs 0.93±0.03%, $P<0.05$), although C18:3 n-3 did not differ anymore. The total FA in milk did not differ across pre-partum feeding levels either (3.71±0.10, $P>0.05$). In conclusion, when the cows were underfed during the last third of pregnancy, less SFA but more MUFA and essential PUFA were found in colostrum. Later, the milk FA differences were nearly vanished.

Theatre 7

Different types and doses of colostrum to optimize the passive immune transfer and health in lambsA. Belanche¹, F. Canto¹ and O. Calisici²¹University of Zaragoza, Animal Production and Food Science, Miguel Servet 177, Zaragoza, 50013, Spain, ²Phytobiotics Futterzusatzstoffe GmbH, Wallufer Str. 10a, Eltville am Rhein, 65353, Germany; belanche@unizar.es

Optimizing the artificial rearing of young ruminants represents a challenge in modern dairy production systems. However, access to sufficient quantity and quality of colostrum represents a limitation in many farms, which can lead to failure in the passive immune transfer. The objective of this experiment was to investigate the effects of a vacuum-dried bovine colostrum powder (BCP) on the health and of lambs. At birth, fifty-five newborn lambs were separated from their dams and randomly divided into five experimental groups (n=11). Animals received equal volumes pooled ovine colostrum (OC), pooled bovine colostrum (BC), reconstituted BCP at medium (BCPM) or high dose (BCPH). All these lambs received artificial milk feeding whereas a fifth group of lambs sucked maternal colostrum (in unknown quantities) followed by a natural lactation on de dam as control (CTL). Colostrum was provided by oro-gastric intubation at 2 h (6% of BW) and 6 h (6% of BW) whereas at 12 h after birth lambs received milk a similar dose of milk replacer (expect for the BCPH which received BCP). Blood samples were collected at 0, 1, 3, 14, 45 and 52 days of age to monitor plasma metabolites. Results showed a greater IgG concentration in OC than in BC or BCP resulting on a higher IgG intake. All artificially reared lambs (OC, BC, BCPM and BCPH) showed a similar concentrations of IgG at 24 h of age leading to a lower efficiency of IgG absorption for the OC and BCPH treatments ($P=0.09$). No differences were noted among these treatments in terms of plasma metabolites, health and productivity. The presence of anaemia due to the use of heterologous colostrum was discarded. However, CTL lambs had 1.8 to 2.0 times higher serum IgG concentration than artificially reared lambs when measured by ELISA or refractometer, respectively. Control lambs also had lower incidence of diarrhoea and higher BW gain during the post-weaning period. In conclusion, the use of pooled OC, pooled BC or bovine colostrum powder can be considered as successful strategies to artificially rear ruminants, despite maternal rearing provides extra health and productive benefits.

Oxidative status in female Holstein calves fed with or without transition milkC.S. Ostendorf¹, M. Hosseini Ghaffari¹, B. Heitkönig¹, C. Koch² and H. Sauerwein¹¹University of Bonn, Bonn, 53111, Germany, ²Hofgut Neumühle, Münchweiler, 67728, Germany; costendo@uni-bonn.de

This study examined the effects of feeding transition milk to calves on their blood oxidative status, comparing two groups: transition milk (TRANS, n=14) and milk replacer (MR, n=15). All calves received 3.5-4 l of colostrum milked from their dams within 2 h after birth, and 1-1.5 l of colostrum 11.5 h later. Calves were fed according to their feeding group with 12 l/d maximal feed allowance until d 6 of life. All calves received MR (12 l/d; 140 g/l) and were weaned at d 98 of life. Samples from colostrum and from transition milk collected before every feeding were pooled per calf and day. Blood was sampled before colostrum feeding, 12 h after birth, daily during the first 5 d, weekly until weaning (wk 14), and at wk 16. Antioxidant capacity was assessed as the ferric-reducing ability of plasma (FRAP), and reactive oxygen metabolites by the dROM test. An oxidative stress index (OSi) was calculated: dROM/FRAP × 100, and total protein (TP) was also quantified via the Bradford assay. Data were analysed using mixed models with group, time, and the interaction therefrom as fixed effects. Time was significant for all variables assessed ($P < 0.05$). Except for TP, neither group nor the group by time interaction affected dROM, FRAP, and OSi. The observed interaction for TP was due to initially greater TP concentrations in the TRANS which levelled off later. The dROM values increased with colostrum intake and remained relatively constant during the remaining wks. The FRAP concentrations were highest after birth and then showed a continuous decrease with the lowest value observed at wk 16. The OSi values increased after colostrum feeding and were then fluctuating including an increase around weaning (wk 13-16), and reaching the greatest values in wk 16. TP and FRAP levels in milk were highest in colostrum and decreased thereafter but did not affect serum levels in calves. Overall, these results provide insight into the oxidative status of dairy calves in the preweaning period but suggest that the oxidative status as characterized by the variables investigated herein is neither affected during feeding transition milk nor thereafter.

Effects of concentrate feeding and hay quality on adipogenesis and inflammation in dairy calves

R. Khiaosa-Ard, A. Sener-Aydemir, S. Kreuzer-Redmer and Q. Zebeli

University of Veterinary Medicine Vienna, Veterinärplatz 1, 1210 Vienna, Austria; ratchaneewan.khiaosa-ard@vetmeduni.ac.at

We previously showed that concentrate feeding increased the intake of n-6 polyunsaturated fatty acids and the contents of their metabolites, which are lipid mediators, in the adipose tissue of young calves as compared to hay-only feeding. Here, we investigated whether concentrate feeding also affects the cellularity and gene expression related to metabolism and inflammation of the adipose tissue. From the first week to 15 weeks of life, 20 Holstein-Friesian calves (17 males and 3 females) were adapted to one of the four diets differing in the concentrate amount: 0 or 70% on a DM basis, milk excluded) and hay quality: medium-quality hay (MQH) or high-quality hay (HQH). The daily intake of hay, concentrate and milk was recorded. Two regions of kidney fat: proximal and distal to the kidneys were taken for analysis. For qPCR results, data were normalized by the housekeeping genes ACTB and RPL19 and reported as fold changes relative to the average of MQH-only samples. Data were analysed as a 2×2 factorial design with respect to concentrate feeding, hay quality, and adipose region. The proximal region showed larger adipocyte size and higher expression of several adipose genes including LEP (leptin), GLUT4 (glucose transporter type4), PPARG (peroxisome proliferator-activated receptor gamma), FASN (fatty acid synthase), and ADIPOR1 and ADIPOR2 (adiponectin receptor 1 and 2) than the distal region ($P < 0.01$). An effect of concentrate feeding on adipose cellularity and adipose gene expression was region dependent. Both concentrate feeding groups and HQH-only enlarged the adipocyte size. However, very large adipocytes ($>5,000 \mu\text{m}^2$) were more frequent with concentrate feeding. Concentrate feeding increased the expression of TNF α , LEP, FASN, and PPARG in the proximal region and decreased the expression of NF-kB, IL-6, IL-10, and ADIPOR2 in the distal region. Using ΔCt values, ADIPOR2 positively correlated with TNF α , NF-kB, and IL-1 β , and IL-10 and GLUT4 with NF-kB, IL-1 β , and IL-6, while LEP negatively correlated with IL-10 ($r=0.45-0.56$, $P < 0.01$). This study marked the role of concentrate feeding in adipogenesis and inflammatory regulation.

Synergistic benefits of marine derived bioactives to maintain the gut barrier in an ex vivo modelM.A. Bouwhuis¹, I. Nooijen², E. Van Der Steeg² and S. O'Connell^{1,3}¹Celtic Sea Minerals, Strand Farm, Carrigaline, Co. Cork, Ireland, ²TNO, Sylvisweg 71, 2333 BE Leiden, the Netherlands, ³Munster Technological University, Plant Biostimulant Group, Shannon ABC, Clash Road, Tralee, co. Kerry, Ireland; m.bouwhuis@celticseaminerals.com

A healthy gut barrier restricts entry of pathogens, bacteria and other toxins in the diet/environment to submucosal tissue and bloodstream of pigs. Two marine derived bioactives from red seaweed *Lithothamnion* sp. (LG) and brown seaweed *Ascophyllum nodosum* (ANE) have shown individual potential *in vitro* to strengthen the gut barrier. Hence, the objective of the current experiment was to investigate the effects of LG and ANE and their combination on gut permeability in the *ex-vivo* InTESTine™ system. Ileal tissue from one pig was mounted into the InTESTine™ system and incubated for 5 hours. Eleven test conditions were used with 3 control conditions. Due to the calcium (Ca) level of LG (30%w/w), 3 control conditions were used (2.0, 3.8 and 5.3 mM Ca) to match Ca levels of the test conditions. The eleven test conditions consisted of solubilised LG at 63.2 µg/well, ANE (liquid form) at 2.3 µg/well and the remaining 9 conditions were set up as a 3×3 factorial design with LG at 37.8, 63.2 and 88.7 µg/well and ANE at 2.3, 4.5 and 9.1 µg/well. All 14 test conditions were incubated with and without *Salmonella enterica enteritidis* (SEE) (n=4 for each condition). Tissue permeability (P_{app} ; 10⁻⁶ cm/s) was measured by paracellular transfer of mannitol from 0-120, 120-240 and 240-300 minutes. Data was analysed by ExcelStat (16.7, 2022.4.1) using Tukey's adjustment. The results showed an interaction between time, SEE challenge and test condition ($P<0.001$). The SEE challenge resulted in an 6.73 fold increase in gut permeability ($P<0.001$). Between 120-240 minutes, no effect of different Ca levels was observed ($P>0.05$). However, inclusion of both LG+ANE (2.3 µg/well ANE with any level of LG, as well as 4.5 µg/well ANE with either 37.8 or 63.2 µg/well LG) reduced P_{app} , showing less damage to the gut barrier compared to the control treatments or LG or ANE individually ($P<0.05$). Hence, it can be concluded that an SEE challenge disrupts the gut barrier and that LG and ANE work synergistically together to maintain a healthy gut barrier.

Theatre 11

Effects of milk replacer diets on the intestinal development of suckled pigletsG.Y. Duan^{1,2}, C.B. Zheng³, J. Zheng^{1,2}, P.W. Zhang³, M.L. Wang³, J.Y. Yu^{1,2}, B. Cao⁴, M.M. Li⁴, F. Cong⁴, Y.L. Yin^{1,2,3} and Y.H. Duan^{1,2}¹University of Chinese Academy of Sciences, Beijing, 100049, China, P.R., ²Institute of Subtropical Agriculture, Chinese Academy of Sciences, Hunan Provincial Key Laboratory of Animal Nutritional Physiology and Metabolic Process, Changsha, 410125, China, P.R., ³Hunan Agricultural University, College of Animal Science and Technology, Changsha, 410128, China, P.R., ⁴Fengyi (Shanghai) Biotechnology R&D Center Co., Ltd, Shanghai, 200120, China, P.R.; duanyehui@isa.ac.cn

This study aimed to investigate the effect of milk replacer diets on the intestinal development of suckling piglets. Sixteen healthy seven-day-old crossbred (Duroc × Landrace × Yorkshire) male piglets with similar body weight (3.98±0.14 kg) were selected and randomly divided into two groups (n=8): (1) suckling group (continued to be suckled by the sow); (2) milk replacer-feeding group (separated from the sow at 7 days of age and bottle-fed by a milk replacer). The trial lasted for 21 days. Results showed that the final body weight has no significant difference between the two groups ($P>0.05$). However, compared to the suckling group, piglets in the milk replacer-feeding group had higher serum concentrations of proinflammatory cytokines (TNF-α, IL-1β, and IL-6) and lower protein expression levels of TLR4 and NF-κB in the small intestine ($P<0.05$). In addition, compared to the suckling group, piglets fed with milk replacer diet exhibited lower villi folds in the small intestine, accompanied by reduced protein expression of Ki67, mTOR, lipogenesis-related proteins (PPARγ and SREBP1), and tight junction proteins (Occludin, Claudin and ZO-1) as well as downregulated mRNA expression levels of MUC2 ($P<0.05$). Otherwise, compared to the suckling group, piglets in the milk replacer-feeding group illustrated higher protein expression levels of ULK1, TFEB, Parkin, and PNK1 ($P<0.05$). Moreover, milk replacer feeding significantly increased the activity of duodenal alkaline phosphatase and sucrose ($P<0.05$). In summary, piglets given a milk replacer displayed damaged intestinal morphology and function and elevated intestinal autophagy without effects on body weight within the 3-week feeding period.

The impact of early thermal manipulation on the hepatic energy metabolism of mule duckC. Andrieux¹, M. Morisson², V. Coustham¹, S. Panserat¹ and M. Houssier¹¹UPPA, INRAE UMR1419 NuMéA, 173 Route de Saint-Jean-de-Luz, 64310 Saint Pée sur Nivelle, France, ²ENVT, INRAE, GenPhySE, 24 Chemin de Borde Rouge, 31320 Castanet-Tolosane, France; charlotte.andrieux@univ-pau.fr

Increasing egg incubation temperature has been shown to have a significant impact on energy metabolism in poultry, and more precisely on hepatic metabolism in mule duck. We therefore investigated the effects of thermal manipulation (TM) on the hepatic metabolism and *foie gras* production performance. The impacts of the TM were measured throughout the life of the mule duck and during two different metabolic challenges, from embryogenesis to slaughter day. One hour after the rise in temperature, the relative expression of around 10% of the genes studied in the liver (8/78 genes), involved in lipid and carbohydrate metabolisms, was significantly modulated showing a direct effect of temperature on metabolism (Anova tests, 8 ducks). Thereafter, hatchability sometimes decreased depending on the time and intensity of the TM (Chi tests, 265 to 279 ducks), while under most conditions, hatching body weight and body temperature were lower (Student tests, 100 ducks). Several months after the thermal stimulus, refeeding after a 23 h-fast induced a change in energy metabolism in TM duck livers compared to control ducks, with an increase in hepatic cell size (+1 μm on average), a change in liver lipid composition (+4% of saturated fatty acids 4 h after the meal) and changes in the relative expressions of metabolic genes (14 genes, Anova tests, 8 ducks). On the other hand, overfeeding (OF) induced an 8% increase in *foie gras* weight in the TM group compared to the control group without any negative impact on the quality of the *foie gras* (Student tests, 36 to 58 ducks), but again, differences in lipid composition were noticed (student test, 8 livers) associated with modulations in the expression of hepatic genes involved in energy metabolism. Our results confirm that embryonic TM can program liver metabolism of mule duck, and that this programming can be revealed by different feeding challenges. TM could be a lever to reduce the number of OF meals, thereby improving animal welfare and reducing production costs. Finally, this new technique could be combined with optimized breeding methods to produce fattened livers without force-feeding.

Session 92

Poster 13

Feed efficiency and responses of plasma and milk isotopic signatures in Charolais beef cowsA. De La Torre¹, J. Pires¹, I. Cassar-Malek¹, I. Ortigues-Marty¹, F. Blanc¹, L. Barreto-Mendes¹, G. Cantalapiedra-Hijar¹ and C. Loncke²¹Univ. Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Theix, 63122 Saint-Genès-Champanelle, France,²Univ. Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation systémique appliquée aux ruminants, 91123 Palaiseau, France; anne.de-la-torre-capitan@inrae.fr

Productive and metabolic responses are supported by body reserves changes in beef cows when facing feed restriction (FR). Because dynamics of natural abundance of ^{13}C ($\delta^{13}\text{C}$) and ^{15}N ($\delta^{15}\text{N}$) in milk may reflect body changes in dairy cows, the objectives were: (1) to test if plasma and milk isotope signatures change in response to FR in beef cows; and (2) to study their associations with phenotypic feed efficiency. Twenty-two Charolais cows were studied from calving until wk 21 of lactation. Residual feed intake (RFI) was calculated on wks 1 to 8 of lactation when cows were allowed *ad libitum* intake of the same diet. On wk 9, cows underwent a 4-day FR to meet 50% of net energy requirements, followed by *ad libitum* intake. Individual production (MY) and metabolic (NEFA) responses were monitored from d-10 to d19 relative to FR. The $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ were analysed in plasma [before (d-10, d-2, d1); during (d2-5) and after (d6-d8, d11 and d19) FR] and in milk [before (d-10, d-2, d1); during (d4, d5) and after (d11, d19) FR]. The effects of FR and RFI on plasma and milk $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ were tested using mixed model and Spearman correlations. RFI ranged from -0.01 to -0.69 for negative RFI and from 0.04 to 1.15 kg DMI/d for positive RFI and had no effect on plasma and milk isotopic signatures. Plasma NEFA and $\delta^{15}\text{N}$ increased, and $\delta^{13}\text{C}$ decreased during FR ($P < 0.0001$). Accordingly, milk $\delta^{15}\text{N}$ increased and $\delta^{13}\text{C}$ decreased during FR ($P < 0.0001$). Plasma NEFA was correlated across the experiment with plasma $\delta^{15}\text{N}$ ($r = 0.41$, $P < 0.0001$) and $\delta^{13}\text{C}$ ($r = 0.40$, $P < 0.0001$), whereas no correlation was shown with milk isotopes signatures. Plasma $\delta^{15}\text{N}$ was correlated with milk $\delta^{15}\text{N}$ ($r = 0.66$, $P < 0.001$), but no relation was observed between plasma and milk $\delta^{13}\text{C}$. These results suggest that only plasma isotope signatures respond to body reserves changes in Charolais cows but correlations with plasma NEFA were moderate. To date, no clear relations with RFI were found. Further work is ongoing to model kinetics of $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ to explore links with feed efficiency.

How the composition of Holstein cow colostrum differs according to the immunoglobulins G level*A. Goi¹, A. Costa² and M. De Marchi¹**¹University of Padova, viale università, Legnaro 35020, Italy, ²University of Bologna, via Tolara di Sopra, Ozzano dell'Emilia 40064, Italy; angela.costa2@unibo.it*

In cattle, the narrow-sense quality of colostrum depends on the immunoglobulins G (IgG) concentration. Conventionally, IgG must be >50 g/l to consider colostrum acceptable for feeding newborn calves and administration must take place as soon as possible after birth to exploit the maximum gut permeability. High- and low-quality colostrum are expected to differ in terms of composition traits different from IgG, such as amino acids. By using 521 colostrum samples collected within 6 h from calving, we compared the composition of samples belonging to different quality levels: <50 (I), $50-69.99$ (II), and ≥ 70 g/l (III) of IgG. Samples belonged to 521 Holstein cows reared in 9 farms that calved between 2019 and 2020. The traits analysed comprise content of fat, total protein, ash, somatic cell score (SCS) and concentration of essential AA, namely Arg, His, Ile, Leu, Lys, Met, Phe, Thr, Trp, and Val. All traits were determined with their respective gold standard and analysis of variance accounted for the fixed effect of farm ($n=9$), calving season (Jan-Feb, Mar-Apr, May-Jun, Jul-Aug, Sep-Oct, Nov-Dic), parity (3 classes: 1, 2, and 3-8), quality level, and the interactions of quality level with parity and calving season. Except for fat, all the traits were the greatest when IgG was ≥ 70 g/l and the lowest when <50 g/l. Somatic cell count was not different in samples belonging to the II and III quality class and the estimates of fat content were 5.57 ± 0.41 (I), 4.82 ± 0.25 (II), and $4.36 \pm 0.26\%$ (III), with class II being similar ($P>0.05$) to both I and III. The interaction with parity was significant for fat and SCS. Samples in class III presented greater SCS compared to I and II. Regardless of the quality level, primiparous cows' colostrum had in general greater fat content compared to the others. Such findings suggest that colostrum composition vary according to the IgG level, other than to parity and season. Although colostrum yield (kg) was not available to us to evaluate the presence of a dilution effect, we can conclude that the narrow-sense quality of colostrum (IgG-based) goes in parallel with the broad-sense quality.

Session 92

Poster 15

An educational kit for effective prevention and management of energy deficit in dairy cows*M. Gelé¹, M. Boutinaud², A. Bouqueau¹, M. Marguerit¹, J. Jurquet¹, Y. Le Cozler² and J. Guinard-Flament²**¹IDELE, 149 rue de Bercy, 75595 Paris, France, ²PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France; yannick.lecozler@agrocampus-ouest.fr*

Energy deficit (ED) occurs when energy intake is lower than the animal's needs at early lactation or later when cow is underfed. Severe ED can alter milk production, reproductive and health performances, and thus the economy of the dairy farm. Despite this, a recent survey showed there is an inappropriate knowledge on ED in the dairy sector (dairy farmers, farmer advisers, etc.). That is why the partners of the Biomarq'lait project, financed by the French Ministry of Agriculture and Food, decided to synthesise current knowledge on the ED to provide an educational kit for French agricultural and agronomy students. A survey showed a strong interest of teachers for this topic and enabled the kit to be structured into three materials: a video, three summary sheets, and an evaluation test. The video presents the key points of prevention and management of energy deficit in dairy cows, while the three sheets give more details about the knowledge on ED. The evaluation test is in a fun format and allows students to assess their level of knowledge before and/or after the training session. This kit will be offered to all agricultural and agronomic schools at the start of the 2023-2024 school year.

Inflammation status weakly modulated by short-term feed restriction in lactating beef cowsC. Delavaud¹, J. Pires¹, M. Barbet², I. Ortigues-Marty¹, I. Cassar-Malek¹, M. Bonnet¹ and A. De La Torre¹¹INRAE, UCA, VetAgroSup, UMR Herbivores, Theix, 63122 Saint-Genès-Champanelle, France, ²INRAE, U1414 Herbipole, Theix, 63122 Saint-Genès-Champanelle, France; carole.delavaud@inrae.fr

Variations in feed intake modify metabolism and may have putative effects on inflammation status. There is scarce data on suckling cows experiencing acute shifts in feed allowance. The objective was to study inflammation and metabolic responses to a short nutritional stress induced by experimental feed restriction (FR) after 9 weeks of lactation in lactating beef cows. Twenty-two primiparous Charolais cows underwent a 4-day FR to meet 50% of net energy requirements (FR1 wk9, FR2 wk12, FR3 wk13, FR4 wk14). Dry matter intake was measured and residual feed intake (RFI) was calculated on wk 1 to 8 of lactation when cows were allowed *ad libitum* intake of the same diet. RFI ranged from -0.01 to -0.69 for negative RFI (RFI-) and from 0.04 to 1.15 kg DMI/d for positive RFI (RFI+). Blood samples were collected from coccygeal vessels before am feeding on days -13, -6, -1, +4, and +91 relative to FR1. Plasma was stored at -80 °C until analysed for IL-1 α , IL-8, IL-10, IL-17 α , MCP-1, MIP-1 β , TNF α and VEGF α using Milliplex® Bovine Cytokine/Chemokine Panel (BCYT-33K-10, Merck, DE). Plasma stored at -20 °C was analysed for NEFA, glucose, β -hydroxybutyrate (β OH) and urea. Data were analysed using mixed models and repeated measures with cow as random effect. In both RFI group, FR1 increased NEFA, β OH and urea concentrations, whereas glucose decreased between d-16 to d+4. IL-1 α , IL-10, MCP-1 and TNF α were closely correlated (Spearman: $r > +0.8$, $P < 0.0001$). Whatever the RFI group, IL-8 and VEGF α were increased by FR1. A significant interaction between RFI and day was observed for IL-1 α and TNF α with constant increase between d-6 to d+4 for RFI- cows, whereas no change was observed for RFI+. The relation between the effect of FR on cytokines and chemokines and RFI was observed despite large inter-individual variations. Although FR appears to increase the chemokine IL-8 and proinflammatory VEGF α , the lack of effects of FR on the other cytokines suggests that, in the presence of a weak modulation of the metabolic status, it has no marked effect on the inflammation status.

Metabolic profiles of grazing dairy cows with or without feed restriction during early lactation

A.L. Astessiano, M. Garcia-Roche, D. Custodio, G. Ortega, P. Chilibraste and M. Carriquirry

Facultad de Agronomía, Garzon 780, 11600, Uruguay; lauaste@gmail.com

Twenty-four multiparous Holstein cows were selected to assess the effect of feed restriction on energy metabolism (468 ± 73 kg body weight and 2.75 ± 0.16 body condition score (BCS) units). Cows were randomly assigned at 31 ± 14 days in milk (DIM) to ADLIB or RESTR treatments (36.5 vs 16.5 kg DM/cow/d pasture allowance and 5.3 vs 2.6 kg DM/cow/d energy concentrate). From 31 to 40 DIM cows went through an adaptation period (fed ADLIB), from 41 to 46 DIM cows were fed according to their treatments and from 46 to 57 DIM cows went through a flushing period (fed ADLIB). Milk production was recorded daily, BCS and plasma samples were recorded or collected twice during every period. Plasma metabolites and insulin were measured with colorimetric and radioimmunoassay commercial kits, respectively. Data were analysed using a mixed model that included period, treatment, and their interaction as fixed effects. Milk yield was lower for the RESTR group during feed restriction (25.0 vs 29.8 ± 0.7 , $P < 0.01$) and BCS was greater during adaptation (2.77 vs 2.60 and 2.62 ± 0.05 for 38, 48 and 56 DIM, $P < 0.01$). Concentration of insulin in plasma was lower at 46 DIM (12.8 , 9.7 , 9.5 , 6.4 , 9.0 and 10.9 ± 1.1 μ U/ml for 31, 38, 44, 46, 51 and 56 DIM, $P < 0.01$), while glucose concentration was lower for the RESTR than the ADLIB group (3.54 vs 3.78 ± 0.09 mmol/l, $P < 0.05$), non-esterified fatty acid concentration was greater for the RESTR than the ADLIB group at 44, 46 and 51 DIM (0.46 vs 0.27 , 0.61 vs 0.38 , 0.36 vs 0.24 ± 0.04 mmol/l, $P < 0.01$) and beta-hydroxybutyrate was greater for the RESTR group than the ADLIB group at 46 DIM (0.66 vs 0.39 ± 0.05 mmol/l, $P < 0.01$). Finally, urea concentration decreased progressively with lactation (6.5 , 7.4 , 7.1 , 5.7 , 5.5 and 4.9 ± 0.27 mmol/l for 31, 38, 44, 46, 51 and 56 DIM, $P < 0.0001$), and no differences were found for cholesterol or gamma-glutamyl transferase. Our results show that feed restriction in early lactation decreased glucose concentration in plasma and increased lipid mobilization.

Hepatic mitochondrial function in grazing dairy cows with or without feed restriction

M. García-Roche, D. Custodio, A. Astessiano, G. Ortega, P. Chilibroste and M. Carriquiry
 Universidad de la República, 809 Garzón, 11200, Uruguay; mercedesg@fagro.edu.uy

To assess the effect of feed restriction on hepatic mitochondrial function during early and mid-lactation, multiparous Holstein cows ($n=24$, 468 ± 73 kg body weight and 2.75 ± 0.16 body condition score units) were randomly assigned to: *ad libitum* (ADLIB, $n=12$) or restriction (RESTR: 50% of ADLIB offered intake, $n=12$) treatments in three period trials at 31 and 146 $\pm$ 17 days in milk (DIM). All cows were fed ADLIB in the adaptation period (31 to 40 and 146 to 157 DIM), then fed according to their treatments (41 to 46 and 157 to 162 DIM) and finally went through a flushing period (fed ADLIB, 46 to 57 and 162 to 170 DIM). Pasture height and milk production were recorded daily, milk composition was analysed during every period and liver biopsies were collected and cryopreserved at the end of every period. Mitochondrial function was assessed measuring oxygen consumption rates in liver biopsies. Pasture dry matter intake (DMI) was estimated from pre and post grazing pasture height measured with a plate meter. Energy corrected milk yield (ECM) and mitochondrial function were analysed using a repeated model that included treatment, experimental period, stage of lactation as fixed effects and their interactions. Pasture DMI was 9.4 ± 1.1 and 17.0 ± 2.4 kg DM/d and 11.5 ± 1.4 and 9.0 ± 4.4 kg DM/d for RESTR vs ADLIB cows during early and mid-lactation, respectively, in the latter ADLIB cows were supplemented with 9.5 ± 1.7 kg DM/d ryegrass haylage due to low pasture cover. Supplementation with an energy concentrate represented 20% of total DMI. The interaction between treatment, period and stage of lactation was not significant for the variables analysed. However, the interaction between period in treatment and between period and stage affected ECM as it was lower for the RESTR group during feed restriction (24 vs 28 $\pm$ 1, $P<0.05$, RESTR vs ADLIB respectively) only during early lactation. Respiration linked to ATP synthesis was greater during mid than early lactation (10.0 vs 6.9 ± 1.7 pmolO₂/min/mg, $P<0.01$) and greater for the ADLIB than RESTR group (11.0 vs 6.0 ± 1.4 pmolO₂/min/mg, $P<0.01$). Our results show that mitochondrial function is decreased during early lactation and during feed restriction.

On-farm emergency slaughtered dairy cows: causes and haematological biomarkers

F. Fusi^{1,2}, I.L. Archetti², S.M. Chisari², V. Lorenzi², C. Montagnin², R. Salonia³, L. Bertocchi² and G. Cascone³

¹University of Parma, Food & Drug, Parco Area delle Scienze 27a, PR, 43100, Italy, ²IZS Lombardia ed Emilia Romagna, Via Bianchi 9, BS, 25124, Italy, ³IZS Sicilia, Via Marinuzzi 3, PA, 90129, Italy; francesca.fusi@izsler.it

The management of end-of-career cows and their on-farm killing are major animal welfare (AW) issues to be addressed. Since Reg.(EC) No 853/2004 allows 'an otherwise healthy animal which suffered an *accident* that prevented its transport' to be emergency slaughtered on-farm (OFES), blood samples were collected from 33 OFES cows during *ante-mortem* inspections run by official veterinarians on 25 cattle farms in the province of Ragusa (Sicily, Italy) from May 2021 to April 2022. Any time an OFES cow was sampled, another healthy cow with similar characteristics (farm, age, production stage) was sampled too, as a negative control. The following parameters were analysed: total proteins, globulins, albumin/globulin ratio (A/G), urea, glucose, non-esterified fatty acids (NEFA), beta-hydroxybutyrate, total cholesterol, triglycerides, total bilirubin, aspartate aminotransferase (AST), gamma-glutamyl transferase, creatinine, magnesium, calcium, phosphorus, iron, potassium, chlorine, sodium, creatine kinase, oxidative stress (ROMs), positive (haptoglobin) and negative (albumin) acute phase proteins. Average herd size was 147 (min=21, max=437) and 18 out of 25 farms were assessed for their AW level through the ClassyFarm system, with an average total AW score of 73 (min=62; max=88). Average age of OFES cows was 4.7 yrs (min=1.8; max=9.35); out of 33, 30 were lactating cows and 3 dry cows. The causes of OFES were: traumatic leg injuries associated with slips and falls in 69.6% ($n=23$) cows; traumatic injuries associated with calving in 27.2% ($n=9$) cows; and mastitis in 3% ($n=1$) cows (according to Italian rules in force until early 2022). Comparing OFES and healthy cows, significant differences were found for the levels of globulins, A/G ratio ($P<0.05$) and of albumin, urea, haptoglobin, glucose, NEFA, total bilirubin, AST, calcium and iron ($P<0.01$), confirming some findings of previous studies. These are preliminary results of a larger project on metabolomics and osteocalcin in OFES cows, funded by the Italian Ministry of Health, grant IZSSI 09/20 RC.

The effect of early feed restriction of ewe lambs on milk miRNAome of the filial generationA. Martín¹, F. Cecilian², F.J. Giráldez¹, R. Calogero³, C. Lecchi² and S. Andrés¹¹Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas s/n, 24346, Grulleros (León), Spain, ²Università degli Studi di Milano, Department of Veterinary Medicine and Animal Sciences, Via dell'Università, 6, 26900, Lodi, Italy, ³Università di Torino, Department of Biotechnology and Health Sciences, Molecular Biotechnology Center, 10126, Turin, Italy; alba.martin@csic.es

Feed restriction during the early life of ewe lambs (F0) triggers the transfer of epigenetic marks to the next generation (F1). However, the effects of this factor on milk production and composition, including its abundance in regulatory miRNA (with a role in the modulation of immune response of the offspring), has not been tested so far. Therefore, in this study, the replacement ewe lambs (F0) obtained in a previous project (a group of ewes fed milk replacer *ad libitum* (ADL) vs a group of ewes restricted (RES) to 62.5% the intake level of milk replacer during the suckling period) were raised under similar post-weaning conditions and mated to obtain the progeny (F1). The F1 dairy ewes were also mated, and six of these F1 dairy ewes were selected and divided into two groups: the F1-ADL group (n=3) and the F1-RES group (n=3). Milk production was controlled during the peak lactation period, and milk samples were obtained for each gland separately to measure chemical composition, somatic cell counts (SCC), bacteriology and miRNA. The miRNAome was determined following a Next Generation Sequencing approach. The first preliminary results indicate significant differences in the abundance of five miRNAs; thus, oar-miR-150, oar-miR-221, oar-miR-23a, oar-miR-27a, oar-miR-376c were all down modulated in F1-RES when compared to F1-ADL. Most of these miRNAs play a role in development, apoptosis, muscle differentiation, reproduction, or milk production. Moreover, SCC were significantly reduced in milk samples of F1-RES dairy sheep. No significant differences were found in milk production, the chemical composition of milk (fat, protein, lactase), nor in bacteriology (colony forming units, cfu). These results provide some evidence of the effects of nutritional programming events on the milk's bioactive components.

Quercetin supplementation in perinatal sows diet influencing suckling piglets and its mechanism

Y. Li, Q.L. Yang, Y.X. Fu, S.S. Zhou, J.Y. Liu and J.H. Liu

Northeast Agricultural University, Animal Nutrition and Feed Science, #600 Changjiang Road, Xiangfang District, Harbin, Heilongjiang Province, 150030, China, P.R.; liyaolzw@163.com

Similar 24 Landrace × Large white sows were randomly divided into control and three experimental groups, fed by basal diet supplemented with 0.000, 0.025, 0.050 and 0.075% quercetin, respectively, with 6 replicates in each group. The experiment started from the 100th day of gestation to the end of the next oestrus mating. Compared with control, 0.075% quercetin significantly increased weaning weight at day 28 ($P < 0.05$). Quercetin significantly reduced serum MDA content, 0.050 and 0.075% quercetin significantly increased content of serum and liver GSH, reduced serum ROS content, and 0.075% quercetin significantly reduced content of liver MDA and NO ($P < 0.05$). 0.050%, 0.075% quercetin significantly reduced content of serum IL-6, TNF- α , MCP-1 and IL-1 β ($P < 0.05$). Quercetin significantly increased content of IGF-1 and DA, decreased content of NE and EPI in serum ($P < 0.05$). At the genus level, 0.050 and 0.075% quercetin significantly increased the relative abundance of *Lactobacillus*, *Dorea* and *Peptococcus*, respectively; reduced the relative abundance of *Escherichia-Shigella*; Quercetin significantly increased the relative abundances of *Phascolarctobacterium*, *Prevotellaceae_NK3B31_group* and unclassified_f_Lachnospiraceae; 0.075% quercetin significantly reduced the relative abundance of norank_f_Muribaculaceae ($P < 0.01$). Quercetin significantly affected metabolites of sphingolipid metabolism, histidine metabolism and arginine biosynthesis. 0.050% quercetin significantly increased L-ornithine, N-acetyl-L-glutamic acid and N-acetyl-citrulline; 0.050 and 0.075% quercetin significantly increased L-aspartic acid and L-histidine; quercetin significantly reduced 1-methylhistidine, histamine, SM (d18:0/16:1(9Z)), ceramide and phytosphingosine, and significantly increased sphingosine content ($P < 0.01$). In conclusion, optimal quercetin supplementation in diet of perinatal sows increased weaning weight in piglets via relieving oxidative stress and inflammatory response, regulating colonic microflora and metabolic pathways of sphingolipid metabolism, histidine metabolism, arginine synthesis.

Development of muscle injury in weanling piglets under chronic immune stress

Y. Duan

Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, 410125, China, P.R.; duanyehui@isa.ac.cn

This study aimed to explore the effects of lipopolysaccharide (LPS)-induced chronic immune stress on muscle growth, inflammatory state, mitochondrial morphology and function, and oxidative status in piglets. Eighty healthy Duroc × Landrace × Yorkshire piglets (21±2 days old, barrow, 6.98±0.14 kg body weight) were selected and randomly allotted to two groups: control group (pigs were injected with 0.90% sterile saline) and LPS-challenged group (pigs were challenged with LPS on days 1, 3, 5, 7, 9, 11, 13, 15 of the trial at an initial dose of 80 µg per kg body weight, which was increased by 30% at each following injection). The pigs were slaughtered at 1, 5, 9, and 15 d of LPS injection. Results showed that, compared with the CON group, the chronic immune stress weakened the muscle growth manifested as decreased muscle mass and myofiber area from 1 d to the last day, accompanied by increased serum pro-inflammatory cytokines (IL-1β, IL-6, and TNF-α) and reduced protein expression of CD163 from 1 d to 15 d ($P<0.05$). The impaired mitochondrial morphology and function were correlated with excessive mitochondrion-derived ROS, reduced membrane potential, depletion of mitochondrial ATP, exceed mitophagy, and unbalanced fusion and division of mitochondria ($P<0.05$). In addition, AMPK signalling pathway was activated whereas the mTOR signalling was inactivated in *longissimus dorsi muscle* (LDM) from 5 d to 15 d ($P<0.05$). In terms of redox system, chronic immune stress markedly increased the accumulation of MDA and MPO in LDM, and the protein expression of 8-OHdG in LDM and *soleus muscle* (SM) ($P<0.05$). Collectively, the chronic immune stress was extremely detrimental to the muscle growth and development accompanied by alteration of mitochondrial function and crumble redox system, which then activated signal transduction, such as the autophagy system and AMPK.

The great power of being tiny: *in vitro* gut systems in livestock research

S.K. Kar

Wageningen Livestock Research, Animal Nutrition, De Elst1, 6708 WD, the Netherlands; soumya.kar@wur.nl

A better understanding of digestive physiology requires an interdisciplinary approach because of the complexity of the subject. As alternatives to animal experimentation, researchers break down the processes involved in digestion to simple *in vitro* models that provide insight and clarity into the digestive physiology. These *in vitro* models cannot fully or accurately mimic the phenomenon of digestive physiology under *in vivo* conditions. Undoubtedly, such *in vitro* gut systems have their own advantages over *in vivo* models in conducting research, such as no ethical constraints, speed, high throughput, and the ability to provide more mechanistic insights. The available *in vitro* gut systems for (livestock) research can be broadly divided into two categories: *in vitro* digestion models and cell culture models. *In vitro* digestion models offer specific features such as (multiple) compartments and static or (semi)dynamic systems that allow researchers to study either (bio) availability/digestibility or digestion kinetics. Cell culture models are usually based on primary cell cultures or immortalized cell lines from the gut. In addition, researchers have developed intestinal organoids, often referred to as 'mini-guts', an enhanced, near-physiological *in vitro* system. Researchers use cell culture-based *in vitro* systems to study gut health and functionality, including nutrient uptake and barrier function. In addition, researchers use such cell culture models to generate robust host (gut) tissue data that enable them to test/screen food or feed ingredients. Over time, *in vitro* gut systems are becoming more sophisticated as researchers add additional biological layers such as the microbiome and immune cells, or technologies such as 'gut-on-a-chip', a biomimetic system for a physiological organ on a microfluidic chip. Certainly, the advances made by multiple (scientific) disciplines to understand the complexities in digestive physiology can be applied by livestock researchers to enhance the development of *in vitro* gut systems and their use in livestock research.

Comparison of adult intestinal stem cell derived organoids between different ages and sex in pigs

R.S.C. Rikkers¹, O. Madsen², S.K. Kar¹, L. Kruijt¹, A.A.C. De Wit¹, E. Van Der Valk¹, L.M.G. Verschuren³, S. Verstringe⁴ and E.D. Ellen¹

¹Wageningen Livestock Research, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands, ²Wageningen University & Research, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands, ³Topigs Norsvin Research Center B.V., P.O. Box 43, 6640 AA Beuningen, the Netherlands, ⁴Nutrition Sciences NV, Boeiebos 5, 9031 Drongen, Belgium; lisanne.verschuren@topignorsvin.com

Adult intestinal stem cell derived organoids are an *in vitro* research tool that is used in livestock animal research. Organoids are self-renewing and self-organizing ‘mini-organs’ and can be used to study gut health and function, and to unravel complex phenotypes. The transcriptomic resemblance of intestinal tissue and tissue-derived organoids of pigs has been studied before, but a comparison between ages and sex is missing. The aim of this study was to investigate the transcriptomic similarities in cultured organoids between: (1) four different ages in pigs to determine a potential age effect; (2) males and females to determine a potential sex effect. Ileal tissue was collected from 40 male pigs at four different ages (1, 4, 11 and 26 weeks) and 9 female pigs (26 weeks). These tissue samples were used to culture 3D organoids. Transcriptomic RNA profiles of the organoids were compared between the four ages and between sex. Average Pearson correlations of transcriptomic profiles within the 1, 4, 11 and 26 weeks were respectively, 0.96 ± 0.04 , 0.93 ± 0.06 , 0.98 ± 0.03 and 0.90 ± 0.09 , suggesting low variability within age groups. Furthermore, the correlation between all 40 male samples was 0.93 ± 0.05 , suggesting a high similarity between ages. Within males and females (26 weeks), we observed correlations of 0.90 ± 0.09 and 0.91 ± 0.15 , respectively, and overall of 0.90 ± 0.12 . These first results indicate that the resemblance of intestinal derived organoids between the ages is high and the age at which the intestinal stem cells are derived has limited influence. Moreover, the resemblance between males and females is high. Although additional in depth analysis is required, we suggest that organoids could be a promising tool to study complex phenotypes for gut health and function slaughter animals (26 weeks), reducing the number of experimental animals.

Butyric glycerides directly and indirectly enhance chicken enterocyte resistance to pathogens

A. Mellouk, N. Vieco-Saiz, V. Michel, O. Lemâle, T. Goossens and J. Consuegra

Adisseo SAS, Research in Nutrition, 8 route noire, 03600 Malicorne, France

Butyric acid supplementation to the feed is mainly used for its benefits on chickens’ gut health. As a source of butyrate, mono-, di-, and triglycerides of butyric acid provide a better distribution of butyrate in the entire gastrointestinal tract. Here, we aim to study direct and indirect effects of these butyric glycerides’ mixture on avian enterocyte’s resistance to pathogen colonization. The Chic clone-8E11 immortalized chicken enterocytes (8E11) was used to conduct this study *in vitro*. First, we measured, by CellELISA, their resistance to *C. jejuni* (C.j.) and *S. Typhimurium* (S.T.) adhesion after a preincubation with sodium butyrate (SB) or butyric glycerides enriched with monobutyryl (MB). At 2 mM, MB significantly reduced the adhesion of C.j. and S.T. to 8E11 cells by 84 and 60%, respectively. SB reduced only S.T adhesion by 20% ($n=3$, $P<0.001$). MB also protected 8E11 cells from the toxicity of *C. perfringens* α toxin measured by Resazurin cell survival test. MB maintained 8E11 survival levels at 80 vs 15 and 20% in the control and SB groups, respectively ($n=3$, $P<0.001$). Next, we measured, by Seahorse®, the effects of the digested and non-digested butyric glyceride treatments on 8E11 cell mitochondrial activity. Only SB and butyrate released by lipase cleavage significantly increased, up to twice, the initial and maximal oxygen consumption rate ($n=8$, $P<0.001$). In mammals, this metabolic response is known to induce an intestinal ecology shift to an anoxic profile favouring anaerobic microbiota and disfavoring aerobic pathogens. In summary, we show *in vitro* how butyric glyceride mix confers a triple antimicrobial effect to enhance animal resilience against pathogenic challenges. Besides the described effect of α -monoglycerides, we demonstrate that butyric glycerides act directly on enterocytes making them more resistant to pathogens adhesion and toxicity. In addition, butyric acid, when released by lipase, become a source of energy not only for mammalian but also avian enterocytes and can therefore indirectly drive a microbial shift towards a resistant profile to pathogen invasions.

Spheroid and organoid models to study animal reproduction

K. Reynaud, M. Ta, C. Puc  at, M. Billet, C. Mah  , L. Schmaltz, L. Laffont, P. Mermillod and M. Saint-Dizier
INRAE, Reproductive Physiology and Behaviour, INRAE, UMR PRC, 37380, France; karine.reynaud@inrae.fr

For decades, primary cell or cell line culture models have been used to answer a multitude of scientific questions. In reproductive biology, the presence of cells in coculture makes it possible, for example, to improve oocyte maturation and then the rate of embryo development to the blastocyst stage and the survival after freezing. However, these cell cultures are performed in monolayers and the cells rapidly dedifferentiate. The 3D culture models, spheroids and organoids, could allow the preservation of cellular characteristics and thus better mimic the organ microenvironment. Spheroids are groups of primary cells that form spontaneously *in vitro* and do not adhere to the substrate. It is possible to create spheroids of multiple organs and their name will depend on the organ of origin (nerve tissue/neurospheres, colon/colospheres, mammary gland / mammospheres, etc.). An example of oviduct spheroids produced in bovine and porcine species will be described as well as potential applications to better understand the physiology of the organ, to evaluate the fertility of the males (tests of binding with spermatozooids) or to support the development of embryos *in vitro*. Organoids, on the other hand, are self-organising biological systems, derived from stem cells and reproducing the structure and cell types of organs as well as some of their functions. The cells used to generate organoids can be adult stem cells/aSCs or induced pluripotent stem cells/iPSCs. Adult stem cells do not require any treatment before culture, unlike induced stem cells, for which the differentiation protocols can be complex, with purification (cell sorting with antibodies) and cell expansion steps. Cells are grown in matrigel domes with culture medium and growth factors specific to the organ of origin. Over the last 15 years, intensive research has made it possible to create organoids from a very large number of tissues: nerve tissue, lung, stomach, colon, pancreas, liver, kidney and bladder. In reproduction, organoids of cervix, uterus, oviduct and ovary have been described. Examples of oviduct organoids from different domestic mammals and their applications in research and development will be described.

Session 93

Theatre 5

3D-cell culture systems; a breakthrough to improve the human and animal disease research

E.S. Smirnova¹, K.A. Adhimoolam² and T.M. Min³

¹Jeju National University, Department of Animal Biotechnology, Jeju International Animal Research Center (JIA) and Sustainable Agriculture Research Institute, Jeju, 63243, Korea, South, ²Jeju National University, Subtropical Horticulture Research Institute, Jeju, 63243, Korea, South, ³Jeju National University, Department of Animal Biotechnology, Bio-Resources Computing Research Center, Sustainable Agriculture Research Institute (SARI), Jeju, 63243, Korea, South; tsmmin@jejunu.ac.kr

Many disease models are available for studying the disease mechanisms and screening therapies in humans and animals. These models help us to understand the disease biology; however, they have considerable issues. In particular, a dearth of good *in vitro* and *in vivo* models has impeded progress in understanding the fundamental mechanisms underlying diseases. In recent times, innovative techniques and the modification of current techniques in preclinical models have ascended. In particular, 3D-cell culture systems (based on the spheroids, organoids, and tissue heterogeneity) are promising since they are more realistic and can imitate the biological and physiological properties and functionalities of grown cells and tissues. Here, we demonstrated the reliability and efficiency of 3D-cell culture of Caov-3 from a human ovarian adenocarcinoma over typical monolayer culture on a flat surface in cancer research. It created a more natural complex environment and architecture of tumours. Besides, the use of curcumin, which has shown anti-cancer effects, against 3D-generated Caov-3 tumour spheroids has shown improved drug penetration, promising more predictive drug responses for preclinical studies, and also 3D system resulted in higher tumour take rates than single cell suspension retrieval after injection, thus reducing overall animal experiment time. Collectively, if the potential advantages of 3D culture systems are given a chance to become a standard for *in vitro* research, it will be helpful to improve human and animal disease research.

Slurry chemical characteristics and ammonia emissions assessed by different methodsL. Sarri¹, E. Fuertes¹, E. Pérez-Calvo², A.R. Seradj¹, R. Carnicero¹, J. Balcells¹ and G. De La Fuente¹¹Universitat de Lleida – Agrotecnio Center, Ciència Animal, Av. Alcalde Rovira Roure, 191, 25198 Lleida, Spain, ²DSM Nutritional Products, Wurmisweg 576, 4303 Kaiseraugst, Switzerland; laura.sarri@udl.cat

Reduction of crude protein (CP) and addition of feed additives are practical and cost-effective strategies to reduce ammonia (NH₃) emissions from slurry in order to achieve the Paris Agreement targets. Moreover, animal welfare limitations in *in vivo* (VV) trials encourage the development of *in vitro* (VT) techniques. The aim of this study was to compare the chemical characteristics and NH₃ emissions of slurry from pigs fed different dietary treatments in a pig farm (VV) and under VT conditions. A 2×2 factorial design was conducted with 80 growing pigs fed 2 CP levels [standard (16%) vs low (14.5%)], combined with the addition or absence of a mixture of additives (MA; carbohydrases, organic acids, and essential oils). Pigs were distributed in 4 separate modules, dividing the dietary treatments, which drained into 4 slurry pits. Portable flux chambers were used to measure NH₃ at the pit level. Four pigs per treatment were allocated in metabolic cages for individual urine and faeces collection, which were mixed as slurry per pig and placed in artificial slurry pit simulators. Subsamples of the same mixture were added daily. Chemical characteristics and NH₃ emissions were determined at 2 time points between 4 weeks. Statistics were performed using JMP®, with GLM procedures and Tukey's test. Chemical characteristics differed due to the presence of feed in VV slurries. Ammonia emission was higher in VT, as it is a non-leaking system, and decreased considerably over the 4 weeks. An interaction between CP and MA was identified in VV on pH, where MA only reduced pH in low CP diet, whereas in standard CP it may promote microbial growth. Higher N content was observed in high CP diets and MA supplementation. Reduction NH₃ emissions with the inclusion of MA was detected in both methods, but especially in VT method, which was accompanied by an acidic pH. Overall, NH₃ was reduced around 40-50%, or 17% for low CP diet in VV method. In conclusion, VT method was capable to detect changes on NH₃ emissions when MA was included, but VT was not sensitive enough to detect changes due to protein level.

Session 93

Theatre 7

***In vitro* protein fractionation methods for ruminant feeds**B.Z. Tunkala¹, K. Digiacoimo¹, P.S. Alvarez Hess², F.R. Dunshea^{1,3} and B.J. Leury¹¹The University of Melbourne, Agricultural Sciences, Parkville campus, 3010, Parkville, Australia, ²Agriculture Victoria Research, 1301 Hazeldean Road, 3821, Ellinbank VIC, Australia, ³Faculty of Biological Sciences, The University of Leeds, Leeds, LS2 9JT, United Kingdom; btunkala@student.unimelb.edu.au

Estimating protein fractions of feeds is vital to ensure optimum protein supply and degradation in the digestive system of ruminants. This study investigated the possibility of using the ANKOM gas production system and preserved rumen fluid to estimate the protein fractions and *in vitro* degradability of protein-rich feeds. Three *in vitro* methods: (1) gas production method (2) Cornell Net Carbohydrate and Protein System (CNCPS), and (3) the unavailable nitrogen (uN) assay of Ross (uN_{Ross}) were used to quantify the protein fractions of four feeds (lupin meal, vetch grain, Desmanthus hay, and soybean meal). Rumen fluid mixed with 5% dimethyl sulfoxide (DMSO) and frozen at -20 °C (D-20°C) was also compared against fresh rumen fluid in the gas production and uNRoss methods. The *in vitro* degradable protein (IVDP) was higher for vetch grain (46 and 70%) at the 4th and 8th hours of incubation, whereas soybean meal (85%) exceeded the other feeds after the 16th hour of incubation ($P < 0.001$). The greatest ammonia-N concentration was from soybean meal (1.27 mg/g) and lupin meal (0.87 mg/g) fermented for four hours using fresh rumen fluid. Protein fraction a is degradable in rumen. Fraction b is degradable in intestine. Fraction c is undegradable fraction. The proportion of fraction 'b' for soybean (82.1% CP) and lupin meals (39.4% CP) from the CNCPS method were not different ($P > 0.5$) from the fraction 'b' estimation of the gas production method for the same feeds ($r = 0.99$). Regardless of the methods, a greater fraction a was found from vetch grain (39.6-46.6% CP), and the proportion of fraction c in Desmanthus hay (39.1-41.5% CP) exceeded other substrates ($P < 0.001$). All three methods ranked the feeds identically in the proportions of available or ('a+b') protein fractions as vetch grain, soybean meal, lupin meal, and Desmanthus hay in decreasing order. The positive correlation between fractions across different methods and identical ranking of feeds suggests the possibility of using ANKOM gas production system for protein fractionation.

Storage conditions of rumen inoculum: impact on gas productions in mini dual flow fermentersV. Berthelot¹, M. Charef-Mansouri¹, A.-M. Davila² and L.P. Broudiscou³¹Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 place de l'agronomie, 91120 Palaiseau, France, ²Université Paris-Saclay, INRAE, AgroParisTech, UMR Physiologie de la Nutrition et Alimentation, 22 place de l'agronomie, 91120 Palaiseau, France, ³INRAE, UPPA, UMR Nutrition, Métabolisme, Aquaculture, 173 Route Saint Jean de Luz, 64310 Saint-Pée-sur-Nivelle, France; valerie.berthelot@agroparistech.fr

A mini dual flow fermenter, with a working volume of 80 ml compared to 1 l in previous devices, has been designed to study rumen microbial metabolism, potentially without the need of fresh inoculum. The study aimed to optimise a method of rumen content preservation to restore normal *in vitro* fermentations and methanogenesis after a 5-day adaptation period in the device. Different conditions (cryoprotectant, temperature of storage) and times of storage were tested. Two cannulated dry goats were used as donors of rumen inoculum. Each condition for each goat inoculum was tested in triplicate for 7 days with a diet (hay 0.6; barley 0.2, soybean meal 0.2) given twice a day at 08:30 h and 15:30 h. The first experiment tested the effect of freezing storage temperature (-20 vs -80 °C) with DMSO (5%) used as a cryoprotectant at 3 times of storage (fresh as control, 1 and 4 months). Daily gas volume and methane productions after 5 days of adaptation were similar in devices with fresh inoculum and with rumen inoculum stored at -20 and -80 °C for 1 month. After 4 months of storage, gas volume and methane production of inoculum stored at -80 °C were closed to control ones but at -20 °C methanogenesis was greatly impaired with a significant interaction between temperature and animal donor inoculum. The second experiment tested the use of 2 cryoprotectants (glycerol or DMSO) at 5%, at 3 times of storage at -80 °C (fresh, 2.5 and 12 months). Gas volume and methane productions were closed to productions of fresh inoculum up to 12 months of storage. Even though gas volumes were higher with glycerol compared to DMSO, methanogenesis was similar with the 2 cryoprotectants. Based on these data, rumen inoculum can be kept for at least one year at -80 °C without any gas production and methanogenesis impairment in our mini dual flow fermenters.

Session 93

Theatre 9

Dynamics of rumen microbiome and methane emission during *in vitro* rumen fermentationR. Dhakal¹, R. Sapkota², P. Khanal³, A. Winding² and H.H. Hansen¹¹University of Copenhagen, Department of Veterinary and Animal Sciences, Grønnegårdsvej 3, Frederiksberg C, 1870, Denmark, ²Aarhus University, Department of Environmental Science, Roskilde, Denmark, 4000, Denmark, ³Nord University, Faculty of Biosciences and Aquaculture, Skolegata 22, Steinkjer, 7713, Norway; dbk638@ku.dk

Dynamics of the rumen microbial communities during *in vitro* rumen fermentation of maize silage was studied to understand rumen fermentation characteristics. Maize silage was used as a basal feed in three fermentations, and the process was stopped after 6, 12, 24, 36, and 48 hours. Total gas production, dry matter degradability, and methane concentration were measured at these time points, and rumen fluid samples were collected for microbiome analysis. Amplicon sequencing of 16sRNA genes (V4 region) was used to profile the microbial community structure in the rumen during the fermentation process. The following linear relationship between methane concentration and methane yield with total gas production and degraded dry matter was obtained for: Methane concentration (%/gm DM) = 0.0503 × Total gas – 0.3247 (R²=0.9082); Methane yield (ml/g DM) = 0.1301 × (Total gas) – 5.689 (R²=0.9337); Methane yield (%/gm DM) = 15.688 × (degraded dry matter %) + 0.279 (R²=0.8553); Methane yield (ml/g DM) = 40.258 × (degraded dry matter %) – 3.8595 (R²=0.8584). Microbiome analysis revealed the dominance of Bacteroidota, Cyanobacteria, Desulfobacterota, Euryarchaeota, Fibrobacterota, Firmicutes, Patescibacteria, Protobacteria, Spirochaetota, and Verrucomicrobiota. Significant temporal variation was observed in Bacteroidota, Campilobacterota, Firmicutes, Proteobacteria, and Spirochaetota. Alpha diversity estimates using Observed and Shannon index analyses found hardly any difference among the different time points during fermentations. In conclusion, the *in vitro* fermentation characteristics can be predicted based on a few measured *in vitro* parameters for a given feed type in rumen fluid from similar cows. These results indicate that the dynamics of the rumen microbes change with the advancement of time, resulting in the changes seen in the parameters of fermentation kinetics.

Effects of *Asparagopsis armata* inclusion on methane production in semi-continuous fermentersP. Romero¹, S.M. Waters², D.R. Yañez-Ruiz¹, A. Belanche³ and S.F. Kirwan²¹Estación Experimental del Zaidín (CSIC), Profesor Albareda, 1, 18008, Granada, Spain, ²Teagasc, Animal and Bioscience Research Department, Grange, Dunsany, Co. Meath, C15PW93, Ireland, ³Universidad de Zaragoza-CITA, Departamento de Producción Animal y Ciencia de los Alimentos, Miguel Servet 177, 50013 Zaragoza, Spain; stuart.kirwan@teagasc.ie

Recent studies have highlighted the potential of *Asparagopsis taxiformis* to reduce CH₄ production from ruminants, despite its availability being scarce in temperate regions. Alternatively, *Asparagopsis armata* can be grown in temperate regions and it also contains bromoform as the main bioactive compound to reduce rumen methanogenesis. The objective of this study was to evaluate the effects of *A. armata* at different inclusion levels on CH₄ production *in vitro* using the artificial Rumen Simulation Technique. The experiment was run over 21 days using 16 rusitec vessels (n=4) which were randomly allocated to 4 dietary treatments: Control, without seaweed (CTL); *A. taxiformis* supplemented at 25 g/kg DM (AT) or *A. armata* supplemented at 30 (AA1) or 40 g/kg DM (AA2). The *in vitro* basal diet consisted of 50:50 grass silage: concentrate on a dry matter (DM) basis. Rumen inoculum was sourced from four rumen-cannulated beef cattle on grass silage *ad libitum* plus 2 kg concentrates. Seaweed supplementation had no effect on pH in the fermentation or in the overflow effluent vessels ($P>0.05$). There was no difference observed in total gas production between treatments ($P>0.05$). However, vessels that received AA1 reduced CH₄ in terms of gas percentage, CH₄ production by 59.76 and 66.66%, respectively, compared to the control treatment ($P>0.01$). Under *in vitro* conditions, the inclusion of *A. armata* supplemented at 30 g/kg demonstrated the greatest CH₄ mitigation potential.

Session 93

Theatre 11

Calcium propionate mitigated adverse effects of incubation temperature shift on *in vitro* fermentation

T. He, S. Long and Z. Chen

China Agricultural University, College of Animal Science and Technology, No. 2, Yuanmingyuan West Road, Haidian District, Beijing, 100194, Beijing, China, P.R.; hetengfei@cau.edu.cn

This study aimed to investigate the comprehensive effects of calcium propionate (CaP) and different incubation temperature modes on rumen methane production, fermentation characteristics, and microbial communities *in vitro*. A 2×2 factorial experiment with four treatments was conducted over a 72-hour period, including with or without 2.5% CaP (dry matter basis) in the substrate under the mode of constant incubation temperature of 39 °C or incubation temperature shift (39 °C for 4 h followed by 30 °C for 2 h, 12 cycles, ITS). The results showed that ITS inhibited ($P<0.01$) total gas production, methane production, and methane concentration at 12 h and 72 h and reduced the concentration of ammonium nitrogen, propionate, butyrate, and total volatile fatty acids in fermentation liquid. The addition of 2.5% CaP significantly increased ($P<0.05$) the gas production of 72 h, theoretical maximum gas production, concentrations of propionate and valerate, while it had no observable effect on the production or concentration of methane. Furthermore, 2.5% CaP demonstrated a significant ($P<0.05$) increase in the relative abundance of phylum Bacteroides. The relative abundance of *Methanomicrobiales* at genus level decreased under the ITS condition and was positively correlated ($r=0.52$, $P<0.05$) with methane production at 72 h. In addition, CaP increased the relative abundance of *Ruminococcus* at genus level, which was positively correlated ($r=0.63$, $P<0.05$) with the maximum theoretical gas production. Overall, these findings suggest that including 2.5% CaP might alleviate the negative impact of ITS on *in vitro* fermentation parameters by regulating the microbial composition and could sustain the reduction in methane production.

In vitro generation of ovine monocyte-derived macrophages for SRLV infection studiesE. Grochowska¹, M. Ibrahim¹, M. Wu² and K. Stadnicka³¹Bydgoszcz University of Science and Technology, Department of Animal Biotechnology and Genetics, Mazowiecka 28, 85084, Poland, ²University of Molise, Department of Agricultural, Environmental and Food Sciences, Via Francesco De Sanctis 1, 86100, Italy, ³Collegium Medicum, Nicolaus Copernicus University, Faculty of Health Sciences, Łukasiewicza 1, 85821, Poland; grochowska@pbs.edu.pl

Animal health has a great impact on animal productivity, quality, and quantity of given products, and consequently, on the economic outcome of animal production. Among animal pathogens, viruses are on top as the biggest threats to animal health and safety. The infection of small ruminant lentivirus (SRLV) in sheep causes pain, lower productivity, inevitable death, and consequently significant economic losses. There is no effective cure or vaccination. Monocytes and macrophages play crucial roles in SRLV infection. However, the transcriptomes of infected monocytes/macrophages are not very well studied. The study aimed to select the most suitable conditions of cell culture to differentiate sheep blood monocytes into macrophages and to establish an effective RNA extraction protocol to obtain RNA of sufficient quantity for transcriptome sequencing. Peripheral blood mononuclear cells (PBMC) were separated from the blood of Polish Merino male lambs by Histopaque density gradient centrifugation. Monocytes were purified from PBMCs by two methods: adherence and magnetic-activated cellular sorting (MACS). Monocytes or PBMCs were suspended in RPMI 1640 medium with glutamine, 10% FBS, 1% Penicillin-Streptomycin, 1% Amphotericin B, macrophage colony-stimulating factor (m-CSF), and interleukin 4 (IL-4). Five conditions of monocyte culture in a medium with different concentrations of m-CSF and IL-4 were tested. The use of the MACS cell sorting technique resulted in a higher purity of the monocyte population than adherence method. The medium with the addition of 100 ng/ml m-CSF + 20 ng/ml IL-4 enabled the most effective generation of monocyte-derived macrophages (MDM). The established protocol with MACS monocyte sorting step and addition of 100 ng/ml m-CSF + 20 ng/ml IL-4 enables generation of MDMs for transcriptome studies in SRLV infected sheep. This research was supported by National Science Centre, Poland (grant no. 2020/39/I/NZ9/01304).

Session 93

Poster 13

Resistance of probiotics to antibiotics and antagonism to poultry pathogensN. Akhavan^{1,2}, K. Stadnicka¹, D. Thiem² and K. Hryniewicz²¹Collegium Medicum, Nicolaus Copernicus University, Health Science, Jagiellońska 13/15, 85-067 Bydgoszcz, Poland,²Nicolaus Copernicus University, Microbiology, Faculty of Biological and Veterinary Sciences, Lwowska 1, 87-100 Toruń, Poland; niloo@doktorant.umk.pl

The performance of broilers is dependent on the function and growth of the digestive system, which is stimulated by early colonization by beneficial bacteria. During the last few years, there were a lot of studies showing that *in ovo* injection with probiotics can improve performance efficiency, stimulate the immune system and decrease poultry pathogens. For this reason, in our studies, the candidate probiotics (three *Lactobacillus* strains, *Bifidobacterium lactis* and *Carnobacterium divergens*) were characterized in terms of their resistance to common antibiotics with the use of an E-test and determination of MIC (Minimum inhibitory concentration) values. In addition, we analysed the potentially antagonistic properties of probiotics against the major poultry pathogens (*Listeria monocytogenes*, *Salmonella Typhimurium*, *Salmonella Enteritidis* and *Escherichia fergusonii*) with the agar well diffusion assay and cell-free supernatant assay (CFS). According to the results of the ANOVA test, all analysed probiotics were resistant towards ciprofloxacin in the range of 0.002 to 32 µg/ml, whereas *L. rhamnosus* H25 and *L. plantarum* showed resistance against amoxicillin and tetracycline too. Determined MIC values depend on the used antibiotic. In general growth of *Lactobacillus* sp. and *B. lactis* was inhibited in higher antibiotic concentrations (100 mg/l) than *C. divergens* (25 mg/l). In our antagonistic study, we observed that *L. rhamnosus* H25 and *L. plantarum* revealed an inhibition against *L. monocytogenes*. Potential resistance to common antibiotics and antipathogenic activities are addressing the broader ecosystem and is not limited to the host performance only. Therefore, the obtained results provide a piece of relevant information about the probiotic's bioactivity, before their application on farms. National Science Centre OVOBIOM_UMO-2019/35/B/NZ9/03186, IDUB program NCU Poland.

Metabolic footprint of prebiotics and probiotics in Chick8E11 and Caco-2 intestinal cell linesS. Zuo¹, W. Studziński², K. Stadnicka¹ and P. Kosobucki²¹Ludwik Rydygier Collegium Medicum Nicolaus Copernicus University in Torun, Faculty of Health Sciences, 85-821, Bydgoszcz, Poland, ²Bydgoszcz University of Science and Technology, Department of Food Analysis and Environmental Protection, 85-326, Bydgoszcz, Poland; sanling.zuo@doktorant.umk.pl

Probiotics and prebiotics have been widely studied in poultry as an early strategy to program host health and performance by manipulating gut microbiota towards optimal metabolism. This study aimed to identify metabolic footprints of candidate probiotics in intestinal cells *in vitro* to explain the molecular mechanism of their effects in chicken intestinal cells. Prebiotic candidates, special seaweed extract and protein hydrolysate, were tested to stimulate the probiotic growth. Probiotic was cultivated in medium with addition of 2% [v/v] prebiotic solution. The new chicken cell line Chick8E11 and Caco-2 (as reference) were inoculated with probiotic *Bifidobacterium lactis*, respectively, at a ratio of 30:1 (bacteria:cells) for 48 h (replicates=3). The supernatants were subjected to the targeted analysis with gas chromatography-mass spectrometry to reveal changes in organic acids including short chain fatty acids (SCFAs). It was found that *B. lactis* produced different metabolites depending on the type of prebiotics stimulating its growth. Its lactic and valeric acid levels were changed ($P<0.05$) by protein hydrolysate. In the co-culture of cells and probiotic, the change in acetic acid was found in the Caco-2 system, whilst the acetate and propionate levels were changed in the Chick8E11 system. Also, significant changes were found in organic acid levels (succinic acid and L-alanine), and for essential and non-essential amino acids (leucine and serine) ($P<0.05$). SCFAs play an important role in maintaining the gut normal function. Other organic acids are closely related to metabolic pathways such as cellular glucose metabolism, TCA cycle, and G protein-coupled receptors. The results obtained from *in vitro* studies may serve as a basis to predict the potential of bioactive candidates' function in the host. The results of this study will be compared with metabolic profile of *in ovo* stimulated chicken gut. The research was supported by grant 2019/35/B/NZ9/03186(OVOBIOM) funded by the National Science Centre and IDUB program at NCU Poland.

Cellular imagery evaluation of butyric acid biological activities in Caco-2 cell lineD. Gardan-Salmon¹, B. Saldaña², J.I. Ferrero² and M. Arturo-Schaan¹¹DELTA VIT – CCPA GROUP, ZA du Bois de Teillay, 35150 Janzé, France, ²NOVATION – CCPA GROUP, C/ Marconi 9, 28823 Coslada (Madrid), Spain; dgardan-salmon@ccpa.com

In the context of reducing antibiotic use in animal production, greater attention is given to natural alternatives to improve intestinal health and welfare. Relevant *in vitro* models may be employed to evaluate the biological properties and to better understand the mode of action of these natural alternatives. Butyric acid (BA) is a short chain fatty acid naturally formed in the colon of monogastric animals by microbial fermentation. Recent studies show that BA is a regulator of inflammatory processes in the small intestine and can enhance intestinal barrier function and mucosal immunity. Thus, BA is an adequate candidate for dietary intervention for livestock animals facing stress and diseases impairing gut health and homeostasis. Our study aimed at investigating the ability of BA to modulate inflammation and oxidative stress *in vitro* in an intestinal cell line. IL-1 β -induced Caco-2 cell line was used to study inflammation through fluorescent immunostaining imagery of NF- κ B translocation into the nuclei. Oxidative stress mitigation was measured using menadione as reactive oxygen species inducer in Caco-2 cells and Deep Red CellROX fluorescent probe for imagery. Briefly, Caco-2 cells were cultured for 4 days (37 °C, 5% CO₂); cells were then pre-treated with BA (8 to 100 μ g/ml) for 1 h; and then co-incubated with IL-1 β (100 ng/ml) or menadione (50 μ M) for 1 h prior to cellular imagery. BA alleviated inflammation induced by IL-1 β by significantly reducing the % of NF- κ B positive nuclei (-36% with 8 μ g/ml of BA; $P<0.01$). BA reduced oxidative stress induced by menadione by reducing oxidized probe quantity (-19% to -23% with 8 μ g/ml and 20 μ g/ml of BA respectively; $P<0.05$). Using cellular imagery on Caco-2 cells, our results showed that BA can exert anti-inflammatory effect through NF- κ B modulation as well as antioxidant effects in enterocytes. This *in vitro* approach is a promising sustainable and original imagery tool to better evaluate the biological properties of feed ingredients prior to *in vivo* evaluation.

Effect of silage sample preparation on rumen fermentation (*in vitro*)J.A. Huntington¹, T. Snelling¹, L.A. Sinclair¹, H. Warren², D.A. Galway¹ and D.R. Davies³¹Harper Adams University, Agriculture and Environment, Edgmond, Newport, Shropshire, TF10 8NB, United Kingdom, ²Alltech, European Biosciences Centre, Dunboyne, Co. Meath, A86X006, Ireland, ³Silage Solutions Ltd, Bwlch y Blean, Ceredigion, SY23 2HN, United Kingdom; jhuntington@harper-adams.ac.uk

Sample preparation for *in vitro* rumen fermentation kinetics model can affect resultant fermentation product profiles. Second cut ryegrass ensiled in varying conditions of compaction density, hygiene and sealing were used to determine the effect of sample preparation for rumen fermentation kinetics (*in vitro*). Samples of the ensiled ryegrass with a dry matter ranging between 397 and 408 g/kg FM were either oven dried (60 °C) then milled (2 mm screen), freeze dried or frozen fresh (freeze dried & frozen fresh silages were not milled) prior rumen fermentation (*in vitro*). Samples (1.0 g DM based on oven DM, 60 °C) were incubated in 200 ml buffered (Mould's buffer) rumen fluid (20%) at 39 °C for 48 h. Cumulative increase in headspace pressure was used to determine rumen fermentation profile. Following rumen fermentation (*in vitro*) final culture headspace gas was collected and methane concentration measured. Final rumen cultures were then filtered (P1 glass sinters) to determine 48 h DM degradability. Method of sample preparation was found to affect ($P<0.001$) DM degradability, fermentation profile and methane evolution. Drying the sample reduced DM degradability with mean values of 0.772^a, 0.692^b and 0.571^c SED=1.949; $P<0.001$ for fresh frozen, freeze dried and oven dried +milled silages, respectively. Rumen fermentation profiles were different for the different sample preparations and mean gas pressure was also found to be reduced by drying, with mean PSI of 13.04^a, 9.82^c and 10.60^b for frozen fresh, freeze dried and oven dried +milled, respectively (SED=0.304; $P<0.001$). Freeze dried samples generated the highest concentration of methane whilst fresh frozen the lowest; mean methane concentrations were 71.92^a, 57.16^b and 52.90^c % of headspace gas for freeze dried, oven dried +milled and fresh frozen, respectively (SED=2.632; $P<0.001$). It was concluded that method of sample preparation had a substantial effect on rumen fermentation parameters with consequences for data interpretation and method standardisation.

Session 93

Poster 17

Repeatability of fermentation kinetics using *in vitro* gas fermentation

B. Jantzen and H.H. Hansen

University of Copenhagen, Department of Veterinary and Animal Sciences, Groennegaardsvej 3, 1870, Denmark; htz757@sund.ku.dk

In vitro gas production (IVGP) fermentation kinetics are widely used to screen feeds and feed additives to reduce the number of animals needed, which in turn, reduces costs. However, information about repeatability is scarce. The objective of this study was to evaluate the variation from IVGP fermentations in the same laboratory using the same feed sample. Rumen fluid from two different farms with either producing dairy cows or dry fasting heifers were used as donor animals. Seventeen 24-hour fermentations, undertaken during a year, were used to evaluate the variation between the following parameters: best fit-gas curve, baseline corrected gas production (TGP: ml at Standard Temperature and Pressure/gram dry matter), methane concentration and yield, pH and apparent dry matter degradability (dDM). Significant differences between donor animal types were found for methane concentration and yield, pH of individual animals within type and pH of the fermented fluid. Observed variation was non-significant within donor types for methane concentration and yield and pH after fermentation. The rate of early gas production was significantly different by donor types, but TGP was not significantly different at 24 hours when corrected for baseline gas production. No dDM differences after 24 hours of fermentation between and within donor types were detected. Best fit curves were different by donor type, being either a monophasic version of the sigmoidal model or an exponential curve for the heifers or the production animals respectively. However, no differences were observed within type. A high repeatability was seen, when using the same donor types.

Evaluation of rumen bypass protein in processed soybean meal products

A. Chariopolitou, A. Plomaritou, A. Tzamourani, K. Droumtsekas and A. Foskolos

University of Thessaly, Department of Animal Science, Campus Gaiopolis, Larissa, 41222, Greece; anplomaritou@uth.gr

To meet increased protein requirements due to increased milk production, various feedstuffs have been developed to escape rumen degradation providing directly metabolizable protein to the ruminant. However, important differences among commercially available products do exist. Thus, the objective of this study was to evaluate commercially available bypass soybean meals with a fast and reliable *in vitro* method. Four different soybean meal products were selected: unprocessed soybean meal (SBM) and three commercially available processed soybean meal products (PROT1, PROT2 and PROT3). Eight samples of each product were collected and assessed for their protein digestibility using the Daisy^{II} incubator. Briefly, 1 g of sample was weighted into fibre bags (Ankom F57) in duplicate. Rumen fluid from five cows was collected before feed delivery using rumen fluid extractor. Bags were incubated in Daisy incubation bottles containing 1:1 rumen fluid and buffer solution. After 24 h of ruminal incubation bags were removed and washed in a washing machine. All the original samples and the residue in bags were analysed for Dry Matter (DM; 24 h in a 55 °C oven) and N content (Kjeldahl). Dry matter 24 h digestibility (DMD) ranged from 39.3 to 69.4% and crude protein 24 h digestibility (CPD) ranged from 12.5 to 53.2%, with significant differences between the SBM and the bypass products. Furthermore, significant differences were observed among bypass products, where PROT3 had the lowest DMD (39.3 vs 56.6 and 55.5% for PROT3 vs PROT1 and PROT2, respectively; $P<0.0001$) and the lowest CPD (12.5 vs 31.1 and 29.9% for PROT3 vs PROT1 and PROT2, respectively; $P<0.0001$). When CPD of bypass products was corrected for SBM rumen digestibility, the % of ruminal protection was estimated. In this case, even though the PROT1 and PROT2 did not show statistically significant differences between them (41.4 and 43.7%, respectively), the PROT3 provided greater ruminal protection than the other two (76.5%; $P<0.0001$). In conclusion, significant differences were found among the available processed soybean meal products and frequent assessment should take place in order to best describe their nutritional value.

Session 93

Poster 19

Effect of rumen inoculum on predicted *in vivo* methane production from barley and oats

P. Fant, M. Ramin and P. Huhtanen

Swedish University of Agricultural Sciences, Department of Animal Nutrition and Management, Skogsmarksgränd, 907 36 Umeå, Sweden; petra.fant@slu.se

The first objective was to examine the effect of rumen inoculum (RI) on predicted *in vivo* CH₄ production in an *in vitro* gas production experiment. The second objective was to compare predicted CH₄ values with observed CH₄ values from a feeding trial conducted simultaneously using the same diets. The feeding trial was a 4×4 Latin square design with 16 Nordic Red dairy cows. Diets consisted of 60% grass silage and 40% grain: barley, oats with hulls (hulled oats), dehulled oats, or a 50:50 mix of hulled and dehulled oats on dry matter (DM) basis. The *in vitro* experiment was a 2×4 factorial design replicated in 4 runs with 2 types of RI and the same 4 diets as in the feeding trial. The RI was obtained by stomach tubing from cows in the feeding trial fed either hulled oats (2 cows) or barley (2 cows) as grain component. Predicted *in vivo* CH₄ production was estimated from the *in vitro* according to Ramin and Huhtanen. Data were analysed in SAS by the MIXED procedure. Orthogonal contrasts were specified for barley vs all oat diets, and linear and quadratic effects of replacing hulled oats with dehulled oats. There were no interactions between diet and RI ($P=0.40$). *In vitro* organic matter (OM) digestibility was not affected by RI ($P=0.28$), but predicted CH₄ tended to be higher ($P=0.07$) in the RI from oat fed cows than from barley fed cows (25.5 and 24.6 g/kg DM, respectively). *In vitro* OM digestibility increased linearly ($P<0.01$) from 884 to 919 g/kg OM when hulled oats was replaced by dehulled oats, but predicted total gas ($P=0.21$) and CH₄ ($P=0.23$) were not affected. However, predicted CH₄ tended to be lower ($P=0.06$) in the oat diets than in the barley diet (24.8 and 25.8 g/kg DM, respectively). The CH₄ ranking of the oat diets was consistent with the results in feeding trial. Due to low number of observations ($n=4$), the relationship between predicted and observed CH₄ (g/kg DM intake) was not significant ($P=0.25$, $R^2=0.56$, RMSE 2.2% of observed CH₄ mean). In conclusion, rumen inoculum did not affect the diet comparison in this study indicating a minimum effect of rumen microbiome on observed differences in *in vivo* CH₄ emission between barley and oats.

Comparison of *in vitro* and *in vivo* methane production in dairy cows

D.W. Olijhoek, É. Chassé, M. Battelli, M.V. Curtasu, M. Thorsteinsson, M.H. Kjeldsen, W.J. Wang, G. Giagnoni, M. Maigaard, C.F. Børsting, M.R. Weisbjerg, P. Lund and M.O. Nielsen
 AU Viborg – Research Center Foulum, Aarhus University, Dept. of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark; dana.olijhoek@anivet.au.dk

Ideally, *in vivo* methane production from individual cows fed different diets could be predicted by a low-cost *in vitro* method. Therefore, this study aimed to assess the correlation between *in vivo* methane emission from dairy cows measured using respiration chambers or GreenFeed (C-Lock Inc, Rapid City, USA) and *in vitro* methane production when identical diets were incubated in a system simulating rumen fermentation (Ankom RF, Ankom Technology, Macedon, USA). Two experiments were conducted. In *in vitro* Exp. 1, total gas and methane production were determined when dried samples (0.5 g) of 43 different TMRs (from 11 feeding trials) and silages (maize and grass) as control feeds were incubated in 90 ml buffered rumen fluid obtained from 3 heifers (pooled). In *in vitro* Exp. 2, TMR samples (0.5 g) with high (63% of DM) and low content (35% of DM) of forage were incubated in 90 ml buffered rumen liquid obtained and separately tested for 16 Danish Holstein cows fed each of these diets in 2 different experimental periods. All *in vitro* incubations lasted 48 h to record total gas production and gas samples were collected at 24 h to determine methane production. Data were analysed as Pearson correlations. Preliminary results of Exp. 1 showed a weak correlation ($r=0.35$; $P=0.02$) between methane production from the diets determined *in vitro* (ml CH₄/g incubated DM) and *in vivo* (L CH₄/kg DMI). Graphical visualization of *in vitro* and *in vivo* methane production of Exp. 2 showed clustering by the diet fed to the cow, but not by the diet incubated *in vitro*. The correlation between *in vitro* and *in vivo* methane production was stronger when cows were fed a diet low in forage ($r=0.56$; $P=0.001$) than high in forage ($r=0.17$; $P=0.34$). Further statistical analyses will be performed. These first results highlight the impact of the diet fed to cows that deliver rumen liquid for *in vitro* trials and the lack of considerable consistency in methane production assessed *in vitro* compared to *in vivo*, and this was particularly pronounced when cows were fed diets high in forage.

What impairs laying hens' foot health? A retrospective German study

N. Volkmann^{1,2}, A. Riedel^{1,2}, N. Kemper¹ and B. Spindler¹

¹University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTN), Bischofsholer Damm 15, 30173 Hannover, Germany, ²University of Veterinary Medicine Hannover, Foundation, Science and Innovation for Sustainable Poultry Production (WING), Heinestraße 1, 49377 Vechta, Germany; nina.volkmann@tiho-hannover.de

One of the most common foot health problems and welfare issues in laying hens housed in non-cage systems is food pad dermatitis (FPD) with an inflammation of the subcutaneous tissue of food pad. To identify potential risk factors for this disorder, the present retrospective study investigated 22 German laying hen herds during production, while housing system, herd size, observation time, season, litter type and quality as well as foot health were recorded. Both feet of randomly selected animals ($n=4,534$) were evaluated with regard to the occurrence and extent of footpad changes using a modified 4-point scoring system (FPD Score); the highest degree of FPD per animal was noted, as well as whether the animal was affected on one or both sides of its feet. Statistical analyses were carried out using SAS 9.4 software with a significance levels of P less than 0.05. Effects on the FPD Score were analysed using a generalized linear mixed model; pairwise comparisons were carried out using Tukey Kramer t -tests. In total, 73.4% of the hens had healthy feet with no alterations, 26.1% showed moderate FPD in at least one foot, 0.4% were classified as those with a moderate FPD2 and one hen showed severe FPD. Of the affected animals ($n=1,205$), 45.7% had FPD on one foot and 54.3% on both sides. While only few animals showed FPD at the first two visits, the ratio of affected animals increased with the laying peak. At the end of the laying period 37.5% of the hens showed moderate alterations. FPD Score was statistically affected by the time of visit ($P<0.0001$), the season ($P<0.0001$) and the type of litter ($P=0.0157$). This retrospective study showed that more than a third of the animals had alterations in their footpads at the end of laying period. In addition to the age of the hens, effects of litter type and the season as risk factors could be determined.

Pododermatitis in broilers: prevalence and risk factors present in reused beddings

J. Montalvo, M. Cevallos and M. Cisneros

Central University of Ecuador, Faculty of Veterinary Medicine and Zootechnics, Jeronimo Leiton y gato sobral, 170129, Ecuador; mcisneros@uce.edu.ec

The purpose of this research was to study the prevalence and possible risk factors that predispose broiler chickens raised in recycled beddings to develop contact pododermatitis. The information was collected from eight sheds, at 11 times between day 1 to day 40 in two different types of beds (bed reused one time or treatment 1 (T1) and bed reused two times or treatment 2 (T2)). 23 birds were sampled in each shed, by giving a total of 2,024 individuals at the end of the investigation. To analyse the data obtained, a nested mixed model was necessary to use, and it analysed fixed and covariates effects, as well as random ones. For the analysis, the R software, version 4.1.3, and the lme4 package were used. As important results, it can be mentioned that on day 40, 320 birds (51.9%) with pododermatitis in T1 beds and 669 birds (47.5%) with pododermatitis in T2 beds were quantified. It is important to clear up that, although the prevalence among treatments is almost similar, birds exposed to T2 beds presented more severe pododermatitis lesions. The mixed model analysis showed that the severity of footpad dermatitis increased by 0.228 in birds exposed to T2 litters; likewise, the birds presented a daily increase in the severity of footpad dermatitis of 0.046 or 0.46 per 10 days in the breeding bed. In conclusion, the overuse of recycling of breeding beds and the age of the birds (variable related to weight and time in breeding) were the main risk factors that could predispose meat-producing birds to develop pododermatitis by contact.

Digital dermatitis in French young bulls fattening farms

A. Waché¹, M. Petitprez², E. Dod Ioan³, M. Delacroix⁴ and C. Guibier⁵

¹Livestock Institute, Morel street, 49071 Beaucouzé, France, ²Animal Health Protection Group of Picardie, De Gennes street, 02007 Barenton-Bugny, France, ³Eurolia Vet clinic, St Quentin street, 80400 Ham, France, ⁴Veterinarian, Souleyant, 42130 Marcoux, France, ⁵Chamber of Agriculture of Aisne, Blondelle street, 02007 Laon, France; aureore.wache@idele.fr

Digital dermatitis (DD) has been discovered in some young bulls fattening farms of north of France suffering economic losses. Because little is known on DD in this kind of farming, a study was set up to describe this disease and make hypotheses on the risk factors favouring its development. This is the 1st study carried out in France on this issue in young bull fattening. 14 pens from 8 fattening farms were followed for several months. In each pen, the 4 feet of bulls were observed by a professional trimmer at the beginning, the middle and the end of fattening period. All visible podal lesions without trimming were recorded and DD lesions were described. At each visit, litter's temperature of pens was recorded and data on farming conditions and practices were collected. Descriptive statistical analyses, multiple correspondence analysis and hierarchical bottom-up classification were then performed. By the end of the study, animals affected by DD were observed in 7 out of the 8 farms. A total of 242 bulls were included in the analysis, fattened in lots from 11 to 32 animals. Results showed a significant difference in intra-pen prevalence between farms (e.g. 4% in farm E2 against 85% in farm E1 at mid-fattening) and also between pens of some same farms. A total of 257 DD lesions were described, 49% of which were located on front feet. Several risk factors have been identified including: overcrowding, a bedding temperature >40 °C, moving animals of pen without changing the litter, composition of batches with young cattle from more than 5 different suckler-cows farms, scraping area that communicate, presence of the infirmary-pen next to the fattening pens. A larger scale study would be needed to validate these hypotheses regarding risk factors. However, this 1st study allowed to describe and to better understand this disease in French fattening farms and to identify practices on which it could be possible to act to limit the development of the disease, and therefore economic losses.

Prevalence and factors associated with teat-end hyperkeratosis in dairy cowsF.G. Silva^{1,2}, C. Antas¹, A.M.F. Pereira¹ and C. Conceição¹¹Mediterranean Institute for Agriculture Environment and Development & Change, University of Évora, Department of Zootechnic, Largo dos Colegiais 2, 7004-516 Évora, Portugal, ²Veterinary and Animal Research Centre & Al4Animals, University of Trás-os-Montes e Alto Douro, Department of Animal Science, Quinta de Prados, 5000-801 Vila Real, Portugal; fsilva@uevora.pt

Teat-end hyperkeratosis is a welfare problem associated with dairy cows' production system, that causes pain and discomfort to the animal. Although a lower degree of teat-end hyperkeratosis can be considered normal, more severe cases highly impact animal welfare. The identification of risk factors allows the dairy farmer to take preventive measures to reduce severe teat-end hyperkeratosis. This study aimed to identify the risk factors associated with teat-end hyperkeratosis in dairy cows. From a Holstein-Friesian dairy farm, 492 cows (mean of 3.3 in the number of lactations) were observed during the milking time, and the degree of hyperkeratosis of all teats (n=1,968) were evaluated in a 4 points scale (no lesion (1), smooth ring (2), rough (3) and very rough skin (4)). Parity, days in milking, teat length and teat-end shape, udder health, milking procedures, and behaviour parameters were all evaluated to identify risk factors for teat-end hyperkeratosis. From all the teats evaluated, 41.3% had no lesion (1), 43.1% had a score of 2, 14.2% had a score of 3 and 1.4% showed severe hyperkeratosis signs (4). On average, cows had a degree of hyperkeratosis of 1.8 ± 0.7 . The sum of the worst cases of hyperkeratosis (scores 3 and 4) was 15.6%, a value reported in the literature within the recommended limits. Cows with more lactations, longer and rounded shape teats, with mastitis at least once, and with a higher milking time had a superior degree of teat-end hyperkeratosis ($P < 0.05$). Although the prevalence of severe teat-end hyperkeratosis (scores 3 and 4) was not very high in the present study, there were several animal and management-based factors, that increased the degree of teat-end hyperkeratosis. Furthermore, the factors influencing the degree of teat-end hyperkeratosis may also be related to culling on a commercial dairy farm, which may conceal the actual impact on animal welfare.

Session 94

Theatre 5

Milk calcium content to detect hypocalcaemia in dairy cows at the onset of lactationT. Aubineau¹, R. Guatteo² and A. Boudon³¹Innoval, Tabarly, 35530 Noyal-Sur-Vilaine, France, ²INRAE, BIOEPAR, Chantrerie, 44300 Nantes Cedex, France, ³INRAE, PEGASE, Prise, 35590 Saint-Gilles, France; thomas.aubineau@innoval.com

Subclinical and clinical hypocalcaemia are major health issues in dairy cattle. The main objective of this study was to describe calcium (Ca) dynamics in both milk and blood at the onset of lactation in dairy cows to assess the possibility of identifying cows with hypocalcaemia from their milk Ca content. We performed a longitudinal analysis of 32 multiparous and 18 primiparous cows starting two weeks before the expected date of calving. Blood samples were collected 15 days before expected calving. Then, blood and milk samples were collected on a daily basis from day 1 (day of calving) to day 7, and again on day 15. These data were used to describe the dynamics of plasma and milk Ca, using generalized linear mixed models with repeated values. We identified the sampling days that demonstrated the strongest correlations between plasma Ca and milk Ca. Then, we assessed the ability of milk Ca to distinguish between two different patterns of hypocalcaemia (delayed or persistent) via receiver-operating characteristic analysis. Blood Ca dynamics were largely similar in both multiparous and primiparous cows, with a strong decline from prepartum sampling (98.75 ± 1.63 mg/l and 98.13 ± 2.54 mg/l, respectively) to day 1 (76.87 ± 2.35 mg/l and 88.21 ± 1.03 mg/l), followed by a progressive increase that reached initial values on day 5 (multiparous, 91.58 ± 1.54 mg/l) or 6 (primiparous, 98.13 ± 2.54 mg/l). In both multiparous and primiparous cows, a decline in milk Ca levels was observed, with a sharp decrease from day 1 ($1,917 \pm 67$ mg/kg and $1,823 \pm 94$ mg/kg, respectively) to day 3 ($1,342 \pm 34$ mg/kg and $1,341 \pm 34$ mg/kg), then relative stability until day 15 ($1,282 \pm 39$ mg/kg and $1,226 \pm 25$ mg/kg). We observed moderate correlations between blood Ca and milk Ca. Nevertheless, we could identify cut-off values of milk Ca allowing to discriminate between two patterns of persistent or delayed hypocalcaemia, with good to fair sensitivity (90 and 84.6%, respectively) and specificity (79.5 and 80.6%, respectively). The next step will be to confirm these results in broader field conditions in order to assess their accuracy and estimate predictive values in a field context.

PRRSV stabilisation programs in French farrow-to-finish farms: a way to reduce antibiotic use

C. Teixeira Costa, G. Boulbria, V. Normand, C. Chevance, J. Jeusselin, T. Nicolazo and A. Lebreton
 Rezoolution, ZA de Gohélève, 56920 Noyal-Pontivy, France; c.teixeira-costa@rezoolution.fr

PRRSV-1 affects more than 60% of farrow-to-finish farms in Brittany, with serious economic consequences. Moreover, agricultural advisors describe an increased use of antibiotics when PRRSV-1 is circulating in pig farms. The objective of this study was to assess the impact of PRRSV-1 stabilization programs on reducing antibiotic usages. The study was carried out on 19 farrow-to-finish farms that successfully implemented a PRRSV-1 stabilization protocol between 2007 and 2019. For each, antibiotic usages (expressed in mg/PCU and ALEA) were compared one year before implementation of control measures (P1) and one year following the end of PRRSV-1 monitoring signing the success of the plan (P2). Then, the evolutions of antibiotic usages (differences between P1 and P2, expressed in percentages) were calculated and analysed taking into account the level of consumption in P1. For this, according to our dataset, three categories of level's consumption in P1 were created for ALEA (high, medium and low consumers) and two for mg/PCU (high and low consumers). All comparisons were realised using non-parametric tests with R Studio software. Concerning the overall antibiotic usages, our results showed a significant decrease in the antibiotic consumption between P1 and P2 for mg/PCU ($P=0.049$) and a tendency for ALEA ($P=0.061$). The evolution of antibiotic usages, expressed in ALEA, differed significantly between high and low levels of usage in P1 ($P<0.01$) and a tendency existed between high and medium levels of consumption ($P=0.08$). Likewise, a tendency was also observed between high and low consumers for mg/PCU ($P=0.07$). In our knowledge, it is the first study showing the impact of PRRSV-1 stabilization programs on antibiotic usages. Indeed, our results highlight the impact of a stabilization protocol against PRRSV-1 on antibiotic consumption, especially on farms that use high levels. These hopeful results show the interest of further investigations about the relationship between PRRSV-1 and antibiotic usages.

Monitoring of antimicrobial use on French pig farms from 2010 to 2019 using INAPORC panels

A. Poissonnet¹, I. Corge¹, C. Chauvin² and A. Hemoni¹

¹IFIP Institut du Porc, Ille et Vilaine, La Motte au Vicomte, 35650 Le Rheu, France, ²Anses, 22, 31 rue des fusillés, 22440 Ploufragan, France; anne.hemoni@ifip.asso.fr

There has been a strong implication of both the French swine industry and the national authorities on reducing the use of antimicrobials in pig production since 2010. The annual monitoring of antimicrobial sales by the French Veterinary Medicines Agency (Anses-ANMV) provides overall estimations but not detailed results on actual use of antimicrobials in pig farms. This study's objective was to understand the main areas of reduction in antibiotic use based on INAPORC panels, which were surveys of representative samples of pig farms performed in 2010, 2013, 2016 and 2019. The INAPORC panels included between 119 and 171 farms, randomly selected from the BDPORC national database. The same method was applied for each panel. For each antimicrobial they bought, farmers described, during a phone call, their antimicrobial usage pattern, like category of animals treated and indications of treatment. The amounts of antibiotics used in the corresponding age group was expressed in number of Animal Daily Dose / animal (ADD/a). Over this nine-year period, the mean ADD/a for sows decreased by 52%, mainly in the last three years (-48%). Since 2016, premixes and oral medicines (powders and solutions) decreased by 65 and 42%, respectively. The main reason for treatment remains urogenital problems (64%), mainly treated with tetracyclines. A significant decrease of 66% on antibiotic use for suckling piglets was observed, which was partly due to the reduction in oral medicines and the stop of antibiotics in premix. Exposure of weaned piglets to antibiotics decreased by 78% between 2010 and 2019. Since 2016, this reduction began to slow down (-28%). Colistin was no more used as a premix in 2019, contrary to the previous periods, and was no more the most used antibiotic during the post-weaning period, even if digestive problems were always the first reasons of treatment. In fattening pigs, antibiotic use decreased by 81% between 2010 and 2019 and by 36% between 2016 and 2019. In conclusion, the INAPORC panels provide detailed references on antibiotic use in the French pig production and demonstrate the continued commitment to improving current practices.

Digital drug registration and its relation to veterinary slaughter findingsH. Göрге¹, I. Dittrich¹, N. Kemper² and J. Krieter¹¹Kiel University, Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany, ²University of Veterinary Medicine Hannover, Institute of Animal Hygiene, Animal Welfare and Farm Animal Behavior, Bischofsholer Damm 15, 30173 Hannover, Germany; hgoerge@tierzucht.uni-kiel.de

Smart solutions to support farmers in their daily routine have to meet a growing demand for documentation, transparency and animal welfare standards of the public and legislature. For this purpose, a digital tool to collect treatment data at animal level at the time of application was implemented at a pig farm that met the documentation requirements of the European Union. The digitally collected data was used for descriptive analyses to determine the status quo of the farm's health status and put into relation with veterinary slaughter findings. Data was collected between August 2020 and September 2022 on a combined farm housing 147 sows per production day with 2.3 litters and 31 piglets weaned per sow per year. The treatments related to the locomotor system stand out in all the production stages until slaughter. Out of 8,713 suckling piglets 1.8% were treated, 4% were treated as rearing piglets ($n=7,803$) and 4.7% were treated in the fattening stable ($n=6,989$). The other frequent treatment reasons vary in the production stages: gastrointestinal treatments (1.5%) for the suckling piglets, respiratory treatments (4.5%) for the rearing piglets and treatments of tail lesions (2.3%) for the fattening pigs. To examine the relation to slaughter findings linear logistic regression models were used. Treatments as suckling and rearing piglets (Odds ratio (OR) 1.6, $P=0.0077$) as well as treatments as fattening pigs (OR 1.9, $P<0.0001$) increase the chance of slaughter findings compared to chances of pigs having received no treatments. Interestingly, treatments in early and late stages of the pigs' lives had no effect on the chance of slaughter findings. Batches were investigated in the model with varying chances for slaughter findings, which could be traced back to accumulated treatment events either in the early or late stages of the pigs' lives. Overall, the tool is useful for digitalising treatments and provides a data basis of good quality for further inquiries.

Theatre 9

A critical lens to regulations around veterinary antimicrobial use across countries and speciesG. Olmos Antillón¹ and I. Blanco-Penedo^{1,2}¹SLU, Veterinary Epidemiology Unit, Department of Clinical Sciences, Uppsala, 750 07, Sweden, ²UdL, Department of Animal Science, Lleida, 25198, Spain; gabriela.olmos.antillon@slu.se

Central to addressing the antimicrobial resistance (AMR) crisis has been curbing antimicrobial use (AMU) in all sectors, emphasising the livestock sector. The primary approach has been surveillance and antibiotic stewardship overseen by evolving national AMR programs (NPs). However, these strategies' meaning and practical significance for veterinarians and animal caretakers are contested. We seek to situate veterinary-AMU practices within a paradigm framed by social practice theory. The relevance of such an approach focuses on the life course of AMU across four clinical conditions in two contrasting species (dairy cattle and dogs) in countries with contrasting veterinary-AMU (Brazil, Spain and Sweden). For that, NPs, legislation and guidelines framing AMU were critically appraised and coupled with a thematic analysis of in-depth interviews ($n=20$) with national experts who described current national best practices. As a result, the data provide a situated understanding of how the veterinary profession at different geographies and species reconciles practices in entirely different scenarios. Our analysis indicates that NPs expect results in human behaviour change by focusing on increasing awareness and top-down regulatory and policy imperatives. Guidelines are often based on assumptions unaligned with the prevalent practices or heterogeneity of conditions within their respective countries. A cross-country theme is a call to follow the basic principles of AMU, which are based on the assumption that there is a valid veterinary client-patient relationship. However, failures are found on at least one of the many steps for such a relationship to be successfully achieved (e.g. recording of outcome follow-up). It is also clear that NPs' social accountability is not equally shared among stakeholders. A more significant burden is placed on veterinarians working in the livestock sector and farmers, which may further undermine the moral license of these stakeholders currently challenged by other world problems. Our finding supports the need for NPs to be revised based on contextual knowledge of specific settings to be meaningful and practical.

An approach of the place of animal health and role of veterinarian in sustainable farming systemsA. Scholly-Schoeller¹ and G. Brunschwig²¹VetAgro Sup – INRAE, UMR Herbivores, 1 avenue Bourgelat, 69280 Marcy l'Etoile, France, ²VetAgro Sup – INRAE, UMR Herbivores, 89 avenue de l'Europe, BP 35, 63370 Lempdes, France; gilles.brunschwig@vetagro-sup.fr

Research has majorly ignored herd health in agroecological systems. Therefore, this study intends to bolster the value of livestock health, and develop a better understanding of health management in agroecosystems. We first explore the needs and expectations of farmers regarding the support of health currently provided. A sociological study was conducted, based on observations and semi-structured interviews in sixteen farms. The choice of the farms was based on the selection of mixed farming systems with a large animal species diversity in various regions of France and Switzerland, in order to explore a diversity of situations, without claiming to be representative. These interviews dealt with four main subjects: (1) farm presentation; (2) sustainability in the agrosystems; (3) health practices used by the farmer; and (4) expectations for veterinary medicine. The data gathered allows the establishment of profiles of sustainable farms. This also enabled us to identify the existing practices of health management which are involved in sustainable farms. The healthcare practices used by the farmers interviewed were classified into eight categories: (1) choose animals adapted to the production system: breeds resilient in harsh environments, ability to maximize the forage resource; (2) develop herd immunity and balance: resistance to parasites and pathologies; (3) feeding practices: systems based on local and natural feeding resources, as pastoralism; (4) agronomic practices: soil and forage management involved in feed quality; (5) husbandry practices: reproduction and milk practices, rearing of the young; (6) medical practices: minimize chemical drugs, using of alternatives medicines; (7) managing parasitism: a result of a plurality of practices; (8) take time, observe, and learn: farmers' knowledge is based on observation of animals in their context and way of life, to prevent and understand their needs. Finally, all the interviewed farmers believe that the current veterinary approach, mainly based on curative treatments, is not sufficient to support an agroecological evolution and that a holistic perspective has to be developed.

Session 94

Theatre 11

Developing an animal welfare benchmarking framework for Australian lot-fed cattleT. Collins¹, E. Taylor¹, A. Barnes¹, E. Dunston-Clarke¹, D. Miller¹, D. Brookes², E. Jongman² and A. Fisher²¹Murdoch University, School of Veterinary Medicine, South Street, Murdoch, WA 6150, Australia, ²University of Melbourne, Faculty of Science, Parkville, VIC 3010 Australia, Australia; t.collins@murdoch.edu.au

Societal concerns about sustainability and animal welfare in commercial livestock production systems are increasing. Yet increased intensification of beef cattle production to meet rising global demand for animal protein is evident with over one million head of cattle on-feed in Australian feedlots. Despite the feedlot context presenting numerous welfare challenges, including animal, resource, and management factors, no recognised welfare assessment protocol for the Australian industry exists. This paper describes a framework for benchmarking animal welfare in lot-fed cattle that aims to: (1) measure welfare performance over time and enable validation of care; and (2) drive animal welfare improvement. Following consultation with the industry, a refined pilot assessment framework was trialled over seven months in eight feedlots in Queensland, Western Australia, and South Australia. A pen-side assessment technique was developed based on the four principles of the Welfare Quality® (WQ) framework, including forty-eight measures deemed applicable and feasible in the feedlot context. Measures that captured the health, behaviour and demeanour of livestock were collected in home pens monthly. Principal Components Analysis and Generalised Linear Mixed Modelling compared the effect of environmental and management measures on cattle behaviour within home pens. Recommendations for the timing of data collection (early morning and midafternoon) and sample size requirements (2 pens and ideally 3 replicate pens, per feed program and breed) were made with significant variability in some cattle outcomes (e.g. cattle activity and rest) found between visits, feedlot, observation time, and feeding program. The implementation of an evidence-based animal welfare benchmarking framework will enable feedlot producers to track their performance in animal welfare over time, and for the feedlot industry to further demonstrate its commitment to animal welfare.

H2020 mEATquality: on-farm animal welfare assessment in slaughter pigs

T. Rousing, L.D. Jensen, M.L.V. Larsen and L.J. Pedersen

Aarhus University, Animal and Veterinary Science, Blichers Allé 20, P.O. Box 50, 8830 Tjele, Denmark; lene.juulpedersen@anivet.au.dk

In the Horizon mEATquality project (Project id: 101000344-mEAT quality-H2020-FNR-2020-2, Project home page: <https://meatquality.eu/>), one of the tasks is to improve the quality of pork from conventional and organic farming systems by understanding how it is affected by extensive vs intensive production factors on-farm. One of the quality parameters that is in focus is animal welfare. In the project, an animal welfare assessment protocol has been developed including a farmer interview regarding management and caretaking procedures (e.g. medicine usage, mortality rates, invasive procedures, grouping strategies and feeding management), as well as a protocol for direct registrations of slaughter pig health (e.g. Body condition score, fouling, lesions, lameness and symptoms of respiratory disease) and behaviour (e.g. avoidance, aggressive behaviour, mounting and play) as well as resource measurements (space allowance, water and feed quality and quantity, etc.) available for the animals. Before applying the protocol in practice, two training sessions were arranged in the countries of project partners doing the assessments. In the autumn of 2022 and in the spring 2023, on-farm data has been collected to assess animal welfare in a total of 80 slaughter pig herds in Spain, Italy, Poland and Denmark with 20 herds per country. The herds were selected to reflect the variety of herds found in the respective countries and are thus including both conventional and organic farms, full-line farms (including sows, weaners as well as slaughter pig groups), different breeds, smaller and larger herds, etc. The EAAP presentation will include a presentation of the welfare assessment protocol, the procedures for calibrating observers across countries, as well as results of the animal welfare assessments for different types of farms.

Session 94

Variability in pig hair cortisol concentrations at the end of the fattening period

P. Levallois¹, M. Leblanc-Maridor¹, S. Gavaud², B. Lieubeau², G. Morgant¹, C. Fourichon¹, J. Hervé² and C. Belloc¹

¹Oniris, INRAE, BIOEPAR, 101, route de Gachet, 44300, France, ²Oniris, IECM, 101, route de Gachet, 44300, France; pierre.levallouis@oniris-nantes.fr

Hair cortisol is an indicator of chronic stress and could be used to assess the exposure of pigs to stressors in the weeks/months prior to a non-invasive hair sampling. In particular, hair cortisol could be an indicator to identify stressful management practices for pigs. The objective of this study was to describe hair cortisol concentration (HCC) variability between farms, between batches of a same farm and within a batch. We assumed that stressors could differ between farms and/or between batches and would lead to a variability of HCC. Moreover, within a batch, individual behaviour and individual response to stressors may also induce variability between pigs. Twenty farrow-to-finish pig farms were recruited in western France considering the diversity of their management practices and of their health statuses. Hair was sampled in two distinct batches, eight months apart. The necks of 24 fattening pigs were clipped during each sampling session the week before slaughtering. The management practices and health statuses of the farms were described. To describe the variability in HCC, a linear model was used with three explanatory variables: batch, farm and the interaction between both. A hierarchical clustering on principal components was also performed, with four active variables: the means and the standard-deviations of the two batches per farm. HCC ranged from 0.4 to 121.6 pg/mg, with a mean of 25.9±16.2 pg/mg. Within a batch, the coefficient of variation of HCC ranged from 15 to 71%. On six farms, HCC differed significantly between the two batches. HCC varied significantly among farms and three clusters of farms were identified: low and homogeneous concentrations (n=3 farms), heterogeneous concentrations with either between-batch significant increase (n=8) or decrease (n=9). The diversity of management practices and health statuses allowed us to discuss explanatory hypotheses for the observed variations in cortisol concentration. The variations of HCC described herein confirm the interest in considering this biomarker in an animal welfare perspective.

Identification and characterization of IUGR piglets

C. Ollagnier, R. Ruggeri, J. Bellon and G. Bee

Agroscope, Rte de la Toleyre 4, 1725, Switzerland; catherine.ollagnier@agroscope.admin.ch

Intra Uterine Growth Restriction (IUGR) has economical and animal welfare impact. Research to resume or prevent IUGR conditions are impaired by a poor diagnosis. Three methods to diagnose IUGR were compared in one study involving 268 piglets. These methods were based on the head shape, birth weight (BtW) and the brain-to-liver weight ratio (BrW/LW). In addition, muscle histology and cardiac anatomy were analysed. The brain and liver volume of all piglets born alive and stillborn were determined using the computerized tomography scan (CT). Two days after birth, piglets with typical IUGR dolphin head shape, bulging eyes, and wrinkles perpendicular to the mouth were scored 3. If none of the IUGR characteristics applied, the piglet was defined as normal and scored 1. The rest of the piglets were scored 2. On the same day, 30 piglets were euthanized to sample the heart, the semitendinosus muscle (STM), the brain and the liver. The volume and weight of the liver and the brain were measured to calculate their densities. The brain and liver volumes measured by CT were then converted to BrW/LW to assess the IUGR status. Piglets with BrW/LW > 0.78 were considered IUGR and normal, otherwise. The heart and its left ventricle were weighted, the diameter of the aorta, and the wall thickness of the left ventricle and of the aorta were measured. The mRNA expression levels of myosin heavy chain (MHC) I, IIa, IIb, and IIx were evaluated in the STM. Our results showed a discrepancy between the three methods of IUGR identification. Indeed, 68% of the piglets with a score 3 based on the head shape and 25% of the piglets with a birth weight < 1 kg, were considered as normal according to their BrW/LW. The IUGR pigs had a lighter heart than the normal piglets. For a same heart weight, IUGR piglets had a larger relative aortic diameter ($P < 0.001$), relatively thicker aorta ($P < 0.001$) and larger left ventricular posterior wall ($P < 0.001$). In the STM, IUGR pigs had a lower relative mRNA expression level of MHC IIa ($P < 0.01$), IIb ($P < 0.01$) and IIx ($P = 0.01$). The identification of IUGR piglets based only on the head morphology and/or BtW does not always correspond with an increased BrW/LW. This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement N° 955374.

Investigating the association between sole ulcers and sole temperature in dairy cattle using IRT

A. Russon, A. Anagnostopoulos, M. Barden, B. Griffiths, C. Bedford and G. Oikonomou

University of Liverpool, UK, Department of Livestock and One Health, Leahurst Chester High Road Neston Merseyside, CH64 7TE, United Kingdom; amyrusson16@icloud.com

Our aim was to explore the association between the presence of sole ulcers and the sole temperature using infrared thermography (IRT). We enrolled 2,334 cows from four farms. Each cow was assessed at four different time points: pre-calving, just after calving, during early lactation and late lactation. The variables tested included: sole ulcers and their corresponding severity grade (0-3), ambient temperature, days in milk, height, body condition score, mobility, parity, type of farm, and the foot imaged (left or right). At each assessment, a thermal image of the sole of each hindfoot was taken using a Flir E8 Wi-Fi Thermal Camera, collating in 12,698 images. Statistical analysis was conducted using R studio. A multiple variable linear regression model was calculated to determine the influence of various explanatory variables on the sole temperature. Across the four farms, the sole temperature significantly increased with the presence of a sole ulcer. The most remarkable temperature difference was between sole ulcers of grades 0 and 3, with a difference of 5.13 °C (SE=0.76, $p \leq 0.001$), indicating that a greater amount of radiation was emitted when more damage to the sole occurred. Lactation stage and the ambient temperature were critical variables in the IRT measurements, influencing the sole temperature significantly. At the early lactation assessment, the mean sole temperature was decreased by 1.0 °C (SE=0.067, $p \leq 2e16$), whereas at the fresh stage, the mean sole temperature was increased by 0.16 °C (SE=0.060, $P=0.0082$). These results could be explained by various external factors. As through multivariable regression analysis, 66% of the sole temperature results were influenced by the variables tested. Other factors not assessed could include the diverse management practices of each farm. Further studies investigating how thermal images combined with relevant information (e.g. ambient temperature) could be utilised as a monitoring tool for sole ulcers on farm. These results, along with published literature, suggest that infrared thermography can be a reliable, early detection tool, for the presence of sole ulcers.

Osteopathic manipulative treatment: a complementary approach to promote milk production in cowsC. Omphalius¹, A. Hardouin², M. Launay Ventelon² and S. Julliand¹¹Lab To Field, 26 bd Dr Petitjean, 21000 Dijon, France, ²Ecole Française d'Ostéopathie Animale, 6 pl Boston, 14200 Hérouville Saint-Clair, France; cleo.omphalius@lab-to-field.com

The use of osteopathy is increasingly popular in the dairy industry with the ambition to treat certain health issues and improve milk production. However, data on the impact of osteopathic manipulative treatment (OMT) is scarce. Our objective was to evaluate the effect of an OMT on milk production during one month through a monocentric longitudinal study with 100 Holstein cows (32 primiparous, 68 multiparous) managed similarly. Milk yield (MY) was individually monitored (automatic milking system) for 2 weeks before OMT and 2 homogeneous groups (Control [C, n=50] and Treated [T, n=50]) were formed at d0 according to the cows' basal MY (daily average between d-14 and d0), parity, and stage of lactation. At d0, cows in group T received an OMT by an animal practitioner (n=4, trained in the same school) using similar practices, while group C did not (sham treatment). Individual MY, fat and protein contents were daily recorded and averaged over 2 weeks after d0 (d0-d14) or d15 (d15-d28). Data analysis included the effects of OMT, practitioner, and their interaction using a MIXED procedure (SAS) with basal yield as covariable. No interaction or practitioner effect was observed. Cows in group T (30.6 kg/d) tended to produce more milk than those in group C (29.8 kg/d; $P=0.054$) for d0-d14, but no difference was observed during d15-d28 ($P=0.767$). The higher MY in group T was exacerbated when only multiparous cows were considered ($C=30.0$ kg/d and $T=31.3$ kg/d for d0-d14; $P=0.036$). A trend of increasing protein yield was also observed in multiparous cows (+37 g/d for d0-d14; $P=0.068$) but fat yield was not altered. The increased MY may be related to a higher mobility of treated cows. Indeed, the number of milkings per day was numerically higher in group T than C for multiparous for d0-d14 (2.87 vs 2.76 milkings/d; $P=0.153$). The insignificant effect in primiparous cows could be due to their naturally higher activity. This first study describing the OMT effect on dairy cows highlights possible benefits for short-term production. Additional observations would be valuable to assess when OMT is the most beneficial for performance, health, and welfare.

The relationship between stress levels and skin allergy or atopy problem by analysing hair cortisolG.W. Park^{1,2}, M. Ataollahi² and K.H. Park²¹CO-ANI, Kangwondo, Chuncheonsi, Kangwondaehakgil 1, Dept of animal life sciences 1st building Room#420, 24341, Korea, South, ²Kangwon national university, Animal life sciences, Kangwondo, Chuncheonsi, Kangwondaehakgil 1, Dept of animal life sciences 1st building Room#420, Kang, 24341, Korea, South; kpark74@kangwon.ac.kr

The cortisol as stress indicator for dogs can be affected by various factors such as feed, health, animal skin conditions, especially allergy or atopy, and walk frequency. Using dog hair to measure the cortisol is one of methods to measure chronic stress. It is less stressful method than another invasive method like blood sampling. The objective of this study was to assess that allergy or atopy of dogs can affect the chronic stress level. For this reason, we have used the most raised dog's hair in Korea to evaluate the cortisol concentration. For five species of dogs, Bichon fries (n=49), Maltese (n=27), Poodle (n=69), Pomeranian (n=22), and mixed breeds (n=27) were selected. The cortisol hormone was extracted by using methanol and analysed via enzyme-linked immunosorbent assay (ELISA). For statistical treatment unpaired t-test was used because the subjects which had allergies or not were randomly assigned. The result showed that the cortisol concentration of dogs suffering from allergies or atopy was 9% higher in the Bichon frise, 14% higher in the Maltese, 18% higher in the Poodle, 23% higher in the Pomeranian, and 21% higher in mixed breeds. Even though the dogs which have atopy or allergy problem showed higher cortisol level, there was no significant difference in whether dogs had skin problems or not. Although the results didn't show a significant difference, dogs are needed to feed high quality protein sources to prevent allergy or atopy. It can make the dog's stress level lessened.

SECURIVO: self-assessment tools for biosecurity in veal calves' farms

M. Chanteperdrix¹, M. Drouet¹, M. Mounaix¹, M. Tourtier¹, D. Le Goic², C. Jaureguy², P. Briand³, M. Coupin⁴, A. Hemonic⁵ and N. Rousset⁶

¹Institut de l'Élevage, 8 route de Monvoisin, 35650 Le Rheu, France, ²SNGTV, 5 rue Moufle, 75011 Paris, France, ³CRAB, Rue Maurice Le Lannou – CS 74 223, 35042 Rennes Cedex, France, ⁴CRAPL, BP 70510, 9 Rue André Brouard, 49105 Angers, France, ⁵IFIP, 5 rue Lespagnol, 75020 Paris, France, ⁶ITAVI, 7 Rue du Faubourg Poissonnière, 75009 Paris, France; manuel.tourtier@idele.fr

In France, controlling health in veal calf farming is one of the major and priority challenges of the sector. Biosecurity, whether external or internal, has an impact on health as a preventive factor against the diseases' introduction or spread in farms. Carrying out biosecurity self-assessments is one of the ways of raising farmers' awareness about the need to comply with recommendations and thus improve compliance. In 2015, the interprofession INTERBEV launched a major awareness-raising campaign by creating an interprofessional charter for good health control and proper use of medicinal treatments. In addition, to support farmers in an approach to reduce the use of antibiotics, the French Livestock Institute in partnership with SNGTV and CRAB has developed a specific training course thanks to which, since September 2018, more than 200 farmers have been able to improve their skills on the reasoned use of antibiotics and on the levers to reduce the risks of emergence of infectious diseases during a dozen training sessions. These training sessions highlighted areas of progress that vary from farm to farm but are undeniable in the sector despite the awareness-raising actions carried out in recent years. In this context, the SECURIVO project has created: (1) 12 technical brochures on biosecurity to help veal calf farmers to improve the biosecurity level of their farms, (2) 2 self-assessments to enable veal calf farmers to self-assess the biosecurity level of their farms: a 'detailed' self-assessment for a complete and precise assessment of each biosecurity topic in 123 questions and a 'quick' self-assessment for a quick and general assessment in 30 basic questions, (3) A dedicated website to enable veal calf farmers to carry out the self-assessments, to access personalized assessments and to consult the technical brochures.

Temporally synchronized ruminal vs reticular fluid pH and short chain fatty acids in dairy cows

A. Kidane, K.S. Eikanger and M. Eknæs

Faculty of Biosciences, Norwegian University of Life Sciences, Norway, Oluf Thesens vei 6, 1430 Ås, Norway; alemayes@nmbu.no

Sub-acute ruminal acidosis (SARA) is a metabolic disorder, typically of dairy cows fed diets high in fermentable carbohydrates and low in fibre content. The fluctuation in rumen pH, and the extent and duration of its depression determine the severity of SARA. Timely detection of SARA is challenging due to lack of overt clinical symptoms. Indwelling electronic sensors used to monitor behaviour, health and fluctuations in the rumen pH often reside in the reticulum. This technique may have limitations, especially for detection of SARA, due to spatial variation in pH in the reticulo-rumen. Here, we assessed the correlations between ruminal fluid (RumF) vs reticular fluid (RetF) pH and short chain fatty acids (VFA) in lactating dairy cows getting *ad libitum* access to grass silage supplemented with concentrate feed formulated to meet requirements according to the Nordic feed evaluation system (NorFor). Time synchronized RumF (n=72) and RetF (n=72) samples were collected from 8 rumen cannulated Norwegian red dairy cows at 3 time points in each of the 3 sampling days separated by a 35-day interval. The pH of the samples was measured immediately, and then aliquots of both RumF and RetF samples were analysed for VFA. Correlation analysis indicated statistically significant relationship between RumF vs RetF pH ($r = 0.716$; $P < 0.0001$). However, mean RetF pH was higher than RumF pH by 0.358 (SEM = 0.0189 units; Paired t-test, $P < 0.0001$), and this difference was larger at the lower RumF pH range (i.e. increasing mean difference with decreasing RumF pH). Furthermore, the RumF pH showed larger fluctuation (SD 0.230 units) than RetF pH (SD 0.171 units). The higher pH in the RetF was accompanied by lower total VFA concentration in the location (98.1 mM; SEM 1.06) compared to that of RumF (108.4 mM; SEM 1.65). The observed differences in both pH and VFA with the temporally synchronized samples from the two locations could be explained by differences in location specific rates of substrate fermentation, VFA absorption and digesta passage. These results suggest that using reticular pH as a proxy for rumen pH may undermine any potential SARA cases in dairy cows due to inflated reticular pH, especially at the lower physiological range.

Antimicrobial use and main causes of treatment in Italian buffalo farms

G. Di Vuolo¹, F. Scali², C. Romeo², V. Lorenzi², C.D. Ambra¹, M. Serrapica¹, G. Cappelli¹, F. Fusi², E. De Carlo¹, G.L. Alborali², L. Bertocchi² and D. Vecchio¹

¹Istituto Zooprofilattico Sperimentale del Mezzogiorno, via della salute, 2 Portici, 80055, Italy; ²Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, via Bianchi, 9 Brescia, 25124, Italy; domenico.vecchio@izsmportici.it

Antimicrobial resistance (AMR) is a major global health emergency; 25,000 people die each year in Europe from infections sustained by resistant bacteria. Inappropriate antimicrobial use (AMU) in humans and animals is reinforcing AMR, threatening public health. For this reason, there is growing institutional attention to implementing actions for the optimization of AMU. In particular, the World Health Organization's Global Plan of Action on Antimicrobial Resistance recommends a close intersectoral collaboration between public health and animal health (One Health). The purpose of this study was to report the first data on AMU in Italian dairy buffalo farms and the principal causes of treatment. Data from 102 farms were collected over a three-year period (2015-2017); AMU was estimated separately by age group (adults, heifers and calves) using the Defined Daily Dose for Italy (DDDAit). The causes of treatment were clustered in urogenital, gastrointestinal, respiratory, locomotor, osteoarticular, mastitis, dry therapy, septicemia, cutaneous, nervous, and unknown. The farms involved in the study had an average size of 228 adults, 116 heifers, and 144 calves. Antimicrobials were used almost exclusively on adults, where overall AMU was relatively low, averaging 1.56 DDDAit/head. The three most common causes of AMU in adult buffaloes were: urogenital (37.3%), dry cow therapy (26.9%), and mastitis (22.3%). Although direct comparisons may have some limitations, AMU seems to be lower in buffalo than in other species reared in Italy. The identification of the principals causes of AMU in buffalo represents an important step towards a more efficient AMU analysis of structural and management critical aspects connected to the buffalo breeding system finalized to reduce in sustainable mode the AMU and their connected AMR.

Parasitism may constitute a critical point in pig farms on litter or with outdoor access. This study aimed to identify the herd factors associated with the level of parasite infestation. A study was carried out in 112 alternative French pig farms where faecal samples were taken from 10 sows, 10 pigs aged 10-12 weeks and/or 10 pigs at the end of the fattening period for coprological analysis, as well as blood samples from 10 sows and/or 10 pigs at the end of fattening period for serological analysis for *Ascaris suum* and *Toxoplasma gondii*. Data on the facilities and management of the farm were collected during the on-farm visit and were analysed using principal component analysis to determine farm profiles regarding infestation and farm characteristics. Coccidia oocysts were observed in pig faeces in the largest proportion of farms (84%) followed by eggs of strongyles (55%), *Trichuris suis* (32%) and *A. suum* (16%). The rates of *A. suum* and *T. gondii* seropositive farms were 89 and 71% respectively. Hygiene and especially decontamination of facilities were factors associated with low levels of parasitism in farms. Conversely, keeping animals outdoors or on litter, poor building maintenance, farms with small numbers of animals and summer were parameters associated with high levels of parasitism. The use of multiple anthelmintic treatments on growing pigs was associated with low levels of *T. suis* egg infestation and high levels of *A. suum* seroprevalence. This study highlighted the internal parasite burden in alternative farms. Even if some factors are not under farmers' control (season, outdoor rearing), there is still some room for improvement via hygiene and appropriate use of treatments.

Biosecurity and Animal Welfare relationship on buffalo farms through ClassyFarm assessments

D. Vecchio¹, G. Santucci², V. Lorenzi², C. Caruso³, C.D. Ambra¹, M. Serrapica¹, G. Di Vuolo¹, G. Cappelli¹, F. Fusi², E. De Carlo¹, C. Romeo², F. Scali², G.L. Alborali², A.M. Maisano² and L. Bertocchi²

¹Istituto Zooprofilattico Sperimentale del Mezzogiorno, via della salute, 2 Portici, 80055, Italy; ²Istituto Zooprofilattico sperimentale della Lombardia e dell'Emilia Romagna, Via Bianchi, 9 Brescia, 25124, Italy; ³ASL Cuneo 1, P.zza Gallo Racconigi, 12035, Italy; domenico.vecchio@izsmportici.it

Biosecurity in ruminant production is often an overlooked area, instead it is key aspect of the interactions among the animal production systems, the environment, and human health in a One-Health approach. ClassyFarm is an integrated system for categorising of farms according to the risk assessment methodology. ClassyFarm gathers and processes data referred to biosecurity, animal welfare (AW), health and antimicrobial usage. It can be applied to several livestock species, including water buffalo, for which biosecurity is evaluated on 15 items. The assessment of AW includes 63 non-animal-based measures (N-ABMs) and 17 animal-based measures (ABMs). The N-ABMs are divided into 'Management' (32 items) and 'Housing' (31 items). Each item can be scored as 'insufficient', 'improvable' or 'optimal'. For each item, a weight was determined using an expert opinion elicitation process. Total and partial scores are expressed in percentage on a scale from 0 to 100%. The Biosecurity & AW were assessed on 102 buffalo farms, with an average size of 470 heads. The mean overall AW score was 61.5±13.0% and the Biosecurity was 43.3±18.2%. Statistical analysis was performed by Spearman's rank correlation using GraphPad Prism 8.0.1 (GraphPad Software, San Diego, CA, USA). Biosecurity and AW were positively correlated ($p=0.501$; $P<0.001$). A positive correlation was observed between Biosecurity and both 'management' ($p=0.759$; $P<0.001$) and 'housing' ($p=0.610$; $P<0.001$). No correlation was found between Biosecurity and ABM area. Knowing the Biosecurity and AW levels, their relationship and critical point in animal farm, represent a tool to plan the strategic priorities of human resources and investments, to increase the Farmers' awareness and the health, ethical sustainability of the farm.

Immune function of pre-weaned calves fed a fortified milk replacer under heat stress conditions

A.A.K. Salama¹, S. Serhan¹, L. Ducrocq², M. Biesse², A. Joubert² and G. Caja¹

¹Universitat Autònoma de Barcelona, Ruminant Research Group (G2R), Campus UAB, 08193 Bellaterra, Spain; ²Bonilait protéines, 5 Route de Saint-Georges, 86361 Chasseneuil-du-Poitou, France; ahmed.salama@uab.cat

Heat stress (HS) negatively affects the immunity and health of pre-weaned calves, which needs to be alleviated. Angus × Holstein heifer calves ($n=32$) were used until weaning (d 56) to evaluate the effects of fortifying milk replacer with a combination of antioxidants (vit E, Se, flavonoids, terpenes) under HS conditions. From d 14 to 27 all calves were kept in thermal-neutral (TN) conditions (THI=62) and fed a control milk replacer (CON; $n=20$) or the fortified replacer (FRT; $n=12$). From d 28 to 56, 12 CON and the 12 FRT calves were exposed to HS (day, THI=83; night, THI=77), whereas the remaining 8 CON animals continued in TN. This resulted in 3 treatments (ambient-diet): TN-CON, HS-CON, and HS-FRT. Both milk replacers were produced by Bonilait-Protéines. Calves were milk-fed twice daily (125 g/l) with free access to starter, straw, and water. Rectal temperature (RT, °C) and respiratory rate (RR, bpm) were daily recorded. At d 42, blood samples were obtained and *ex vivo* challenged with *E. coli* lipopolysaccharide (LPS) at low (0.01 µg/ml) and high (5 µg/ml) doses. Fifteen cytokines produced after the LPS challenge were measured by MILLIPLEX Bovine Cytokine Magnetic Bead Panel 1 (EMD Millipore Corp., Burlington, MA). Data were analysed by PROC MIXED v.9 of SAS for repeated measures. HS markedly increased RT and RR (+0.52 °C and +51 bpm; $P<0.01$). At the high LPS dose, both IL-1 α (innate immunity response) and MIP-1 α were lower ($P<0.05$) in HS-CON (2,334 and 9,244 pg/ml) than in HS-FRT (3,264 and 16,483 pg/ml). IL-6 (anti-inflammatory functions) was higher in TN-CON (4,434 pg/ml) than HS-CON (3,137 pg/ml), but similar to HS-FRT (4,176 pg/ml). Regardless of the LPS dose, levels of IL-17 α (sensing 'danger' role) were greater ($P<0.05$) in TN-CON and HS-FRT (30.1 and 26.3 pg/ml, on average) than HS-CON (18.6 pg/ml, on average). In conclusion, calves fed with the fortified milk replacer under HS conditions exhibited an enhanced ability to face infections by producing more anti-inflammatory cytokines, better sensing of danger, and improved immune cell trafficking.

The effect of udder health on milk composition

Z. Nogalski and M. Sobczuk-Szul

University of Warmia and Mazury in Olsztyn, Department of Animal Feeding, Feed Sciences and Cattle Breeding, Olsztyn; ul. Oczipowskiego 5, 10-719 Olsztyn, Poland; zena@uwm.edu.pl

Mastitis is classified as clinical if symptoms of mammary dysfunction and defective milk are evident, or as subclinical if no clinical signs are visible. Subclinical mastitis is most challenging because it is asymptomatic, and the quality of milk may deteriorate when milk with high somatic cell counts (SCC) is included in the bulk tank. The aim of this study was to determine the effect of udder health on milk composition and in particular on the fatty acid profile. A total of 576 milk samples were collected in six herds of Holstein-Friesian cows. Similar feeding was used in all herds. None of the cows showed clear symptoms of clinical mastitis or was treated for mastitis. Samples were collected four times, in winter. Fresh milk samples were analysed to determine their chemical composition by infrared spectrophotometry, and SCC by flow cytometry. Milk fat was extracted and the proportions of 43 fatty acids were determined by gas chromatography. Udder health was evaluated based on SCC classes, in thousands of cells per ml of milk: ≤ 200 – healthy udder, 201-400 – risk of mastitis; 401-1000 – subclinical mastitis, >1000 – severe subclinical mastitis. One-way analysis of variance SCC class, was performed. An increase in SCC was accompanied by a significant decrease in daily milk yield and lactose concentration. The difference in daily milk yield between groups ≤ 200 SCC and >1000 SCC reached 8.6 kg ($P<0.01$). Milk with higher SCC contained more ($P<0.05$) polyunsaturated fatty acids and less ($P<0.05$) monounsaturated fatty acids. The proportion of medium-chain fatty acids (MCFAs) in milk fat increased ($P<0.05$), whereas the proportion of long-chain fatty acids (LCFAs) decreased ($P<0.05$) with increasing SCC. The proportions of butyric acid and oleic acid decreased ($P<0.05$) with increasing SCC. Conclusions: The lack of clinical mastitis symptoms did not mean low somatic cell content and stable milk composition. Project financially supported by the Minister of Education and Science under the program entitled ‘Regional Initiative of Excellence’ for the years 2019-2023, Project No. 010/RID/2018/19, amount of funding 12.000.000 PLN.

An attempt to predict dairy cows chronic stress biomarkers using milk MIR spectraC. Grelet¹, H. Simon¹, J. Leblois², M. Jattiot³, C. Lecomte⁴, R. Reding⁵, J. Wavreille¹, E.J.P. Strang⁶, F.J. Auer⁷, Happymoo Consortium² and F. Dehareng¹¹Walloon Agricultural Research Center, 5030, Gembloux, Belgium, ²Walloon Breeders Association Group, 5590, Ciney, Belgium, ³Innoval, 35530, Noyal sur Vilaine, France, ⁴Eliaance, 75795, Paris, France, ⁵Convis, 9042, Ettelbruck, Luxembourg, ⁶LKV Baden Württemberg, 70190, Stuttgart, Germany, ⁷LKV Austria, 1200, Vienna, Austria; c.grelet@cra.wallonie.be

Having a possibility to regularly monitor chronic stress of dairy cows would be beneficial regarding several aspects. Indeed, when stress becomes chronic (long duration and inability of animals to cope), it is likely to affect emotional state, health, immunity, fertility and milk production of cows, hence impacting welfare, economics and social acceptability of dairy farms. In a previous step of the HappyMoo project, two molecules were highlighted as chronic stress biomarkers: hair cortisol and blood fructosamine. The aim of this study was therefore to attempt predicting these two chronic stress biomarkers using milk mid-infrared (MIR) spectra, to enable routine monitoring. For this purpose, approximately 1,400 individual dairy cows were sampled for hair, blood and milk in Belgium, Luxembourg, Germany, France and Austria in 72 commercial farms. Herds were selected locally with the objective of gathering cows with various levels of stress. Hair samples were collected at the tail switch and analysed by ELISA for cortisol concentration, and blood samples analysed by ELISA for serum fructosamine concentration. Milk was analysed with MIR and all generated spectra were standardized. Quantitative approach using PLS and qualitative approach using PLS-DA were used. Preliminary results show that quantitative models were not able to accurately predict the chronic stress biomarkers ($R^2_{cv}<0.3$). However, a qualitative approach might be a possibility to discriminate stressed from non-stressed cows with a cross-validation correct percentage of good classification (accuracy) of 75%. Further work is needed to better exploit this dataset, however this first study suggests a possibility of using MIR milk spectra to highlight stressed cows. This might enable improvement of welfare, health and production of animals.

Prediction of body condition score for the entire lactation in Walloon Holstein cowsH. Atashi^{1,2}, J. Chelotti^{2,3} and N. Gengler²¹Shiraz University, Department of Animal Science, Shiraz, 7144113131, Iran, ²University of Liège, GxABT, Pass. des Déportés 2, 5030 Gembloux, Belgium, ³Instituto de Investigación en Señales, Sistemas e Inteligencia Computacional, FICH-UNL/CONICET, 3000 Santa Fe, Argentina; hadi.atashi@uliege.be

Body condition score (BCS) is a subjective measure of stored energy reserves of dairy cows. Monitoring changes in body condition throughout the lactation is more valuable than identifying absolute measures of body condition. However, recording BCS values is a time-consuming process and usually there is one BCS record per animal per lactation. The aim was to investigate the ability of a random regression test-day model (RR-TDM) to predict BCS values for the entire lactation in Walloon Holstein cows. Milk yield, fat percentage, protein percentage and BCS records collected on the first-parity cows calved between 2012 and 2022 in 785 herds were used. Records from days in milk (DIM) between 5 d and 365 d were used. Number of test-day records on milk yield traits were 801,095 on 96,770 animals, while the number of records on BCS was 98,390 on 87,231 animals. The (co)variance components and breeding values for the considered traits were estimated based on the integration of RR-TDM using the a multiple-trait (four traits), single-lactation model. Gibbs sampling was used to obtain marginal posterior distributions for the various parameters using a single chain of 200,000 iterates with a burn-in period of 50,000 iterates. Predicted test-day BCS were compared with observed values. The Pearson and Spearman correlation estimated between the predicted and observed BCS values was 0.99 and 0.93, respectively. The root mean squared error (RMSE) and the mean absolute error (MAE) of the prediction were 0.17 and 0.14 BCS unit, respectively. In the next step, BCS records of 1,500 animals were replaced by 0, and were predicted and compared to the observed values. The Pearson and Spearman correlation estimated between the predicted and observed BCS values was 0.57 and 0.56, respectively. The RMSE and the MAE of the prediction were 0.69 and 0.51 BCS unit, respectively. This study showed that MT-RR-TDM has the potential to interpolate the trend of BCS of animals with a single BCS record across the lactation.

Session 95

Theatre 3

Conditions to develop successful mid-infrared (MIR) based BCS and BCS change predictionsJ. Chelotti^{1,2}, H. Atashi^{2,3}, C. Grelet⁴, M. Calmels⁵, J. Leblois⁶ and N. Gengler²¹Instituto de Investigación en Señales, Sistemas e Inteligencia Computacional, FICH-UNL/CONICET, 3000 Santa Fe, Argentina, ²ULiège – GxABT, 5030, Gembloux, Belgium, ³Shiraz University, Department of Animal Science, 71441-13131 Shiraz, Iran, ⁴Walloon Agricultural Research Center, 5030, Gembloux, Belgium, ⁵Seenovia, Le Mans, 72000, France, ⁶Awé groupe, Ciney, 5590, Belgium; nicolas.gengler@uliege.be

Usefulness of Body condition score (BCS) and BCS changes have been validated in many studies and the development of mid-infrared (MIR) based BCS and BCS change predictions is an ongoing effort. Literature shows the importance of several key factors. First type of reference data, quantity and quality, and measurement methods are important. Reference BCS needs also to be synchronized with MIR spectral measurements. Moreover, especially at the beginning of the lactation, closer repetitions yielded the best literature values but results obtained were only valid in the first 120 days. In the HappyMoo project two efforts were made to use existing data: (1) from an experience using the BodyMat system; and (2) from Walloon conformation recording (1 record / lactation). In both cases, reference values were not synchronized and therefore BCS values had to be imputed across the lactation using appropriate modelling strategies. Also 75 vs 25% calibration vs. validation data was used during the MIR calibration process. For 1) 26,207 BCS records on 3,038 cows (mainly Holstein and Montbéliarde breeds) were used. Partial least squares (PLS) were used as the reference method for prediction, achieving a performance of $r=0.58$. Machine learning (ML) methods were also assessed. Among them, Support Vector Machine (SVM) achieved best results ($r=0.59$). For Walloon data 129,870 MIR test-day records on 17,292 animals were available. PLS method achieved the best performance over tested ML methods with $r=0.42$. Studies showed the difficulties to get enough and synchronized BCS records. Imputations are always second-best options. Also observed variability was suboptimal, with little extreme animals. Therefore, conditions for successful future research will be to optimize selection of herds (i.e. most variable for BCS), of BCS recording (e.g. automatic device-based) and methods.

Large-scale analysis of chronic stress in dairy cows using hair cortisol and blood fructosamine

H. Simon¹, C. Grelet¹, S. Franceschini², H. Soyeurt², J. Leblois³, M. Jattiot⁴, C. Lecomte⁵, R. Reding⁶, J. Wavreille¹, E.J.P. Strang⁷, F.J. Auer⁸ and F. Dehareng¹

¹Walloon Agricultural Research Center, Gembloux, 5030, Belgium, ²Gembloux Agro-Bio Tech, Gembloux, 5030, Belgium, ³Walloon Breeders Association Group, Ciney, 5590, Belgium, ⁴Innoval, Noyal-sur-Vilaine, 35530, France, ⁵Eliance, Pôle données et Elevage, Paris, 75595, France, ⁶Convis, Ettelbruck, 9085, Luxembourg, ⁷LKV Baden Württemberg, Stuttgart, 70190, Germany, ⁸LKV-Austria, Vienna, 1200, Austria; h.simon@cra.wallonie.be

Stress in dairy herds can come from many sources. When stress becomes chronic due to long duration and inability of animals to adapt, it can affect the emotional state, health, immunity, fertility and milk production of cows. It therefore has a negative impact on the welfare, economy and social acceptability of dairy farms. Knowing the practices that influence chronic stress would allow proposing strategies to improve animal welfare on farms. The study aims to better understand the relationship between two chronic stress biomarkers and potential explanatory variables related to production, management, health and housing. From a past research, two molecules were identified as biomarkers of chronic stress: capillary cortisol and blood fructosamine. Based on 1,372 ELISA measurements of hair cortisol and blood fructosamine, we studied their variability from 23 qualitative and quantitative features related to the herd management practices collected in 77 farms from 5 different countries (Austria, Belgium, France, Germany, and Luxembourg). The qualitative variables included information on cow diet type, management and housing system. The quantitative features included information on cow characteristics, milk composition, housing conditions, udder health, body condition score, and lameness. Principal components analysis and multivariate regressions highlighted the differences in cortisol and fructosamine results between farms, and relate them to the different herd management practices implemented on each farm. Preliminary results show that there may be multiple sources of stress, but that cortisol and fructosamine levels appear to be strongly influenced by overcrowding. These first and subsequent results could help to identify sources of chronic stress and provide useful guidance to dairy farmers to improve animal welfare.

Session 95

Calculation of dry matter intake and energy balance based on MIR spectral data at European level

V. Wolf¹, L. Dale², M. Gelé³, U. Schuler⁴, U. Müller⁵, N. Gengler⁶, J. Leblois⁷ and M. Calmels⁸

¹CEL 25-90, Roulans, 25640, France, ²LKV Baden-Wuerttemberg, Stuttgart, 70190, Germany, ³IDELE, Paris, 75595, France, ⁴Qualitas AG, Zug, 6300, Switzerland, ⁵University of Bonn, Bonn, 53115, Germany, ⁶Gembloux Agro-Bio Tech, University of Liège, Gembloux, 5030, Belgium, ⁷Awé group, Ciney, 5590, Belgium, ⁸Seenovia, Le Mans, 72000, France; valerie.wolf@cel2590.fr

Calculated energy balance (EB) status of cows at the beginning of lactation is a challenge for farmers. Failure to cover energy needs can lead to metabolic disorders, stress of the immune system, breeding problems and reduced milk production. Working on EB calculation models at European level is a challenge because the evaluation of feeding systems differs between countries. In this study, combination of four datasets coming from France (25,876 daily cow data), Germany (2,801 daily cow data,) and Switzerland (38,000 daily cow data) was made possible thanks to common descriptors: the net energy of lactation (NEL) and the dry matter intake (DMI) of each feed components. For each cow with individual intake, EB, DMI and feed efficiency (as a function of milk yield, fat, and protein content and DMI) were calculated. From the datasets, equations with the MIR spectral data were developed. A country effect was checked on residuals and it appeared that it was not significant. To develop the models, all spectra were standardized. The best models were obtained based on corrected MIR spectral data for days in milk (DIM) with Legendre polynomial correction and by using canonical powered partial least square (CPPLS) and Lasso and Elastic-Net Regularized Generalized Linear Model and by adding fix effects (parity, breed, milking moment, milk yield). The validation R² were of 0.70 for DMI, 0.76 for EB, and 0.75 for feed efficiency. This study shows that it is possible to concatenate and align European databases on EB calculation and that EB can be for dairy cows estimated from MIR spectra with a good accuracy to be used on the field.

Validation of HappyMoo MIR energy balance models on external datasets with feeding restriction

M. Calmels¹, J. Pires², M. Boutinaud³, A. Leduc³, C. Leroux², J. Chelotti⁴, L. Dale⁵, C. Grelet⁶, A. Tedde⁴, J. Leblois⁷ and M. Gelé⁸

¹Seenovia, Le Mans, 72000, France, ²INRAE, UCA, VetAgro Sup, UMRH, Saint-Genès-Champagnelle, 63122, France, ³INRAE, Institut Agro Rennes Angers, UMR 1348 PEGASE, Saint-Gilles, 35590, France, ⁴Gembloux Agro-Bio Tech, University of Liège, Gembloux, 5030, Belgium, ⁵LKV Baden-Wuerttemberg, Stuttgart, 70190, Germany, ⁶Walloon Agricultural Research Center, Gembloux, 5030, Belgium, ⁷Awé groupe, Ciney, 5590, Belgium, ⁸IDELE, Paris, 75595, France; marion.calmels@seenovia.fr

The Interreg HappyMoo project developed three sets of equations related to energy balance (EB). The first set concerns EB, dry matter intake (DMI) and feed efficiency. The second predicts fine milk components (oleic acid, beta-hydroxybutyrate, acetone, citrate), and the third concerns bodyweight and BCS. All models were developed based on European databases, including different countries, breeds and systems. An external validation was performed using feed restriction (FR) trials to ensure the ability of these models to detect energy deficit in case of FR. In the first external dataset, 30 Holstein dairy cows were studied at 21 days in milk and in mid-lactation, after which all cows were submitted to FR. The FR aimed to reduce the intake by 20% by adding straw to dilute energy and protein content in the ration. The second external dataset included 8 Holstein and 10 Montbéliarde mid-lactation cows that underwent 6 days FR with feed allowance reduced to meet 50% of individual energy requirements. The milk samples from these two datasets were analysed for fatty acids and selected metabolites and mid-infrared spectra were recorded and standardized before applying HappyMoo equations. The best performances were obtained for oleic acid ($R^2=0.94$ and 0.91 for the first and second dataset, respectively), then EB and DMI ($R^2\geq 0.55$) but with a strong correlation with oleic acid. For BCS and bodyweight, the shape of the predicted curves coincided with observed values. For BHB, the lack of variability in the validation dataset did not allow to test the equations. In this study, oleic acid seems to be the best indicator to determine the nutritional status of the cow, presenting a good response to variations of nutrient allowance, even in mid-lactation.

Genetic analyses of principal components of milk mid-infrared spectra from Holstein cows

Y. Chen¹, P. Delhez¹, H. Atashi^{1,2}, H. Soyeurt¹ and N. Gengler¹

¹ULiège-GxABT, Passage des Déportés 2, 5030 Gembloux, Belgium, ²Shiraz University, Ghasro, 71441-13131 Shiraz, Iran; yansen.chen@uliege.be

Milk mid-infrared (MIR) spectra are widely used to predict milk composition and phenotypes linked to animal health, efficiency, emissions, resilience, and even milk processability. However, the milk phenome represented by the large number of individual MIR wavenumbers (hereafter called MIR spectral traits) could allow strategies to develop innovative and holistic monitoring and decision-making PLF tools by avoiding phenotypic calibrations. The objectives of this study were to start exploring the complete genetic architecture of MIR spectral traits by studying principal components of milk MIR traits from Holstein cows and their genetic correlations with milk fat percent. In total, 27,855 records for 311 MIR spectral traits and fat percent from 3,303 first-parity Holstein cows were used. All principal components (PCs) of 311 wavenumbers were extracted and single-traits and bivariate (PC and fat percentage) repeatability models were used. The first 75 PCs explained already 99.99% of the phenotypic variance across the 311 wavenumbers. However, the genetic variances of these 75 PCs explained only 85.54% of the total genetic variances of the 311 PCs. Their range of heritability was from 0.00 to 0.47. The mean and standard deviation of genetic correlations (absolute value) between 311 PCs and fat percent were 0.25 and 0.28, respectively. After first 75 PCs, some PCs (e.g. PC 86) still had genetic correlations (here 0.37) with fat percent. This preliminary study showed that phenotypic rank reduction using first 75 PCs might be dangerous, also as even some PCs (e.g. PC 145) with very low phenotypic variances (<0.001%) showed heritability (here 0.05) over 0.01. By estimating heritability and in future studies genetic correlations among MIR spectral traits associated with genomics, understanding the genetic architecture of MIR spectral traits will not only help us optimize their use for breeding, but also manage by avoiding phenotypic calibration steps.

MastiMIR – MIR prediction for udder health

L.M. Dale¹, A. Werner¹, E.P.J. Strang¹, HappyMoo Consortium² and J. Bieger¹

¹Regional association for performance testing in livestock breeding of Baden-Wuerttemberg (LKVBW), Heinrich Baumann Str. 1-3, 70190, Germany, ²<http://www.happymoo.eu>, 4 Rue des Champs Elysées, 5590, Ciney, Belgium; ldale@lkvbw.de

Udder health plays a major role in many dairy farms. In addition to the great economic impact, the well-being of the animal is also of primary importance. Especially subclinical inflammations, which are not visible at first sight, are problematic and costly. An important tool to monitor udder health and identify problem areas are udder health metrics. These key figures are an integral part of the milk performance test for every LKV member and can be viewed in the LKV Herd Manager. Another tool that has been evaluated as part of the HappyMoo project is MastiMIR. MastiMIR is an early warning system for udder disease that evaluates monthly milk spectral data. As milk compositions are related to a cow's health and metabolism, milk MIR spectra can be used to detect mastitis, a process already established with KetoMIR for early detection of ketosis. The goal of procedures such as KetoMIR and MastiMIR is to detect animal health problems early enough to take appropriate countermeasures quickly. Accompanied with bacterial examinations MastiMIR was tested in 25 pilot farms over two years during the HappyMoo project. In consultations with farmers, vets and other experts the focus was on the joint assessment of the animals that had been classified as risk animals on the basis of the spectral data. In addition, the corresponding bacteriological examination results of these animals were viewed. The comparison showed that most of the animals that appeared red on the report (high risk) were also infected with a pathogen. The new tool MastiMIR offers a lot of potential to become another building block for farmers, veterinarians and advisors to improve udder health in Baden-Württemberg farms.

Session 95

Theatre 9

Prediction of lameness and hoof lesions using MIR spectral data

M. Jattiot¹, L.M. Dale², M. El Jabri³, J. Leblois⁴, M.-N. Tran⁴ and HappyMoo Consortium⁵

¹Innoval, rue Eric Tabarly, CS 80038, 35538 Noyal-sur-Vilaine, France, ²LKV Baden-Württemberg, Heinrich-Baumann-Str. 1-3, 70190 Stuttgart, Germany, ³IDELE, 149 rue de Bercy, 75012 Paris, France, ⁴Elevéo, Association Wallonne des Eleveurs, 4 Rue des Champs Elysées, 5590 Ciney, Belgium, ⁵<http://www.happymoo.eu>, 4 rue des Champs Elysées, 5590 Ciney, Belgium; manon.jattiot@innoval.com

Lameness is currently one of the most severe health issues in dairy cows' farming systems. Thus, the project HappyMoo, aiming at predicting welfare related problems using the milk mid-infrared (MIR) spectroscopy has chosen to work on lameness prediction. Two types of data were studied: lameness score (using ICAR scale 1-5) and hoof lesions (using ICAR codes), associated with milk analysis, animal information, and MIR spectral data. Concerning lameness score data, 22,576 observations was used. Pre-processing of the MIR spectral data has been done before comparing different machine learning models to find the best one, based on sensitivity. The variable to predict was binary: 'no lame' vs 'lame'. We found a variability on the performances, accuracy varying from 0.61 (DECISION TREE) to 0.68 (GBM or NEURAL NETWORK), but sensitivity from 0.12 (GBM) to 0.65 (LOGISTIC REGRESSION). Another tested approach was CPPLS – GLMNET model, which had satisfying results in calibration model, but the performances on external validation were not good enough to be used in routine (best sensitivity=0.29). Regarding hoof lesions, the models were first tested by discriminating animals with at least one lesion on one of the 4 limbs vs animals with no lesion. Like for lameness, different models have been applied. The results showed a good prediction of healthy animals (best specificity=0.94 with CNND-N) but sensitivity was bad (0.12). Other groups were constructed according to the type of lesions encountered. The best results in calibration (spe=0.72, sen=0.64) was obtained with CPPLS-GLMNET model for the following discrimination: healthy animals vs ill, considering only the infectious disorders. In conclusion, several models were tested on lameness score and hoof lesions data but the results do not yet seem to be able to predict lameness in dairy cows through milk spectra. More research needs to be done on this topic.

MIR spectral prediction based on heat stress in dairy cattle

L.M. Dale¹, M. Jattiot², A. Werner¹, E.J.P. Strang¹, P. Lemal³, Happymoo Consortium⁴, Klimaco Consortium⁵ and N. Gengler³

¹Regional association for performance testing in livestock breeding of Baden-Wuerttemberg (LKV BW), Heinrich Baumann Str. 1-3, 70190, Germany, ²INNOVAL, 35538, Noyal-sur-Vilaine, France, ³Gembloux Agro-Bio Tech, University of Liège, Passage des Déportés 2, 5030 Gembloux, Belgium, ⁴<http://www.happymoo.eu>, 4 Rue des Champs Elysées, 5590, Ciney, Belgium, ⁵<https://agroecologie-rhin.eu/de/klimaco-2/>, 2 rue de Rome, 67013, Schiltigheim, France; ldale@lkvbw.de

It is well known that heat stress (HS) negatively affects the profitability of dairy farms. However, the effects of HS on detailed milk composition have been much less studied. Until now, early results in different environments (e.g. Belgium, Tunisia, Germany) were reported based on MIR spectrum responses to HS in dairy cows. The effects of HS on milk production traits and the MIR spectrum are reflecting the detailed information on milk samples in Baden-Württemberg. The model was built in the period 2012 to 2019 and the external validation was made between 2020 and 2022. Data from public weather station, temperature and humidity data, was merged with milk recording data. Values for the daily average temperature-humidity index (THI) were calculated. All statistical analysis was performed in R using 'glmnet', and spectral data were first standardized and then pre-processed by 1st derivative. Results showed that there were differences in MIR spectra recorded under HS and thermoneutral conditions; certain wavenumbers of the MIR spectrum responded differently. The THI index was built based on the report between individual cow THI and the mean THI value of the farm. Pearson correlations based on the THI index and milk parameters were calculated with 'corrplot' library in R. The negative correlation with THI index were on milk traits, such as milk yield: 0.15, and lactose: 0.12, acetate: 0.33, blood NEFA: 0.2 and positive correlations with fat: 0.59, protein content: 0.40, blood BHB: 0.25, blood glucose: 0.30, blood calcium: 0.21 and fatty acids more as 0.35. Further analysis is needed to identify potential milk-based MIR phenotypes that could be used in this context for herd management and breeding for HS resistance.

Session 95

Theatre 11

Use of MIR spectra-based indicator for genetic evaluation of heat stress in dairy cattle

P. Lemal¹, L.M. Dale², M. Jattiot³, J. Leblois⁴, M. Schroyen¹ and N. Gengler¹

¹ULiège – GxABT, Passage des Déportés, 2, 5030 Gembloux, Belgium, ²LKV BW, Heinrich Baumann Str. 1-3, 70190 Stuttgart, Germany, ³INNOVAL, Rue Eric Tabarly, 35538 Noyal-sur-Vilaine, France, ⁴Elevéo, Rue des Champs Elysées 4, 5590 Ciney, Belgium; pauline.lemal@uliege.be

Heat stress (HS) detection and its genetic evaluation is still a challenge. Indeed, milk yield and milk content represent a small fraction of variability induced by HS. A solution could be to use the information of whole mid-infrared (MIR) spectra that are already routinely measured to evaluate fat and protein content. Recently, a MIR spectra-based HS indicator (called hereafter MIR indicator) has been developed to evaluate HS. The objective of this study was to evaluate the interest of using this new MIR indicator for genetic evaluation of HS by comparing it with milk yield. Milk yield data and the MIR indicator for 53,842 Holstein cows were obtained from 2015 to 2022 for a total of 837,492 records. The threshold at which milk yield starts to be affected by HS was estimated at a temperature-humidity index (THI) of 61. The MIR indicator follows a linear relation with the THI and thus no clear threshold is observable. However, a higher relative variation along the THI scale is observed for the MIR indicator compared to milk yield (1.2 and 0.15 respectively). A two-trait random regression reaction norm model was fitted with a threshold of 61 for milk yield and 50 for the MIR indicator. Heritability was 0.32 for the MIR indicator at the thresholds and this value was similar at high THI. Regarding reaction norm effects, the MIR indicator showed a negative genetic correlation with milk yield. Because a low value of the MIR indicator is expected at high THI for heat-tolerant cows, a negative genetic correlation between the regression on the THI for milk yield and the MIR indicator was considered favourable. If confirmed, this new MIR indicator could be a valuable tool for genetic evaluation of HS because of its variation along the THI scale and the high heritability values, including at high THI.

A unique overview of enteric methane emissions by dairy cows in Bretagne, FranceS. Mendowski¹, O. Garcia¹, C. Bruand², M. Tournat¹, T. Viot² and L. Meriaux²¹Eco-Sens, La Messayais, 35210 Combourtille, France, ²Eilyps Group, 17 boulevard Nominoë, 35740 Pacé, France; s.mendowski@eco-sens.com

As enteric methane (CH₄) represents 53% of the GHG emissions in dairy farms, its decrease is an effective way to reduce their carbon footprint. The CH₄ emissions occurred during ruminal fermentations, so adapting dairy cow diets is a good way to reduce them. What are the real levels of CH₄ emissions in French dairy farms? By combining the equation used by Eco-Sens to predict CH₄ from milk fatty acids and milk yield and the data collected by Eilyps, a unique overview of dairy cows CH₄ emissions in Bretagne, west of France, was performed. The database contains 59.561 CH₄ intensity (iCH₄) data from 2.481 farms, predicted between 2019 and 2021, linked to other data that allows to study the effect of years, months, forage (pastured grass, stored grass, maize) and breeds on iCH₄. Results show iCH₄ variations between and within the different systems. The iCH₄ vary from 11 to 20 g/l of milk (mean of 16.2 g/l). The iCH₄ are not constant during a year: April and December are the months with the lowest and highest iCH₄ means (15.3 and 16.9 g/l of milk, respectively), mainly due to the large use of pasture in this area in spring. Prim'Holstein is the breed for which iCH₄ are the lowest in average (15.8 g/l of milk), because their slightly higher level of milk yield. In average, farms with more than 75% of maize silage in diet emit less CH₄ than farms with more than 75% of grass (fresh or stored) in diet. However, pasture-based diets allow the lowest CH₄ emissions, due to the improvement of milk fatty acid profile reflecting fermentations in rumen that emit less CH₄. Individual farm results show that some farms using more than 75% of grass have lower CH₄ emissions than some farms using more than 75% of maize silage. This study confirms that diet has an impact on reducing CH₄ emissions: from a technical point of view, reducing CH₄ emissions is concomitant with feed efficiency, with high quality and well valued forages. From an economic point of view, reducing CH₄ emissions is linked to increasing food cost margin. This study will make it possible to position each farm in relation to its CH₄ emissions and to implement a concrete reduction action plan.

Genetic parameters analysis of milk citrate for Holstein cows in early lactationH. Hu¹, Y. Chen¹, C. Grelet² and N. Gengler¹¹ULiège-GxABT, Passage des Déportés 2, 5030 Gembloux, Belgium, ²Walloon Agricultural Research Center (CRA-W), Chaussée de Namur 24, 5030 Gembloux, Belgium; hongqing.hu@doct.uliege.be

Delivering innovative and holistic monitoring and decision-making PLF tools relies on the availability of critical biomarkers. Negative energy balance is a difficult trait complex as there is a difference between perceived imbalance and physiological imbalance. Milk citrate is considered to be an early biomarker of negative energy balance for dairy cows in early lactation, but its genetic analysis is lacking. The objectives of this study were to (1) show the distribution of milk citrate content in early lactation; (2) analyse the genetic parameters of milk citrate. The coefficient of determination (R²) and root mean square error (RMSE) of the predicted milk citrate model by milk mid-infrared (MIR) spectra in external validation were 0.86 and 0.76 mmol/l, and available from DIM 5 to 50 d. Records were divided into three traits according to the first (citrate1), second (citrate2), and from third to fifth party (citrate3+). After editing, the data included 134,517 records, from 52,198 cows, and 4,479 animals in the pedigree with 566,170 SNPs. A multiple-trait repeatability model was used in this study. The citrate is decreasing in early lactation, on average from 10.04 to 8.58 mmol/l from DIM 5 to 50 d. When cows start to be in energy balance (DIM ≈ 40 d), milk citrate was 8.82 mmol/l. The average of citrate1 was 8.93 mmol/l; citrate2 was 8.93 mmol/l; citrate3+ was 9.17 mmol/l. The heritability for citrate1 was 0.40; for citrate2, 0.37 and for citrate3+, 0.35. The ranges of genetic correlations between the three traits were from 0.98 to 0.99, and of phenotypic correlations, from 0.41 to 0.42. This study showed that considering MIR-based milk citrate as an indicator to identify negative energy balance should be possible in early lactation, and this indicator could help select for animals less affected by negative energy balance.

Milk fluctuations in daily milk yield associated with diseases in Chinese Holstein cattleA. Wang¹, D.K. Liu², C. Mei³ and Y.C. Wang¹¹China Agricultural University, No.2 Yuanmingyuan West Road, Haidian District, Beijing, 100193, China, P.R., ²Hebei Sunlon Modern Agricultural Technology Co. Ltd., Dingzhou, 073000, China, P.R., ³Dongying Austasia Modern Dairy Farm Co. Ltd., Dongying, 257000, China, P.R.; wangyachun@cau.edu.cn

Disease-associated milk loss is one of the key constraints on herd profitability and sustainable productivity. In this context, our study aimed to quantify phenotypic variability of milk fluctuations caused by diseases and to explore fluctuation traits that can contribute to disease resilience breeding from yield perspective. By combining high-frequency daily milk yield with disease records, we calculated milk variability trends in a fixed window around the treatment day of each case of five diseases: udder health, reproductive disorders, metabolic disorders, digestive disorders, and hoof health. The average milk yield for all diseases decreased rapidly from 6 to 8 days before treatment day, with the largest decreases observed on treatment day. Furthermore, significant fluctuations caused by diseases were determined. Milk fluctuation was defined as a period of at least 10 successive days of negative deviations in which yield dropped at least once below 90% of the expected values. We defined development and recovery phases using 3,847 fluctuations caused by 4,185 disease cases, and estimated genetic parameters of fluctuation traits such as milk loss, duration and variation rate for each phase. In general, each disease-associated milk fluctuation lasted for 21.19 ± 10.36 days with a milk loss of 115.54 ± 92.49 kg. Milk fluctuations in recovery phase were 3.3 days longer in duration, 11.04 kg higher in loss, and 0.35 kg/d slower in variation rate compared to development phase. Fluctuation traits are inheritable with heritability estimates ranging from 0.02 to 0.19, and favourable moderate to high genetic correlations with milk yield, milk loss during entire lactation, and resilience indicators, which may support breeding for high disease resilience cows through fluctuation traits. Overall, this study confirms the high impact of diseases on milk yield and provides important insights into the interrelationship of relevant traits in Holstein cattle breeding programs, and shows the potential of using automatic monitoring of milk yield to assist disease management in dairy cows.

Session 96**Theatre 1****Impact of genomic selection for methane emissions in a high performance sheep flock**S.J. Rowe¹, T. Bilton¹, P. Johnson¹, S. Hickey², A. Jonker³, N. Amyes², K. McRae¹, S. Clarke¹ and J. McEwan¹¹AgResearch Ltd, Invermay Agricultural Centre, Puddle Alley, Mosgiel 9092, New Zealand, ²AgResearch Ltd, Ruakura Research Centre, 10 Bisley Road, Hamilton, 3214, New Zealand, ³AgResearch Ltd, Grasslands campus, Tennent Drive, 11 Dairy Farm Road, Palmerston North 4442, New Zealand; suzanne.rowe@agresearch.co.nz

The use of breeding for mitigation of methane emissions in livestock has been demonstrated under single trait selection. The objective of this longitudinal study is to demonstrate the inclusion of methane emissions into a selection index. Genomic breeding values for methane were included in the selection index of a high performance maternal sheep flock of 750 composite ewes for a full generation. During that period, growth, meat quality, health, production and methane emissions were closely monitored. We present genetic trends for all traits and demonstrate increases in productivity with a sustained lowering of methane emissions. Economic weighting relies on government policy, pricing mechanisms and the expression of the trait in a format that is auditable. Here we discuss the technical, political and economic challenges associated with ruminant breeding schemes for mitigation in methane in New Zealand. We show physical impact of incorporating methane emissions into the breeding scheme and the economic gains under two different accounting strategies. We review the measurement technologies available together with the potential impact of incorporating genomic selection for methane emissions into the national breeding goal.

Improving feed efficiency in meat sheep increases CH₄ emissions measured indoor or on pasture

F. Tortereau¹, J.-L. Weisbecker¹, C. Coffre-Thomain², Y. Legoff², D. François¹, Q. Le Graverand¹ and C. Marie-Etancelin¹

¹GenPhySE, Université de Toulouse, INRAE, ENVT, Chemin de Borde Rouge, 31326 Castanet-Tolosan Cedex, France,

²INRAE Experimental unit P3R, La Sapinière, 18390 Osmoy, France; flavie.tortereau@inrae.fr

Ruminants are often criticized when it comes to environmental impacts, due to CH₄ production and to the part of concentrates in the diets. A major objective in breeding ruminants is to limit both feed-food competition and greenhouse gas (GHG) emissions. We divergently selected, over 4 generations, Romane meat sheep on their Residual Feed Intake (RFI) from 3 to 5 months old under a 100% concentrate diet. We present here two results of GHG measurements (performed with sheep GreenFeed, C-Lock) on males and females belonging to these divergent lines (animals were from the RFI- (efficient) or RFI+ (inefficient) line). A total of 124 males belonging to the 3rd and 4th generations of selection, reared indoor, had both GHG and forage intake measurements. On average, males weighed 64.6 kg and emitted 1,345 g/d of CO₂ and 39.26 g/d of CH₄. Positive correlations were estimated between CO₂ and CH₄ (0.59) and between gases and forage intake (0.24 for CH₄ and 0.54 for CO₂) and body weight (0.38 for CH₄ and 0.78 for CO₂). No significant difference in body weight was observed between RFI- and RFI+ males. RFI- males ate less forage (1.13 kg/d for RFI- and 1.22 kg/d for RFI+) but they emitted significantly more CH₄ (38.86 g/d for RFI- and 37.50 g/d for RFI+), and less CO₂ (1,326 g/d for RFI- and 1,335 g/d for RFI+). We confirmed this result with 85 ewes from the 4th generation of selection, first fed indoor with dry forage and then fed on pasture: RFI- ewes emitted significantly more CH₄ than RFI+ ewes, whatever the diet. GHG emissions were positively correlated between both diets (0.48 for CH₄ and 0.56 for CO₂). Animal effects for GHG emissions, obtained from a repeatability model were significantly correlated under the two diets (from 0.66 for CH₄ to 0.78 for CO₂ intensity). Both studies highlight unfavourable relationship between feed efficiency and gas emissions: the most efficient animals ate less, but emitted more CH₄ than the least efficient ones. Moreover, phenotyping GHG indoor under a forage-based diet is of high interest when phenotyping GHG on pasture is not feasible.

Effects of sire and diet on rumen volume and relationships with feed efficiency

N.R. Lambe, A. McLaren, K.A. McLean, J. Gordon and J. Conington

SRUC, SRUC Hill and Mountain Research Centre, FK20 8RU, United Kingdom; nicola.lambe@sruc.ac.uk

The rumen plays an important role in the digestion of food by ruminants and previous research has found that larger reticulo-rumen volumes, as measured by CT scanning (RRvol), are associated with increased methane emissions. Across two years, twin-born Texel × Scotch Mule lambs from 10 sires were split across two finishing systems (diets) at weaning (~12 weeks old) for a total of eight weeks: outdoors (n=242, grazed on grass) and indoors (n=237, fed pelleted grass nuts and recorded through individual feed intake recording equipment). At the end of the study, lambs finished on grass nuts indoors were significantly heavier, grew quicker, and had more fat and muscle (as measured by ultrasound and CT scanning) at the same live weight, than lambs grazing lowland pastures ($P < 0.001$ for all). Lambs grazed outdoors had significantly larger liveweight-adjusted RRvol post-trial ($P < 0.001$). Sire had a significant effect on all measured traits. However, diet interactions with sire were non-significant for growth, carcass traits or RRvol, suggesting that lambs from the same sires ranked similarly in each system. Residual feed intake (RFI) was calculated for each lamb finished indoors, by adjusting average daily dry matter intake for live weights, average daily liveweight gain, fat and muscle weights, as well as sex and year. RRvol had no significant effect on RFI ($P > 0.05$), regardless of whether RRvol was measured before or after the feeding trial, or whether or not it was adjusted for lamb live weight. These results add to our understanding of traits associated with feed efficiency and methane emissions from sheep systems, and the relationships among them.

Evaluating the effect of herbage composition on methane output in sheep

F.M. McGovern, P. Creighton, E. Dunne and S. Woodmartin

Teagasc, Animal and Bioscience, Animal & Grassland Research & Innovation Centre, Mellows Campus, Athenry, Co. Galway, Ireland, H65 R718, Ireland; fiona.mcgovern@teagasc.ie

Understanding the influence of diet composition on methane (CH₄) output in ruminant animal production systems is of critical importance to the development of mitigation strategies. In Ireland enteric CH₄ emissions account for 60.7% of the national greenhouse gas emissions from the agricultural sector. The aim of this study was to investigate the possible relationship(s) between CH₄ output, diet quality and dry matter intake (DMI) in sheep. A 5×5 Latin square design experiment was undertaken to investigate five dietary treatments: Perennial ryegrass (*Lolium perenne* L.; PRG) only or PRG plus white clover (*Trifolium repens* L.), red clover (*Trifolium pratense* L.), chicory (*Chicorium intybus* L.) or plantain (*Plantago lanceolata* L.) at a ratio of 75% PRG and 25% of the respective forage on a dry matter (DM) basis. Twenty wether sheep were housed in metabolism crates across five feeding periods. Daily offered herbage samples were collected from each animal prior to freeze drying and chemical analysis. Methane measurements were collected from each animal on the final day of each feeding period using portable accumulation chambers. The final dataset contained 600 records of individual DMI and 100 records of methane output. Data were analysed using linear mixed models with relationships between variables of interest examined using Pearson rank correlations. Dry matter intake ranged from 1.55±0.038 (PRG) to 1.76±0.038 kg DM/animal/day (PRG + Chicory). Methane output ranked highest for animals offered the PRG or the PRG + Chicory diets ($P<0.05$). Results showed a Pearson rank correlation between DMI and methane output of 0.46 while this ranged from 0.38 to 0.76 depending on the diet type offered. The overall percentage of leaf and stem offered to animals influenced methane output with correlations of -0.42 and 0.57, respectively. In addition, the regression coefficient between methane output and DMI had an $R^2=0.62$. Data from this study highlights the impact of diet quality on methane output in small ruminants and shows the importance of optimising sward management in pasture based production systems.

Dry matter intake across life stages in sheep

E. O'Connor^{1,2}, N. McHugh¹, E. Dunne¹, T.M. Boland² and F.M. McGovern¹

¹Teagasc, Animal and Grassland Research and Innovation Centre, Athenry, Co. Galway, H65 R718, Ireland, ²University College Dublin, School of Agriculture and Food Science, Belfield, Dublin 4, D04 V1W8, Ireland; edel.oconnor@teagasc.ie

Dry matter intake (DMI) is a key livestock production metric as it determines not only the feed budget required for the flock but also the animals realised growth potential. The objective of this study was to investigate the relationship between estimated DMI across life stages in sheep. Dry matter intake was estimated over a seven-year period from 2016 to 2022 using the n-alkane technique on animals grazing perennial ryegrass swards or based on a silage diet during the winter indoor housing period. For DMI estimated during the grazing period, animals were orally dosed with a n-alkane bolus for 11 consecutive days, with faecal samples collected from day 7 to 12. To determine DMI on a silage based diet lambs and pregnant ewes were individually penned indoors and the quantity of feed offered and refused was measured daily. Dry matter intake on a total of 621 female animals was collected across various life stages including: as lambs (<12 months), nulliparous hoggets (12 to 24 months) and ewes (primiparous or greater; 24 to 72 months). Ewes were further classified as pregnant, lactating or dry (non-pregnant and non-lactating). Animal live-weight and methane output, coinciding with DMI measurements were also available over a three year period from 2020 to 2022. Factors affecting DMI were modelled using a linear mixed model with life stage, breed and live-weight of the animal included as fixed effects and animal included as a random effect. The average DMI (expressed in kg DM per day) measured at each life-stage was 0.91 kg DM/day (lambs), 1.17 kg DM/day (hoggets), 1.19 kg DM/day (pregnant ewes), 2.30 kg DM/day (lactating ewes) and 1.31 kg DM/day (dry ewes). Lactating ewes had a significantly higher DMI compared to all other life stages ($P<0.01$); while DMI did not differ amongst lambs, hoggets and pregnant ewes ($P>0.05$). Moderate positive correlations were estimated between DMI and methane output (0.38) and animal live-weight (0.64). Results from this study show that DMI differs across life stage and is a contributing factor to the amount of methane the animal produces.

Selecting feed-efficient sheep with concentrates alters their efficiency with forages and behaviourC. Marie-Etancelin¹, J.L. Weisbecker¹, D. Marcon², L. Estivalet², Q. Le Graverand¹ and F. Tortereau¹¹INRAE- UMR GENPHYSE, chemin de Borde Rouge, 31326 Castanet Tolosan Cedex, France, ²INRAE- UE P3R, Domaine de la Spinière, 18390 Osmoy, France; christel.marie-etancelin@inrae.fr

Selecting to improve feed efficiency is an objective shared by all animal productions, with the aim of reducing feed consumption and rejects while maintaining production abilities. To make such a selection, the Residual Feed Intake (RFI) is the most convenient trait. We divergently selected Romane meat sheep on their RFI under a 100% concentrate diet. In the 3rd and 4th generations of selection, a total of 332 Romane males, belonging either to the RFI- (efficient) or RFI+ (inefficient) lines with a difference of 2 genetic standard deviations between lines, were phenotyped. Feed efficiency and feeding behaviour traits were recorded during 2 phases: a first phase under a 100% concentrate diet from 3 to 5 months of age and then a second phase under a mixed diet (forage *ad libitum* + 700 g of concentrate) from 6 to 8 months of age. The significant difference in RFI between lines under a concentrate diet (131 g/d) was still significant under the mixed diet although reduced (51 g/d), with RFI- being more efficient than RFI+. In terms of feed intake (FI), the RFI+ males ingested more feed than the RFI- ones whatever the diet: +123 g/d of concentrate during the first phase and +80 g/d of forage with no difference in restricted concentrate during the second phase. Between the 2 diets, correlations were of +0.27 for RFI and +0.22 for FI. During the concentrate diet phase, RFI- males had a lower daily duration of intake and fewer daily visits to the feeders. During the mixed diet phase, there was only a trend toward fewer daily visits (P=6%) at forage feeder for RFI- sheep, no difference in restricted concentrate intake behaviour, but a significantly slower water drinking rate for the efficient animals. Analysis of feeding times per hour highlighted that efficient animals ate more often after peak feeder times, about one hour later. Could efficient sheep be dominated while accessing feeders?

Theatre 7

Genome-wide association study of footrot and mastitis in UK Texel sheepK. Kaseja¹, S. Mucha¹, J. Yates², E. Smith², G. Banos¹ and J. Conington¹¹Scotland's Rural College (SRUC), Roslin Institute Building, EH25 9RG, Edinburgh, United Kingdom, ²The British Texel Sheep Society, Stoneleigh Park, CV8 2LG, Warwickshire, United Kingdom; karolina.kaseja@sruc.ac.uk

The aim of this study was to investigate the genetic background of footrot and mastitis using available phenotypes and genomic data provided by UK Texel Sheep Association. Initially, 10,193 genotypes underwent quality control leaving 9,505 genotypes for further analysis. Selected genotypes were imputed to a subset of 45,686 markers from 50k array, distributed on 27 chromosomes. Phenotypes were collected on 32 farms across the UK and included 9,123 records for footrot (FRT) and 4,787 records for mastitis – recorded as California Mastitis Test (CMT), which is highly correlated with the somatic cell count. Both traits were recorded on five points scale, ranging from zero indicating no infection to four indicating severe infection. De-regressed estimated breeding values (EBV) were used as pseudo-phenotypes for GWAS. No genome-wide significant SNPs were found for either trait. Three SNPs were found to be significant on the chromosome-wise level for FRT on chromosomes 19, 23 and 26 and one SNP on chromosome 17 for CMT. SNPs on chromosomes 23 and 26 were very close of the genome-wise significance level of 5.96, reaching 5.50 and 5.23, respectively. SNP reported on chromosome 26 was within the previously reported QTLs associated with health traits such as FEC worm count and FEC eggs per worm. SNP reported on chromosome 17 was within the 14 Mbp from somatic cell score QTL. These results indicate that both traits are highly polygenic. Further research which includes more genotyped and phenotyped animals with perhaps denser DNA array is required in order to increase the chance to discover potentially important SNPs affecting FRT and CMT in the UK Texel breed. This work was supported by SMARTER H2020 project no. 772787.

Genetic parameters of nematode resistance in dairy sheepB. Bapst¹, K. Schwarz², S. Thüer² and S. Werne²¹Qualitas AG, Genetic/Genomic evaluation, Chamerstrasse 56, 6300 Zug, Switzerland, ²Research Institute for Organic Agriculture (FiBL), Ackerstrasse 113 / Postfach 219, 5070 Frick, Switzerland; beat.bapst@qualitasag.ch

Resistance of gastrointestinal nematodes (GIN) in sheep to anthelmintics is rapidly increasing. The results of several studies indicate that selection for increased nematode resistance in sheep is possible, and the trait of interest is faecal egg count (FEC). Phenotyping of FEC is rather time-consuming and often costly, auxiliary traits that are more effective and easier would be greatly appreciated. The extent of *Haemonchus contortus* infestation is often measured by the coloration of the conjunctiva and the so-called FAMACHA© test. In our study, we aimed to test whether FAMACHA could also be used as auxiliary trait for FEC. Additionally we aimed to provide genetic parameters for FEC, milk yield and packed cell volume (PCV). We phenotyped 1,150 naturally infected Lacaune ewes on 15 commercial Swiss farms. Phenotypic correlation between FEC and FAMACHA as well as FAMACHA and PCV resulted in 0.25 (SE 0.03) and -0.35 (SE 0.08), respectively. Subsequent genetic analysis was carried out with a multi-trait animal model in order to estimate the genetic parameters of the traits mentioned above. We found moderate heritabilities of FEC, FAMACHA, PCV and milk yield in the range of 0.30 to 0.36 (SE 0.08 for all traits). The particular focus was on the genetic correlation of FEC and FAMACHA and was estimated to be 0.03 (SE 0.22). The distribution of the FAMACHA score indicated a medium to high worm infestation, but FEC was relatively low compared to other studies. Eventually the infection pressure was not high enough to yield a good genetic correlation of FEC and FAMACHA. In general, it can be concluded that the heritability for FEC is very appealing and that a selection program could be based on them. FAMACHA as an auxiliary trait could not be confirmed in this study. Either further studies need to be designed differently to better explore the relationship between FAMACHA and FEC or other possible auxiliary traits need to be sought and developed. This study was funded by SMARTER H2020 project no. 772787.

Theatre 9

Contrasting genetic resistance to GIN on growth performance and feed efficiency of Corriedale lambsE.A. Navajas¹, G. Ciappesoni¹ and I. De Barbieri²¹Instituto Nacional de Investigación Agropecuaria, Las Brujas, 90100, Uruguay, ²Instituto Nacional de Investigación Agropecuaria, Tacuarembó, 45000, Uruguay; enavajas@inia.org.uy

Genetic improvement of resistance to gastrointestinal nematodes (GIN) in sheep is a well-known strategy to reduce the negative consequences of GIN, whose control is limited by resistance to anthelmintics, on sheep health and performance. Genetic selection using faecal egg count (FEC) as selection criteria is in place in sheep breeding programmes of different countries, including Uruguay. The assessment of ocular mucous membrane colour using a chart to determine anaemia (FAMACHA©), which is easier to record than FEC, is also used as indicator of GIN infection. The aim of this study was to explore the association between FEC EBV and phenotypic FEC and FAMACHA, as well as body weights (BW), body condition score (BCS) and residual feed intake (RFI) by comparing resistant (R) and susceptible (S) lambs, according to their FEC EBVs. Lambs with the lowest (R, n=83) or highest (S, n=78) 25% FEC EBV (estimated in 2023) were identified in a dataset of 317 Corriedale female lambs of four cohorts (2018-2022). Uruguayan genetic evaluation protocol was used to measure FEC. When faecal samples were taken for FEC, FAMACHA score (five classes) was assessed, as well as BW and BCS. RFI is the difference between actual and predicted feed intake based on average daily gain (ADG) and metabolic body weight (MW), using data recorded in 46-day tests. Lineal models that included year and R/S group as class fixed effects were used. Least-square mean comparison indicated that R lambs had significantly lower FEC values than S lambs ($P < 0.05$) as expected, as well as lower FAMACHA scores ($P < 0.05$), which agrees with the moderate genetic and phenotypic correlations estimated in this breed. In contrast, non-significant differences between R and S ($P > 0.05$) were found for BW, BCS and RFI. Our results are aligned with the non-significant correlations of FEC EBV with feed efficiency traits (feed intake, MW and ADG) reported in commercial lambs and in a comparison of Corriedale divergent FEC selection lines under natural and artificial GIN. Overall, improving genetic resistance to GIN, reduces FEC and FAMACHA, without unfavourable effects on production or feed efficiency.

Australian Merino: animal welfare and resilience in extensive systems

M. Del Campo¹, J.L. De Araújo Pimenta², I. De Barbieri¹, P. Lorenze¹, F. Rovira¹ and J.M. Soares De Lima¹

¹INIA – National Institute of Agricultural Research, Ruta 5 km 386, 45000 Tacuarembó, Uruguay, ²UNESP, Jaboticabal, SP, CEP 14884-900, Brazil; mdelcampo@inia.org.uy

In extensive systems, perinatal lamb's losses could be enhanced by the sum of factors such as lamb weight at birth (BW) and low resistance to climatic adversities, live weight (LWC) or body condition of the mother at calving (BCC), calving difficulty (CD), type of delivery (DT), maternal ability (MA). The objective of this project (financed by Smarter H2020 and Rumiar) was to characterize these variables in a flock under genetic evaluation, made up of 400 dams and their progeny for 4 years: 2018 to 2021. The variables were: (1) LWC; (2) BCC (scale from 0 to 5); (3) CD, scale from: 0 (without assistance and of short duration) to 4 (with veterinary assistance); (4) MA at the time of identifying the lamb (scale from 1 to 5) where 1 is when she abandons the lamb and 5 is when she is in permanent contact with the lamb; (5) TP (single, twin, triplet); (6) BW and g) survival of lambs at 72 hours after birth (S72). Ordinal and binary logistic regressions (SAS, v9.3) were performed. Main variables that affected CD were BCC, DT and BW ($P < 0.05$). Calving without difficulty (CD=0) was associated with BCC<3.2 for single, twin or triplet births, regardless of the mother's category. Twin and triplet births presented higher CD compared to single births ($P < 0.05$) also regardless of the mother category. Mortality average at 72 hours for the 4 years was 8.6%, mainly affected by CD, DT and BW. In relation to CD, for values of 2 (calving that needs assistance although low,) S72 was decreased to 50%. S72 was lower in multiple births (93.7% single, 91.2% twins, 68% triplets). Lambs from multiple births had a lower BW than single lambs (single 4.8 kg, twins 4.1 kg, triplets 3.4 kg, $P < 0.05$). In the present experiment, MA becomes very important in multiple births, where S72 increases from 87.5 to 94.6% when passing from MA3 to MA4. BW has a high incidence in S72 for both sheep and ewes. In the case of ewes, this is compromised with BW values <3.8 kg. In summary, a high CD compromises the sheep welfare and would affect lambs survival mainly in multiple births, where S72 is also affected by low BW.

Prediction of feed efficiency related traits from plasma NMR spectra

A. Marquisseau, F. Tortereau, N. Marty-Gasset, C. Marie-Etancelin and Q. Le Graverand

GenPhySE, Université de Toulouse, INRAE, ENVT, Chemin de Borde Rouge, 31326 Castanet-Tolosan Cedex, France; flavie.tortereau@inrae.fr

Feed efficiency is a key trait to integrate in breeding programs, particularly in order to limit the feed-food competition and the environmental impact of livestock production. The calculation of feed efficiency criteria requires individual feed intakes to be recorded, which is too expensive in small ruminants to be reasonably proposed. An option to make this trait more affordable is to predict feed intake or efficiency from a variety of predictors that can be easily recorded. As it has been evidenced that the animal metabolism is one of the main biological function underlying feed efficiency, we propose to examine the predictability of feed efficiency related traits from plasma metabolome. Plasma samples from 265 Romane male lambs fed a 100% concentrate diet were analysed with NMR. NMR spectra were divided into 877 buckets of 0.01 ppm, and the considered values were the area under the curve of each bucket. These variables were CLR transformed before multivariate analyses (sparse Partial least squares, sPLS) used for prediction. Prediction performances of feed intake and RFI were assessed through 5-fold nested cross-validation repeated 50 times, i.e. over 250 models. Accuracies of prediction from NMR buckets were compared to the accuracy obtained from body weights, growth, body composition (called zootechnical traits hereafter). As a result, we highlighted that buckets did not improve the prediction of feed intake from zootechnical traits: an average R^2 of 0.7 was obtained from zootechnical traits with or without buckets, against 0.2 from buckets only. For RFI, R^2 were below 0.1 whatever the set of predictors. Considering whole spectra did not help predict feed efficiency nor feed intake. However, the main buckets involved in RFI prediction were consistent with metabolites previously associated to feed efficiency: such as beta-hydroxyisovaleric acid or L-tyrosine.

Metabolism in lambs from two feed-efficiency genetic lines subjected to different early rearing practicesG. Cantalapiedra-Hijar¹, M.M. Milaon¹, S. Parisot², C. Durand², M. Vauris¹, F. Tortereau³ and C. Ginane¹¹INRAE, UMR Herbivores, Clermont-Ferrand-Theix, 63000, France, ²INRAE, UE0321 La Fage, Roquefort-sur-Soulzon, France, ³INRAE, UMR13888 GenPhySE, Auzeville Tolosane, France; gonzalo.cantalapiedra@inrae.fr

The genetic selection for feed efficiency may have negative impacts on animal resilience, as both traits rely on energy-demanding mechanisms that may conflict with each other. This study aimed to investigate whether metabolism differed in lambs from two genetic lines with divergent feed efficiency when subjected to two contrasting early rearing practices. Eighty Romane ewe lambs from two divergent genetic lines for residual feed intake (RFI), were reared either indoors with artificial rearing (AR) or in the rangeland with maternal rearing (MR) from birth to 3 months. After this initial period, they were allocated by 20 lambs into four experimental rangeland plots, 2 AR and 2 MR, balanced for the RFI line effect. After 3 weeks in the plots, blood samples from 8 animals per condition (line × rearing) were randomly selected for plasma analysis (n=32). Plasma samples were analysed by LC-MS to quantify around 270 targeted metabolites. Results were analysed through Metaboanalyst software using both the statistical (two-way ANOVA) and enrichment analysis options. No interaction between the RFI line and early rearing practice was found (FDR>0.05) on plasma metabolome. Nine plasma metabolites were affected by the RFI line ($P<0.05$), including two belonging to the urea cycle (ornithine and citrulline) and having lower plasma concentration in efficient RFI lambs. However, none reached significance after FDR corrections (FDR>0.05). Accordingly, enrichment analysis found no significant metabolic pathway associated with the RFI line (FDR<0.05). On the other hand, several plasma metabolites belonging to the families of phosphatidylcholines, acyl-carnitines, sphingomyelins, and ceramides showed higher concentrations in AR vs MR lambs (FDR<0.05). Additionally, twelve metabolic pathways, most of them related to lipid metabolism, were found to be enriched in the AR vs MR lambs (FDR<0.05). Overall, our results do not support different metabolic regulation in lambs genetically divergent for RFI when subjected to contrasting early rearing practices and then exposed to challenging environment.

Session 96

Poster 13

Genetic link between fertility and resilience in sheep and goat divergent selection experimentsR. Rupp¹, C. Oget-Ebrad¹, S. Parisot², T. Fassier³, G. Tosser Klopp¹ and S. Freret⁴¹INRAE, Université de Toulouse, ENVT, GenPhySE, Castanet Tolosan, France, ²INRAE, UE0321, Domaine de La Fage, Roquefort Sur Soulzon, France, ³INRAE, P3R, Small Ruminants Phenotyping Facility, Osmoy, France, ⁴INRAE, IFCE, CNRS, Université de Tours, PRC, Nouzilly, France; gwenola.tosser@inrae.fr

The challenge for breeding is to improve resilience traits simultaneous with efficiency and reproduction. However very little information exists about possible trade-off between resilience and reproduction in small ruminants. The aim of this study was to investigate such possible trade-off in four divergent selection experiments in dairy sheep and goat. In each experiment we analysed the success to artificial insemination (AI) using dates of AI and natural mating for return to oestrus and dates of lambing/kidding. The first experiment was a divergent selection in Lacaune sheep on mastitis (SCS). The second was an experiment in Lacaune sheep selected for the SOCS2 gene associated to susceptibility to mastitis, with favourable (CC) and unfavourable (CT and TT) genotypes. The third experiment was a divergent selection in Alpine goats on mastitis (SCS). The fourth experiment was a divergent selection in Alpine goats on longevity. The data included 1,254, 5,375, 481, and 305 females and 3,671, 5,375, 788, and 617 AI events, respectively – and the fertility rate in these four experiments was 68.8, 70, 51.9, and 59.4%. We further estimated the odds ratio (OR) for success to AI using a logistic regression according to the genetic line, with year and lactation number as fixed effects. No effect on AI fertility was associated with selection on longevity in goats or mastitis (SCS) in sheep. However, an important favourable effect on AI fertility was associated: (1) with divergent selection on mastitis (SCS) in goat: $OR_{SCS- \text{ vs. } SCS+} = 1.65$ (1.22-2.23); and (2) SOCS2 genotype in sheep: $OR_{CC \text{ vs. } TT} = 1.36$ (1.08-1.70). The results suggest that selection for resilience in dairy sheep and goats is not associated with an adverse effect on reproduction in these species. On the contrary, selection for some resilience traits seems to drive significant beneficial effects in terms of fertility after AI. This study has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No 772787 (SMARTER).

Phenotypic and genetic variability of health and welfare traits in French dairy goatsI. Palthiere¹, A. Bailly-Salins², A. Gourdon², M. Chassier³, R. De Cremoux³, M. Berthelot⁴ and R. Rupp¹¹GenPhySE, Université de Toulouse, INRAE, INPT, ENVT, Chemin de Borde Rouge, 31326 Castanet-Tolosan, France, ²Capgenes, 2135 Route de Chauvigny, 86550 Mignaloux-Beauvoir, France, ³French Livestock Institute, 149 Rue de Bercy, 75595 Paris Cedex 12, France, ⁴French Agency for Food, Environmental and Occupational Health and Safety (Anses), 60 rue de Pied de Fond, 79024 Niort, France; rachel.rupp@inrae.fr

The objective of the study was to investigate the phenotypic and genetic variability of health and welfare traits in French dairy goats. A total of 1,977 primiparous goats of Alpine and Saanen breeds, from 14 farms, were involved in the study during the years 2020-2021. Eleven indicators were assessed individually and once for each goat: abscess, arthritis, nasal discharge, ocular discharge, dirty and light soiling hindquarters, lameness, body condition, bag-shaped udder, dehorning issues, hair coat condition, claw issues. For the study, all the indicators were considered as binary traits (0: absence of disorder; 1: presence of disorder). The total number of disorders per animal was defined as the sum of the disorders for the eleven indicators. The disorder frequency ranged between 0.5 and 23% depending on the 11 indicators. Two groups of indicators were observed: those with a frequency lower than 5% (n=7) and those with a frequency about 20% (n=4: dehorning issues, bag-shaped udder, abscess, claw issues). The total number of disorders per goat was 0.94, on average in the total dataset, and ranged between 0 and 5. 40% of goats showed no disorder. Heritabilities were estimated using linear models for 4 traits suspected to be under genetic control and with sufficient frequency (>5%). They ranged between 4% (abscess) and 26% (bag-shaped udder). Arthritis and the total number of disorders had intermediate values (11 and 15%, respectively). These first results suggest that selection may be a potential strategy to improve health and welfare traits in dairy goats. This study has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No 772787 (SMARTER).

Session 96

Poster 15

Assessment of phenotypic and genetic variability of rumen temperatures in goatsI. Palthiere¹, C. Huau¹, T. Fassier², R. Rupp¹ and L. Bodin¹¹GenPhySE, Université de Toulouse, INRAE, INPT, ENVT, Chemin de Borde Rouge, 31326 Castanet-Tolosan, France, ²P3R, INRAE, Small Ruminants Phenotyping Facility, Osmoy, 31326, France; rachel.rupp@inrae.fr

The aim of this study was to identify the factors of variation of rumen temperatures in goats and to estimate the genetic parameters of that trait. 97 Alpine goats from an INRAE experimental farm were monitored continuously during their first lactation (267 days on average, from kidding to dry off) using Medria rumen temperature boluses (ThermoBolus San'Phone®). Temperatures were collected every 5 min (288 records per day) and have been corrected to account for drinking events. The average rumen temperature was 39.68±0.51 °C on the whole data set (n=7,273,000). The average temperature during the day increased from about 5.00am to about 5.00pm and decreased afterwards: the minimum temperatures (39.28 °C) were observed in early morning (between 5.00am and 5.30am) whereas the maximum temperatures were observed in late afternoon (39.94 °C between 4.30pm and 5.00pm). In addition to the time, the phenotypic variability was also explained by the date, the birth year, the stage of lactation and the milk yield of the goat. Genetic parameters were estimated using a linear repeatability model. Data were spread into 5 periods according to their raw mean temperature and standard deviation (4.30am-6.00am, 6.40am-1.20pm, 3.30pm-8.00pm, 9.00pm-3.00am) and each one was analysed separately. Repeatability varied from 0.20 (4.30am-6.00am) to 0.32 (3.30pm-8.00pm), and heritability from 0.03 (4.30am-6.00am) to 0.12 (9.00pm-3.00am). For this last period, breeding values ranged from -0.10 to +0.14 °C. These results suggest that body temperature measured by internal sensors has a genetic control, which is potentially linked to basal metabolism or response to various stressors (heat stress, infection). This study has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No 772787 (SMARTER).

Heritability of novel metabolite-based resilience biomarkers in dairy goatM. Ithurbide¹, T. Fossier², M. Turret³, J. Pires³, T. Larsen⁴, N.C. Friggens⁵ and R. Rupp¹¹INRAE, Genphyse, Castanet Tolosane, France, ²INRAE, P3R, Small Ruminants Phenotyping Facility, Osmoy, France, ³INRAE, Université Clermont Auvergne, Vetagro Sup, 3UMR Herbivores, Saint-Genès-Champagnelle, France, ⁴Aarhus University, Faculty of Agricultural Sciences, Research Centre Foulum, 8830 Tjele, Denmark, ⁵INRAE, AgroParisTech, Université Paris-Saclay, UMR 0791 Modélisation Systémique Appliquée aux Ruminants, Paris, France; marie.ithurbide@inrae.fr

The aim of this study was to estimate the heritability (h^2) of metabolite-based resilience biomarkers in dairy goat. Metabolites were measured repeatedly during two periods of stress: around parturition and during a feeding challenge (48 h with straw only) in early first lactation in two INRAE facilities (P3R Bourges and Paris). The 4 blood metabolites were: glucose (Glu), beta-hydroxy-butyrate (BOHB), urea and non-esterified fatty acids. The 14 milk metabolites were: BOHB, Glu, urea, glucose-6-phosphate (Glu6P), galactose, isocitrate, glutamate, NH_2 -groups, lactate dehydrogenase (LDH), choline, malate, urate, triacylglycerol, and cholesterol. The metabolite trajectories were described both by simple mean concentration per challenge period and by a functional PCA method. Variance components were estimated using an animal model (wombat®) for blood metabolites around kidding, and for trajectories of blood and milk metabolites upon the feeding challenge on 201, 228 and 138 goats respectively. The model included the fixed effects of facility and year. The total pedigree included 1,148 animals. We found 25 blood and milk metabolites parameters (out of 159) that were significantly heritable ($h^2\text{-}2\text{SE} > 0$) with h^2 estimates ranging from 0.30 (± 0.03) to 1.00 (± 0.25) with SE from 0.03 to 0.33. Among them: milk urate, BOHB, LDH, and Glu6P during feeding challenge and blood Glu around kidding. The heritability estimation of 250-d milk yield, fat and protein content were respectively 0.26 (± 0.16), 0.53 (± 0.19) and 0.68 (± 0.19), showing the consistency of our dataset despite the small number of individuals. These results show the potential of metabolite-based biomarkers for genetic selection of resilience. This study has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No 772787 (SMARTER).

Poster 17

Rumen size of sheep: difference between a modern and a native Norwegian sheep breedB.A. Åby¹, M.A. Bhatti² and G. Steinheim¹¹NMBU, Department of Animal and Aquacultural Sciences, Box 5003, 1432 Ås, Norway, ²NMBU, Department of International Environment and Development Studies, Box 5003, 1432 Ås, Norway; bente.aby@nmbu.no

Globally, sheep account for approx. 4% of the GHG emissions from the livestock sector, mainly through enteric methane (CH_4) emissions. Rumen size is shown to be relevant for enteric CH_4 emissions, with larger rumen volumes being associated with higher emissions. Breed variation in rumen size, relative to body size, may thus be one factor contributing to between-breed differences in CH_4 emissions. Two of the most contrasting sheep breeds in terms of selection history in Norway are the Norwegian white sheep (NWS; large, long tailed composite breed) and the Old Norwegian Spæl (ONS; small Nordic Short-tailed landrace). These breeds were previously compared in two experiments at NMBU, where adult ONS ewes had lower enteric CH_4 , corrected for dry matter intake, when fed harvested grass silage and fresh cut grass. In this pilot study, we therefore hypothesized that there would be significant differences in rumen size between the breeds. The test animals (23 adult ewes, 40 lambs) came from two farms in Viken county rearing both breeds. On October 18, 2022, the animals were slaughtered at a commercial abattoir (Nortura Gol) shortly after the summer grazing period. Rumens were collected and ruminal contents were removed before the organs were cleaned and visceral fat removed. The rumens were then weighed after being squeezed dry. The data for lambs and adult ewes were analysed separately using two general linear models. Both models included the effects of carcass weight, breed, and farm. Additionally, the effect of birth year was included for adult ewes, while age at slaughter was included for lambs. For adult ewes, rumen weight corrected for carcass weight, was lower ($P < 0.05$) for ONS compared to NWS (LSMEANS 1,589 vs 1,832 grams), while there were no breed differences for lambs. Our results suggest that previously observed breed differences between ONS and NWS in enteric CH_4 emissions (i.e. lower enteric methane emissions, corrected for dry matter intake, for ONS) may be linked to differentiation in rumen size. However, this needs to be confirmed in a controlled study also including enteric CH_4 measurements on the test animals.

Diurnal feed intake pattern of two sheep breeds fed different silage qualities*I. Dønnem, B.A. Åby and G. Steinheim**Norwegian University of Life Sciences, Faculty of Bioscience, Oluf Thesens vei 6, 1433 Ås, Norway; ingjerd.donnem@nmbu.no*

Sheep farming in Norway is mainly based on using grass silage as feed in the indoor period during winter. When formulating a feed ration based on silage for sheep, knowledge about feed intake is important. Feed intake is affected by factors such as size and anatomical differences between animals, silage characteristics, and feeding management. The aim of this study was to investigate effects of grass silage quality and sheep breed on feed intake and the diurnal intake pattern. Grass silage qualities investigated were: (1) early; cut in the boot stage; and (2) average; cut in the heading stage. The two breeds were the modern Norwegian White Sheep (NWS), selected for production and maternal traits and the Old Norwegian Spæl (ONS), a lighter, rural breed. Mean weights of NWS and ONS were 91 and 60 kg. Mature ewes in early gestation, 20 of each breed, were individually fed the two different silage qualities *ad libitum* in three weeks periods in a 2×2 crossover design. Feed was offered morning and afternoon, and intake was continuously logged throughout the experiment, by an automatic system from BioControl. The results showed significant differences in feed intake between silage qualities. Average daily dry matter intake of early and average silage was 2.48 and 1.84 kg for NWS, and 1.34 and 1.14 kg for ONS. The diurnal feed intake pattern was different between the two silage qualities. The average harvested silage had two distinct peaks during the day, coinciding with feeding hours. Early harvested silage had a more even curve during the day and had higher frequency of eating bouts. The ewes also consumed more of this quality at night. Rumination behaviour was not measured, but the results indicate that silage intake is limited as a result of increased rumination time of low-quality silage. The feed intake pattern was similar for the two breeds, however the ONS had higher frequency of eating bouts, but lower intake per bout. This reflects the anatomically and behaviourally differences between the two breeds, including the ONS having a smaller rumen relative to size. In conclusion, improved silage quality increased eating frequency during both day and night, and breed differences should be accounted for when predicting silage intake.
