Welcome to the EAAP + WAAP + INTERBULL 2023 in Lyon

On behalf of the French Organising Committee, we are very delighted to welcome you to attend the Joint International Congress on Animal Science co-organised by the European Federation of Animal Science (EAAP), the World Association for Animal production (WAAP) and Interbull to be held in Lyon, the capital of the Auvergne-Rhône-Alpes French region, from August 26th to September 1st, 2023.

The general topic of this Congress is 'Climate change, biodiversity and global sustainability of animal production'. Different sessions are jointly organised between the EAAP, WAAP, Interbull and also other partners to cover various areas of knowledge related to animal science, such as genetics, nutrition, physiology, animal health and welfare.

The Auvergne-Rhône-Alpes region covers an area of 69,711 km² in the central-east part of the south of France. It is characterised by diverse natural resources and topographies (including high mountains to the east and volcanos to the west), climates, cultures, folklore, architecture, and languages. The region accounts for 11.9% of the French economic output. It hosts 48,500 farms (with an average of 59 ha), including 51.9% of them for the production of animal products and 10.4% with both plant and animal production. About 20% and 13% of the farms concern the production of beef and milk respectively, and 11% are with sheep, goats or other herbivores. This places the Auvergne-Rhône-Alpes region 3rd in place amongst the other French regions in agriculture. The region had 13% of organic farms, 30% with other labels or quality signs and 30% with short supply chains.

Apart from the outstanding scientific programme, social activities is organised in Lyon, which was the former capital of the Gauls at the time of the Roman empire, a major economic hub during the Renaissance and today the third-largest city and second-largest metropolitan area of France. The city is known as 'the gastronomic capital of the world' and is recognised for its historical and architectural landmarks and for its universities.

The city is also known for its light festival and is a major centre for chemical, pharmaceutical and biotech industries. Several exceptional sites of the region are inscribed on the UNESCO World Heritage List including the historical district of Lyon.

We welcome you and wish you an exceptional stay in Lyon!

Jean-François Hocquette

Senior scientist of INRAE

President of the French Association for Animal Production

The Joint International Congress on Animal Science (EAAP annual congress, WAAP congress and Interbull meeting) is locally co-organised by INRAE (The French National Research Institute for Agriculture, Food, and Environment) and the French Association for Animal Production (AFZ), on behalf of the European Federation of Animal Science (EAAP) and the World Association for Animal production (WAAP) and by "France Génétique Elevage" on behalf of Interbull.

Science for people, life & earth

The French National Research Institute for Agriculture, Food, and Environment (INRAE) is a major player globally in **research and innovation on agriculture, food and the environment**. It is a community of 12,000 people with 273 research, experimental research, and support units located in 18 regional centres throughout France.

Internationally, **INRAE is among the top research organisations in the agricultural and food sciences, plant and animal sciences, as well as in ecology and environmental science**. INRAE's goal is to be a key player in providing the knowledge base supporting the necessary acceleration of agricultural, food and environmental transitions, to address the major global challenges.

The Organization

EAAP (The European Federation of Animal Science) organises every year an international meeting which attracts between 900 and 2,000 people. The main aims of EAAP are to promote, by means of active co-operation between its members and other relevant international and national organisations, the advancement of scientific research, sustainable development and systems of production; experimentation, application and extension; to improve the technical and economic conditions of the livestock sector; to promote the welfare of farm animals and the conservation of the rural environment; to control and optimise the use of natural resources in general and animal genetic resources in particular; to encourage the involvement of young scientists and technicians. More information on the organisation and its activities can be found at www.eaap.org

YoungEAAP

What is the YoungEAAP?

YoungEAAP is a group of young scientists organized under the EAAP umbrella. It aims to create a platform where scientists during their early career get the opportunity to meet and share their experiences, expectations and aspirations. This is done through activities at the Annual EAAP Meetings and social media. The large constituency and diversity of the EAAP member countries, commissions and delegates create a very important platform to stay up-to-date, close the gap between our training and the future employer expectations, while fine-tuning our skills and providing young scientists applied and industry-relevant research ideas.

Committee Members at a glance

- Ines Adriaens (president)
- Jana Obsteter (vice president)
- Giulia Gislon (secretary)

YoungEAAP promotes Young and Early Career Scientists to:

- Stay up-to-date (i.e. EAAP activities, social media);
- Close the gap between our training and the future employer expectations;
- Fine-tune our skills through EAAP meetings, expand the special young scientists' sessions, and/or start online webinars/trainings with industry and academic leaders;
- Meet to network and share our graduate school or early employment experiences;
- Develop research ideas, projects and proposals.

Who can be a Member of YoungEAAP?

All individual members of EAAP can join the YoungEAAP if they meet one of the following criteria: Researchers under 35 years of age OR within 10 years after PhD-graduation

Just request your membership form (ines.adriaens@kuleuven.be) and become member of this network!

Industry Members Club

EAAP started in 2023 a new initiative to create closer connections between European livestock industries and the animal science network. Therefore, the “EAAP Industry Club” was shaped with the specific aim of bringing together the important industries of the livestock sector with our European Federation of Animal Sciences. All companies dealing with animal production (nutrition, genetic, applied technologies, etc.) are invited to join the “EAAP Industry Club” because industries will have opportunity to increase their visibility, to be actively involved in European animal science activities, and to receive news and services necessary to industries. In addition, through the Club, industries will enlarge their scientific network and will receive specific discounts on sponsoring activities.

The Industries that already joined the “EAAP Industry Club” are:

METEX
ANIMAL NUTRITION

The Club gives:

Visibility • Company name and logo at EAAP website and all relevant documents • Slides with name and logo at Official Events • Priority links with EAAP Socials • Invite, through EAAP dissemination tools and socials, people to events organized by your company

• Information disseminated through a brand new Industry Newsletter

Networking • Joining the Study Commissions and Working Groups • Suggest topics to be considered for Annual Meetings Scientific Sessions • Organize Professional Panel through the EAAP platforms

Economic Benefits • One free registration to each Annual Meeting and at every meeting organized by EAAP • Five individual memberships at no cost • Many possible discounts (~30%) to increase company visibility through: EAAP Newsletter, EAAP website, EAAP Annual Meetings and workshops

• Support young scientist by sponsoring scholarships named by the company • Co-Organize and sponsor webinars

Make yourself more visible within the livestock industry via the animal science network!

For more information please contact eaap@eaap.org

75th Annual Meeting of the European Federation of Animal Science

Florence, Italy, September 1st-5th, 2024

Organizing Committees

The 75th EAAP annual meeting is organized by the Italian Association of Animal Science and Production (ASPA).

At last... a trace mineral source that improves digestibility!

Are your trace minerals making your dairy cows efficient?

Increasing feed efficiency of dairy cows means more milk is being produced out of the same amount of feed. For optimal performance, cows need a healthy rumen that digests fibre efficiently.

Peer reviewed research shows that completely replacing sulphates with IntelliBond improves fibre digestibility^[1,2,3,4,5,6,7,8,9] and can increase milk production^[9,10].

Ask your nutritionist about the benefits of switching to a diet 100% free from sulphate trace minerals.

Founded on 9 October 1979 at the initiative of representative organisations in the cattle sector, INTERBEV was recognised on november 18th, 1980 as an interbranch organisation for meat and livestock by ministerial decree.

Its role today is to defend and promote the common interests of both breeding and small-scale, industrial and commercial activities within the meat sector, represented by 22 National Organisations of all industry sections. INTERBEV does this by way of five species specific sections and this ensures the development and promotion of each sector: bovines, calves, sheeps, horses and goats. INTERBEV is represented in the various regions of France by its 12 Regional Committees, which are responsible for putting into place the inter-professional strategies as well as relaying and adapting any national communications on a local level.

The inter-professional organisation's strategic base set up by INTERBEV in 2017, is a collective approach to social responsibility, integrating the industry's plans set out at the French National Food Conference.

This strategy, called PACTE, is based on 5 core values: Progress , Future, Dialogue, Transparency and Expertise .

Its objective is to provide a global response to the expectations of society and those involved in the industry in terms of good production and consumption practices, with evidence and guarantees in support of this. It aims to highlight the strengths of the sector, to identify areas for improvement by working particularly with environmental and animal welfare NGOs and to use collective tools, in order to provide sustainable food.

This approach is under the guidance of the internationally recognised ISO 26000 standard, entitled Social Responsibility. In 2018 INTERBEV was the first food industry inter-professional organisation to be awarded a level 3 out of 4 AFNOR certificate "CSR commitment confirmed", later confirmed in 2021.

Scientific programme EAAP 2023

Sunday 27 August 2023 9.00 – 18.00	Monday 28 August 2023 8.30 – 13.00
Session 01 WAAP Plenary Session Chair: Chemineau 9:00 – 12:30 Control of green house gas emissions in ruminants farming Chair: Peyraud / Mottet 14:00 – 18:00 Biodiversity as a lever for sustainable animal production Chair: Rieu / Gauly	Session 02 Sustainable livestock farming – defining metrics and rationalising trade-offs? – Part 1 Chair: Lee / O'Mara Session 03 Up side and down side of 'genomic selection' Chair: Miglior / Jornaux Session 04 Adaptation of breeding strategies and genetics to climate change, right animal for right environment Chair: Kargo / Sturaro Session 05 Climate care dairy farming: follow up – Part 1 Chair: Galama / Rees Session 06 Production of high quality animal products and implementation of new technologies in animal husbandry Chair: Georgieva / Hocquette Session 07 Challenges of fish nutrition for sustainable aquaculture Chair: Medale / Skiba Session 08 Various topics in pig production Chair: Trevisi / Vigors Session 09 Insect applications Chair: Sanchez / Gligorescu Session 10 Impact of epigenetics and genetics in determining animal physiology Chair: Jammes Session 11 Improving pig welfare in conventional production systems Chair: Gottardo / Blanco Penedo Session 12 Technologies for outdoor systems: which application and opportunities? Chair: Maroto-Molina / Gautier Session 13 Innovations and technological advancements in small ruminant production with particular emphasis in Mediterranean semi-extensive or extensive systems Chair: Hadjipavlou / Lauvie

Monday 28 August 2023 14.00 – 18.00	Tuesday 29 August 2023 8.30 – 12.30
Session 14 Sustainable livestock farming – defining metrics and rationalising trade-offs? – Part 2 Chair: Lee / O'Mara Session 15 Breeding for climate change – mitigation Chair: Pszczola / Neumann Session 16 Alternative and new feed resources to reduce feed/food competition and enhance circularity of livestock production Chair: Ranilla García / Stergiadis Session 17 Climate care dairy farming: follow up – Part 2 Chair: Edouard / Becciolini Session 18 Carcass grading for quality and efficiency – underpinning future sustainability of beef and lamb Chair: Pethick / Neveu Session 19 Advances in nutritional modelling and feeding systems (in memory of Daniel Sauvant) Chair: Baumont / Cannas Session 20 Early career competition 'Innovative approaches to pig and poultry production', supported by Wageningen Academic Publishers Chair: Vigors / Nilsson Session 21 Insects as feed: sustainability, legislation and safety Chair: Veldkamp / Barbosa Session 22 Environmental stress: mitigating the adverse effects on animal physiology Chair: Zachut Session 23 Improving animal welfare in conventional production systems Chair: Minozzi / Trocino Session 24 New traits and proxies from sensor technologies for breeding purposes Chair: Pocrnic / Lourenco Session 25 Molecular measures of diversity and their role in monitoring and management of breeds Chair: Danchin / Fernandez	Session 26 EAAP Plenary Session, Leroy and WAAP Awards Lectures Chair: Casasús

Tuesday 29 August 2023	Wednesday 30 August 2023 8.30 – 13.00
14.00 – 15.00 Poster session	Session 41 Open the black box: using omics to better understand biological interpretation of complex traits Chair: Tiezzi / Pocrnic
15.00 – 18.30	
Session 27 Breeding programs & strategies Chair: Egger-Danner / Martin Session 28 Breeding for improved animal health and welfare Chair: Kargo / Tiezzi Session 29 Innovative animal products and farming systems oriented to new consumer demand and trend Chair: Resconi / Realini Session 30 Looking back, looking forward – Research on Beef production and quality in China and France (CSBF) and between Australia-France-China (The Triangle Project) Chair: Liu / Pethick Session 31 Pasture based solutions to realise a role for ruminants in a sustainable food system Chair: Boland / Baumont Session 32 Beyond rumen: role of nutrition in cattle's intestinal health Chair: Kreuzer / Pinotti Session 33 Horses in farms and territories: challenges and new solutions Chair: Vial / Tapprest Session 34 Sustainable pig and poultry production, including the use of water Chair: Bee / Brodziak Session 35 Is there a future for experimental animal research in Europe and, if so, what is it? Chair: Chalvon-Demersay / Van Milgen Session 36 Technologies in insect production + controlling quality Chair: Heckmann / Deruytter Session 37 Omics and integrative analyses towards understanding inter-organ cross-talk and whole body physiology of livestock Chair: Louveau Session 38 Equal opportunities and open communication for early career scientists Chair: Pszczola / Sell-Kubiak / Newton / Obsteter / Gislou Session 39 TechCare and ClearFarm: pilots on PLF tools for monitoring animal welfare Chair: Morgan-Davies / Llonch Session 40 The transition from pregnancy to lactation in dairy goats and sheep Chair: Hernández-Castellano / Salama	Session 42 Animal genetics to address food security and sustainability Chair: Soelkner / Granados Session 43 Better calves for better farms: how the young stock can be the key to success Chair: Costa / Keatinge Session 44 Building on a resilient dairy sector – from animal, farm and regional perspective – Part 1 Chair: Kuipers / Schuenemann Session 45 Transformation of livestock practices in response to society's expectations on animal welfare, market demand for animal products and environmental issues Chair: Thenard / Boyle Session 46 Innovation in ruminant nutrition and feeding Chair: Stergiadis / Alvarez Rodriguez Session 47 One-health, one nutrition, one Earth: role of nutrition in livestock production Chair: Latifa / Weill Session 48 How can poultry farming systems evolve to meet the major societal and environmental challenges? Chair: Stadnicka / Meda Session 49 Monoguthealth – Part 1 Chair: Bee / Trevisi Session 50 Insect genetics and reproduction Chair: Sandrock / Maya Session 51 Leveraging the microbiome for resilience and sustainability in ruminant production – insights from H2020 HoloRuminant Chair: Kenny / Morgavi Session 52 Nitrogen management in the dairy supply chain and other tools to improve the efficiency and sustainability of cattle farming Chair: Righi / Tsiplakou Session 53 PLF for health and welfare – Part 1 Chair: Maselyne / Calderon Diaz Session 54 Life Green Sheep and Farm management to adapt goat and sheep farming to climate change: solutions and experiments Chair: Throude / Satzori

Wednesday 30 August 2023	Thursday 31 August 2023
14.00 – 15.00 Poster session	8.30 – 12.00
15.00 – 18.30	
Session 55 Breeding for climate change – adaptation Chair: Sell-Kubiak / Pszczola Session 56 Establishing breeding programs in extensive systems (including developing regions) with climate change in mind Chair: Leroy / Berg Session 57 Grassland management and grassland-based feeding systems for efficient and sustainable milk and meat production Chair: Berard / Probo Session 58 The future of animal products: improved quality management, more alternatives or cell-based products? Chair: Ellies-Oury / Chriki Session 59 Environmental challenges of cattle tropical grazing systems Chair: Dossa / Salgado Session 60 Minerals in animal nutrition: supplementation – Part 1 Chair: Alvarez Rodriguez / Windisch Session 61 Resilient livestock farming systems in the face of climate and other global challenges – adaptation and mitigation Chair: Sturaro / Pouloupoulou Session 62 Poultry and pig low-input and organic production systems' welfare Chair: Daş / Holinger Session 63 Monoguthealth – Part 2 Chair: Bee / Trevisi Session 64 Project session: Farmyng Chair: Kihanguila / Gasco Session 65 Remote sensing applied to livestock farming: discovering physiological and ethological clues to optimize productive performance and animal welfare Chair: Montanholi Session 66 Innovation in non-ruminant nutrition and feeding Chair: Alvarez Rodriguez / Stergiadis Session 67 PLF for health and welfare – Part 2 Chair: Pastell / Stygar Session 68 Small Ruminant Technologies (Sm@RT) and Thematic network EuroSheep Chair: Morgan-Davies / Grisot	Session 69 Methods & genomic prediction Chair: Sell-Kubiak / El-Ouazizi Session 70 Genetic parameters & GWAS Chair: Egger-Danner / Martin Session 71 Building on a resilient dairy sector – from animal, farm and regional perspective – Part 2 Chair: Brocard / Klopčič Session 72 What are the stakeholder and societal expectations of intrinsic and extrinsic quality of animal products? Chair: Martin Session 73 Molecules in animal nutrition: over and above building blocks Chair: Van Milgen / Geraert / Mercier Session 74 Balancing the feed for the economy, the environment, and society Chair: De Campeneere / Bruggeman Session 75 Livestock based circularity for health and sustainable land use Chair: Siqueira / De Olde Session 76 Humans and horses: from One Health to One Life perspectives Chair: Evans / Montovani Session 77 Trade-offs between health, production and welfare in pigs and poultry: which tools do we have and which research is needed? Chair: Nilsson / Millet Session 78 Insect nutrition (substrates) & insect health Chair: Biasato / Lefebvre Session 79 Improved insight into the reproductive physiology of livestock Chair: Kenny Session 80 Animal behaviour Chair: Dantas / Boyle Session 81 Precision feeding Chair: Druyan / Bloch Session 82 Product quality and efficiency of small ruminant production systems Chair: Hernández-Castellano / Tsiplakou
	12.00 – 13.00 Commission meetings Cattle / Genetics / Health and Welfare / Horse / Insects / LFS / Nutrition / Physiology / Pig / PLF / Sheep and Goats

Thursday 31 August 2023

14.00 – 18.00

Session 83

Genetic diversity

Chair: Neumann / Schiavo

Session 84

EuroFAANG: genotype-to-phenotype
research across Europe and beyond

Chair: Clark / Kuhn

Session 85

Climate care dairy farming: herd management – Part 3

Chair: Cieślak / Kuipers

Session 86

How to address stakeholder and societal expectations
of intrinsic and extrinsic quality of animal products?

Session 87

Carbon sources and sinks within
global livestock systems

Chair: Salami / Pouloupoulou

Session 88

Minerals in animal nutrition: basal diet – Part 2

Chair: Alvarez Rodriguez / Windisch

Session 89

Explainable models and artificial intelligence
supporting farming decisions

Chair: Foy / Odintsov

Session 90

Genetics in horses

Chair: Stock / Cox

Session 91

Nitrogen excretion and ammonia emission
in pig and poultry production

Chair: Millet / Brodziak

Session 92

Inflammation and energy metabolism
in young and adult livestock

Chair: Sauerwein

Session 93

Recent advances on in vitro systems (from cell culture
to in vitro digestion methods): relevance as alternatives
to animal experimentation for livestock research

Chair: Louveau

Session 94

Free communications in animal health and welfare

Chair: Boyle / Calderon Diaz

Session 95

Happy Delivering innovative and holistic milk
based monitoring and decision-making PLF
tools – collaboration with HappyMoo

Chair: Gengler / Knijn

Session 96

ERANET-funded 'Grass To Gas' and

EU-funded 'SMARTER' projects

Chair: Conington / Vouraki

Scientific programme

Session 01. WAAP Plenary Sessions

Date: Sunday 27 August 2023; 9.00 – 18.00

Chair: Chemineau / Peyraud / Mottet / Rieu / Gauly

Theatre Session 01

invited	The real place of livestock in GHG emissions and their control for climate change <i>K. Johnson</i>	149
invited	Global emissions from livestock systems: updated baselines, projections, and mitigation options <i>D. Wisser, G. Tempio, A. Falcucci and G. Cinardi</i>	149
invited	Genetic control of ruminant methane emissions in livestock <i>A.E. Van Breukelen, M.N. Aldridge, R.F. Veerkamp and Y. De Haas</i>	150
invited	Effective strategies to mitigate enteric methane emissions by ruminants <i>C. Arndt</i>	150
invited	Tannins, legumes and methane production by ruminants <i>H.H. Lardner</i>	151
invited	Enteric methane reduction in ruminants by early-life interventions <i>D.P. Morgavi</i>	151
invited	Sustainable intensification of animal production with silvopastoral systems <i>J. Chára</i>	152
invited	Sustainability of low-input livestock systems <i>A. Mottet</i>	152
invited	Agroecological transformation of tropical livestock production through integrating improved forages <i>A.M.O. Notenbaert</i>	153
invited	Livestock-wildlife conflicts: a struggle for land use and conservation in the U.S. Mountain West <i>J.B. Taylor and H.N. Wilmer</i>	153
invited	Community-based breeding programs (CBBP): platforms for genetic improvement and biological discovery <i>J.M. Mwacharo, A. Haile and B. Rischkowsky</i>	154

Session 02. Sustainable livestock farming – defining metrics and rationalising trade-offs? – Part 1

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Lee / O'Mara

Theatre Session 02

invited	'Sustainable livestock systems': what does this mean? – welcome and introduction <i>F. O'Mara and M. Lee</i>	154
invited	Friend or Foe? The role of animal-source foods in healthy and environmentally sustainable diets <i>L. Merbold, T. Beal, C. Gardner, M. Herrero, L. Iannotti, S. Nordhagen and A. Mottet</i>	155

invited	The economic sustainability of dairy production systems in the EU and beyond <i>F. Thorne, E. Dillon, T. Donnellan, P. Jeanneaux, R. Jongeneel and L. Latruffe</i>	155
invited	Methods to assess the sustainability of livestock systems: challenges and opportunities <i>E. De Olde</i>	156
invited	SustAinimal – a multi-actor knowledge centre for livestock in future Swedish food systems <i>M. Hetta, S. Agenäs, D.J. De Koning, H. Oscarsson, P. Peetz Nielsen and A. Wallenbeck</i>	156
invited	Breeding livestock for sustainable systems <i>P.W. Knap, K.M. Olson and M.A. Cleveland</i>	157
invited	Panel discussion (morning) <i>A. Granados and A.S. Santos</i>	157
	Use of grazing with dairy goats to design sustainable food systems <i>H. Caillat, E. Bruneteau and B. Ranger</i>	158
	Benefits and limits of farm animals to control herbage mass, pests and weeds in orchards: a review <i>G. Maillet, A. Dufils, F. Angevin, S. Ramonteu, J.L. Peyraud and R. Baumont</i>	158
	A new concept for agro-ecological efficiency at different scales of ruminant production systems <i>H. Nguyen-Ba, P. Veyssset and A. Ferlay</i>	159

Session 03. Up side and down side of ‘genomic selection’

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Miglior / Jornaux

Theatre Session 03

invited	Issues and perspectives in genomic selection in limited size breeds: the case of Italian Simmental <i>N.P.P. Macciotta, L. Degano, D. Vicario and A. Cesarani</i>	159
	Impact of genomic selection on genetic diversity in five European local cattle breeds <i>J.J. Winding, T.H.E. Meuwissen, P. Croiseau, G. Restoux and R. Bonifazi</i>	160
	Accounting for sequential genomic selection in broiler breeding <i>J. Hidalgo, D. Lourenco, S. Tsuruta, V. Breen, W. Herring and I. Misztal</i>	160
	Changes in the genome due to genomic selection in two pig populations <i>Y.C.J. Wientjes, M.P.L. Calus, P. Bijma, A.E. Huisman and K. Peeters</i>	161
invited	Practical approaches to managing increased homozygosity caused by genomic selection <i>C. Baes, C. Obari, B. Makanjuola, C. Rochus, C. Maltecca, F. Schenkel and F. Miglior</i>	161
invited	Positive and negative effects of genomic selection <i>I. Misztal</i>	162
	Storing and analysing a million genomes on a desktop computer <i>G. Gorjanc, J. Obsteter, G. Mafra Fortuna, R. Ros-Freixedes, M. Johnsson and I. Pocrnic</i>	162
	Large scale screening for genetic defects in Holstein cattle using transmission disequilibrium test <i>F. Besnard, M. Boussaha, H. Leclerc, J. Jourdain, D. Boichard and A. Capitan</i>	163
	Genomic selection strategies and their potential to maintain rare alleles and de-novo mutations <i>M.F. Schrauf, Y.C.J. Wientjes, H.A. Mulder and J. Vandenplas</i>	163

Genomic prediction with selected sequence variants in gestation length of New Zealand dairy cattle <i>Y. Wang, K.M. Tiplady, E.G.M. Reynolds, M.A. Nilforooshan, C. Couldrey and B.L. Harris</i>	164
Novel runs of homozygosity islands in the Finnish Ayrshire population <i>K. Sarviaho, P. Uimari and K. Martikainen</i>	164

invited

Sometimes we win, sometimes we lose: the consequences of genomic selection <i>D. Lourenco, F. Guinan, G. Wiggans, J. Dürr, S. Tsuruta and I. Misztal</i>	165

Session 04. Adaptation of breeding strategies and genetics to climate change, right animal for right environment

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Kargo / Sturaro

Theatre Session 04

Old, native cattle breeds; from critically endangered to successfully utilized in niche productions <i>N. Svartedal and O. Vangen</i>	165
Kenyan pastoralists and climate change: breeding as a possible adaptation strategy? <i>J. Jandl, M. Wurzinger, L. Gichuki, B. Habermann, R. Siamito and T.A. Crane</i>	166
Adapting climate-smart breeding practices for small ruminants in pastoral communities of Kenya <i>J.M. Ojango, E. Oyieng, J.W. Gitau, N. Ndiwa, J. Gachora and A.W.T. Muigai</i>	166
Zooarchaeology for conservation biology: introducing ARETI <i>A. Spyrou, G. Hadjipavlou and D. Bradley</i>	167
A robustness proxy based on variations in energetic allocation to growth in Duroc fattening pigs <i>G. Lenoir, L. Flatres-Grall, R. Muñoz-Tamayo, I. David and N.C. Friggens</i>	167
Genetic architecture of skin histology with implications for heat tolerance in beef cattle <i>R.G. Mateescu, F.M. Rezende, K.M. Sarlo Davila, A. Hernandez, A.N. Nunez Andrade, G.A. Zayas, E.E. Rodriguez and P.A. Oltenacu</i>	168
Ewe-lamb allocation trade-offs shape ewe lifetime production depending on dietary energy scarcity <i>M. Hiltbold and F. Douhard</i>	168
System performance of three dairy-beef genotypes divergent in carcass merit <i>N. Byrne, D. Fahy, M. Kearney and N. McHugh</i>	169
Characterization and main factors of variation of milk production in suckler cows <i>B. Sepchat, M. Barbet and A. De La Torre</i>	169
Mediterranean Baladi cattle presents adaptive traits to cope with climate change in the Near East <i>A. Shabtay, E. Lipkin, M. Soller, F. Garcia-Solares, J. Sölkner, E. Shor-Shimoni, A. Bagnato, M.G. Strillacci and M. Cohen-Zinder</i>	170
Effect of some environmental variables on milk traits in dairy sheep <i>F. Correddu, A. Cesarani, G. Gaspa, I. Peana, G. Fois, C. Dimauro and N.P.P. Macciotta</i>	170
Genomic tolerance to harsh climate conditions in beef cattle as a result of cross-breeding program <i>R. Tian and H. Asadollahpour Nanaei</i>	171
Expected selection responses in breeding plans aiming to limit environmental impacts of trout farming <i>S. Pouil, J. Aubin and F. Phocas</i>	171

Defining resilience traits in sheep from fibre diameter variation of wool <i>E.G. Smith, S.F. Walkom, D.J. Brown and S.A. Clark</i>	172
Evaluating the impact of uncertainty in estimated breeding values on optimal contribution selection <i>I. Pocrnic, J. Ortiz and G. Gorjanc</i>	172
Increasing genetic gain without compromising diversity by selection based on mating qualities <i>T.A.M. Niehoff, J. Ten Napel, P. Bijma, T. Pook, Y.C.J. Wientjes, B. Hegedűs and M.P.L. Calus</i>	173

Session 05. Climate care dairy farming: follow up – Part 1

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Galama / Rees

Theatre Session 05

invited Holistic perspectives on climate care cattle farming <i>G. Van Duinkerken</i>	173
Climate care farming aspects in China <i>W. Wang</i>	174
Producer adoption of climate-smart agriculture practices on U.S. grazing lands <i>A. Blair, K. Cammack, H. Menendez, J. Brennan and K. Ehlert</i>	174
Assessing impacts of new legislation on Dutch dairy farms using a revised linear programming model <i>A. Van Der Linden, L.M. Alderkamp, C.W. Klotwijk, G. Holshof, N. Van Eekeren, F. Taube and C.E. Van Middelaar</i>	175
Gaseous emissions (building, storage, pasture) of dairy systems combining or not grazing and housing <i>N. Edouard, X. Vergé, C. Flechard, Y. Fauvel and A. Jacotot</i>	175
Agri-food and net zero: a science-policy-society perspective <i>R. McGuire, S. Huws, C. Foyer, P. Forster, M. Welham, L. Spadavecchia, D. Curry and N. Scollan</i>	176
Testing the effects of grassland swards for yield, greenhouse gas emissions and soil health <i>P.R. Hargreaves, D.Z. Kreismane, A. Dorbe, K. Klumpp, J. Bloor, A. Cieślak, M. Szumacher, A. Szejner and R.M. Rees</i>	176
How to mitigate methane and ammonia emissions at the farm level with innovative approaches <i>P.J. Galama, H.J. Van Dooren, H. De Boer and C. Schep</i>	177
Effect of mitigation measures on GHG and ammonia emissions of pilot farms in European countries <i>D. Ruska, K. Naglis-Liepa, P. Hargreaves, A. Lenerts, M. De Vries, P. Galma, A. Kuipers, A. Cieslak, J. Bell, R. Rees, V. Juskiene and M. Skorupka</i>	177
Economic aspects of mitigation practices on pilot dairy farms in Europe <i>K. Naglis-Liepa, D. Ruska, A. Lenerts and D. Kreismane</i>	178
Specialized or integrated systems: on-farm eco-efficiency of dairy farming in northern Germany <i>R. Loges, T. Reinsch, I. Vogeler, C. Kluss and F. Taube</i>	178
Modelling methane emission from dairy cows, barn, and storage <i>S. Lashkari, F.R. Dalby and C.F. Børsting</i>	179
Impact of sorbent application on NH ₃ and CO ₂ and CH ₄ gas emissions from dairy cattle manure <i>V. Juskiene, R. Juska, G. Kadziene, D. Stankeviciene and R. Juodka</i>	179

Poster Session 05

Greenhouse gas emissions on dairy farms in Slovenia 180
M. Klopčič, T. Perčič, M. Bric, S. Rogina, G. Šen, T. Kramer, J. Klopčič, D. Drašler and A. Dolinar

Session 06. Production of high quality animal products and implementation of new technologies in animal husbandry

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Georgieva / Hocquette

Theatre Session 06

'Greenanimo' – green future through research 180
S.Y. Georgieva

PLS-DA analysis on hand-held spectrometer for on-line prediction of beef marbling in slaughterhouses 181
M. Kombolo, A. Goi, M. Santinello, N. Rampado, S. Atanassova, J. Liu, P. Faure, L. Thoumy, A. Neveu, D. Andueza, M. De Marchi and J.-F. Hocquette

Application of computed tomography and hyperspectral images for enhanced meat quality evaluation 181
T. Stoyanchev, I. Penchev, S. Georgieva, A. Daskalova and S. Atanassova

Effect of husbandry factors on marbling deposition 182
A. Nicolazo De Barmon, I. Legrand, J. Normand and J.J. Bertron

Effect of birth type on meat quality in Ile-de-France lambs 182
E. Achkakanova, I. Penchev and S. Georgieva

Relationships between lamb feed efficiency, rumen volume and carcass quality measured by CT scanning 183
N.R. Lambe, A. McLaren, K.A. McLean, J. Gordon and J. Conington

Do biomarkers of residual feed intake in beef cattle remain consistent regardless of feeding level? 183
G. Cantalapiedra-Hijar, K. Nedelkov, P. Crosson and M. McGee

Practical application of Observer XT software for behaviour and welfare research in sheep and cattle 184
N.A. Bozakova and M. Halil

Software tools and technologies used to study animal behaviour-benefits and capabilities of Observer 184
M. Halil, N. Bozakova and S. Georgieva

Animal welfare: from research to practice 185
I. Veissier, V. Brunet, D. Ledoux and A. De Boyer Des Roches

Effects of warm climatic periods on dairy cow behaviour and welfare in a maritime European climate 185
M.J. Haskell, I. Sullivan, M. March and L. Shewbridge-Carter

Behavioural and hormonal effects of intensive sheep farming on milking behaviour in a milking parlour 186
I. Nedeva, T. Slavov, V. Radev, S. Georgieva and I. Varlyakov

Combining cattle and sheep in a grassland-based system: which effects for system multiperformance? 186
S. Prache, K. Vazeille, B. Sepchat, P. Note, P. Veyssset and M. Benoit

Milking temperament and its relation with test day milk yield in Bulgarian Murrah buffaloes 187
T. Stepancheva, I. Marinov and Z. Gergovska

Poster Session 06

Introduction of lupins in lamb diets: effects on carcass, meat quality and intramuscular fatty acids <i>M. Almeida, S. Garcia-Santos, D. Carloto, A. Arantes, J. Lorenzo, J.A. Silva, V. Santos, J. Azevedo, C. Guedes, L. Ferreira and S. Silva</i>	187
Lipid composition of dromedary camels (<i>Camelus dromedarius</i>) raised in extensive and intensive system <i>M. Lamraoui, J. Pestana, M. Costa, C. Alfaia, Y. Khelef, N. Sahraoui, A.M. Almeida and J.A.M. Prates</i>	188
Effective application of UAVS in modern livestock agriculture <i>T. Petrova, Z. Petrov and M. Marinov</i>	188
Effects of dietary beet pulp on rumen fermentation, beef quality, and intramuscular adiposity <i>M. Baik, S.H. Lee and S.Y. Kim</i>	189
The identification of high-quality <i>Perilla frutescens</i> Tan lamb meat by multi-metabolomics analyses <i>Y. Yu, B.Y. Zhang, X.Z. Jiang, Y.M. Cui, H.L. Luo and B. Wang</i>	189
Effect of feeding garlic-citrus supplement on carcass characteristics and fatty acid profile of beef <i>M.E. Eckhardt, T. Brand, S.A. Salami, B.M. Tas, J.F. Legako, T.E. Lawrence and L.W. Lucher</i>	190
Main microclimatic indicators in a milking parlor for dairy cows <i>D. Dimov, T. Penev, I. Marinov, J. Mitev, T. Miteva and M. Stoyanov</i>	190
Estimation of rib composition and intramuscular fat from DXA or smartphone imaging in crossbred bull <i>C. Xavier, B. Meunier, I. Morel, Q. Delahaye, Y. Le Cozler, M. Bonnet and S. Lerch</i>	191
Perception of beef by the Algerian consumer <i>M. Sadoud and J.F. Hocquette</i>	191
Effect of intramammary infection on milk protein profile measured at the quarter level in dairy cows <i>V. Bisutti, D. Giannuzzi, A. Vanzin, A. Toscano, M. Giancesella, S. Pegolo and A. Cecchinato</i>	192
Antioxidant and anti-hypertensive properties of acid whey from Greek yoghurt <i>E. Dalaka, A. Vaggeli, G.C. Stefos, I. Palamidi, A. Savvidou, I. Politis and G. Theodorou</i>	192

Session 07. Challenges of fish nutrition for sustainable aquaculture

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Medale / Skiba

Theatre Session 07

invited Recent developments in aquaculture feeds – an industry perspective <i>A. Obach</i>	193
Nutritive value of soybean meals from different origins fed to Nile tilapia <i>N.V. Nguyen, H. Le, V.K. Tran, D.H. Pham, T.L.T. Tran, J.M. Hooft and D.P. Bureau</i>	193
EcoXtract® green solvent increases rainbow trout performances and decreases susceptibility to VHSV <i>D. Rigau, N. Abdedaim, T. Rochat, L. Jep, F. Terrier, P. Boudinot, S. Skiba-Cassy, L. Jacques and C. Langevin</i>	194
Environmental impact of aquafeed for rainbow trout containing alternative protein meals <i>M. Berton, C. Fanizza, V. Stejskal, M. Prokešová, M. Zare, H.Q. Tran, F. Brambilla, E. Sturaro, G. Xiccato, A. Trocino and F. Bordignon</i>	194

invited	New strategies for fish nutrition <i>S. Skiba-Cassy, J. Roy, L. Marandel, E. Cardona and F. Medale</i>	195
	Rainbow trout hepatic cell lines reveal differences of DL-Methionine and DL-HMTBa function <i>M. Klünemann, K. Pinel, K. Masagounder, I. Seilliez and F. Beaumatin</i>	195
	Millennial salmon – sustainable salmon feed using black soldier fly meal <i>M.L. Lefranc, H.B. Bergoug and K.K. Kousoulaki</i>	196
	Digestibility of ingredients derived from food by-products (insect and single-cell) in Asian seabass <i>R. Le Boucher, W. Chung, J. Ng Kai Lin, L. Tan Shun En, C.S. Lee and C. Wu</i>	196
invited	Specialty feeds to enhance the health value of farmed fish <i>J. Dias, A. Ramalho-Ribeiro, A. Gonçalves, M.T. Dinis and P. Rema</i>	197

Poster Session 07

	Evaluation of growth performance of pure <i>Clarias gariepinus</i> and its hybrid in monosex culture <i>F.O. Olukoya, O.T.F. Abanikanda, K.O. Kareem-Ibrahim, M.S. Hedonukun and S.O. Adebambo</i>	197
	The effect of feeding on dissolved oxygen and turbidity in trout cultivated in an aquaponics <i>I. Sirakov, K. Velichkova, A. Asenov and R. Rusev</i>	198
	Factors affecting feeding of fish cultivated in recirculation aquaculture system <i>K. Velichkova and I. Sirakov</i>	198
	Effect of mycotoxin co-occurrence on zootechnical performance and health indices of <i>Sparus aurata</i> <i>C. Papadouli, S. Vardali, T. Karatzinos, M. Maniaki, P. Panagiotaki, D. Kogiannou, C. Nikoloudaki, I. Nengas, M. Henry, G. Rigos and E. Golomazou</i>	199
	Fasting influences on several blood chemistry changes: indicators of malnutrition in Nile tilapia <i>S. Boonanuntanasarn, P. Pasomboon, S. Seedum and W. Auppakhun</i>	199
	Technological developments and 3D imaging for the diagnosis of aquaculture fish diseases <i>M. Merhaz, M. Frétaud, D. Rigau deau and C. Langevin</i>	200
	Comparative analyses of growth parameters of pure and hybrid African Catfishes fed two feed types <i>O.T.F. Abanikanda, F.O. Olukoya, K.O. Kareem-Ibrahim, S.M. Adebambo and M.S. Hedonukun</i>	200
	Influence of feeding frequency on growth parameters of African Catfish <i>F.O. Olukoya, K.O. Kareem-Ibrahim, A.A. Jimoh, K.O. Bakare, Z.F. Shopeyin, S.A. Shitta and O.T.F. Abanikanda</i>	201
	The impact of a probiotic supplementation in aquaculture – a bioinformatic modelling <i>A. Brzoza, L. Napora-Rutkowski, M. Mielczarek, T. Kaminska-Gibas, T. Suchocki and J. Szyda</i>	201

Session 08. Various topics in pig production

Date: Monday 28 August 2023; 8.30 – 13.00
Chair: Trevisi / Vigors

Theatre Session 08

	Role of daily feeding rhythms in the genetics of feed efficiency in growing pigs <i>H. Gilbert, L. Agboola, A. Foury, M. Teissier, F. Gondret and M.P. Moisan</i>	202

Using sequence variants to detect SNP and pathways affecting pig gut microbiota and feed efficiency <i>H. Gilbert, M. Teissier, K. Fève, S. Legoueix, Y. Billon, V. Déru, A. Aliakbari, J. Bidanel, O. Zemb, Y. Labrunet and J. Riquet</i>	202
Using digestive efficiency to improve feed efficiency in pig breeding schemes <i>V. Déru, M.J. Mercat, D. Picard, B. Ligonésche, G. Lenoir, L. Flatrès-Grall, F. Ytournal, J. Bidanel and H. Gilbert</i>	203
Can automatic records of activity predict maternal ability and health in sows? <i>K. Nilsson, A. Bergh and A. Wallenbeck</i>	203
Cross-breeding strategies to optimize litter size – a way to improve piglet survival? <i>K. Nilsson and A. Wallenbeck</i>	204
Genetic parameters for genetic variance uniformity in Swiss pigs' birth weight <i>C. Kasper, A. Lepori, J.P. Gutiérrez, N. Formoso-Rafferty, E. Sell-Kubiak and I. Cervantes</i>	204
A multivariate gametic model for the analysis from reciprocal crosses for two Iberian varieties <i>H. Srihi, D. López-Carbonell, N. Ibáñez-Escriche, J. Casellas, P. Hernández, S. Negro and L. Varona</i>	205
Impact of vaccination against GnRF on growth performance and meat quality of gilts at market weight <i>N. Quiniou, P. Chevillon and F. Colin</i>	205
Using different gas mixtures for pig stunning – influence on meat quality and gene expression <i>J. Gelhausen, T. Krebs, T. Friehs, J. Knöll, I. Wilk, D. Mörlein and J. Tetens</i>	206
Lean tissue grows slower in the belly and loin regions of Australian domestic pork carcasses <i>L.T. King, F. Anderson, M. Corlett, A. Williams and G.E. Gardner</i>	206
Carcass characteristics and boar taint in entire male pigs from commercial French organic farms <i>S. Lombard, A. Roinsard and A. Prunier</i>	207
Boot swabs to assess efficiency of cleaning and disinfection of slatted floors in pig barns <i>R.H. Mateus-Vargas, N. Kemper, K. Butenholz, N. Volkmann, C. Sürle and J. Schulz</i>	207
The impact of temperature on transmission of African swine fever in contaminated livestock vehicles <i>Y. Gao, A. Boklund, L. Nielsen, L. Alban and M. De Jong</i>	208
Porcine ear necrosis is associated with social behavior and blood biomarkers in weaned pigs <i>T. Nicolazo, C. Clouard, C. Teixeira Costa, G. Boulbria, A. Lebre, V. Normand and E. Merlot</i>	208
Pelleting and botanical source influence starch utilization in growing pigs <i>A. Agouros, M. Le Gall, K. Quéméneur, Y. Lechevestrier, L. Montagne, N. Quiniou and E. Labussière</i>	209
Effects of a blend of phyto-genic feed additives on performance in fattening pigs fed liquid feed <i>A. Samson, W. De Gaiffier, E. Janvier and S. Constantin</i>	209

Poster Session 08

Genetic parameters of digestive coefficients in three pig breeds <i>C. Carillier-Jacquin, P. Ganier, J. Bidanel, C. Hassenfratz, B. Blanchet, V. Deru, E. Labussiere and H. Gilbert</i>	210
Breeding for uniformity in piglet birth weight to improve survival <i>C. Kasper, A. Lepori, J.P. Gutiérrez, N. Formoso-Rafferty, E. Sell-Kubiak and I. Cervantes</i>	210
Genetic lines influence carcass traits and quality of pork <i>X. Li, M. Ha, R. Warner, R. Hewitt, D. D'Souza and F. Dunshea</i>	211

Boar taint: pedigree-based BLUP and genomic BLUP, and associations with green-ham quality traits <i>S. Faggion, P. Carnier and V. Bonfatti</i>	211
Diversity of pig breeds reared in the Czech Republic <i>E. Krupa, Z. Krupová, E. Žáková, N. Moravčíková and I. Vrtková</i>	212
Wild boar and domestic pig identification based on GBS study <i>A. Koseniuk, G. Smołucha, A. Gurgul, T. Szmatoła, M. Oczkowicz and A. Radko</i>	212
Structural analysis of the HK2 gene in the aspect of pigs performance and meat quality parameters <i>K. Woźniak, A. Terman, D. Polasik, G. Żak, M. Tyra and K. Ropka-Molik</i>	213
Methods to maximize accuracy of selection in maternal genetic model for genetic evaluation of pigs <i>M. Satoh</i>	213
Parentage control of pigs based on SNP data <i>E. Žáková, Z. Krupová, E. Krupa, J. Stibal and I. Vrtková</i>	214
Prediction of piglet survival based only on birth weight or within-litter birth weight variability <i>J.M. Mbuthia, C. Kasper, M. Zenk, G. Bee, C.C. Metges and G. Daş</i>	214
Effect of fenugreek cotyledons on farrowing sow performances <i>M. Le Bot, J. Laurain, E. Belz and A. Benarbia</i>	215
Effects of different dietary fibres on constipation in sows during late pregnancy <i>D. Lu, Y. Pi, H. Ye, D. Han, B. Kemp, N. Soede and J. Wang</i>	215
Effect of transportation condition of pigs during transport for slaughter under different season <i>D.C. Song, S.Y. Chang, J.W. An, S.H. Park, K.H. Jeon and J.H. Cho</i>	216
<i>Salmonella</i> excretion level by pigs and impact of disinfection on antibiotic resistance of <i>E. coli</i> <i>C. Soumet, A. Kerouanton, A. Bridier, B. Anger, V. Dorenlor, V. Rose, F. Eono, C. Houdayer, E. Houard, E. Eveno, F. Souchaud, B. Houry, C. Valentin, P. Houée, I. Attig, N. Haddache, M. Denis and C. Fablet</i>	216
Climate change adaptation in mixed pigs-beef cattle systems in grasslands areas: key role of organic <i>S. Mugnier, L. Valero, C. Husson, F. Von Kerssenbrock, B. Dounies, H. Rapey and C. Philippeau</i>	217
Financial implications associated with ante- and post-mortem inspection findings in finishing pigs <i>D.L. Teixeira, L.C. Salazar and L.A. Boyle</i>	217
Training during rearing: effect on body reserves' flexibility & long-term reproduction in rabbit doe <i>J.J. Pascual, E. Martínez-Paredes, L. Ródenas, E. Blas and M. Cambra-López</i>	218

Session 09. Insect applications

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Sanchez / Gligorescu

Theatre Session 09

Replacement of poultry by-product meal by black soldier fly larvae meal in diets for dogs <i>B. Agy Loureiro, R.K. Nobrega Cardoso, R. Silva Carvalho, W.A. Zamora Restan, M. Dalim, N. Martin Tome and A. Paul</i>	218
<i>Hermetia illucens</i> meal in Rainbow trout diet – preliminary data of a commercial scenario <i>S. Bellezza Oddon, I. Biasato, C. Caimi, P. Badino, F. Gai, M. Renna and L. Gasco</i>	219

Mealworm protein hydrolysate as a novel functional ingredient for aquaculture applications <i>L. Sanchez</i>	219
Effect of black soldier fly larvae oil on performance and health of lactating sows and piglets <i>C. Omphalius, M. Walraven, S. Julliand and H. Bergoug</i>	220
Effects of dietary <i>Tenebrio molitor</i> meal and chitosan on health and meat quality of weaned piglets <i>C. Zacharis, E. Bonos, A. Tzora, I. Skoufos, G. Magklaras, I. Giavasis, I. Giannenas, E. Antonopoulou, C. Athanasiou and A. Tsinas</i>	220
Defatted insect meals: impact on <i>in vitro</i> ruminal fermentation and lipid biohydrogenation <i>M. Renna, M. Coppa, C. Lussiana, A. Le Morvan, L. Gasco, L. Rastello and G. Maxin</i>	221
Can the mixture of <i>Hermetia illucens</i> and <i>Tenebrio molitor</i> meals improve performance in broilers? <i>I. Biasato, M. Gariglio, E. Fiorilla, V. Bongiorno, E.E. Cappone, S. Bellezza Oddon, L. Gasco and A. Schiavone</i>	221
Including different products from black soldier fly larvae in the diet of slow-growing broilers <i>A. Rezaei Far, T. Veldkamp, J. Van Harn, S. Naser El Deen, P. Van Wikselaar and I. Fodor</i>	222
Effect of feeding black soldier fly larvae products to slow-growing broilers on welfare and health <i>A. Doerper, G. Gort, I.C. De Jong, T. Veldkamp and M. Dicke</i>	222
The immune response of slow-growing broiler chickens fed black soldier fly larvae meal <i>A. Rezaei Far, C.A. Jansen, J. Van Harn, P. Van Wikselaar, S.K. Kar and T. Veldkamp</i>	223
Does BSF meal have an impact in broilers with a subclinical necrotic enteritis challenge? <i>T. Veldkamp, J.J. Mes, A. Rezaei Far, S. Naser El Deen, P. Van Wikselaar, I. Fodor, R. Van Emous and L. Van Eck</i>	223
Black soldier fly larval diet eliminate chicken coronavirus at an early infection stage <i>Y. Zhang, C.Y. Yang, C.J. Li, Z.H. Xu, P. Peng, C.Y. Xue, J.K. Tomberlin, W.F. Hu and Y.C. Cao</i>	224
Black soldier fly larvae meal alter chicken gut microbiota to restricts coronavirus infection <i>C.Y. Yang, Y. Zhao, O. Peng, C. Li, Y. Cao and Y. Zhang</i>	224
Black soldier fly larvae meal as the main protein source improves feed efficiency in laying hens <i>A. Rezaei Far, I. Fodor, P. Van Wikselaar, S. Naser El Deen and T. Veldkamp</i>	225
Antibacterial and anticoccidial activities of black soldier fly extract <i>L. Sedano, E. Chambellon, F.I. Bussiere, E. Helloin, M. Vian, C. Guidou, C. Trespuech and A. Silvestre</i>	225
Poster Session 09	
The metabolizable energy value of black soldier fly larvae fat used in broiler chicken diets <i>B. Kierończyk, M. Rawski, K. Stuper-Szablewska, K. Dudek and D. Józefiak</i>	226
<i>Hermetia illucens</i> larva fat affects broiler chicken breast meat quality <i>B. Kierończyk, M. Rawski, Z. Mikołajczak, P. Szymkowiak, K. Stuper-Szablewska, M. Dudek and D. Józefiak</i>	226
Evaluation of two black soldier fly products on hens' performance, hatchability, and health traits <i>P. Hristakieva, N. Mincheva, I. Ivanova, K. Velikov and A. Petrova</i>	227
Insect meals digestibility for rainbow trout aquafeeds: <i>in vivo</i> and <i>in vitro</i> preliminary results <i>C. Caimi, F. Moyano Lopez, S. Bellezza Oddon, M.J. Aznar, V. Zambotto, F. Gai and L. Gasco</i>	227

Suitability of full-fat and defatted black soldier fly meal as ingredient for chicken diets <i>D. Murawska, D. Witkowska, M. Gesek, T. Bakula and J. Błażej-Gabowska</i>	228
Protein and amino acids digestibility of two black soldier fly larvae meal forms in broilers <i>A. Cerisuelo, E.A. Gómez, A. Martínez-Talaván, L. Piquer, D. Belloumi, C. Cano, M. Martínez, C. Fernández and S. Rojo</i>	228
CIPROMED: a PRIMA project on the use of alternative proteins in the Mediterranean value chains <i>C.G. Athanassiou, S. Smetana, A. Tassoni, L. Gasco, F. Gai, A. Shpigelman, D. Pleissner, M. Gastli, L. Conceição, F. Robinson, J.-I. Petrusán and C.I. Rumbos</i>	229
Replacing fishmeal by <i>Hermetia illucens</i> larvae on growth performance and meat quality in broiler <i>K.H. Jeon, D.C. Song, S.Y. Chang, J.W. Ahn, H.A. Cho, S.H. Park, H. Kim and J.H. Cho</i>	229
Investigation of the suitability of two <i>Tenebrio molitor</i> meals in diets of weaned piglets <i>C. Zacharis, G. Magklaras, I. Giavasis, I. Giannenas, E. Antonopoulou, A. Tsinas, C. Athanasiou, A. Tzora, I. Skoufos and E. Bonos</i>	230
Effect of different black soldier fly frass in plant yield and nutritional value <i>I. Rehan, I. Lopes, D. Murta, O. Moreira and R. Menino</i>	230

Session 10. Impact of epigenetics and genetics in determining animal physiology

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Jammes

Theatre Session 10

invited The place of epigenetics in the livestock of tomorrow <i>E.M. Ibeagha-Awemu and M. Wang</i>	231
A capture-based approach for DNA methylation analysis in cattle <i>V. Costes, A. López-Catalina, O. Gonzalez Recio, M. Ben Sassi, D.E. Rico, G. Foucras, C. Le Danvic, C. Hozé, M. Boussaha, D. Boichard, H. Jammes and H. Kiefer</i>	231
DNA-methylome analysis of milk somatic cells upon subclinical mastitis in Holstein cattle <i>S. Pegolo, D. Giannuzzi, A. Vanzin, V. Bisutti, A. Toscano, E. Capra, P. Ajmone Marsan and A. Cecchinato</i>	232
Feed efficiency correlates with the transcriptomic response to feed intake in the pig duodenum <i>G. Devailly, K. Fève, S. Saci, J. Sarry, S. Valière, J. Lluch, O. Bouchez, L. Ravon, Y. Billon, H. Gilbert, M. Beaumont and J. Demars</i>	232
Epigenetic biomarkers for environmental enrichment and parity in pregnant sows <i>M.M. Lopes, A. Chaulot-Talmon, A. Frambourg, H. Kiefer, C. Gerard, J. Demars, E. Merlot and H. Jammes</i>	233
A large population study to assess the magnitude of foetal programming in cattle <i>C. Fouéré, C. Hozé, M. Boussaha, H. Kiefer, M.P. Sanchez and D. Boichard</i>	233
Non-coding exonic microsatellite in bovine Nrf2 gene influences sperm oxidative stress capacity <i>K. Anwar, G. Thaller and M. Saeed-Zidane</i>	234
Maternal methionine restriction affects liver metabolism and foie gras production in duck offspring <i>C.M.D. Bonnefont, A. Sécula, H. Chapuis, L. Bodin, L.E. Bluy, A. Bonnet, A. Cornuez, M.-D. Bernadet, J. Barrieu, E. Cobo, X. Martin, H. Manse, L. Gress, M. Lessire, F. Mercierand, M.-C. Le Bourhis, A. Collin and M. Morisson</i>	234

Garcinol promotes hepatic gluconeogenesis by inhibiting PCAF acetyltransferases in late-pregnant Sow 235
W.L. Yao, Q.Y. Fu and J.X. Ning

Early high nutrition affects epigenetics related to lipogenesis in grass-fed Wagyu 235
D. Nishino, S. Khounsaknalath, K. Saito, A. Saito, T. Abe, E. Kobayashi, S. Yasuo and T. Gotoh

Poster Session 10

Construction of a single-cell transcriptome map of sheep horn development 236
X.H. He, Y.Y. Luan, S.J. Wu, Y.H. Ma and L. Jiang

The effect of short and long term cryopreservation on chicken primordial germ cells 236
M. Ibrahim, K. Stadnicka, E. Grochowska, B. Lazar, E. Varkonyi and M. Bednarczyk

The effect of garcinol on muscle *post mortem* glycolysis and meat quality in pigs 237
T.X. Wang, L. Huang and X.M. Liu

The effect of methionine supplementation on DNA methylation during the suckling period of ewe lambs 237
A. Martín, O. Madsen, F.J. Giráldez, J. De Vos and S. Andrés

Effect of supplementary diet at cow-calf phase on DNA methylation in muscle of Angus-Nellore calves 238
R. Curi, L. Rodrigues, R. Cooke, W. Baldassini, L.A. Chardulo and O. Machado Neto

Session 11. Improving pig welfare in conventional production systems

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Gottardo / Blanco Penedo

Theatre Session 11

invited Improving pig welfare in commercial pig farms 238
K. O'Driscoll

Effects of different nutritional strategies on the prevalence of tail biting in weaned piglets 239
E. Janvier, W. De Gaiffier, J. Piqué, S. Lebas and A. Samson

Validation of an Irish tail biting risk assessment tool 239
R.M. D'Alessio, C.G. Mc Aloon, C. Correia-Gomes, A. Hanlon and K. O'Driscoll

Improving finishing pig welfare by providing rooting and bedding materials 240
M. Ocepek, R.C. Newberry and I.L. Andersen

Impact of enrichment material and space allowance on damaging behaviour in pigs 240
M. Cupido, S.M. Mullan, K.M. O'Driscoll and L.A. Boyle

An investigation of early life indicators in relation to ear necrosis in pigs 241
L. Markland, K. O'Driscoll, F. Leonard and L. Boyle

invited Improving the welfare of sows and piglets: an exploration of teeth resection under the 3S framework 241
L. Boyle

Mitigating the impacts of hot conditions on lactating sows through meal delivery or feed 242
N. Quiniou, J. Dupuis and D. Renaudeau

Effect of comfort and enrichment for pregnant sows on the health and resilience of their offspring 242
M. Lagoda, K. O'Driscoll, M. Galli, J. Cerón, A. Ortín-Bustillo, J. Marchewka and L. Boyle

Use of organic nest-building material in free-farrowing pens with short term fixation <i>J. Wahmhoff, N. Kemper, A. Van Asten and I. Traulsen</i>	243
Welfare of group-housed sows in the mating area <i>S. Geisler, A. Van Asten, N. Kemper and I. Traulsen</i>	243
Current knowledge and ways forward to improve welfare of cull sows during transport and in lairage <i>C. Kobek-Kjeldager, L.D. Jensen, L. Foldager, L.M. Gould, K. Thodberg, D.L. Schröder-Petersen and M.S. Herskin</i>	244
Exposure times and stunning effectiveness for argon and nitrogen-argon mixture for pigs at slaughter <i>J. Knöll, J. Gelhausen, T. Friehs, T. Krebs, D. Mörlein, J. Tetens and I. Wilk</i>	244

Poster Session 11

Stability of performance in sows switching between crate and pen from one parity to the next <i>L. Canario, J. Bailly, S. Reignier, M. Poupin, Y. Billon and W. Hébrard</i>	245

Session 12. Technologies for outdoor systems: which application and opportunities?

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Maroto-Molina / Gautier

Theatre Session 12

Preliminary results on the use of weather data to predict production output in a Merino flock <i>P.G. Theron, T.S. Brand, S.W.P. Cloete and K. Dzama</i>	245
GIS-based data integration system as a design tool for rangeland management in productive landscapes <i>M. Odintsov Vaintrub, M. Bianchini, L. Lizzi, F. Paciocco, M. Francioni and P. D'Ottavio</i>	246
Remotely monitored animal behaviour using sensor ear tags on cattle in Switzerland <i>K. Ueda, U. Heikkilä, N. Gobbo Oliveira Erünlü, J. Bérard, O. Wellnitz and S. Rieder</i>	246
Differentiating feeding behaviour in grazing cattle based on IMU data and machine learning algorithms <i>N. Tilkens, A.L.H. Andriamandroso and J. Bindelle</i>	247
Monitoring animal movements by virtual fencing collars – a comparison of different GPS intervals <i>D. Hamidi, M. Kominda, N.A. Grinnell, F. Riesch, J. Horn, M. Hamidi, I. Traulsen and J. Isselstein</i>	247
The impact of virtual fence use on blood markers linked to stress and acute phase response in cattle <i>J. Ranches, M. Ferreira, G.M.P. Hernandez, A.R. Santos, R.C. O'Connor, D. Johnson, D.W. Bohnert and C. Boyd</i>	248
Drones to facilitate the monitoring of grazing animal: which application and opportunities? <i>A. Lebreton, A. Demarbaix, F. Demarquet, J. Douhay, P.-G. Grisot, L. Depuille and E. Nicolas</i>	248
Modular communication gateways, a new opportunity for precision management of agroecological farms <i>M. Odintsov Vaintrub and P. Di Giuseppe</i>	249
Deploying a LoRa network in mountainous areas to connect animals and shepherds <i>T. Kriszt, O. Benoit, G. Besche, J.D. Guyonneau, E. González-García and J.B. Menassol</i>	249

Poster Session 12

- Effect of successive drone herding on behaviour and spatial distribution of grazing cattle 250
H. Anzai and M. Kumaishi
- Evaluation of the RumiWatchSystem to measure activity and grazing behaviour of sheep 250
E. Dunne, N. McHugh and F.M. McGovern
- Remote monitoring of cattle using sensor ear tags 251
K. Ueda, T. Kuntzer, U. Heikkilä, N. Gobbo Oliveira Erünlü, J. Bérard, C. Beglinger, O. Wellnitz and S. Rieder

Session 13. Innovations and technological advancements in small ruminant production with particular emphasis in Mediterranean semi-extensive or extensive systems

Date: Monday 28 August 2023; 8.30 – 13.00

Chair: Hadjipavlou / Lauvie

Theatre Session 13

- invited** Update on sensor technologies for performance recording, management and welfare in small ruminants 251
G. Caja, A. Elhadi, E. González, J.B. Menassol, G. Tessnière, V. Giovanetti, M. Decandia, M. Acciaro, E.M. Sossidou, S.I. Patsios, L.T. Csiszter, L. Grova, G.H.M. Jorgensen, I. Halachmi, A.B. Shamai, T.W.J. Keady, C.M. Dwyer, T. Waterhouse, A. McLaren and C. Morgan-Davis
- P@stor-all: a spatialized information system for decision-making in extensive grazing systems 252
U. Kalenga Tshingomba, L. Sautot, M. Teisseire and M. Jouven
- Day and night sexual activity of rams as recorded by an automatic heat detector 252
M. Alhamada, E. González-García, N. Debus, A. Lurette, J.-B. Menassol and F. Bocquier
- Walking distance and maintenance energy requirements of sheep during mountain pasturing 253
T. Zanon, M. Gruber and M. Gauly
- Percutaneous liver biopsy obtention by ultrasonographic guidance in small ruminants 253
S. González-Luna, X. Moll, S. Serhan, B. Chaalia, A.A.K. Salama, X. Such and G. Caja
- Modelling milk yields of New Zealand dairy goats undergoing normal and extended lactations 254
N. Lopez-Villalobos and S.A. Turner
- Operational use of GPS collars for decision making by agro-silvo-pastoral farmers in Mediterranean areas 254
L. Sautot, I. Candela and M. Jouven
- AGRICYGEN: innovative phenotyping and high-throughput genotyping studies of Cyprus sheep and goats 255
G. Hadjipavlou, S. Andreou, T. Christofi, A.C. Dimitriou, A.N. Georgiou, L. Koniali, G. Maimaris, P. Markou and S. Panayidou
- Genetic improvement of milk production traits in the Cyprus Damascus goat population 255
S. Andreou, A.N. Georgiou, G. Maimaris, A. Dimitriou, L. Koniali and G. Hadjipavlou
- Genetic trends for test day milk yield in White Maritza and Patch-faced Maritza sheep breeds 256
P. Zhelyazkova and D. Dimov
- Genetic and environmental effects on the survival and growth rates of Cyprus Chios lambs 256
T. Christofi, S. Panayidou, L. Koniali and G. Hadjipavlou

Genetic and non-genetic factors affecting survival and growth of Cyprus Damascus goat kids <i>L. Koniali, S. Andreou, T. Christofi and G. Hadjipavlou</i>	257
Feed restriction in dairy ewes decreases milk lipolysis and remodels the milk proteome and lipidome <i>M. Delosière, L. Bernard, C. Hurtaud, H. Larroque, S. Emery, A. Delavaud, M. Taillandier, P. Le Faouder, M. Bonnet and C. Cebo</i>	257
Poster Session 13	
Garlic essential oil supplementation in sheep: effect on fermentation parameters <i>C. Saro, I. Mateos, F.J. Giráldez and M.J. Ranilla</i>	258
Effect of garlic essential oil supplementation on rumen microbial community of sheep <i>I. Mateos, E. Mata-Nicolás, C. Saro, R. Li, R. Baldwin, F.J. Giráldez and M.J. Ranilla</i>	258
High-precision scanning system for complete 3D goat udder and teat imaging and analysis <i>G. Coquereau, P.G. Marnet, L. Delattre, J.M. Delouard and P. Martin</i>	259
Asymmetric udder – a possible indicator of subclinical mastitis in ewes <i>K. Tvarožková, V. Tančin, M. Oravcová, M. Uhrinčat, L. Mačuhová, B. Gancárová and M. Ptáček</i>	259
Effects of the nature of milk replacer on growth performances and carcass and meat quality of kids <i>J. Normand, C. Boyer, S. Meurisse, A. Pommaret and M. Drouet</i>	260
Effect of somatic cell count and stage of lactation on milk production <i>L. Mačuhová, V. Tančin, J. Mačuhová, M. Uhrinčat and M. Oravcová</i>	260
Fit of mathematical models to the lactation curves of dairy sheep <i>L. Guevara, L.S. Gloria, J.C. Angeles-Hernandez, A.M. Fernandes and M.L.C. Abreu</i>	261
Udder health in dairy ewes in Slovakia: current situation <i>V. Tančin, K. Tvarožková, B. Gancárová, L. Mačuhová, M. Uhrinčat, M. Vršková and M. Oravcová</i>	261
Evaluation of udder health of dairy goats using electrical conductivity under practical conditions <i>M. Uhrinčat, V. Tančin, K. Tvarožková, B. Gancárová, L. Mačuhová and M. Oravcová</i>	262
Milk recording protocols and goodness of fit of models applied to dairy sheep lactations <i>L. Guevara, L.S. Gloria, J.C. Angeles-Hernandez, I. Nacarati Da Silva, A.M. Fernandes and A. Peláez Acero</i>	262
Heritability of milk lipolysis in French Alpine goats <i>H. Larroque, C. Robert-Granié, S. Meurisse, P. Trossat, L. Bernard, C. Hurtaud, C. Huau, T. Fassier, R. Rupp and C. Cebo</i>	263
Castration method affects the fatty acid profile of subcutaneous and intramuscular fat in sheep <i>H.A. O'Neill, N. Skele, O.B. Einkamerer, A. Hugo and F.W. Nester</i>	263
Somatic cell count and prevalence of udder pathogens isolated in raw goat milk <i>B. Gancárová, K. Tvarožková, M. Uhrinčat, L. Mačuhová and V. Tančin</i>	264
Lowering crude protein and supplementing rumen protected methionine and lysine in dairy ewes <i>K. Droumtekas, A. Plomaritou, I.C.C. Christou, A. Tsigkas, M.A. Belaid, D. Martinez Del Olmo, J. Mateos and A. Foskolos</i>	264
FASTOChe project: meat sheep grazing on plant species rich in bioactive secondary compounds <i>M. Bernard, H. Hoste, L. Sagot and D. Gautier</i>	265

Session 14. Sustainable livestock farming – defining metrics and rationalising trade-offs? – Part 2

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Lee / O'Mara

Theatre Session 14

Multiple mitigation strategies may lead to reduction in emissions for mixed Kenyan dairy systems <i>M.W. Graham, C. Arndt, D. Korir, S. Leitner, L. Merbold, P. Ndung'u, F. Teillard and A. Mottet</i>	265
Assessing multifunctionality of livestock breeds and species at global level <i>G. Leroy, F. Joly, C. Looft, P. Boettcher and R. Baumung</i>	266
Predicting sustainable futures: does disease in early life result in trade-offs in ewe productivity? <i>J. Duncan, H. McDougall, G. Mitchell, R. Evans, M. Reeves, L. Andrews, E. Geddes, L. Melville, D. Ewing and F. Kenyon</i>	266
The welfare of housed and grazing beef cattle assessed by hormones levels and physical check scores <i>M.J. Rivero and A.S. Cooke</i>	267
Creating a shared framework for standardizing life cycle assessments in livestock production systems <i>P. Goglio, M. Trydeman Knudsen, K. Van Mierlo, N. Röhrig, M. Fossey, A. Maresca, H. Fatemeh, M. Ahmed Waqas, J. Yngvesson, G. Nassy, R. Broekema, S. Moakes, C. Pfeifer, R. Borek, D. Yanez-Ruiz, M. Quevedo Cascante, A. Syp, T. Zylowsky, M. Romero-Huelva and L.G. Smith</i>	267
Defining operational sustainability and the need for systems approach in assessing livestock farming <i>A.H. Herlin, S. Hellstrand and H.U. Sverdrup</i>	268
The global roundtable for sustainable beef; multi-stakeholder engagement driving progress worldwide <i>R. Petre and J. Eisele</i>	268
Developing a decision support system for integral sustainability improvement of Dutch dairy farm <i>M. De Vries, J.W. Reijs, G.J. Doornewaard, A.P. Bos and C.A. Schep</i>	269
Animal welfare index in sustainability assessments <i>L. Rydhmer and E. Rööf</i>	269
Sustainability analysis of large-scale dairy farming in China from water-energy-labour nexus insight <i>X. Du, Q. Wang and Z. Shi</i>	270
Characterizing the socio-economic and environmental performance of Irish beef and sheep farms <i>M.C. Ayala, J.C.J. Groot, K. Kilcline, I.J.M. De Boer, C. Grace, J. Kennedy, B. Moran and R. Ripoll-Bosch</i>	270
Benchmarking the sustainability performance of pastoral dairy-beef production systems <i>M. Kearney, J. Breen, E. O' Riordan and P. Crosson</i>	271
Measuring, reporting and verifying farm sustainability (Food Futures) <i>R. McGuire, A. Aubry, S. Morrison, J. Birnie and N. Scollan</i>	271
invited Closing of the 3 rd ATF-EAAP LFS symposium <i>F. O'Mara and M. Lee</i>	272

Poster Session 14

Environmental performance by type of Iberian farm in the Dehesa ecosystem <i>J. García-Gudiño, J. Perea, E. Angón and I. Blanco-Penedo</i>	272

Ration protein content affects intake, production, efficiency and methane emission of dairy cows <i>F. Schori, C. Kasper and A. Munger</i>	273
Is protein autonomy synonymous with economic efficiency? <i>E. Bertrand, C. Corre and R. Bore</i>	273
Development of multicriteria analysis' methodology in an experimental farms network <i>C. Corre and C. Brasseur</i>	274
Multicriteria analysis on French experimental farm which develops its feed self-sufficiency <i>C. Corre and R. Bor�</i>	274
Partial indicators monitoring in dairy farm: effect of feed efficiency improvement on gross margin <i>G.S.S. Gian Simone Sechi and A.A.S. Alberto Stanislaos Atzori</i>	275
Comparison of methodologies for estimating animal emissions from smallholder cattle systems <i>E. Balcha and C. Arndt</i>	275
Developing a common framework to measure sustainability in food systems with limited arable land <i>P. Bh�rer-Breton, A. Woodhouse, E. Svanes, H.F. Olsen and B. Aspeh�len �by</i>	276
Partial indicators monitoring in dairy farms: feed efficiency implications on gross margin <i>G.S. Sechi and A.S. Atzori</i>	276

Session 15. Breeding for climate change – mitigation

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Pszczola / Neumann

Theatre Session 15

invited Genomic evaluation to reduce enteric methane emissions in Holstein cattle <i>F. Malchiodi, H.R. Oliveira, S. Narayana, A. Fleming, H. Sweett, S. Shadpour, J. Jamrozik, G. Kistemaker, P. Sullivan, F.S. Schenkel, B. Van Doormaal, C.F. Baes and F. Miglior</i>	277
Methane phenotyping for genetic selection – can we measure bulls, not cows? <i>L.R. McNaughton, P. Beatson, G. Worth, D.J. Garrick, D. Garrick, R. Handcock and R.J. Spelman</i>	277
Novel formulas to calculate methane production from concentrations while using sniffers <i>C.I.V. Manzanilla-Pech, M.H. Kjeldsen, T. Villumsen and J. Lassen</i>	278
Predicting methane production and intensity from milk mid-infrared spectra <i>S. Fresco, A. Vanlierde, R. Lefebvre, M. Gaborit, D. Boichard, R. Bore, S. Fritz, N. Gengler and P. Martin</i>	278
Genetic parameters for enteric methane emissions of dairy cows using random regression models <i>A.E. Van Breukelen, M.N. Aldridge, R.F. Veerkamp and Y. De Haas</i>	279
Heritability of methane emission in dairy cows estimated from GreenFeed measures in commercial herds <i>B. Heringstad, K.A. Bakke and G. Difford</i>	279
Rapid measurements for breeding low methane cattle <i>S.J. Rowe, A. Searle, T. Bilton, S. Sevier, S. Gebbie, A. Jonker, P. Janssen, S. Hickey, N. Amyes, S. Worku and J. McEwan</i>	280
Collecting and preparing sniffer records for genetic evaluation of enteric methane in dairy cattle <i>T.M. Villumsen, P. L�vendahl, V. Milkevych, R. Krogh, C.I.V. Manzanilla-Pech, M. Bjerring, J. Lassen and G. Sahana</i>	280

Methods and tools for automated processing of sniffer-based methane emission data from dairy cows <i>V. Milkevych, R.K. Nielsen, T.M. Villumsen, P. Løvendahl and G. Sahana</i>	281
Indicators of genetic selection using sniffer method to reduce methane emissions from Holstein cows <i>Y. Uemoto, T. Tomaru, M. Masuda, K. Uchisawa, K. Hashiba, Y. Nishikawa, K. Suzuki, T. Kojima, T. Suzuki and F. Terada</i>	281
Reducing methane emissions: foundations for genetic evaluations for sustainable Irish beef cattle <i>C.V. Ryan, S. Conroy, T. Pabiou, D.C. Purfield and R. Evans</i>	282
Determining relative values of genetic traits of Chinese dairy cattle in greenhouse gas mitigation <i>Y. Wang, R. Shi, A. Van Der Linden, B.J. Ducro, Y. Wang, Y. Hou, S.J. Oosting and C.E. Van Middelaar</i>	282
Effects of breeding for feed efficiency on carbon footprint of milk – LCA approach <i>S. Hietala, A. Aastapsev, E. Negussie, M.H. Lidauer and T. Mehtio</i>	283

Poster Session 15

Automated CT analysis to identify low emitting ruminants <i>S. Hitchman, L. Grundy, W. Bain, T. Johnson, M. Reis, H. Gunnarsdottir, J. McEwan and S. Rowe</i>	283
Enteric methane emission of Nellore cattle from two lines selected for yearling weight <i>S.B. Gianvecchio, M.S. Borges, J.A. Silva, J.P.S. Valente, J.O.S. Marcatto, L.G. Albuquerque, J.N.S.G. Cyrillo and M.E.Z. Mercadante</i>	284
Genetic correlation between enteric methane emission and feed efficiency and growth traits in cattle <i>M.E.Z. Mercadante, J.P.S. Valente, S.B. Gianvecchio, J.O.S. Marcatto, M.S. Borges, J.A. Silva, I.M.C. Garcia, S.F.M. Bonilha and L.G. Albuquerque</i>	284
Heritability of predicted enteric methane emission in Japanese Holstein cows <i>R. Tatebayashi, A. Nishiura, F. Terada, Y. Uemoto, M. Aihara, T. Suzuki, I. Nonaka and O. Sasaki</i>	285
Using genomic markers and microbiome data to predict methane emissions from Holstein cows <i>N. Saedi, M.S. Lund and E. Karaman</i>	285

Session 16. Alternative and new feed resources to reduce feed/food competition and enhance circularity of livestock production

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Ranilla García / Stergiadis

Theatre Session 16

invited Non-traditional feed ingredients in diets for pigs <i>H. Stein</i>	286
Effect of genotypes on agronomic and antinutritional traits of <i>Lupinus albus</i> L. for livestock <i>M. Oteri, D. Scordia, R. Arnone, V. Nava, F. Gresta and B. Chiofalo</i>	286
Dietary effects of xylanase and flaxseeds on performance, meat quality and bone health in broilers <i>D. Lanzoni, M. Skřivan, M. Englmaierová, M. Marounek, E. Skřivanová, A. Baldi and C. Giromini</i>	287
The effect of hydrolysed yeast on production performance and gastrointestinal health in broilers <i>N. Irshad, V. Perricone, S. Sandrini, C. Lecchi, P. De Faria Lainetti, A. Agazzi and G. Savoini</i>	287
Yoghurt acid whey effects on broiler performance, meat oxidative status and caecal barrier integrity <i>V.V. Paraskeuas, G. Papadomichelakis, A. Pappas, P. Simitzis, E.C. Anagnostopoulos, I.P. Brouklogiannis, E. Griela, I. Palamidi, G. Theodorou, I. Politis and K.C. Mountzouris</i>	288

The effect of <i>Citrus unshiu</i> peel on growth performance, digestibility and immunity in weaning pig <i>A.S. Sureshbabu, A.K. Adhimoolam and T.M. Min</i>	288
The effect of replacing grains with bakery by-products on performance and pigs' diet preference <i>F. Veldkamp, H.M. Vermeer, J. Kater, A. Ten Berge, J.M.J. Rebel and I.C. De Jong</i>	289
Replacing hexane by 2-methyloxolane for defatting soybean meal does not impair dairy cow performance <i>V. Menoury, A. Ferlay, L. Jacques, V. Rapinel and P. Nozière</i>	289
<i>In vitro</i> rumen fermentation traits of <i>Mentha piperita</i> , and products of oil extraction <i>S. Massaro, J. Andersen, G. Secchi, D. Giannuzzi, S. Schiavon, E. Franciosi and F. Tagliapietra</i>	290
<i>In vitro</i> rumen fermentation of mushroom-pretreated <i>Acacia mellifera</i> simulating ruminant digestion <i>C. Rothmann, E.D. Cason and P.D. Vermeulen</i>	290
Valorisation of atypical land in cattle production systems in search of self-sufficiency <i>D. Starling, A. Farruggia and T. Puech</i>	291
Growth of black belly ewe lambs ingesting non-conventional feeds in the form of complete feed blocks <i>D. Barde, E. Traore, R. Arquet, N. Minatchy and H. Archimede</i>	291
Poster Session 16	
Diet effect of <i>Hermetia illucens</i> on proximate and fatty acid composition of broiler meat <i>R. Berrocal, E. Molinero, S. Rueda, M.M. Campo and L. Mur</i>	292
Antioxidant and rumen microbiota shift of Holstein cows by aquatic plant silage in Tibetan plateau <i>B. Li, X. Huang, X. Yang and Y. Wang</i>	292
Feeding olive cake alters the mRNA of SREBF1 in adipose tissue of cows <i>M.C. Neofytou, D. Miltiadou, E. Sfakianaki, S. Symeou, D. Sparaggis, A.L. Hager-Theodorides and O. Tzamaloukas</i>	293
Improving gut functions and egg nutrition with stevia Residue in laying hens <i>M.X. Tang, Y.L. W., C. Y., C. P., H.G. L., Y. L., Y.D. C., W. L., X. X. and X.F. K.</i>	293
<i>In vitro</i> evaluation of olive stones and sorghum used as forage in ruminant diets <i>N. Kellali, N. Merino, E. Mata-Nicolás, I. Mateos, C. Saro, N. Lakhdara and M.J. Ranilla</i>	294
Preservation of agro-industrial co-products as silage for ruminant feed <i>K. Paulos, C. Costa, J.M.S. Costa, L. Cachucho, P.V. Portugal, J. Santos-Silva, F. Lidon, M.R. Marques, E. Jerónimo and M.T.P. Dentinho</i>	294
Combination of organic acid and heat treatment decreased ruminal protein degradation in Soybean meal <i>D.K. Yoo, S.W. Jeong and J.K. Seo</i>	295
Bakery by-products in herbage-based diets for dairy cows: effects on milk yield and reticular pH <i>A.-M. Reiche, M. Tretola, J. Eichinger, A.-L. Hütten, A. Mürger, L. Eggerschwiler, L. Pinotti and F. Dohme-Meier</i>	295
Evaluation of legumes for fermentability and protein fractions using <i>in vitro</i> rumen fermentation <i>B.Z. Tunkala, K. Digiacomo, P.S. Alvarez Hess, F.R. Dunshea and B.J. Leury</i>	296
Dehydration temperature- effect on physicochemical and nutritional characteristics of byproducts <i>M. Alves, K. Paulos, C. Costa, D. Gonçalves, T. Orvalho, J.M.S. Costa, L. Cachucho, J. Santos-Silva, E. Jerónimo and M.T.P. Dentinho</i>	296

Bacterial ecology and silage quality improvement upon treatment with microbial inoculants <i>I. Nikodinoska, M. Franco, M. Rinne and C.A. Moran</i>	297
Growth performance, carcass and meat quality of pigs fed <i>Chlorella vulgaris</i> supplemented diets <i>J.M. Almeida, M. Parreiras, R. Varino, A. Sequeira, R.J.B. Bessa and O. Moreira</i>	297
Inclusion of slow-release ammonia-treated barley in concentrates – feed intake and milk production <i>K.S. Eikanger, M. Eknæs, I.J. Karlengen, J.K. Sommereth, I. Schei and A. Kidane</i>	298
Reducing aggression in finishing pigs through short application liquid calming herbal blend <i>C. Nicolás-Jorrillo, D. Carrión, D. Escribano, A. Brun and E. Jiménez-Moreno</i>	298
Evaluating fermentative profile in corn silage using chemical and biological additives <i>C. Mastroeni, S. Van Kuijk, F. Ghilardelli, S. Sigolo, E. Fiorbelli and A. Gallo</i>	299
Effect of <i>Chlorella vulgaris</i> incorporation in pig diets on pork chemical composition and fatty acids <i>J.M. Almeida, A.P. Portugal, R.J.B. Bessa and O. Moreira</i>	299
<i>Bacillus</i> fermentation products of hog hair waste serve as potential animal feed additives <i>W.J. Chen, K.C. Chang, Z.J. Zhuang, Y.H. Cheng and Y.H. Yu</i>	300
Effect of coffee grounds on digestibility, ruminal fermentation, and microbial protein synthesis <i>M. Medjadbi, I. Goiri, R. Atxaerandio, S. Charef, C. Michelet, J. Ibarruri, B. Iñarra, D. San Martín and A. García-Rodríguez</i>	300
Environmental impact of former food estimated through life cycle assessment <i>M.G.D. Azzena, A. Luciano, L. Pinotti and A.S. Atzori</i>	301
Effect of coffee grounds on productive performance, milk fatty acid profile and methane production <i>M. Medjadbi, I. Goiri, R. Atxaerandio, S. Charef, C. Michelet, J. Ibarruri, B. Iñarra, D. San Martín and A. García-Rodríguez</i>	301
Effect of including fresh pears as feedstuff in lactating ewes' diet on the ewes' milk curd strength <i>I. Caro, J. Mateo, S. Kasaiyan, N. Merino, E. Mata-Nicolás, I. Mateos, C. Saro, A. Martín, F.J. Giraldez and M.J. Ranilla</i>	302
Upcycling of Citrus and Vinification by-products' bioactive compounds for broiler diets <i>A. Mavrommatis and E. Tsiplakou</i>	302

Session 17. Climate care dairy farming: follow up – Part 2

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Edouard / Becciolini

Theatre Session 17

Simplified method developed for estimating the on-farm EFGHG and NH ₃ – presentation & results <i>X. Vergé, P. Robin, V. Becciolini, A. Cieślak, N. Edouard, L. Fehmer, P. Galama, P. Hargreaves, V. Juškieienė, G. Kadžiene, A.-S. Lissy, D. Ruska and M. Szumacher</i>	303
Simulation of three farming strategies on ammonia and GHG emissions and economics <i>P. Galama and H. Pishgarkomileh</i>	303
Exploring the effect of dairy cow replacement decisions on feed efficiency and sustainability <i>A. De Vries</i>	304
Practical monitoring of individual methane production rates in dairy cows: an alternative <i>C.M. Levraut, J.T. Eekelder, P.W.G. Koerkamp, C.F.W. Peeters, J.P.M. Ploegaert and N.W.M. Ogink</i>	304

Air filtering as alternative approach to combat emissions from cattle facilities <i>A. Kuipers, P. Galama, R. Maasdam, S. Spoelstra and P. Groot Koerkamp</i>	305
UAV-based approaches for gaseous emissions assessment in cattle farming <i>V. Becciolini, A. Mattia, M. Merlini, G. Rossi, F. Squillace, G. Coletti, U. Rossi and M. Barbari</i>	305
Reducing N leaching by adapting N application timing and quantities to weather and grass growth <i>L. Bonnard, E. Ruelle, M. O'Donovan, M. Murphy and L. Delaby</i>	306
Reducing greenhouse gases in dairy cattle farming through innovative technologies <i>A. Svitojus and E. Gedgaudas</i>	306
Annual quantification of GHG and NH ₃ emissions coming from compost-bedded pack housing systems <i>E. Fuertes, G. De La Fuente, J. Balcells and R. Seradj</i>	307
A study of the building-integrated photovoltaic cattle houses application scenario in China <i>Q. Wang, X. Du and Z. Shi</i>	307
Effect of manure management and environmental temperature on microbial communities in dairy manure <i>E. Fuertes, R. Seradj, J. Balcells and G. De La Fuente</i>	308

Poster Session 17

Simultaneous comparison of 5 methods to quantify enteric methane emitted by lactating dairy cows <i>A. Vanlierde, F. Dehareng, O. Christophe and E. Froidmont</i>	308

Session 18. Carcase grading for quality and efficiency – underpinning future sustainability of beef and lamb

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Pethick / Neveu

Theatre Session 18

Meeting consumer expectations: a 3G global beef eating quality predictive model for Europe <i>A. Neveu, R. Polkinghorne, R. Watson, H. Cuthbertson and J. Wierzbicki</i>	309
Development of a carcass grading system for South African beef <i>M.S. Faulhaber, P.E. Strydom and N. Hall</i>	309
French consumer evaluation of eating quality of Limousin beef <i>M. Kombolo, J. Liu, I. Legrand, F. Noel, P. Faure, L. Thoumy, D. Pethick and J.-F. Hocquette</i>	310
BeefQ – testing a beef eating quality prediction system for Wales and England <i>P.K. Nicholas-Davies, R. Polkinghorne, A. Neveu, H. Cuthbertson and T. Rowe</i>	310
Assessment of untrained consumers on eating quality in Zebu and crossbred cattle at aging times <i>A. Barro, M. Coutinho, G. Rovadoscki, A.M. Bridi and J.F. Hocquette</i>	311
Loin residual glycogen and free glucose do not affect Australian lamb loin eating quality <i>S.M. Moyes, D.W. Pethick, G.E. Gardner and L. Pannier</i>	311
Combining eating quality and individual cut tracking to maximise value and decrease waste in beef <i>H. Cuthbertson, R. Polkinghorne and A. Neveu</i>	312
Changing the Australian trading language for beef and lamb to adapt to new measurement technologies <i>G.E. Gardner, S. Stewart, P. McGilchrist, C. Steele, H. Calnan, S. Connaughton, K. Mata and R. Apps</i>	312

The precision and accuracy of the Q-FOM grading camera predicting rib eye traits in beef carcasses <i>S.M. Stewart, M. Christensen, H. Toft, T. Lauridsen and R. O'reilly</i>	313
Predicting IMF% and visual marbling scores on beef portion steaks with a Marel vision scanner system <i>L. Pannier, T.M. Van De Weijer, F.T.H.J. Van Der Steen, R. Kranenbarg and G.E. Gardner</i>	313
Improved analysis of dual energy x-ray absorptiometry images enhances lamb eating quality prediction <i>F. Anderson, L. Pannier, C. Payne, S. Connaughton, A. Williams and G.E. Gardner</i>	314
Aligning upper and lower commercial beef DEXA images to predict CT composition <i>H.B. Calnan, A. Williams and G.E. Gardner</i>	314
Calibration of chain-speed DXA units using synthetic phantom blocks in two Australian lamb abattoirs <i>S.L. Connaughton, F. Anderson, A. Williams and G.E. Gardner</i>	315
Objective carcase measurement from commercial supply chains contributing to genetic improvement <i>D.J. Brown, R. Alexandri, S.F. Walkom, D.W. Pethick, P. McGilchrist, S. Stewart, W.S. Pitchford and G.E. Gardner</i>	315
Poster Session 18	
Potential of deep learning video image analysis for automated SEUROP-classification <i>T. Rombouts, M. Seynaeve and S. De Smet</i>	316
Hand-held NIR device predicting chemical intramuscular fat% in pork <i>M.T. Corlett, F. Anderson and G.E. Gardner</i>	316
An optimisation model for operational planning in lamb supply chains <i>G. Wang, F.L. Preston, C. Smith, D. Flanigan, S.M. Miller, W.S. Pitchford and D. Meehan</i>	317
Predicting P8 fat depth in hot beef carcasses using a handheld microwave system <i>J. Marimuthu, R.K. Abraham and G.E. Gardner</i>	317
Meat@ppli, a smartphone application to predict fat content of beef <i>J. Normand, B. Meunier, M. Bonnet and B. Albouy-Kissi</i>	318
Computed tomography vs chemical composition for determination of Australian lamb carcase composition <i>K. Mata, G. Gardner and F. Anderson</i>	318
Assessing dual-energy X-ray absorptiometry prediction of intramuscular fat content in beef <i>C.L.N. Nunes, R.S.R. Vilela, E.B. Schultz, M.I. Hannas, C.M. Veloso, M.M. Ladeira and M.L. Chizzotti</i>	319
In-abattoir 3D image parameters of beef carcasses for predicting carcass classification and weight <i>H. Nisbet, N. Lambe, G. Miller, A. Doeschl-Wilson, D. Barclay and C.A. Duthie</i>	319
Prediction of liveweight from linear conformation traits in beef cattle <i>M. Meister, L. Speiser and A. Burren</i>	320
Beef marbling assessment by accredited graders and a hand-held camera device <i>M. Kombolo-Ngah, N.S.R. Mendes, A. Neveu, A. Barro, M. Christensen and J.F. Hocquette</i>	320
Beef on dairy – meat quality and prediction of intramuscular fat on the slaughter line <i>F.F. Drachmann and M. Therkildsen</i>	321
Pig carcass and cuts lean meat content determined by X-ray computed tomography <i>M. Font-I-Furnols, A. Brun and M. Gispert</i>	321

Relationships between ultimate pH, weight, conformation and fatness of carcasses 322
N. Silva Rodrigues Mendes, R. Rodrigues Silva, T. Ferreira De Oliveira, P.F. Rivet, M.P. Ellies-Oury, S. Chriki and J.F. Hocquette

Elite Dairy Beef – a pathway for male dairy calves into the premium beef market 322
H. Cuthbertson, R. Polkinghorne, A. Neveu, T. Maguire, O. Catalan and R. Law

Session 19. Advances in nutritional modelling and feeding systems (in memory of Daniel Sauvant)

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Baumont / Cannas

Theatre Session 19

The contribution of Daniel Sauvant to modelling in animal science 323
J. Van Milgen and P. Faverdin

invited Systemic modelling of nutrient partitioning: from the seed sown by D. Sauvant to future prospects 323
L. Puillet

Mechanistic model of the dynamics of body retention and utilization of phosphorus and calcium in sow 324
J. Heurtaut, P. Schlegel and M.P. Létourneau-Montminy

Modelling the digestive utilization of calcium and phosphorus in laying hens 324
F. Hervo, B. Méda, A. Narcy and M.-P. Létourneau-Montminy

A dynamic mechanistic model to forecast the oscillatory feeding behaviour of lactating dairy cows 325
E. Fiorbelli, A.S. Atzori, A.T. Büşra, L. Tedeschi and A. Gallo

A dynamic *in silico* model of rumen microbial fermentation and methane production 325
R. Muñoz-Tamayo, S. Ahvenjärvi, A.R. Bayat and I. Tapio

invited Future directions in ruminant feeding systems: opportunities and challenges for sustainability 326
L.O. Tedeschi

Meta-analysis in animal science: a valuable tool to generate new knowledge from previous experiments 326
M.P. Létourneau Montminy, C. Loncke, P. Schmidely, M. Boval, J.B. Daniel and D. Sauvant

Global sensitivity analysis of INRA[®]V5 for dairy cows: Sobol' indices 327
S. Jeon, S. Lemosquet, T. Senga Kiese and P. Nozière

Effects of housing or feeding practice in dairy goats estimated by the INRA[®]V5 feeding system 327
S. Giger-Reverdin, V. Berthelot and D. Sauvant

Dynamic models to inform precision supplementation of heifers grazing dormant native grasslands 328
H.M. Menendez Iii, J.R. Brennan, A.K. Dagle and K. Olson

Comparison of measured enteric methane emission with model calculations of commercial dairy diets 328
L. Koning and L.B. Sebek

Poster Session 19

Optim'Al can optimize dairy cow rations on economic cost and protein autonomy with INRA 2018 system 329
P. Chapoutot, G. Tran, V. Heuze and A. Berchoux

Modelling the dynamics of dairy cattle response to heat stress using system dynamics methodology 329
R. Cresci, B. Atamer Balkan, L.O. Tedeschi and A.S. Atzori

Volatolomics for developing non-invasive biomarkers of ruminal function and health in dairy cows <i>E. Jorge-Smeding, C. Martin, L. Volmerange, E. Rispal, M. Bouchon, Y. Rochette, N. Salah, F. Violleau and M. Silberberg</i>	330
Estimation of total urinary nitrogen excretion in fattening beef cattle from urinary spot samples <i>C. Garcia-Vazquez, P. Nozière, L. Salis, R. Bellagi, J. David and G. Cantalapiedra-Hijar</i>	330
Advancing mathematical modelling for equines <i>E.M. Leishman, C. Cargo-Froom, P. Darani, S. Cieslar and J.L. Ellis</i>	331
Predicting equine voluntary forage intake using meta-analysis <i>E.M. Leishman, M. Sahar, P. Darani, S. Cieslar and J.L. Ellis</i>	331
Score using indicators of reticulo-rumen pH kinetics to characterize subacute ruminal acidosis <i>C. Villot, K. Biard, C. Martin, A. Boudon and M. Silberberg</i>	332
The INRA mechanistic beef growth model captures feed efficiency ranking in Charolais bulls <i>G. Cantalapiedra-Hijar and S. Lerch</i>	332
A framework for predicting the environmentally attainable intake of dairy cows <i>J.F. Ramirez-Agudelo, L. Puillet and N.C. Friggens</i>	333
An integrated tool to apply the INRA2018 feeding system in ruminant rationing: INRAtion®V5 <i>P. Nozière, J. Agabriel, R. Baumont, P. Chapoutot, L. Delaby, R. Delagarde, A. De La Torre, P. Faverdin, S. Giger-Reverdin, P. Hassoun, A. Lamadon, G. Maxin, D. Sauvant, B. Sepchat, P. Souvignet and S. Dutot</i>	333
Milk yield and mammary metabolism in response to increasing amino acids and protein supplies <i>S. Lemosquet, C. Loncke, J.C. Anger, A. Hamon, J. Guinard-Flament and M.N. Haque</i>	334
Ruminal fatty acid biohydrogenation pathways in lambs and kids fed a high concentrate diet <i>V. Berthelot, Y.D. Yekoye and L.P. Broudiscou</i>	334
Can high fat concentrates offset the high methane production caused by high forage diets? <i>N. Ayanfe, S. Ahvenjärvi, A. Sairanen and A.R. Bayat</i>	335
Updates of the expenditures and requirements for growing dairy goats <i>S. Giger-Reverdin and D. Sauvant</i>	335
Feed efficiency relates to the ability of supporting lactation in dairy cows facing feed restriction <i>L. Barreto-Mendes, J. Pires, A. De La Torre, I. Ortigues-Marty, I. Cassar-Malek and F. Blanc</i>	336
Effects of rumen protected calcium gluconate on hindgut dynamics and nutrient partitioning <i>M. Hall and J.G.H.E. Bergman</i>	336

Session 20. Early career competition 'Innovative approaches to pig and poultry production', supported by Wageningen Academic Publishers

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Vigors / Nilsson

Theatre Session 20

The impact of observation frequency and duration, on resilience traits in pigs <i>W. Gorssen, C. Winters, R. Meyermans, L. Chapard, K. Hooyberghs, S. Janssens, A. Huisman, K. Peeters, H. Mulder and N. Buys</i>	337

Are tail biting and tail necrosis really only a problem in the domestic pig? <i>I. Czycholl, K. Büttner, W. Baumgärtner, C. Puff and J. Krieter</i>	337
Innovative rearing strategies for heavy pigs: weight and chemical composition of dry-cured hams <i>A. Toscano, D. Giannuzzi, I.H. Malgwi, V. Halas, P. Carnier, L. Gallo and S. Schiavon</i>	338
Comparison of different non-linear growth models on post-weaning growth of pigs <i>K.O. Kareem-Ibrahim, O.T.F. Abanikannda and O.A. Folorunsho</i>	338
Effect of glutamine and/or milk supplementation post-weaning on pig growth and intestinal structure <i>E.A. Arnaud, G.E. Gardiner, S.R. Vasa, J.V. O'Doherty, T. Sweeney and P.G. Lawlor</i>	339
Effect of lysine level in finisher diets on performance in crossbreds from two terminal sire lines <i>S. Goethals, K. Hooyberghs, N. Buys, S. Janssens and S. Millet</i>	339
Birth weight effects on performance and gut health status of weaned piglets <i>C. Negrini, F. Correa, D. Luise, S. Viridis, M. Mele, G. Conte, M. Mazzoni and P. Trevisi</i>	340
Effects of sugary and salty ex-food in pigs' diets on growth performance and pork sensory traits <i>S. Mazzoleni, M. Tretola, C.E.M. Bernardi, P. Lin, P. Silacci, G. Bee and L. Pinotti</i>	340
Performances, milk quality, and piglet growth in lactating sows fed former food products <i>P. Lin, G. Bee, S. Neuenschwander and M. Girard</i>	341
Effect of arginine supplementation on the productive performance of gestating sows: a meta-analysis <i>S. Viridis, D. Luise, P. Bosi and P. Trevisi</i>	341
Are pre-weaning piglet and sow parameters a proxy for uniformity and daily gain? <i>K. Hooyberghs, S. Goethals, W. Gorssen, L. Chapard, R. Meyermans, B. Chakkingal Bhaskaran, S. Millet, S. Janssens and N. Buys</i>	342
Dietary polyphenol extracts improve the performance of broilers challenged with necrotic enteritis <i>S.A. Salami, L. Chew, B.S. Lumpkins and B. Tas</i>	342
Effects of <i>Bacillus subtilis</i> DSM 32315 or <i>Bacillus velezensis</i> CECT 5940 on chicken PBMCs <i>F. Larsberg, M. Spreichert, D. Hesse, G. Loh, G.A. Brockmann and S. Kreuzer-Redmer</i>	343
Effect of creatine monohydrate <i>in ovo</i> feeding on progeny performance of young breeder flocks <i>C.A. Firman, V.K. Inhuber, D.J. Cadogan, W.H.E.J. Van Wettere and R.E.A. Forder</i>	343

Poster Session 20

Statistical modelling and estimation of pig body weight based on its linear body measurements <i>O.T.F. Abanikannda, K.O. Kareem-Ibrahim and Z.A. Ahmad</i>	344

Session 21. Insects as feed: sustainability, legislation and safety

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Veldkamp / Barbosa

Theatre Session 21

invited The potential of insects in sustainable agri-food systems <i>K.B. Barragán-Fonseca</i>	344
Sustainability potential of insect production systems <i>S. Smetana, A. Bhatia, U. Batta, N. Mouhrim and A. Tonda</i>	345

Maximizing sustainability in insect production: a multi-objective optimization approach <i>A. Anita, N. Mouhri, A. Green, D. Peguero, A. Mathys, A. Tonda and S. Smetana</i>	345
Lowering impacts of chicken meat through <i>H. illucens</i> larvae supplementation in the feed? <i>D. Ristic, S. Kechovska, C.L. Coudron, A. Schiavone, J. Claeys, F. Gai and S. Smetana</i>	346
Use of locusts as feed and food: turning threats into opportunities <i>H.P.S. Makkar, V. Heuzé and G. Tran</i>	346
<i>Chrysomya chloropyga</i> in broiler feed: valorising abattoir waste for sustainable feed <i>E. Pieterse, E.Y. Gleeson and L.C. Hoffman</i>	347
Waste side story: a success role for mealworms <i>C. Ricciardi, L. D'Orleans, C. Oundjian, M. Leheup, T. Lefebvre and F. Peyrichou</i>	347
Ammonia emissions of <i>Hermetia illucens</i> larvae grown on different diets <i>C.L. Coudron, S. Berrens, M. Van Peer, J. Claeys and D. Deruytter</i>	348
Chemical & microbiological safety of insect rearing on yet to be legally authorised residual streams <i>E.F. Hoek- Van Den Hil, A.F.G. Antonis, Y. Hoffmans, K. Van Zadelhoff, R. Deurenberg, O.L.M. Haenen, M.E. Bruins, J.W. Van Groenestijn, A. Borghuis, F. Schaafstra, T. Veldkamp, P. Van Wikselaar and M. Appel</i>	348
Growth and chemical composition of insects reared on 'yet to be legally authorised' residual streams <i>S. Naser El Deen, P. Van Wikselaar, A. Rezaei Far, I. Fodor, E.F. Hoek - Van Den Hil, Y. Hoffmans, M.E. Bruins, J.W. Van Groenestijn, A. Borghuis, F. Schaafstra and T. Veldkamp</i>	349
Safety and production performance of insects reared on catering waste <i>E.F. Hoek- Van Den Hil, S. Naser El Deen, K. Van Rozen, P. Van Wikselaar, H.J.H. Elissen, R.Y. Van Der Weide, A. Rezaei Far, I. Fodor, N. Meijer and T. Veldkamp</i>	349
Mycotoxin accumulation and metabolism by insects: an overview <i>K.C.W. Van Dongen, K. Niermans, E.F. Hoek-Van Den Hill, J.J.A. Van Loon and H.J. Van Der Fels-Klerx</i>	350
Manure as a substrate for insect rearing: ecological progress or health risk? <i>A. Anselmo, A. Cordonnier, L. Plasman, J. Maljean, C. Aerts, D. Evrard, A. Marien, E. Janssen, V. Ninane, S. Gofflot, P. Veys, M.-C. Lecrenier, V. Baeten and D. Miché</i>	350
Poster Session 21	
Quality characteristics of black soldier fly produced by different substrates <i>A.R. Hosseindoust, S. Ha, J. Mun, H. Tajudeen, S. Park and J. Kim</i>	351
The value of organic fertilizer from <i>Hermetia illucens</i> frass in the sustainable agriculture <i>S. Kaczmarek and K. Dudek</i>	351
Effects of rearing substrates and processing methods on black soldier fly meal quality <i>S. Ha, A.R. Hosseindoust, Z. Khajehmiri, J. Mun, H. Tajudeen, S. Park and J. Kim</i>	352
The use of insect meals for broiler feeds with a lower environmental footprint <i>P. Chantzi, I. Giannenas, E. Bonos, E. Antonopoulou, C. Athanasiou, A. Grigoriadou, A. Tzora and I. Skoufos</i>	352
Diet mediated PUFA accumulation and $\omega 6$ - $\omega 3$ ratio improvement in mealworm larvae (<i>Tenebrio molitor</i>) <i>S. Yoon, C. Ricciardi, C. Oundjian, M. Leheup, T. Lefebvre and F. Peyrichou</i>	353
Agro-industry by-products for <i>Tenebrio molitor</i> rearing to generate a new aquaculture feed ingredient <i>I. Vieira, D. Murta and M.V. Santos</i>	353

Transfer of veterinary drug residues from substrate to black soldier fly larvae and frass 354
K.C.W. Van Dongen, E. De Lange, L. Van Asseldonk and H.J. Van Der Fels-Klerx

Session 22. Environmental stress: mitigating the adverse effects on animal physiology

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Zachut

Theatre Session 22

Drinking heated water improves the growth performance and rumen microbiota of beef cattle in winter 354
T. He, S. Long, X. Wang, T. Liu and Z. Chen

Elevated temperature induces transcriptional and epigenetic changes in the lungs of chickens 355
D. Schokker, J. De Vos, P.B. Stege, O. Madsen, H.J. Wijnen, S.K. Kar and J.M.J. Rebel

Supplementing heat stressed cows with plant extract affects performance welfare and oxidative stress 355
J.R. Daddam, D. Daniel, I. Pelech, G. Kra, H. Kamer, U. Moallem, Y. Lavon and M. Zachut

Immunomodulatory effect of exosomes from the plasma of heat-stressed cows on bovine monocytes 356
L.G. De Matos, S. Dimauro, M. Falco, J.F.S. Filipe, C. Zamboni, F. Cecilian, V. Martini, A. Agazzi, A. Scarafoni, G.C. Heinzl, G. Sala, A. Boccardo, A. Maggolino, P. Depalo and C. Lecchi

invited Late gestation heat stress: programming effects on three generations 356
J. Laporta

Temporal patterns of environmental heat stress in Holstein heifers: association with age at calving 357
V. Tsiamadis, G.E. Valergakis, A. Soufleri, G. Arsenos, G. Banos and X. Karamanlis

Effect of stocking density on heat stress in fattening pigs 357
L. De Prekel, D. Maes, A. Van Den Broeke and M. Aluwé

Chromium yeast alleviates heat stress in Holstein mid-lactation dairy cows 358
F. Ma, Y. Wo, Q. Shan and P. Sun

May anti-oxidants reduce glyphosate-based herbicides adverse effects on chicken embryo-development? 358
M. Fréville, A. Estienne, C. Ramé, C. Rat, J. Delaveau, P. Froment and J. Dupont

Bromide as a thyroid hormone disruptor 359
H.L. Lucht and N.H. Casey

The impact of THI on milk characteristics, productivity, and metabolism in lactating dairy cows 359
G. Meli, V. Fumo, G. Savoini and G. Invernizzi

Poster Session 22

A selected phytogetic solution improves performance and thermal tolerance of heat stressed pigs 360
A. Morales, P. Sakkas, M. Soto, N. Arce, N. Quilichini and M. Cervantes

Effects of Met, Lys and His supplementation on the metabolic response to heat stress in dairy cows 360
Á. Kenéz, E. Jorge-Smeding, Y.H. Leung, A. Ruiz-González and D.E. Rico

Evaluation of earwax and hair cortisol level in relation to environmental stressors in Hanwoo cattle 361
M. Ataallahi, G.W. Park, E. Nugrahaeningtyas, M. Dehghani, J.S. Lee and K.H. Park

Effects of energy levels and heat stress on growth performance and blood metabolites in Hanwoo calves <i>Y.H. Jo, J.G. Nejad, J.S. Lee, K.K. Park, E.J. Kim and H.G. Lee</i>	361
The effect of a summer diet on heat stress in lactating sows and their piglets <i>A. Van Den Broeke, L. De Prekel, D. Maes and M. Aluwé</i>	362
Physiological implication of omega-3 fatty acid supplementation on animal welfare in laying hens <i>S.K. Kang</i>	362
The effect of different bedding materials on dust and toxic gas concentrations in calf housing <i>D. Witkowska, A. Ponieważ and D. Murawska</i>	363
Mitigate density stress by using a proprietary orange essential oil <i>A.N. Nalovic, A.A. Auvray and J.G. Gabarrou</i>	363
The effects of heating drinking water or calcium propionate on fattening beef cattle in winter <i>T. He, Z. Chen and S. Long</i>	364
Water quality in dairy cattle farms: impact on animal production, reproduction and health <i>V. Resende</i>	364
Study on the effect of improving the pig gut microbiota of <i>Rhodobacter sphaeroides</i> <i>D. Shin, J. Park, S. Son, H. Lee and J. Kim</i>	365
Algae-based beta-glucan mitigates the adverse effects of heat stress in lactating sows <i>J. Mun, A. Hosseindoust, S. Ha, S. Park, H. Tajudeen, S. Oh and J. Kim</i>	365
Effect of dietary mineral level and creep feeding on sows performance under high ambient temperature <i>H. Tajudeen, A. Hosseindoust, J.Y. Mun, S. Ha, S. Park, S. Yoon and J. Kim</i>	366

Session 23. Improving animal welfare in conventional production systems

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Minozzi / Trocino

Theatre Session 23

invited Pre-weaned dairy calf welfare: from the 'End the Cage Age' movement to the EFSA mandate <i>M. Brscic</i>	366
Impact of individual pens removal on veal calves' behaviour <i>D. Bastien and V. Lefoul</i>	367
Quarter level milk yield in dairy cows before and after separation in a cow-calf contact system <i>S. Ferneborg and S. Agenäs</i>	367
Two different training protocols to encourage dam-reared calves to drink supplemental milk <i>J. Sørby, S. Ferneborg, S.G. Kischel and J.F. Johnsen</i>	368
Effects of automatic TMR feeding system on the health status of finishing bulls and heifers <i>O. Martinić, L. Magrin, P. Prevedello, G. Fabbri, G. Cozzi and F. Gottardo</i>	368
Associations between feed push-up frequency, feeding behaviour and milk yield in dairy buffaloes <i>G. Esposito, E. Raffrenato, G. Bosoni, F. Caruso and F. Righi</i>	369
Comparing dairy cow welfare in loose-housing and in tie-stall systems using animal-based indicators <i>V. Lorenzi, L. Bertocchi, C. Montagnin and F. Fusi</i>	369

Time-controlled hay racks horses: what effect on behaviour? <i>M. Roig-Pons and S. Briefer</i>	370
Exploring techniques to mitigate heat stress in feedlot lambs <i>P.G. Theron, T.S. Brand, S.W.P. Cloete and K. Dzama</i>	370
Management practices and welfare of dairy goats in Greece <i>G. Arsenos, S. Vouraki, V. Papanikolopoulou, L.V. Ekateriniadou and I. Sakaridis</i>	371
Risk factors for navigation ability of laying hens at housing in an aviary system <i>C. Ciarelli, F. Bordignon, G. Pillan, G. Xiccato and A. Trocino</i>	371
Busy birds – what do turkey hens use dust baths for? <i>K. Skiba, M. Kramer, P. Niewind, B. Spindler and N. Kemper</i>	372
Pre-slaughter fasting on stress response and meat quality in rainbow trout (<i>Oncorhynchus mykiss</i>) <i>A. De La Llave-Propín, A. Martínez Villalba, R. González Garoz, J. De La Fuente, C. Pérez, E. González De Chavarri, M.T. Díaz, A. Cabezas, M. Villarroel and R. Bermejo-Poza</i>	372

Poster Session 23

Effects of a new cooled cubicle waterbed on cow behaviour and lameness: a randomized control trial <i>O. Levrard, R. Guatteo, A. Lehébel, L. Bouglé, M. Tourillon, N. Brisseau and A. Relun</i>	373
Evaluation of milk and residual milk production of dairy Gyr cows <i>R.C. Castanheira, M.I. Paiva, K.T. De-Sousa, M.S.V. Salles, E.A. Silva and L. El Faro</i>	373
Environmental enrichment and tactile stimulation on the welfare of F1 Holstein × Gir calves <i>C.O. Miranda, A.E. Vercesi Filho, M.L.P. Lima, F.F. Simili, M.S.V. Salles, E.G. Ribeiro, J.A. Negrão and L.E.F. Zadra</i>	374
Heat stress indicators in dairy cattle breeding provided by automatic milking systems (AMS) <i>M.A. Leandro, J. Stock, J. Bennewitz and M.G.G. Chagunda</i>	374
Impact of floor type and group size on veal calves' behaviour <i>D. Bastien and V. Lefoul</i>	375

Session 24. New traits and proxies from sensor technologies for breeding purposes

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Pocrnic / Lourenco

Theatre Session 24

Heterogeneity of 3D cameras feed intake heritabilities in Holstein, Jersey and Nordic Red cows <i>C.I.V. Manzanilla-Pech, R.B. Stephansen and J. Lassen</i>	375
Genomic correlations of MIR-predicted and measured feed efficiency traits in Holstein Friesian <i>A. Seidel, C. Heuer, L.M. Dale, A. Werner, H. Spiekers and G. Thaller</i>	376
Heritability of dry matter intake in Norwegian Red with measures on feed intake in commercial herds <i>K.A. Bakke and B. Heringstad</i>	376
Assessing the potential of faecal NIR spectra for the prediction of feed efficiency in dairy cows <i>S. Ampuero Kragten, T. Haak, K.-H. Südekum and F. Schori</i>	377

Genetic parameters for potential auxiliary traits for lameness based on data from PLF technologies <i>K. Schodl, B. Fuerst-Waltl, F. Steininger, M. Suntinger, H. Schwarzenbacher, A. Köck, D4dairy Consortium and C. Egger-Danner</i>	377
Breeding for resilience based on rumination time data of Chinese Holstein heifers <i>W. Lou, R. Shi, B. Ducro, A. Van Der Linden, H.A. Mulder, S.J. Oosting and Y. Wang</i>	378
Validation of a high-throughput movable 3D device for the acquisition of the whole cattle body <i>A. Lebreton, C. Allain, L. Delattre, J. Loof, Y. Do and M. Bruyas</i>	378
MIRS coupled with machine learning for the prediction of cow colostrum immunoglobulins concentration <i>A. Costa, A. Goi and M. De Marchi</i>	379
Extracting video-based phenotypes in a pig breeding programme <i>C. Coello, Ø. Nordbø, R. Sagevik, F. Cheikh, M. Ullah, K.H. Martinsen and E. Grindflek</i>	379
Impact of the social effect on feeding behaviour in pigs <i>P. Núñez, S. Gol, J. Reixach and N. Ibañez-Escriche</i>	380
Assessing lactating sow behaviour using sensor technology and machine learning <i>G. Dumas, L. Maignel, J.-G. Turgeon and P. Gagnon</i>	380
Relationships between sow activity over the days after farrowing and litter weight gain <i>O. Girardie, D. Laloë, M. Bonneau, Y. Billon, J. Bailly, I. David and L. Canario</i>	381
Multi-camera tracking of turkeys in large groups using instance segmentation <i>Z. Wang, P. Langenhuizen, B. Visser, H.P. Doekes, P. Bijma and P.H.N. De With</i>	381
Evaluation of tracking individual broilers using video data <i>J.E. Doornweerd, G. Kootstra, R.F. Veerkamp, B. De Klerk, M. Van Der Sluis, A.C. Bouwman and E.D. Ellen</i>	382

Poster Session 24

Genetic variation of new sheep traits measured by dual energy Xray absorptiometry <i>C.E. Payne, B. Paganoni, S.F. Walkom, G.E. Gardner and D.J. Brown</i>	382

Session 25. Molecular measures of diversity and their role in monitoring and management of breeds

Date: Monday 28 August 2023; 14.00 – 18.00

Chair: Danchin / Fernandez

Theatre Session 25

invited Monitoring within-breed genetic variation at global level <i>G. Leroy, R. Baumung, G. Mészáros, I. Curik, J.J. Windig, B. Rosen, Y.T. Utsunomiya, P. Burger, L. Coli, P. Boettcher, A. Stella, C. Looft and J. Soelkner</i>	383
Real-time monitoring of genetic diversity in animal populations: the RAGEMO project <i>C. Danchin, I. Palhière, B. Servin and G. Restoux</i>	383
Evolution of the genomic relationship between a local breed and its mainstream sister breed <i>H. Wilmot, M.P.L. Calus and N. Gengler</i>	384
Fine decomposition of inbreeding into the source of the co-ancestries <i>S. Antonios, S.T. Rodríguez-Ramilo, J.M. Astruc, L. Varona and Z.G. Vitezica</i>	384

Predicting homozygosity-by-descent to manage inbreeding and diversity <i>N.S. Forneris and T. Druet</i>	385
GWAS analyses for dairy traits in Cyprus sheep and goat breeds reveal important protein networks <i>G. Maimaris, A.N. Georgiou, A.C. Dimitriou and G. Hadjipavlou</i>	385
A severely introgressed South China pig breed in urgent need of purification <i>L. Cao, T. Luan, T.H.E. Meuwissen, P. Berg, J. Yang and Z. Wu</i>	386
Insights into ancient and recent inbreeding patterns in Alpine Grey cattle using ROH analysis <i>G. Gomez Proto, E. Mancin, B. Tuliozi, C. Sartori and R. Mantovani</i>	386
Study of Bottleneck effect for conservation of Poonchi chicken from international borders of India a <i>M. Azad, D. Chakraborty, K. Kour, D. Kumar and P. Birwal</i>	387
Up to date results from the ongoing <i>in situ</i> genetic management of the local breed Noire de Challans <i>R. Rouger, H. Deloison, M. Teissier, G. Restoux and S. Brard-Fudulea</i>	387
An empirical approach to assess increase in homozygosity: the Gochu Asturcelta pig <i>K.D. Arias, J.P. Gutiérrez, I. Fernández, I. Álvarez and F. Goyache</i>	388
Preliminary analysis of Nubian goats and their influence on Old English and Anglo-Nubian goats <i>S.A. Rahmatalla, D. Arends, G.B. Neumann, H. Abdel-Shafy, J. Conington, M. Reissmann, M.K. Nassar and G.A. Brockmann</i>	388
Towards a flexible definition of core sets based on the haplotype diversity of German sheep <i>J. Geibel, C. Reimer, A. Weigend, Y. Shakya, H. Melbaum, K. Gerdes and S. Weigend</i>	389
Use of genomic information for the determination of insemination doses per sire in a gene bank <i>C. Reimer, S. Weigend, T. Pook and J. Geibel</i>	389
Poster Session 25	
Is it possible to skip the SNP selection step for breed assignment? <i>H. Wilmot, T. Niehoff, H. Soyeurt, N. Gengler and M.P.L. Calus</i>	390
Copy number variation regions differing in segregation patterns spanned different sets of genes <i>K.D. Arias, J.P. Gutiérrez, I. Fernández, I. Álvarez and F. Goyache</i>	390
Genomic characterization as tool in the breed recognition process <i>C. Danchin and D. Duclos</i>	391
Homozygosity by descent in mice divergently selected for environmental birth weight variability <i>C. Ojeda-Marin, J.P. Gutiérrez, N. Formoso-Rafferty and I. Cervantes</i>	391
Inbreeding depression is associated with recent HBD segments in Belgian Blue beef cattle <i>M. Naji, J.L. Gualdron Duarte, N.S. Forneris and T. Druet</i>	392
Assessing the intrapopulation structure of Slovak Spotted cattle by genome-wide data <i>R. Kasarda, N. Moravčíková, J. Candrák, J. Prišták and I. Pavlík</i>	392
Genomic selection has aided Nordic Jersey to decrease risks of inbreeding <i>S. Tenhunen, J.R. Thomasen, L.P. Sørensen, P. Berg and M. Kargo</i>	393
Management of local cattle breed diversity in Croatia: use of molecular and pedigree indicators <i>A. Ivanković, Z. Ivkić, G. Šubara, M. Pečina, J. Ramljak and M. Konjačić</i>	393

Genomic differences between the domesticated pig breed and its ancestor wild boar <i>N. Moravčíková, R. Kasarda, M. Hustinová, E. Krupa, Z. Krupová and E. Žáková</i>	394
Genetic polymorphism of kappa-casein in Serbian Holstein-Friesian cattle <i>M. Zorc, M. Šaran, L.J. Štrbac, D. Janković, P. Dovč and S. Trivunović</i>	394
Estimation of recent and ancestral inbreeding for X-chromosome in Old Kladrub horse <i>L. Vostry, M. Shihabi, J. Farkas, G. Kövér, H. Vostra-Vydrova, B. Hofmanova, I. Nagy and I. Curik</i>	395
Genetic diversity and population structure of a Peruvian nucleus cattle herd using SNP data <i>F.-A. Corredor, D. Figueroa, R. Estrada, W. Salazar, C. Quilcate, H. Vasquez, J. Gonzales, J. Maicelo, P. Medina and C. Arbizu</i>	395
Within-breed stratification for across-breed reference population <i>H. Wilmot, T. Druet, I. Hulsege, N. Gengler and M.P.L. Calus</i>	396

Session 26. EAAP Plenary Session

Date: Tuesday 29 August 2023; 8.30 – 13.00

Chair: Casasús

Theatre Session 26

invited The livestock sector and research in animal science in France <i>X. Fernandez, J.F. Hocquette and S. Ingrand</i>	396
invited Solutions to achieve healthy and sustainable diets worldwide <i>H. Guyomard, A. Forslund, A. Tibi, B. Schmitt, P. Debaeke and J.-L. Durand</i>	397
invited Moving towards bold food systems resilience <i>J. Fanzo</i>	397
invited A social-ecological agenda for transforming land management toward sustainability <i>T. Plieninger</i>	398
invited EAAP beyond Europe: establishing and using capacity to feed the world <i>H. Sölkner</i>	398

Session 27. Breeding programs & strategies

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Egger-Danner / Martin

Theatre Session 27

Effect of genomic selection on allele frequencies of QTL associated to number of teats in pigs <i>C.A. Sevillano, B. Harlizius, M.S. Lopes, M. Van Son and E.F. Knol</i>	399
Management of genetic defects in breeding programs <i>S.T. Rodríguez-Ramilo, I. Palhière, J. Raoul and J. Fernández</i>	399
Genetic management of cryptorchidism and horn mutations in Manech tête Rousse dairy sheep breed <i>J. Raoul, F. Fidelle, C. André, M. Ben Braiek, S. Fabre, A. Gouzenes, D. Buisson and I. Palhière</i>	400
Strategies to improve selection compared to selection based on estimated breeding values <i>T. Pook, T. Niehoff, Y. Wientjes, L. Zetouni, M. Schrauf and M. Calus</i>	400

The validity of breeding goals <i>R. Wellmann</i>	401
Beyond scenarios-optimization of breeding program design using evolutionary algorithms (MoBPSopti) <i>A. Hassanpour, J. Geibel and T. Pook</i>	401
Ecobreed – what is the economically optimal longevity of a cow? <i>S. Schlebusch</i>	402
Differences in breast milk composition in rabbit lines divergently selected for intramuscular fat <i>P. Hernández, N. Ibáñez, I. Heddi, M. Martínez-Álvaro and A. Zubiri-Gaitán</i>	402
Combined genomic evaluation of Australian Merino and Dohne Merino sheep populations <i>M. Wicki, D.J. Brown, P.M. Gurman, J. Raoul, A. Legarra and A.A. Swan</i>	403
Effect of germplasm exchange strategies on genetic gain and diversity in dairy stud populations <i>E.A. Lozada-Soto, F. Tiezzi, J. Jiang, J.B. Cole, P.M. Vanraden, S. Toghiani and C. Maltecca</i>	403
Local livestock breeds in Flanders are confirmed to be 'at risk'! <i>S. Janssens, L. Chapard, R. Meyermans, W. Gorssen and N. Buys</i>	404
Probabilistic breeder's equation used for retrospective and prospective analyses <i>D. López-Carbonell, I. Pocrnic, G. Gorjanc and L. Varona</i>	404

Poster Session 27

Re-organising the Danish dairy cattle sector with alternative breeding goals and crossbreeding <i>J.B. Clasen, R.D. Kring, J.R. Thomasen and S. Østergaard</i>	405

Session 28. Breeding for improved animal health and welfare

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Kargo / Tiezzi

Theatre Session 28

invited How to balance selection for litter size in pigs with survival, health and welfare <i>P.W. Knap, A. Huisman, C. Sørensen and E.F. Knol</i>	405
Selection for robustness and welfare in Iberian pig through birth weight uniformity as criterion <i>J.P. Gutiérrez, N. Formoso-Rafferty, F. Sánchez-Esquiliche, M. Muñoz, J.M. García-Casco and I. Cervantes</i>	406
Resilience parameters in fattening pigs are heritable and associated with tail biting and mortality <i>W. Gorssen, C. Winters, R. Meyermans, L. Chapard, K. Hooyberghs, J. Depuydt, S. Janssens, H. Mulder and N. Buys</i>	406
The impact of phenotyping, genotyping, and the boar's origin on the genetic gain of organic pigs <i>R.M. Zaalberg, J.B. Clasen, T.M. Villumsen, J. Jensen and T.T. Chu</i>	407
Genetic correlations between ostrich behavioural traits and slaughter traits <i>P.T. Muvhali, M. Bonato, A. Engelbrecht, I.A. Malecki and S.W.P. Cloete</i>	407
Genome-wide copy number variants associated with calving ease and retained placenta in Holstein cows <i>I.C. Hermisdorff, H.R. Oliveira, G.A. Oliveira Júnior, T.C.S. Chud, S.G. Narayana, C.M. Rochus, A.M. Butty, F. Malchiodi, P. Stothard, F. Miglior, C.F. Baes and F.S. Schenkel</i>	408

Indirect effects in infection transmission enhance genetic selection and other interventions <i>A.D. Hulst, P. Bijma and M.C.M. De Jong</i>	408
Optimizing dairy cattle breeding goals to improve production and udder health of crossbred cows <i>A. Bouquet, H.M. Nielsen, V. Milkevych, M. Kargo, J.R. Thomasen and M. Slagboom</i>	409
Genes and variants involved in resistance to paratuberculosis in Holstein and Normande cattle <i>V. Sorin, A. Boulling, A. Delafosse, M. Boussaha, C. Hozé, R. Guatteo, C. Fourichon, S. Fritz, D. Boichard and M.P. Sanchez</i>	409
A genome-wide association study for clinical mastitis in Italian Holstein <i>F. Galluzzo, G. Visentin, G. Mészáros, J.B.C.H.M. Van Kaam, R. Finocchiaro, M. Marusi and M. Cassandro</i>	410
About the genetic connection between milk and health traits in dairy cows within functional regions <i>H. Schneider, J. Heise, A.-M. Krizanac, C. Falker-Gieske, J. Tetens, G. Thaller and J. Bennewitz</i>	410
Poster Session 28	
Frequency of genetic disorders in genomically tested females in the Netherlands <i>C. Schrooten and E. Mullaart</i>	411
Genome regions and metabolic processes associated with tick resistance in beef cattle <i>P. Martin, T. Hüe, J. Mante, A. Lescane, D. Boichard and M. Naves</i>	411
Innovative strategy using phenotypes and genetics to optimize partial sampling applied to boar taint <i>A. Markey, J. Wavreille, P. Mayeres, A.C. Huet, D. Duarte and N. Gengler</i>	412
Genetic susceptibility determined by SNP2 in piglets challenged with F4-Enterotoxigenic <i>E. coli</i> <i>A. Middelkoop, H. Kettunen, X. Guan, J. Vuorenmaa, R. Tichelaar, M. Gambino, M.P. Rydal and F. Molist</i>	412
Reference genes selection for RT-qPCR in chickens after in ovo synbiotic and choline administration <i>E. Grochowska, P. Guz, K. Stadnicka and M. Bednarczyk</i>	413
Genetic parameters of coronet scores related to hoof disorders in Japanese dairy cattle <i>Y. Saito, A. Nishiura, T. Yamazaki, S. Yamaguchi, O. Sasaki and M. Satoh</i>	413
Selection for a lower growth rate to avoid reaching bone apposition limits in chickens <i>C. Leterrier</i>	414
Daily milk yield, variance and skewness of milk deviations in cows' resilience <i>L. Zavadilová, E. Kašná, J. Vařeka and Z. Krupová</i>	414
Lameness scoring and its use in genetic selection to improve claw health in Austrian Fleckvieh cows <i>A. Köck, C. Fuerst, B. Fuerst-Waltl, M. Suntinger, K. Linke, J. Kofler, K. Schodl, F.J. Auer and C. Egger-Danner</i>	415
Association between udder health genomic breeding values and dairy and health traits in French cows <i>R. Lefebvre, S. Barbey, F. Launay, M. Gaborit, L. Delaby, P. Martin and D. Boichard</i>	415
Validating resilience indicators derived from longitudinal performance measurements <i>M. Ghaderi Zefreh, R. Pong-Wong and A. Doeschl-Wilson</i>	416
Approaching the genetic evaluation models for clinical mastitis in Spanish dairy cows <i>M.A. Pérez-Cabal, I. Cervantes, J.P. Gutiérrez, J. López-Paredes and N. Charfeddine</i>	416

Milk somatic cell counts in winter and summer are genetically different traits in Norwegian goats <i>H.B. Olsen, J. Jakobsen and T. Blichfeldt</i>	417
Effects of two different traditional sire breeds on performance and behaviour of rearing pigs <i>A. Lange, M. Wutke, S. Ammer, A.K. Appel, H. Henne, A. Deermann and I. Traulsen</i>	417
Evaluation of milk parameters and mastitis predisposition in Cyprus Chios sheep <i>S. Panayidou, T. Christofi, A.N. Georgiou and G. Hadjipavlou</i>	418
Influence of early rearing system on later performance of commercial laying hens <i>Q. Berger, N. Bédère, P. Le-Roy, S. Lagarrigue, T. Burlot and T. Zerjal</i>	418
Differentially expressed genes in tissues of Pietrain sired pigs challenged with high fiber/fat diet <i>E.U. Nwosu, B. Chakkingal Bhaskaran, E. Kowalski, W. Gorssen, R. Meyermans, S. Janssens, S. Millet, M. Aluwé, S. De Smet and N. Buys</i>	419
GWAS based on imputed sequence-level genotypes in a huge cow data set: many roles for the GC gene <i>A.M. Krizanac, C. Falker-Gieske, C. Reimer, J. Heise, Z. Liu, J. Pryce, J. Bennewitz, G. Thaller and J. Tetens</i>	419
GWAS for clinical metritis in Polish HF cows <i>P. Topolski, T. Suchocki and A. Żarnecki</i>	420
Genetic relationships between mastitis, milk yield traits and somatic cell count in Polish HF cows <i>P. Topolski and W. Jagusiak</i>	420

Session 29. Innovative animal products and farming systems oriented to new consumer demand and trend

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Resconi / Realini

Theatre Session 29

invited A New Zealand perspective of the role of genetics in underpinning future sheep production systems <i>P. Johnson, D. Scobie, S.-A. Newman, S.J. Rowe, S.M. Clarke and K.M. McRae</i>	421
Blockchain technology in the beef breeding sector <i>B. Jornet and I. Achour</i>	421
Using science to optimise production systems to produce a premium product – the LuminaTM Lamb Story <i>P.L. Johnson, S. Saunders and A. McDermott</i>	422
Factors influencing willingness to pay for red meat with potential to improve consumer wellness <i>R. Zhang, Z. Kallas, M.P.F. Loeffen, M. Lee, L. Day, M.M. Farouk and C.E. Realini</i>	422
Perception of the use of rangeland and roughage by actors of the organic pig and layer hen sectors <i>L. Montagne, M. Goujon and F. Marie</i>	423
invited Role of dairy foods in human nutrition <i>C.M. Weaver</i>	423
Organoleptic properties of fast-growing and slow-growing chicken meat <i>R. Berrocal, L. Mur, J.L. Olleta, V. Resconi, M. Barahona, J. Romero and M.M. Campo</i>	424
Implementation of sustainable livestock farming principles for generating innovative animal products <i>M. Cohen-Zinder, E. Shor-Shimoni, H. Omri, F. Garcia Solares, S. Kaakoosh and A. Shabtay</i>	424

Recent changes and future expectations about meat consumption 425
F. Montossi, G. Ares, L. Antúnez, G. Brito, M. Del Campo, C. Saunders, M. Farouk and C.E. Realini

invited Sustainability in the beef sector: aligning consumer and farmer perspectives 425
M. Henchion and V.C. Resconi

Poster Session 29

FT-MIR spectroscopy to discriminate intramuscular fat of beef fed conventional vs sustainable diets 426
S. León-Ecay, I. Goenaga, A. López-Maestresalas, A. Gobeti Barro, M.P. Ellies-Oury, M. Beruete and K. Insausti

Study of the genetic parameters of the destructured meat defect of ham on 3 male lines 426
A. Le Dreau, C. Garcia Baccino, D. Penndu, A. Buchet, P. Doussal and B. Ligonésche

Consumers' perception towards using seaweed as an alternative to antibiotics in rabbits in Spain 427
S. Al-Soufi, J. García, E. Cegarra, A. Muñíos, M. Miranda and M. López-Alonso

Perceptions of viticulture-livestock complementarity in Burgundy: first insights 427
R. Ibdih, O. Aguirre-Saavedra, S. Ambrosino, G. Houndafoche, M. Seignon, Y. Tanguy-Roump and C. Philippeau

Feeding seaweed as an alternative to antibiotics in growing rabbits improves the meat fat profile 428
S. Al-Soufi, J.M. Lorenzo, J. García, E. Cegarra, A. Muñíos, M. Miranda and M. López-Alonso

Effects of lamb genotype, primal cuts, and vegetables on baby soups' sensory acceptability 428
M.R. Marques, M. Pimpão, C. Oliveira and J.M. Almeida

Lipid fraction composition of the longissimus thoracis of Lidia beef breed 429
M.M. Campo, M. Barahona, V.C. Resconi, J.V. Romero, S. Romero, S. Zabala, J. Villalon and J.L. Olleta

Innovation in the production and marketing of local breed products, path to long-term sustainability 429
A. Ivanković, G. Šubara, E. Šuran, M. Cerjak, J. Ramljak and M. Konjačić

The ability of the Distell fatmeter to predict intramuscular fat in Yellowtail Kingfish 430
D. Milotic, F. Anderson, G. Partridge, A. Lymbery and G. Gardner

Effect of game species on fatty acids, meat quality and shelf life 430
M.N. Hlohlongoane, U. Marume, O.C. Chikwanha and C. Mapiye

Selection for A2 β -casein genotype in Holstein bulls 431
L. Jiménez-Montenegro, L. Alfonso, J.A. Mendizabal and O. Urrutia

Session 30. Looking back, looking forward – Research on Beef production and quality in China and France (CSBF) and between Australia-France-China (The Triangle Project)

Date: Tuesday 29 August 2023; 15.00 – 18.30
 Chair: Liu / Pethick

Theatre Session 30

Consumer perception of the challenges facing livestock production and meat consumption 431
J.J. Liu, S. Chiriki, M. Kombolo, M. Santinello, S. Pflanzner, É. Hocquette, M.P. Ellies-Oury and J.F. Hocquette

invited Sustainable development of China's beef industry driven by a successful triangle beef cooperation 432
Q. Meng

invited	The production and quality improvement of mutton in China <i>H.L. Luo</i>	432
	Comparison of sheep meat eating quality thresholds for Chinese, American and Australian consumers <i>R.A. O'Reilly, D.W. Pethick, G.E. Gardner, A.B. Pleasants and L. Pannier</i>	433
	Differences in liver nutrient metabolism contribute to residual feed intake of beef cattle <i>Z.M. Zhou</i>	433
	Marbling in French cattle: average level and factors of variations <i>A. Nicolazo De Barmon, I. Legrand and J. Normand</i>	434
	Effect of high sulphur diet on rumen fermentation and epithelial barrier function in beef cattle <i>H. Wu, Y. Li, Q.X. Meng and Z.M. Zhou</i>	434
	Research progress on quality characteristics and regulation of yak meat in China <i>L.Z. Hao, B.Q. Bai, Y. Xiang, Q.X. Meng, J.Z. Niu, Y.Y. Huang and S.J. Liu</i>	435
	Comparison of beef eating quality terminology databases <i>A. Barro, K. Insausti, M. Kombolo, M.P. Ellies-Oury and J.F. Hocquette</i>	435
	Comparison of slaughter performance and meat quality of Tan sheep under different feeding regimes <i>X.G. Zhao, C. Zhang, M. Liu and H.L. Luo</i>	436
	Effect of <i>Piper sarmentosum</i> extract on the growth and nutrient digestion of Hainan Black goat <i>G.D. Ren, Z.Y. Sheng, Y.X. Chen, X.G. Zhao, H. Zhang, H.L. Zhou, W.L. Lv and H.L. Luo</i>	436
	Effects of grazing intensities and supplementary levels on the nutritional composition of lamb meat <i>H. Yang, J. Ji and H.L. Luo</i>	437

Poster Session 30

	Perspectives on consumer attitudes to meat consumption <i>P. Purslow, W. Zhang and J.F. Hocquette</i>	437
	Effects of different grazing intensities and supplementary feeding levels on meat quality of Hulunbu <i>X.H. Ma, Z. Li, X.G. Zhao, H. Yang and H.L. Luo</i>	438
	Progress of yak carcass grading in Qinghai-Tibet Plateau of China <i>S.S. Zhang</i>	438

Session 31. Pasture based solutions to realise a role for ruminants in a sustainable food system

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Boland / Baumont

Theatre Session 31

invited	Future-proofing the sustainability of pasture based beef production systems <i>A.K. Kelly and T.M. Boland</i>	439
	Effect of sward type on growth performance and methane output of lambs in the post-weaning period <i>S. Woodmartin, P. Creighton, T.M. Boland, A. Monaghan and F. McGovern</i>	439
	On farm grass growth prediction in Ireland – 4 year evaluation <i>E. Ruelle, L. Bonnard, D. Hennessy, L. Delaby and M. O'Donovan</i>	440

Incorporating plantain forage into a grazing dairy system: effect on farm productivity <i>O. Al-Marashdeh and H.M.G.P. Herath</i>	440
Dry matter production of multispecies swards under dairy grazing in two chemical nitrogen scenarios <i>C. Hearn, M. Egan, M.B. Lynch and M. O'Donovan</i>	441
Nitrogen herbage yield in grass and grass-white clover swards receiving zero nitrogen <i>A. Murray, B. McCarthy and D. Hennessy</i>	441
Grassland-based dairy farms of French Massif Central adapt to climate change with diverse strategies <i>L. Allart, V. Oostvogels, F. Joly, C. Mosnier, N. Gross and B. Dumont</i>	442
Effect of grazing intensity on nitrogen cycle of alpine summer pasture soil <i>S. Raniolo, A. Squartini, L. Da Ros, F. Camin, L. Bontempo, L. Maretto, D. Gianelle, M. Ramanzin, E. Sturaro and M. Rodeghiero</i>	442
The visibility of the invisible: analysing heifers reactions while learning the virtual fence system <i>D. Hamidi, N.A. Grinnell, M. Komainda, L. Wilms, F. Riesch, J. Horn, M. Hamidi, I. Traulsen and J. Isselstein</i>	443
Sheep integration into cropping systems for agroecological transition of farming systems in France <i>F. Stark, J. Ryschawy, R. Mettauer, M. Grillot, I. Shaqura and M. Moraine</i>	443
Nutrient cycling and efficiency: a comparative flow analysis of meat and dairy sheep farming systems <i>F. Stark, N. Amposta, W. Nasri, M. Lamarque, S. Parisot, P. Salgado and E. González-García</i>	444
Pasture-based ruminants and biodiversity in contrasting contexts: an account of farmers' narratives <i>V.J. Oostvogels, B. Dumont, H.J. Nijland, L. Allart, I.J.M. De Boer and R. Ripoll-Bosch</i>	444
Poster Session 31	
Meat quality in Podolian young bulls grazing on wood-pasture in a South Italy marginal area <i>F. Giannico, S. Tarricone, A. Caputi Jambrenghi, L. Tedone, D. Campanile and M.A. Colonna</i>	445
Good management of the pasture makes it possible to reduce the supplementation of autumn calves <i>D. Douhay</i>	445
Investigating the effects of lactation number, stage, and milking interval on nitrogen use efficiency <i>Y.M. Hu</i>	446
Plasma urea and diet crude protein concentration relationship in grazing dairy cows <i>R. Delagarde and N. Edouard</i>	446
An assessment of woody forage resources indigenous to southern Africa <i>M. Trytsman, F.L. Müller, M.I. Samuels, C.F. Cupido and A.E. Van Wyk</i>	447
The Effect of heterofermentative lactic acid bacteria on quality of King Napier grass <i>P. Lounglawan</i>	447
Grass chemical composition to predict methane production from grazing sheep at high latitude <i>Q. Lardy, M. Hetta, M. Ramin and V. Lind</i>	448
Forage height of native grasslands as an indicator of spatial and temporal grazing management <i>P. Aparicio, I. Paparamborda and P. Soca</i>	448
Improve the efficiency of fattening grazing sheep on rangeland by supplementary feeding <i>Y. Zhang and M. Xu</i>	449

The use of sheep of native breeds in the control of invasive plants 449
M. Pasternak, M. Puchała, J. Sikora and A. Kawęcka

Session 32. Beyond rumen: role of nutrition in cattle's intestinal health

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Kreuzer / Pinotti

Theatre Session 32

invited Post-rumen health and its implications on health and performance 450
M.V. Sanz-Fernandez

invited Impacts of inflammation and inflammatory diseases on reproduction in dairy cows 450
J.E.P. Santos

invited The role of mycotoxins in the rumen and intestinal health of dairy cows 451
A. Gallo

invited Absorption, metabolism and secretion of tocopherol (vitamin E) stereoisomers in dairy cows 451
S.K. Jensen and S. Lashkari

invited The role of rumen health (acetate) on milk fat synthesis and dietary strategies to increase milk fat 452
K.J. Harvatine and C. Matamoros

Session 33. Horses in farms and territories: challenges and new solutions

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Vial / Tapprest

Theatre Session 33

EUNetHorse-European network to improve the resilience and the performance of equine farms 452
M. Addes

Robustness of equine business structures and global coherence 453
S. Boyer

The equine network, a tool for horse professionals, advisors and teachers 453
G. Mathieu

Does the diversity of the French territories impact farms keeping equines? 454
J. Veslot and G. Bigot

Equestrian practitioners: essential services to support self-organization 454
C. Eslan, C. Vial and S. Costa

Agricultural animal traction in France: characterization of the practice and its users 455
M.M. Miara, M.G. Gafsi and P.B. Boudes

Effects of milking interval and frequency on milk yield in the mare 455
J. Auclair-Ronzaud, M. Bouchet, L. Laschon, E. Lambolez and L. Wimel

Mineral profile of pasture-based mare milk from Basque Mountain horse breed: effect of lactation 456
A. Blanco-Doval, L.J.R. Barron and N. Aldai

Sustainable utilisation of horse manure 456
M. Meyer, C. Eiberger, T. Schilling, D. Winter and L.E. Hoelzle

Use of green waste compost as an alternative bedding to straw in horse husbandry <i>H. Unseld, D. Winter and M. Meyer</i>	457
Grazing management on practical horse farms <i>C. Siede, M. Komainda, B. Tonn, S.C.M. Wolter, A. Schmitz and J. Isselstein</i>	457
Use of digital technologies in horse husbandry to increase animal welfare and health <i>M. Pfeiffer, D. Winter, U. Dickhoefer and L.T. Speidel</i>	458

Poster Session 33

Working time requirements of work processes in the individual keeping of horses <i>L.T. Speidel, D. Winter and U. Dickhoefer</i>	458
Equine traction in viticulture: what about the workload of the horse-driver pair? <i>B. Pasquiat, N. Delepouve and C. Bénézet</i>	459
Physiological and behavioural responses of donkeys to effort and discomfort <i>N. Seguin, C. Bonnin, A. Ruet and S. Biau</i>	459
Offering horse meat in restaurants to develop the demand <i>C. Vial, M. Sebbane and A. Lamy</i>	460
Relationship between average daily gain and an estimation of consumed grass <i>L. Wime, C. Lesoudard and J. Auclair-Ronzaud</i>	460
Comparison of flying and soil invertebrates' biodiversity on meadows with or without horse grazing <i>G. Goudet, F. Reigner and M. Beltramo</i>	461
Alterations of faecal microbiota in Jeju crossbred weanling horses <i>J.A. Lee, M.C. Shin, J.Y. Choi and S.M. Shin</i>	461
Colic incidence among horses in different husbandry systems <i>E. Schlotterbeck, L.T. Speidel and D. Winter</i>	462

Session 34. Sustainable pig and poultry production, including the use of water

Date: Tuesday 29 August 2023; 15.00 – 18.30
Chair: Bee / Brodziak

Theatre Session 34

The effect of feeding a soy-free diet on performance and carbon footprint of the feed intake by pigs <i>S. Millet, M. Lourenço, S. Palmans and C. De Cuyper</i>	462
Exploring variation in feed efficiency of grower-finisher pigs <i>M. Van Der Heide, J.V. Nørgaard and J.G. Madsen</i>	463
Former food slightly affect pig faecal microbiota without impairing jejunal integrity and physiology <i>M. Tretola, S. Mazzoleni, P. Silacci, L. Pinotti and G. Bee</i>	463
Bakery products and legume seeds in the diet of growing-finishing pigs <i>M. Van Helvoort and P. Bikker</i>	464
Recycling agricultural by-products: using purple carrots as an ingredient in layer quails feeding <i>A.S.-G. Sarmiento-García, A.B.-D. Benito-Díaz, C.V.-A. Vieira-Aller and O.O. Olgun</i>	464

Effect of camelina cake doses as soybean meal substitutions on growth and gut health of piglets <i>D. Luise, F. Correa, S. Virdis, C. Negrini, G. Cestonaro, L. Nataloni, G. Titton, E. Sattin, E. Costanzo and P. Trevisi</i>	465
The dietary fibre solubility in the maternal diet does not affect the muscle development of piglets <i>M. Girard, F. Correa, F. Palumbo, P. Silacci and G. Bee</i>	465
Improving the sustainability of the Australian pork industry <i>G.L. Wyburn</i>	466
Are tailor-made health plans effective in triggering changes in pig farm management? <i>P. Levallois, M. Leblanc-Maridor, A. Scollo, P. Ferrari, C. Belloc and C. Fourichon</i>	466
Pork production can contribute positively to human protein supply <i>R.J.E. Hewitt, D.N. D'Souza and R.J. Van Barneveld</i>	467
Environmental and economic assessment of a French free-range chicken production system <i>B. Méda, E. Barlier, E. Péchernart, J.-Y. Limier and S. Mignon-Grasteau</i>	467
Effects of values and calculation changes in three IPCC guidelines on greenhouse gas inventories <i>E. Nugrahaeningtyas, J.S. Lee and K.H. Park</i>	468

Poster Session 34

Bioavailability and repellent activity of phytocompounds against red mites <i>C. Carlu, T. Chabrilat, C. Girard and S. Kerros</i>	468
Riboflavin yield of common raw ingredients for organic poultry diets <i>V. Decruyenaere, N. Everaert, P. Rondia and J. Wavreille</i>	469
Sustainable poultry production: biocontrol measures, dietary approaches and packaging strategies <i>G. Maiorano and S. Tavaniello</i>	469
Genetic correlations between feeding behaviour, meat quality, carcass and production traits in pigs <i>A.T. Kavlak, T. Serenius and P. Uimari</i>	470
The effect of plant-derived terpenes additive in <i>Ascaris suum</i> management in organic fattening pigs <i>H. Bui, E. Belz, J. Ligonnere and M.E.L.A. Benarbia</i>	470
Effect of fattening and slaughter value of gilts on their lifetime piglet production <i>M. Szyndler-Nędza, M. Tyra and A. Mucha</i>	471
Are the ethics of pig breeding addressed in literature? <i>M. Van Der Sluis, R.S.C. Rijkers and K.H. De Greef</i>	471
Benzoic acid reduces environmental impact in fattener pig diets using life cycle assessment <i>E. Perez-Calvo, S. Lagadec, C. Drique, D. Planchenault, S. Potot and C. Valliere</i>	472

Session 35. Is there a future for experimental animal research in Europe and, if so, what is it?

Date: Tuesday 29 August 2023; 15.00 – 18.30
Chair: Chalvon-Demersay / Van Milgen

Theatre Session 35

Is there a future for experimental animal research in Europe? <i>J. Van Milgen and T. Chalvon-Demersey</i>	472

Testing minimally invasive blood collection techniques in pigs used for research <i>F.A. Eugenio, F. Gondret, M. Oster and C. Ollagnier</i>	473
Development of protocols for standard management and recording in pig research facilities <i>A. Wallenbeck, M. Girard, M. Johansen, S. Döpjan, M. Aluwe, C. De Cuyper, E. Labussière, M. Font-I-Furnols, M. Heetkamp and R. Westin</i>	473
Development of a protocol for administering a capsule to sample small intestine content <i>I. García Viñado, M. Tretola, G. Bee and C. Ollagnier</i>	474
A modelling approach to investigate metabolic fluxes of amino acids in the small intestine of pigs <i>C.J.J. Garçon, J. Van Milgen, N. Le Floc'h and Y. Mercier</i>	474
<i>In vitro</i> gas production of pre-treated or untreated feedstuffs using cecum inoculum from horses <i>R.H. Jensen, R.B. Jensen, M.O. Nielsen and A.L.F. Hellwing</i>	475
Round table discussion <i>J. Van Milgen and T. Chalvon-Demersey</i>	475
Poster Session 35	
UpDown – an R Package to characterize unknown disturbances from longitudinal observations <i>I. David, V. Le and T. Rohmer</i>	476
Session 36. Technologies in insect production + controlling quality	
Date: Tuesday 29 August 2023; 15.00 – 18.30 Chair: Heckmann / Deruytter	
Theatre Session 36	
Effect of sex ratio and density mating on reproductive performances in <i>Tenebrio molitor</i> <i>E. Soucat, K. Paul, Q. Li, A. Masseron, F. Gagnepain-Germain, A. Chauveau, E. Sellem and T. Lefebvre</i>	476
Behavioural responses of black soldier fly to olfactory stimuli: evaluation of a Y-tube olfactometer <i>A. Spindola and M. Pulkoski</i>	477
Cold storage: a tool for delayed and stable black soldier fly (<i>Hermetia illucens</i>) pupae eclosion <i>D. Deruytter, S. Bellezza Oddon, L. Gasco and C.L. Coudron</i>	477
Influence of temperature on coloration in honey bees <i>J. Bubnič and J. Prešern</i>	478
The juvenile hormone analogue, pyriproxifen, alters the body composition of <i>Tenebrio molitor</i> larvae <i>V. Hill, T. Parr, J. Brameld and A. Salter</i>	478
Fate of food pathogens during black soldier fly rearing and processing <i>J. De Smet, D. Van De Weyer, E. Gorrens, N. Van Looveren and M. Van Der Borght</i>	479
Insect as animal feed: Fourier-transformed spectroscopy to reveal their protein molecular structure <i>J. Ortuño and K. Theodoridou</i>	479
Proteomics evaluation of the barrier role of insects for the indirect recycling of fast food in feed <i>M.C. Lecrenier, M. Aerts, A. Cordonnier, L. Plasman, O. Fumière and V. Baeten</i>	480
Scaling up fly mating chambers: lessons learned from operating 4 and 24 m ³ fly mating chambers <i>S.P. Salari and M.L. De Goede</i>	480

ALL-Yn: An automated solution for phenotyping <i>Tenebrio molitor</i> larvae <i>Q. Li, T. Mangin, J. Richard, E. Sellem, A. Masseron, F. Gagnepain-Germain, T. Lefebvre and R. Baude</i>	481
Does sex matter? The impact of sex on the buffalo pupation phase <i>N. Gianotten, N. Heijmans and N. Steeghs</i>	481
Assessment of chemical hazards in insect meal production for aquaculture feeds <i>I. Amaral, S.M. Ahmad, M. Ângelo, P. Correia Da Silva, A. Quintas, J.A.A. Brito, D. Murta, M.V. Santos, I. Vieira, T. Ribeiro and L.L. Gonçalves</i>	482

Poster Session 36

Microbiological risk analysis in insect meal production <i>D. Guerreiro, D. Murta, M.V. Santos, I. Vieira, T. Ribeiro and H. Barroso</i>	482
Multi directional approach in fly emergence evaluation and forecasting for <i>Hermetia illucens</i> <i>B. Grodzki, M.G. Zhelezarova, T. Bruder and M. Tejeda</i>	483
Application of NIRS on <i>Tenebrio molitor</i> protein meal <i>J. Richard, L. Daraï, L. Sanchez and B. Lorrette</i>	483

Session 37. Omics and integrative analyses towards understanding inter-organ cross-talk and whole body physiology of livestock

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Louveau

Theatre Session 37

State of the art in understanding interorgan crosstalk and physiology in farm animals <i>I. Cassar-Malek, I. Louveau, C. Bobby, J. Tournayre, F. Gondret and M. Bonnet</i>	484
Gene networks controlling functional cell interactions in the pig embryo revealed by omics studies <i>A. Dufour, C. Kurilo, J. Stöckl, Y. Bailly, P. Manceau, F. Martins, S. Ferchaud, B. Pain, T. Fröhlich, S. Foissac, J. Artus and H. Acloque</i>	484
¹ H-NMR metabolomic study of Large White and Meishan pigs in late gestation: part 1 – foetal placenta <i>J. Guibert, A. Imbert, N. Marty-Gasset, L. Gress, C. Canlet, L. Canario, Y. Billon, A. Bonnet, L. Liaubet and C.M.D. Bonnefont</i>	485
Metabolic pathways leading to different intramuscular fat content in rabbit divergent lines <i>P. Hernández, A. Blasco and A. Zubiri-Gaitán</i>	485
Proteomics profiles of longissimus thoracis muscle of Arouquesa cattle from different systems <i>L. Sacarrão-Birrento, A. Dittmann, S.P. Alves, L. Kunz, D.M. Ribeiro, S. Silva, C.A. Venâncio and A.M. De Almeida</i>	486
Serum metabolomics of newborn lambs before and after colostrum feeding <i>L. Lachemot, J. Sepulveda, X. Such, J. Piedrafita, G. Caja and A.A.K. Salama</i>	486
Characterization of milk small extracellular vesicles to study adaptation to lactation in ruminants <i>C. Bobby, A. Delavaud, J. Pires, L.E. Monfoulet, S. Bes, S. Emery, L. Bernard, C. Leroux, A. Imbert, M. Turret, F. Fournier, D. Roux, H. Sauerwein and M. Bonnet</i>	487
Multi-tissue transcriptome analysis of bovine herpesvirus-1 (BoHV-1) challenged dairy calves <i>S. O'Donoghue, B. Earley, M.S. McCabe, S.L. Cosby, K. Lemon, J.W. Kim, J.F. Taylor, D.W. Morris and S.M. Waters</i>	487

Transcriptome analysis reveals a different immune response depending on a SOCS2 gene point mutation	488
<i>C. Oget-Ebrad, C. Cabau, S. Walachowski, N. Cebron, J. Sarry, C. Allain, R. Rupp, G. Foucras and G. Tosser-Klopp</i>	
Expression quantitative trait loci in whole blood influence putative immune genes in sheep	488
<i>K. Dubarry, M. Coffey and E. Clark</i>	
Thigh muscle proteomics revealed key pathways related to feed efficiency in slow-growing chicken	489
<i>P. Kaewsatuan, C. Poompramun, S. Kubota, W. Molee, P. Uimari and A. Molee</i>	
Poster Session 37	
Multi-breed, multi-tissue systems biology analysis of beef cattle divergent for feed efficiency	489
<i>K. Keogh, D.A. Kenny, P.A. Alexandre, M. McGee and A. Reverter</i>	
Contribution of plasma proteins to the phenotypic signature of feed efficiency in Charolais bulls	490
<i>I. Cassar-Malek, A. Imbert, A. Delavaud, H. Sauerwein, R. Bruckmaier, G. Cantalapiedra-Hijar and M. Bonnet</i>	
Serum metabolomics of fattening bulls fed dry-total mixed ration (TMR) or corn silage-based TMR	490
<i>C. Stöcker-Gamigliano, M.H. Ghaffari, C. Koch, M. Schönleben, J. Mentschel, N. Göres, P. Fissore, I. Cohrs, S. Schuchardt and H. Sauerwein</i>	
Physiological importance of blood vitamin E in production characteristics of Japanese Black steers	491
<i>M. Kim, T. Masaki, K. Ikuta, E. Iwamoto, Y. Uemoto, F. Terada, S. Haga and S. Roh</i>	
Age-related changes in ruminal and blood parameters and intramuscular adiposity in Hanwoo steers	491
<i>S.Y. Kim and M. Baik</i>	
Post-ruminal urea release impact liver proteomics of beef cows at late gestation	492
<i>M.M. Santos, T.C. Costa, R.D. Araújo, J. Martín-Tereso, I.P. Carvalho, M.P. Gionbelli and M.S. Duarte</i>	
Liver transcriptome profiles of dairy cows with different serum metabolotypes	492
<i>M. Hosseini Ghaffari, H. Sadri, N. Trakooljul, C. Koch and H. Sauerwein</i>	
Comparison of metabolomic profile of the offspring of nulliparous and primiparous Holstein cows	493
<i>M. Terré and M. Tortadès</i>	
Transcriptome of the feto-maternal interface in pigs in late gestation: part 1 – foetal placenta	493
<i>A. Bonnet, S. Maman, L. Gress, A. Suin, C. Bravo, G. Cardenas, Y. Billon, L. Canario, N. Vialaneix, C.M.D. Bonnefont and L. Liaubet</i>	
Transcriptome of the feto-maternal interface in pigs in late gestation: part 2 – sow endometrium	494
<i>A. Bonnet, S. Maman, L. Gress, A. Suin, S. Legoueix, C. Bravo, Y. Billon, N. Vialaneix, C.M.D. Bonnefont and L. Liaubet</i>	
1H-NMR metabolomic study of Large White and Meishan pigs in late gestation: part 2 – sow endometrium	494
<i>A. Imbert, N. Duprat, N. Marty-Gasset, L. Gress, C. Canlet, Y. Billon, N. Vialaneix, C.M.D. Bonnefont, A. Bonnet and L. Liaubet</i>	
The effect of dietary <i>Laminaria digitata</i> on urinary and kidney proteomes of piglets	495
<i>D.M. Ribeiro, A. Dittmann, D.F.P. Carvalho, L. Kunz, J.P.B. Freire, J.A.M. Prates and A.M. Almeida</i>	
Vitamin D3 supplementation has little effect on gut microbiome in pigs	495
<i>M. OcZkiewicz, A. Wierzbicka, A. Steg and M. Świątkiewicz</i>	

Session 38. Equal opportunities and open communication for early career scientists

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Pszczola / Sell-Kubiak / Newton / Obsteter / Gislon

Theatre Session 38

Equal opportunities in science <i>I. Adriaens, M. Pszczola and T. Wallgren</i>	496
The responsibilities of authors, readers and learned-societies in animal science publishing <i>J. Van Milgen, I. Ortigues-Marty, G. Bee, M. Wulster-Radcliffe, J. Sartin, T.A. Davis and P.J. Kononoff</i>	496
Animal – open space the new member of the animal consortium <i>G. Bee</i>	497
Artificial intelligence language models in the scientific career <i>M. Pszczola, I. Adriaens and T. Wallgren</i>	497

Session 39. TechCare and ClearFarm: pilots on PLF tools for monitoring animal welfare

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Morgan-Davies / Llonch

Theatre Session 39

TechCare: exploring the use of precision livestock farming for small ruminant welfare management <i>C. Morgan-Davies, G. Tesniere, C. Dwyer, G. Jorgensen, E. Gonzalez-Garcia and J.M. Gautier</i>	498
Monitoring water trough attendance in shed: a potential indicator of sheep health or welfare issues? <i>G. Tesnière, U. Jean-Louis, E. Doutart, S. Duroy, C. Douine, M. Rinn, D. Gautier, A. Hardy, A. Aupiais, F. Guimbert, J.-M. Gautier and C. Morgan-Davies</i>	498
TechCare UK pilots – integrated sheep system studies using technologies for welfare monitoring <i>A. McLaren, A. Waterhouse, F. Kenyon, H. MacDougall, S. Beechener, A. Walker, M. Reeves, N. Lambe, J. Holland, A. Thomson, J. Duncan, A. Barnes, C. Dwyer, F. Gimbert, J.M. Gautier, G. Tesniere and C. Morgan-Davies</i>	499
An attempt to aggregate pig welfare indicators from sensors: achievements and barriers <i>H.L. Ko, L.J. Pedersen, G. Franchi, M.B. Jensen, M. Larsen, I.J.M.M. Boumans, J.D. Bus, E.A.M. Bokkers, X. Manteca and P. Llonch</i>	499
Is sensor technology ready for use in animal welfare assessments of gestating sows? <i>I.J.M.M. Boumans and E.A.M. Bokkers</i>	500
Identification of behavioural pattern associated with mastitis in dairy cows <i>L. Herve, Y. Gómez, K. Chow, A.H. Stygar, G.V. Berteselli, E. Dalla Costa, E. Canali and P. Llonch</i>	500
Use of PLF sensors to monitoring rumination as an alternative for early clinical mastitis detection <i>G.V. Berteselli, E. Dalla Costa, Y. Gómez Herrera, M.G. Riva, S. Barbieri, R. Zanchetta, P. Llonch, X. Manteca and E. Canali</i>	501
Monitoring the stress of light goat kids transported over short journeys <i>M. Sort, A. Elhadi, R. Costa, A. Recio, A.A.K. Salama and G. Caja</i>	501

Monitoring the stress of light suckling lambs transported over short journeys <i>A. Elhadi, J.C. Jesús, R. Costa, A. Recio, A.A.K. Salama and G. Caja</i>	502
Exploration of indicators measured by PLF sensors to monitor pig welfare during transportation <i>H.-L. Ko, P. Fuentes Pardo, F. Jiménez Caparros, X. Manteca and P. Llonch</i>	502
Quantifying the value of early warning system (EWS) based on 'smart water trough' in a sheep farm <i>A. Bar-Shamai, I. Shimshoni, A. Godo, J. Lepar and I. Halachmi</i>	503
Economic feasibility of using sensing technologies for welfare monitoring in the pig value chain <i>A.H. Stygar, M. Pastell, P. Llonch, E.A.M. Bokkers, J.D. Bus, I.J.M.M. Boumans, L.J. Pedersen and J.K. Niemi</i>	503

Poster Session 39

ORIOLE: a web application for cleaning data from the walk-over-weighing device in livestock systems <i>I. Sanchez, E. González-García, B. Fontez and B. Cloez</i>	504
Monitoring liveweight in Sarda dairy sheep using a walk-over-weighing system <i>M. Decandia, M. Acciaro, V. Giovanetti, G. Molle, F. Chessa, I. Llach and E. González-García</i>	504
Stakeholders' attitudes to early warning systems to promote animal welfare in small ruminants <i>E.N. Sossidou, S.I. Patsios, S. Beechener, V. Giovanetti, G. Tesniere, L. Grova, T. Keady, G. Caja, A. Bar-Shamai, L.T. Csiszter and C. Morgan-Davies</i>	505
Comparison between automatic milking and milking parlour system on dairy cows' welfare <i>G.V. Berteselli, S. Cannas, E. Dalla Costa, R. Zanchetta, G. Pesenti Rossi and E. Canali</i>	505
Prioritization of welfare issues and precision technologies for welfare monitoring in dairy sheep <i>A. Elhadi, R. González-González and G. Caja</i>	506

Session 40. The transition from pregnancy to lactation in dairy goats and sheep

Date: Tuesday 29 August 2023; 15.00 – 18.30

Chair: Hernández-Castellano / Salama

Theatre Session 40

invited Update of nutritional requirements of goats for growth and pregnancy in hot environments <i>I.A.M.A. Teixeira, C.J. Härter, J.A.C. Vargas, A.P. Souza and M.H.M.R. Fernandes</i>	506
Intramammary administration of lipopolysaccharides at parturition affects colostrum quality <i>M. González-Cabrera, A. Torres, M. Salomone-Caballero, N. Castro, A. Argüello and L.E. Hernández-Castellano</i>	507
Goat kids are not affected by the intramammary administration of lipopolysaccharides at parturition <i>M. González-Cabrera, M. Salomone-Caballero, S. Álvarez, A. Argüello, N. Castro and L.E. Hernández-Castellano</i>	507
Near-infrared spectroscopy prediction models preliminary results in ewes' colostrum <i>S. González-Luna, E. Albanell, G. Caja and C. L. Manuelian</i>	508
No kid, no milk? Trials about induction of goat lactation without gestation <i>L. Fito, C. Constancis and M. Bouy</i>	508
Perinatal rumen microbiota in relation to feed utilization and biochemical parameters in sheep <i>J.X. Chen</i>	509

Alpine goats divergent for functional longevity differ in metabolic profile during transition period <i>J. Pires, T. Fossier, M. Tourret, C. Huau, N. Friggens and R. Rupp</i>	509
Effects of sodium butyrate supplementation at late gestation of ewes <i>Y.J. Zhang, X.Y. Zhang, X.H. Duan, R.C. Yang and S.W. Zhang</i>	510
New artificial teats to improve goat milking device laboratory tests <i>M. Despinasse, C. Bonin, G. Coquereau and J.L. Poulet</i>	510
invited Olive cake feeding alters the expression of lipogenic genes in mammary and adipose tissue in goats <i>M.C. Neofytou, A.L. Hager-Theodorides, E. Sfakianaki, S. Symeou, D. Sparaggis, O. Tzamaloukas and D. Miltiadou</i>	511

Poster Session 40

Chemical composition and physicochemical characteristics of mountainous goat milk during lactation <i>E. Kasapidou, I.V. Iliadis, G. Papatzimos, M.A. Karatzia, Z. Basdagianni and P. Mitlianga</i>	511
Energy balance and body reserve dynamics in early lactation dairy ewes <i>F. Corbiere, C. Machefer, J.M. Astruc, M. El Jabri, B. Fanca, P. Hassoun, C. Marie-Etancelin, A. Meynadier and G. Lagriffoul</i>	512
Effects of Sulla flexuosa hay as alternative feed resource on goat's milk production and quality <i>S. Boukrouh, A. Noutfia, N. Moula, C. Avril, J.-L. Hornick, M. Chentouf and J.-F. Cabaraux</i>	512
High DCAD and ascorbic acid modify acid base, oxidative stress and kidney function in dairy goats <i>S. Thammacharoen, S. Semsirboon, D.K. Do Nguyen, S. Poonyachoti, T.A. Lutz and N. Chaiyabutr</i>	513
Link between chest circumference at late gestation and milk somatic cell count in Sarda ewe-lambs <i>D. Sioutas, A. Ledda, A. Mazza, A. Marzano, M. Sini and A. Cannas</i>	513

Session 41. Open the black box: using omics to better understand biological interpretation of complex traits

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Tiezzi / Pocrnic

Theatre Session 41

invited Incorporating high-dimensional omics phenotypes into models for predicting breeding values <i>O.F. Christensen</i>	514
Biologically informed genomic predictions with the NextGPjl statistical analysis package <i>E. Karaman, V. Milkevych and L. Janss</i>	514
Fine mapping QTL associated with fertility in dairy cattle using gene expression <i>I. Van Den Berg, A.J. Chamberlain, I.M. MacLeod, T.V. Nguyen, M.E. Goddard, R. Xiang, B. Mason, S. Meier, C.V.C. Phyn, C.R. Burke and J.E. Pryce</i>	515
How heritable are metabolomic features? An omic based approach in pigs <i>S. Bovo, G. Schiavo, F. Fanelli, A. Ribani, F. Bertolini, V. Taurisano, M. Gallo, G. Galimberti, S. Dall'olio, P.L. Martelli, R. Casadio, U. Pagotto and L. Fontanesi</i>	515
Combined transcriptomics and metabolomics in the whole blood to depict feed efficiency in pigs <i>C. Juigné, E. Becker and F. Gondret</i>	516

Imputation of sequence variants in more than 250,000 German Holsteins <i>A.M. Krizanac, C. Falker-Gieske, C. Reimer, J. Heise, Z. Liu, J. Pryce, J. Bennewitz, G. Thaller and J. Tetens</i>	516
Longitudinal study on the rabbit's gut microbiota variation through age <i>I. Biada, M.A. Santacreu, A. Blasco, R.N. Pena and N. Ibáñez-Escriche</i>	517
Studying cattle structural variation and pangenome using whole genome sequencing <i>G.E. Liu</i>	517
Host genetics affect the composition of the lower gut microbiota in dairy cows <i>L. Brulin, S. Ducrocq, J. Estellé, G. Even, S. Martel, S. Merlin, C. Audebert, P. Croiseau and M.P. Sanchez</i>	518
A model including host genotype, gut microbiome, and fat deposition measures in swine <i>F. Tiezzi and C. Maltecca</i>	518
protiPig: microbial analyses of traits related to nitrogen utilization efficiency in pigs <i>M. Schmid, N. Sarpong, M. Rodehutsord, J. Seifert, A. Camarinha-Silva and J. Bennewitz</i>	519
Rumen microbiome promote host metabolism and microbial bile acids bio-transformation in sheep <i>B.Y. Zhang, Y. Yu, X.Z. Jiang, Y.M. Cui, H.L. Luo and B. Wang</i>	519
Blending multivariate models to predict feed efficiency and explore multiple omics in meat sheep <i>Q. Le Graverand, F. Tortereau, C. Marie-Etancelin, A. Meynadier, J.L. Weisbecker and K.A. Lê Cao</i>	520
The effect of dietary <i>Laminaria digitata</i> on the muscle proteome and metabolome of weaned piglets <i>D.M. Ribeiro, D.F.P. Carvalho, C.C. Leclercq, S. Charton, K. Sergeant, E. Cocco, J. Renaut, J.A.M. Prates, J.P.B. Freire and A.M. Almeida</i>	520
Search for new mutations in cattle by systematic whole genome resequencing <i>M. Boussaha, C. Eché, C. Escoufflaire, C. Grohs, C. Iampietro, A. Capitan, M. Denis, S. Fritz, C. Donnadieu and D. Boichard</i>	521
Poster Session 41	
Estimation of non-additive genetic effects for semen production traits in beef and dairy bulls <i>R. Nagai, M. Kinukawa, T. Watanabe, A. Ogino, K. Kurogi, K. Adachi, M. Satoh and Y. Uemoto</i>	521
Evaluating functional properties of feeding black soldier fly larvae in laying hens by FeedOmics <i>A. Rezaei Far, E. Zaccaria, I. Fodor, P. Van Wikselaar, S. Naser El Deen, S. Kar and T. Veldkamp</i>	522
Characterization of two divergent lines through functional inference of ruminal microbiota <i>J. Guibert, A. Meynadier, V. Darbot, C. Allain and C. Marie-Etancelin</i>	522
Blood transcriptomic comparison under different THI in Holstein <i>J.-E. Park, H. Kim, J.-H. Cho, H.-G. Lee, W. Park and D. Shin</i>	523
Metabolome profile of the pectoralis major muscle of red-winged tinamou: a pilot study <i>J.M. Malheiros, C.S.M.M. Vilar, P.F. Silva, L.A. Colnago, J.A.I.I.V. Silva and M.E.Z. Mercadante</i>	523
Post-mortem muscle proteome of crossbred bulls and steers: carcass and meat quality <i>O.R.M. Neto, W.A. Baldassini, L.A.L. Chardulo, R.A. Curi, G.L. Pereira, B.M. Santiago and R.V. Ribeiro</i>	524
ITGA6 homozygous splice-site mutation causes junctional epidermolysis bullosa in Charolais cattle <i>C. Grohs, M. Boussaha, A. Boulling, V. Wolgust, L. Bourgeois-Brunel, P. Michot, N. Gaiani, M. Vilotte, J. Riviere and A. Capitan</i>	524

A sheep pangenome reveals the spectrum of structural variations and their effects on tail phenotypes <i>R. Li, M. Gong, X.M. Zhang, F. Wang, Z.Y. Liu, L. Zhang, S.Q. Gan and Y. Jiang</i>	525
A Chinese indicine pan-genome reveals novel structural variants introgressed from other Bos species <i>X.L. Dai, P.P. Bian, D.X. Hu, F.N. Luo, Y.Z. Huang, R. Heller and Y. Jiang</i>	525
Multi-omic analysis reveal epigenetic regulation during muscle growth and development in sheep <i>Q.J. Zhao, Y.H. Ma and Y. Liu</i>	526
The effect of production system on the muscle proteome of dromedary camel (<i>Camelus dromedarius</i>) <i>M. Lamraoui, D.M. Ribeiro, Y. Khelef, N. Sahraoui, H. Osório and A.M. De Almeida</i>	526
Effect of mitochondrial DNA copy number on productive traits and meat quality in pigs <i>E. Molinero, R.N. Pena, J. Estany and R. Ros-Freixedes</i>	527
Multi-omics analysis revealed the interaction of microbiota and host in rumen of hanwoo <i>W.C. Park, J.W. Son, M.J. Jang, N.R. An, H.J. Choi, S.A. Jung, J.A. Lim, D.H. Kim, J.H. Cha, S.Y. Choi, Y.J. Lim, S.S. Jang, D.J. Lim and H.H. Chai</i>	527

Session 42. Animal genetics to address food security and sustainability

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Soelkner / Granados

Theatre Session 42

Challenge session: animal genetics to address food security and sustainability <i>A. Granados and J. Sölkner</i>	528
Causal structures between gut microbiota and efficiency traits in poultry <i>V. Haas, M. Rodehutscord, A. Camarinha-Silva and J. Bennewitz</i>	528
Exploring crossbreeding to reduce GHG Emissions and feed-food competition in beef production <i>A. Mertens, L. Kokemohr, E. Braun, L. Legein, C. Mosnier, G. Pirlo, P. Veysset, S. Hennart, M. Mathot and D. Stilman</i>	529

Session 43. Better calves for better farms: how the young stock can be the key to success

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Costa / Keatinge

Theatre Session 43

invited Genetic selection for dairy calf disease resistance traits: opportunities and challenges <i>C. Lynch, F.S. Schenkel, N. Van Staaveren, F. Miglior, D. Kelton and C.F. Baes</i>	529
Genetic research on colostrum quality traits and passive transfer of immunity in Greek dairy herds <i>A. Soufleri, G. Banos, N. Panousis, G. Arsenos, A. Kouglioumtzis, V. Tsiamadis and G.E. Valergakis</i>	530
Phenotypic and genetic analysis of beef-on-dairy crossbred calves <i>R.H. Ahmed, C. Schmidtman, J. Mugambe and G. Thaller</i>	530
Assessing passive immune transfer in newborn calves: salivary and serum IgG association <i>F.G. Silva, E. Lamy, S. Pedro, I. Azevedo, P. Caetano, J. Ramalho, L. Martins, A.M.F. Pereira, J.O.L. Cerqueira, S.R. Silva and C. Conceição</i>	531

Biochemical predictors of successful transition from milk to solid feed in Holstein calves <i>P. Kazana, N. Siachos, N. Panousis, G. Arsenos and G.E. Valergakis</i>	531
The impact of dairy farm management on long-term robustness of veal calves <i>F. Marcato, H. Van Den Brand, L. Webb, M. Wolthuis-Fillerup, F. Hoorweg and K. Van Reenen</i>	532
The assessment of transfer of passive immunity in dairy calves affected by neonatal diarrhoea <i>G. Sala, V. Bronzo, A. Boccardo, A.L. Gazzonis, P. Moretti, V. Ferrulli, A.G. Belloli, L. Filippone Pavesi, G. Pesenti Rossi and D. Pravettoni</i>	532
Automatic monitoring of calves' behaviour for a precision weaning approach <i>R. Colletuori, D. Cavallini, A. Formigoni and L. Mammi</i>	533
Can dairy herds be in a positive colostrum stock balance? <i>A. Soufleri, G. Banos, N. Panousis, G. Arsenos, A. Kouglioumtzis, V. Tsiamadis and G.E. Valergakis</i>	533
Dairy-beef calves: current practices and views of calf producers and rearers <i>D.J. Bell, M.J. Haskell, C.S. Mason and C.-A. Duthie</i>	534
Sodium percarbonate as a preservative in waste milk fed to dairy calves <i>D.J. Wilson, G.M. Goodell, R. Dumm, T. Kelly and M. Bethard</i>	534
Pre-transport diet affects the physiological status of calves during transport by road and ferry <i>S. Siegmann, L.L. Van Dijk, N.L. Field, G.P. Sayers, K. Sugrue, C.G. Van Reenen, E.A.M. Bokkers and M. Conneely</i>	535
Clonal dissemination of MDR <i>Pasteurella multocida</i> ST79 in a Swiss veal calves <i>J. Becker, J. Fernandez, A. Rossano, M. Meylan and V. Perreten</i>	535
Effects of feeding milk with antibiotic residues on calf performance during the pre-weaning period <i>A. Flynn, C. Mc Aloon, M. Mc Fadden, J.P. Murphy, S. Mc Pherson, C. Mc Aloon and E. Kennedy</i>	536
Effects of extending lactation for dairy cows on health, development and production of their calves <i>Y. Wang, R. Goselink, E. Burgers, A. Kok, B. Kemp and A.T.M. Van Kneegsel</i>	536
Poster Session 43	
Dam-calf contact rearing in Switzerland: Aspects of management and milking <i>J. Rell, C. Nanchen, P. Savary, C. Buchli and C. Rufener</i>	537
A survey of colostrum management practices in dairy farms of Piedmont region (Italy): a pilot study <i>G.V. Berteselli, G. Pesenti Rossi, G. Vezzaro, E. Dalla Costa, S. Barbieri and E. Canali</i>	537
Serum profiles of dairy calves fed a milk replacer or whole milk at two levels of supply <i>T. Chapelain, J.B. Daniel, J.N. Wilms, J. Martín-Tereso and L.N. Leal</i>	538
Prevalence of foot lesions in French slaughter dairy and beef young bulls housed in indoor feedlot <i>S. Ishak, R. Guatteo, A. Lehébel, N. Brisseau, M. Gall, A. Wache and A. Relun</i>	538
Effect of direct-fed microbial supplementation on performance and health of pre-weaning dairy calves <i>J. Magalhaes, B.I. Cappellozza, T.C. Dos Santos, F.N. Inoe, M.S. Coelho, V. Soares and J.L.M. Vasconcelos</i>	539
The effect of astaxanthin on health and calves performance <i>E. Sosin, I. Furgał-Dierzuk, B. Śliwiński and A. Burmańczuk</i>	539
Strategic grouping of dairy beef calves on arrival at a rearing unit <i>D.J. Bell, C.S. Mason, K.C. Henderson, M.J. Haskell and C.-A. Duthie</i>	540

Calves sexing and crossbreeding to optimize the destination of the young from French dairy farms <i>S. Dominique</i>	540
Inclusion of grass silage in finishing total mixed rations for rosé veal calves <i>M. Vestergaard, M. Bjerring, A.L.F. Hellwing, M.B. Jensen, B. Muhlig, L. Mogensen and N.B. Kristensen</i>	541
Veal calves' housing in France: current situation and investment needs <i>M. Tourtier and C. Martineau</i>	541
Evolution of the use of antibiotics in the veal calves' sector in France between 2013 and 2020 <i>M. Chanteperdrix, A. Cheavance, M. Orlianges, D. Urban, M. Tourtier and P. Briand</i>	542

Session 44. Building on a resilient dairy sector – from animal, farm and regional perspective – Part 1

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Kuipers / Schuenemann

Theatre Session 44

Resilience4Dairy: sharing knowledge to improve sustainability and resilience of the dairy sector <i>V. Brocard, M. Klopčič and J. Boonen</i>	542
<i>invited</i> Indicators and influencing factors of livestock resilience <i>I.D.E. Van Dixhoorn, J. Ten Napel, A. Mens and J.M.J. Rebel</i>	543
<i>invited</i> Reducing stress of dairy cows and farmers to improve resiliency and welfare <i>M.T.M. King and T.J. De Vries</i>	543
<i>invited</i> Building resilience in the dairy sector of China <i>S. Li, W. Wang, W. Du, X. Sun, K. Yao and J. Xia</i>	544
<i>invited</i> Building resilience in farming: dairy cattle and workforce management <i>G.M. Schuenemann and J.M. Piñeiro</i>	544
Working on resilience in the Ukrainian dairy sector <i>L. Stepura</i>	545
Future scenarios for livestock agriculture in New Zealand <i>C. Vannier, T. Cochrane, L. Bellamy, T. Merritt, H. Quenol and B. Hamon</i>	545
<i>invited</i> Breeding approaches to improve robustness and resilience in dairy cows <i>K. May and S. König</i>	546
Resilience from the perspective of farm economics <i>E. Kołoszycz and A. Wilczyński</i>	546
Labour: a key factor in the resilience of the European dairy farmer <i>S. Debevere, L. Dejonghe, I. Louwagie, I. Vuylsteke, E. Béguin, S. Fourdin, P. Rondia, L. Boulet, S. Mathieux and G. Elluin</i>	547
Resilience of dairy farming: the farmers' point of view <i>E. Castellan, C. Bausson and V. Brocard</i>	547

Poster Session 44

Local breed as an alternative to Holstein-Friesian cows in a farm with low level of milk production <i>M. Sobczuk-Szul, Z. Nogalski, M. Momot and P. Pogorzelska-Przybyłek</i>	548

Session 45. Transformation of livestock practices in response to society's expectations on animal welfare, market demand for animal products and environmental issues

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Thenard / Boyle

Theatre Session 45

Product quality as a lever to change farming practices to meet society's expectations <i>V. Thenard, S. Couvreur, L. Fortun-Lamothe, B. Méda and T. Petit</i>	548
Transformation in the dairy sector: a global analysis of sustainability certification standards <i>K. McGarr-O'Brien, J. Herron, L. Shalloo, I.J.M. De Boer and E.M. De Olde</i>	549
The analysis of a co-design process to develop an eco-citizen dairy cattle farming system experiment <i>J.E. Duval, M. Taverne, M. Bouchon and D. Pomiès</i>	549
Perceived quality of meat products in short circuits by producers and their customers <i>C. Couzy, G. Haj Chahine, V. Diot, S. Masselin-Sylvin, S. Meurisse, M. Klingler and C. Bièche-Terrier</i>	550
Value-adding attributes for dairy calves within local beef sector – perceptions among stakeholders <i>L. Schönfeldt, M.G.G. Chagunda and N. Ströbele-Benschop</i>	550
Farmpédia: how to improve the global acceptability of livestock systems with communication <i>A.-L.J. Thadee and G. Brunschwig</i>	551
How and why involve citizens in a participatory research project aiming to design livestock farming? <i>P. Coeugnet, J. Labatut, G. Vourc'h and J.E. Duval</i>	551
Social sustainability: what concepts to approach farmers' satisfaction at work <i>B. Dedieu, J. Duval, P. Girard, N. Hostiou, S. Mercandalli and G. Soullier</i>	552
Implementing agroecological practices: what are the effects on working conditions of dairy farmers? <i>A.-L. Jacquot, M. Gérard, J.E. Duval and N. Hostiou</i>	552
Promoting and guiding transformation of French veal calf farms in response to societal expectations <i>C. Martineau, D. Bastien, M. Chanteperdrix, C. Denoyelle, V. Lefoul and M. Orlanges</i>	553
Designing rabbit breeding systems with access to the outdoors with the innovative design method <i>L. Fortun-Lamothe, M.H. Jeuffroy and L. Le Du</i>	553
Challenges and opportunities for transitioning to 'low anthelmintics use' in livestock systems <i>M. Sautier and P. Chiron</i>	554
The rearing of calves, kids and lambs with adults in dairy systems in the AuRA region, France <i>C. Constancis, A. Igier and F. Debrez</i>	554
Expectations of French suckler farmers in terms of technical support services <i>A. Antoni-Gautier, J. Chambeaud, T. Falcou, C. Galvagnon, N. Lemonnier and J.B. Menassol</i>	555

Poster Session 45

'Antibiotic-free' strategies in chicken production in France: success factors, assets and limitation <i>N. Rousset and J. Hercule</i>	555
Veal calves' production: what societal expectations in terms of animal housing for their welfare? <i>D. Bastien, M. Tourtier and A. Warin</i>	556

Salmon welfare perceived by various stakeholders: where do we stand? <i>C.M. Monestier, L.R.B. Reverchon-Billot, M.S. Stomp and A.W. Warin</i>	556
A review of sustainable livestock strategies to deal with anti-livestock activists <i>M. Dehghani and K.H. Park</i>	557
AuthenBeef: use of blockchain technology in beef production to secure authenticity and traceability <i>G. Arsenos, S. Vouraki, V. Papanikolopoulou, A. Argyriadou, V. Fotiadou, S. Minoudi, D. Karaouglanis, N. Karaïskou, P. Fortomaris and A. Triantafyllidis</i>	557
Structural equation modelling applied to multi-performance objectives in French suckler cattle farms <i>L. Billaudet, I. Veissier, J.J. Minviel and P. Veyssset</i>	558
Systemic enablers and barriers to extending the productive life of Swiss dairy cows <i>A. Bieber, R. Home, M. Rödiger, R. Eppenstein and M. Walkenhorst</i>	558
Providing outdoor access to pigs: what are the profiles of farmers working in those systems? <i>S.B. Brajon, C.T. Tallet, E.M. Merlot and V.L. Lollivier</i>	559
The explosion of sustainability indicators in the European livestock sector <i>B. Van Der Veeke, M. Carozzi, C. Barzola Iza and F. Accatino</i>	559
Pig farmers' and citizens' opinions on outdoor access for livestock <i>S.B. Brajon, C.T. Tallet, E.M. Merlot and V.L. Lollivier</i>	560
Short food supply chains and food safety issues: HACCP utilization, opportunities and limits <i>R. Rafiq, O. Boutou, M.P. Ellies-Oury and B. Grossiord</i>	560
Feeding strategy in organic farming as a lever to improve various quality dimensions of pork <i>C. Van Baelen, L. Montagne, S. Ferchaud, A. Prunier and B. Lebret</i>	561
Body reserve dynamics using metabolites and hormones profiles of Romane ewes in two farming systems <i>A. Nyamiel, D. Hazard, D. Marcon, F. Tortereau, C. Durand, A. Tesnière and E. González-García</i>	561

Session 46. Innovation in ruminant nutrition and feeding

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Stergiadis / Alvarez Rodriguez

Theatre Session 46

Inclusion of macroalgae in high forage beef cattle diets <i>S.A. Terry, T.W. Coates, R.J. Gruninger, D.W. Abbott and K.A. Beauchemin</i>	562
Rumen protected potassium gluconate increases average daily gain of beef <i>A. Santos, J.G.H.E. Bergman, J.A. Manzano and M. Hall</i>	562
Impact of additives and forage levels on performance and enteric methane emissions of Nellore bulls <i>E. Magnani, T.H. Silva, L.B. Tosetti, A. Berndt, E.M. Paula, P.R. Leme and R.H. Branco</i>	563
Differences in digestive traits of young bulls fed contrasted diets and diverging in feed efficiency <i>M. Coppa, C. Martin, A. Bes, L. Ragionieri, F. Ravanetti, P. Lund, G. Cantalapiedra-Hijar and P. Nozière</i>	563
Effect of solid feed intake on feeding behaviour and energy metabolism in growing calves <i>E. Labussiere, L. Montagne, Y. Le Cozler, C. Martineau and D. Bastien</i>	564

Effects of dietary inclusion of willow leaves on feed intake and methane emission in sheep <i>J.J. Thompson, S. Stergiadis, O. Cristobal-Carballo, T. Yan, S. Huws and K. Theodoridou</i>	564
Effect of supplementing Omega-3 rich oil on ruminal fermentation and dietary digestibility in lambs <i>O. Cristobal-Carballo, F. Godoy-Santos, S. Huws, S. Morrison, A. Aubry, E. Lewis and T. Yan</i>	565
Essential oils and integral diets to optimize rumen function and decrease methanogenesis in lambs <i>N. Ghallabi, G. Gonzalo, A. Garcia, O. Catalán, P. Romero, M. Hassan, A.I. Martín-García, D.R. Yáñez-Ruiz and A. Belanche</i>	565
Novel water based delivery of seaweed extracts to improve the sustainability of ruminant production <i>A. Casey, T. Boland, Z. McKay and S. Vigors</i>	566
Supplementation of Ca gluconate improves fertility and time to peak milk yield in dairy cattle <i>D.J. Seymour, M.V. Sanz-Fernandez, J.B. Daniel, J. Martin-Tereso and J. Doelman</i>	566
DFM supplementation during the gestation and dry periods on postpartum performance in dairy cows <i>O. Ramirez-Garzon, D.G. Barber, J. Alawneh, L. Huanle and M. Soust</i>	567
<i>In vivo</i> evaluation of tannins and essential oils mixtures as additives for dairy cows <i>G. Foggi, L. Turini, F. Dohme-Meier, A. Muenger, L. Eggerschwiler, J. Berard, G. Conte, A. Buccioni and M. Mele</i>	567
Palmitic to oleic ratio in fat supplement influenced the digestibility and production of dairy cows <i>J. Shpirer, L. Lifshitz, H. Kamer, Y. Portnick and U. Moallem</i>	568
Xylooligosaccharides and enzyme increased milk yield and reduced methane emissions of Jersey cows <i>L.F. Dong and Q.Y. Diao</i>	568
Defatted black soldier fly larvae meal as substitute of soybean meal in Kenyan dairy cow rations <i>D.J.M. Braamhaar, D.J. List, S.J. Oosting, D. Korir, C.M. Tanga and W.F. Pellikaan</i>	569
Classifying lipogenic and glucogenic diets in dairy cows based on metabolomics profiles <i>X. Wang, S. Jahagirdar, W. Bakker, C. Lute, B. Kemp, E. Saccenti and A.T.M. Van Knegsel</i>	569
Poster Session 46	
Comparative study of digestibility of safflower varieties <i>M. Besharati, N. Khoshnam and D. Azhir</i>	570
Effect of different levels of propolis, nitrate, thyme and mint essential oil on digestibility <i>M. Besharati and M. Mousavi</i>	570
Combination of lactic acid bacteria inoculant in difficult to ensile grass after 15 days of ensiling <i>M. Duvnjak, L. Dunière, B. Andrieu, E. Chevaux and C. Villot</i>	571
Effect of whey on <i>in vitro</i> ruminal methane formation and digestibility in cows <i>H. Luisier-Sutter, L. Isele, M. Terranova, S.L. Amelchanka and M. Schick</i>	571
Ellagic acid and gallic acid reduced methane and ammonia in an <i>in vitro</i> rumen fermentation model <i>M. Manoni, S. Amelchanka, M. Terranova, L. Pinotti, P. Silacci and M. Tretola</i>	572
Effect of toasted soybean on dairy cows milk performances <i>A. Berchoux, M. Duval, E. Hermant, M. Legris and M. Jouffroy</i>	572
The addition of dry ice as an attempt to inhibit proteolysis during ensilage of lucerne <i>M. Borsuk-Stanulewicz, C. Purwin and M. Mazur-Kuśnerek</i>	573

<i>In vitro</i> effects of <i>Bacillus subtilis</i> CH201 and <i>Bacillus licheniformis</i> CH200 on rumen microbiota R. Gresse, G. Copani, B.I. Cappellozza, A. Torrent, D. Macheboeuf, E. Forano and V. Niderkorn	573
Effect of nitrate and its interaction with starch levels on methane production in continuous culture Y. Roman-Garcia, S. El-Haddad, S. Van Zijderveld and G. Schroeder	574
Effect of garlic processing method on <i>in vitro</i> methane production and rumen fermentation N.F. Sari, S. Stergiadis, P.P. Ray, C. Rymer, L.A. Crompton and K.E. Kliem	574
Effects of Red Sorghum and <i>Rhizoma paridis</i> on rumen protozoa, fermentation characteristics <i>in vitro</i> R. Yi, S. Vigors, L. Ma, J.C. Xu and D.P. Bu	575
Phytochemicals can modify the rumen fermentation profile as monensin L. Gonzalez, A.C. Dall-Orsoletta, D. Mattiauda, A. Daudet, T. Garcia, P. Chilibroste, A. Meikle, M. Arturo-Schaan, A. Casal and M.A. Bruni	575
<i>In vitro</i> fermentation of TMR using rumen fluids from cows supplemented with hemp and savory leaves S. Arango, S. Massaro, S. Schiavon, N. Guzzo, M. Montanari, L. Bailoni and F. Tagliapietra	576
<i>Bacillus licheniformis</i> and <i>B. subtilis</i> on <i>in vitro</i> ruminal parameters and greenhouse gas emission B.R. Amancio, E. Magnani, T.H. Silva, A.L. Lourenço, B.I. Cappellozza, R.H. Branco and E.M. Paula	576
Bioproduct from royal palm colonized by <i>Lentinula edodes</i> on <i>in vitro</i> ruminal fermentation B.M. Rocha, R.L. Savio, G.S. Camargo, K.E. Loregian, A.R. Cagliari, A.C. Casagrande, F. Rigon, E. Magnani, T.G. Timm, L.B.B. Tavares, M.I. Marcondes, T.H. Silva, R.H. Branco, E.M. Paula and P.D.B. Benedeti	577
<i>Enterococcus faecium</i> and <i>Saccharomyces cerevisiae</i> on <i>in vitro</i> rumen parameters and greenhouse gases B.R. Amancio, T.H. Silva, G.M. Wachekowski, H. Reolon, T.G. Timm, B.I. Cappellozza, E. Magnani, E.M. Paula and R.H. Branco	577
Rumen protected calcium gluconate improves milk production of cows J.G.H.E. Bergman, B. Skibba and M. Hall	578
Rumen protected calcium gluconate improves lactational performance J.G.H.E. Bergman, F. Morisset and M. Hall	578
Increase milk production by preserving the nutritional value of the dairy ration L.L.C. Jansen, J.G.H.E. Bergman and S.J.A. Van Kuijk	579
VistaPre-T, a crude fermentation extract to support the sustainable use of forages in dairy rations V. Blanvillain, E. Bungenstab and G. Gomes	579
Early lactation trial with a blend of fat encapsulated vitamin B A.D.G. Esselink and C. Gordon	580
The effect of a blend of fat encapsulated vitamin B on milk production of highly productive cows M. Hall and C. Gordon	580
Evaluation of milk performances and enteric methane emissions on by-products feed base A. Berchoux, M. Jouffroy, A. Laflotte and R. Boré	581
Supplementing lambs with plant extract supplement enhances growth and improve feed conversion ratio V. Ballard and P.H. Pomport	581
Effects of <i>Artemisia annua</i> residue on rumen microorganisms and antioxidant function of mutton sheep S.S. Wang, C.F. Peng, Y.R. Shao, M.M. Bai, Y.H. Zhang, M. Zhang, X. Xiong and H.N. Liu	582

Nutrient rich novel feed supplements for grazing lambs <i>A.S. Chaudhry</i>	582
The order of distribution of two forages affects daily intake and diet composition in dairy goats <i>R. Delagarde, J. Belz and B. Bluet</i>	583
Feeding frequency has no effect on intake and milk production in dairy goats fed on fresh herbage <i>R. Delagarde, J. Belz and B. Bluet</i>	583
Effects of dietary energy on late-gestation metabolism in prolific ewes <i>M. Plante-Dubé, C. Sylvestre, R. Bourassa, P. Luimes, S. Buczinski, F. Castonguay and R. Gervais</i>	584
The effect of feeding with hemp seeds addition on physicochemical and sensory properties of beef <i>P. Pogorzelska-Przybyłek, C. Purwin, M. Modzelewska-Kapituła, M. Borsuk-Stanulewicz and K. Tkacz</i>	584
Association of feed efficiency with growth and slaughtering performance in Nellore cattle <i>S.F.M. Bonilha, J.A. Muñoz, B.R. Amâncio, J.N.S.G. Cyrillo, R.H. Branco, R.C. Canesin and M.E.Z. Mercadante</i>	585
Effects of dietary nitrate on performance and enteric methane production in Hanwoo steers <i>R. Bharanidharan, P. Xaysana, R. Ibadhi, J. Lee, B.M. Tomple, J. Oh, M. Baik and K.H. Kim</i>	585
Impact of additives and forage levels on nutrients digestibility and sorting index of Nellore bulls <i>E. Magnani, T.H. Silva, L.B. Tosetti, E.M. Paula, P.R. Leme and R.H. Branco</i>	586
Feed efficiency traits calculated at post-weaning and pre-slaughter periods in Nellore cattle <i>S.F.M. Bonilha, J.A. Muñoz, B.R. Amâncio, J.N.S.G. Cyrillo, R.H. Branco, R.C. Canesin and M.E.Z. Mercadante</i>	586
Environmental protection study on replacing alfalfa with sesbania for feeding ruminants <i>L.Y. Wang and Y.J. Tian</i>	587
Multi performance analysis of soybean self-consumption on a mixed crop-livestock farm <i>M. Jouffroy, A. Berchoux, M. Duval, M. Weens, E. Hermant and M. Legris</i>	587
Effects of leaf size and harvesting season on nutritive quality of white clover <i>X. Chen, K. Theodoridou, O. Cristobal-Carballo and T. Yan</i>	588
Image analysis of feed boluses collected from cows after ingestive chewing <i>B. Delord, M. Berger, R. Baumont, P. Nozière, A. Le Morvan, F. Guillon and M.F. Devaux</i>	588

Session 47. One-health, one nutrition, one Earth: role of nutrition in livestock production

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Latifa / Weill

Theatre Session 47

invited A documented example of the One Health concept <i>P. Weill, N. Kerhoas and B. Schmitt</i>	589
Dietary lipid supplements affect milk composition and butter properties in dairy cows <i>M. Landry, Y. Lebeuf, M. Blouin, F. Huot, J. Chamberland, G. Brisson, D.E. Santschi, É. Paquet, D.E. Rico, P.Y. Chouinard and R. Gervais</i>	589
Decreasing GHG footprint while improving nutrition value in ruminant product: a new challenge <i>S. Mendowski, G. Chesneau, G. Mairesse and N. Kerhoas</i>	590

Effect of dietary protein source and <i>Saccharina latissima</i> on milk fatty acids profiles and bromoform	590
<i>B. Wang, S. Ormston, N. Platosz, J.K. Parker, N. Qin, D. Humphries, Á. Pétursdóttir, A. Halmemies-Beauchet-Filleau, D. Juniper and S. Stergiadis</i>	
Human health markers improvements in clinical trials when animal feed is the only variable	591
<i>N. Kerhoas, P. Weill and B. Schmitt</i>	
The impact of combination of Inulin fibre with the 4 major PAHs present in meat on colorectal cancer	591
<i>L. Abdennebi-Najar, M. Zaoui, N. Ferrand, L. Louadj and M. Sabbah</i>	
Animal feeding strategy: a move towards giving strategic direction to East African countries	592
<i>H. Makkar, K. Agyemang, D. Balikowa, A. Sebsibe and R. Mondry</i>	
invited Macrominerals and trace elements in retail milk: their variation and nutritional implications	592
<i>S. Stergiadis, E.E. Newton, S. Beauclercq, J. Clarke, N. Desnica and Á. Pétursdóttir</i>	
Effect of a spice feed additive on behaviour, saliva composition, and ruminal pH in fattening bulls	593
<i>C. Omphalius, J.-F. Gabarrou, G. Desrousseaux and S. Jullian</i>	
Role of niacin in regulating intestinal health in piglets	593
<i>H.B. Yi</i>	
Effect of maternal nutrition on thymus development in Wagyu (Japanese Black) foetus	594
<i>O. Phomvisith, S. Muroya and T. Gotoh</i>	

Poster Session 47

<i>Bacillus</i> sp. strains protect the intestinal barrier from oxidative stress and deoxynivalenol	594
<i>G. Copani, B.I. Cappellozza and E.J. Boll</i>	
Production and carcass characteristics of growing-fattening rabbits under three feeding phases	595
<i>V.C. Resconi, M. López, J.L. Olleta, J. Romero and M.M. Campo</i>	
Niacin improves intestinal health through up-regulation of AQP's expression induced by GPR109A	595
<i>X. Yang, Y. Qiu, S. Liu and Z. Jiang</i>	

Session 48. How can poultry farming systems evolve to meet the major societal and environmental challenges?

Date: Wednesday 30 August 2023; 8.30 – 13.00
Chair: Stadnicka / Meda

Theatre Session 48

invited How can poultry farming systems evolve to meet the major societal and environmental challenges?	596
<i>P. Thobe and P. Van Horne</i>	
invited Can we enhance environmental impact without compromising bird welfare in broiler systems?	596
<i>I. Kyriazakis</i>	
What is the impact of the farming system on the quality of the chicken breast meat?	597
<i>J. Albechaalany, S. Yilmaz, M.P. Ellies-Oury, M. Bourin, Y. Guyot, J. Saracco, J.F. Hocquette and C. Berri</i>	
Improving broiler wellbeing and micro-climate through PLF application	597
<i>S. Druyan, N. Barchilon and I. Halachmi</i>	

Effects of heat stress and spirulina on productive performances of two slow growth broiler strains <i>E.A. Fernandes, C.F. Martins, D.F.P. Carvalho, L.L. Martins, A. Raymundo, M. Lordelo and A.M. And Almeida</i>	598
invited Evaluating services provided by free-range poultry systems <i>G. Chiron</i>	598
Biosecurity gaps in 7 major poultry producers (breeder and layer farms) in EU: a farmers perspective <i>A. Amalraj, H. Van Meirhaeghe, R. Souillard, A. Zbikowski and J. Dewulf</i>	599
Reducing environmental impact of broiler production: the role of crude protein and soybean meal <i>T. De Rauglaudre, B. Méda, S. Fontaine, W. Lambert and M.P. Létourneau Montminy</i>	599
Elevated platforms for broilers on commercial farms: usage and effects on health and performance <i>J. Stracke, F. May, J. Müsse, N. Kemper and B. Spindler</i>	600
Mutation effects as key driver of maintaining genetic variation for long-term selection in broilers <i>B.S. Sosa-Madrid, N. Ibañez-Escriche, G. Maniatis and A. Kranis</i>	600
Early interventions during incubation and impact on a muscle of locomotory relevance in broilers <i>T. Kettrukat, A. Dankowiakowska, M. Mangan, E. Grochowska, K. Stadnicka and M. Therkildsen</i>	601
Summary of the posters in session 48 by the chairs <i>B. Méda and K. Stadnicka</i>	601
Poster Session 48	
Effect of gallic acid supplementation to corn-soybean-gluten meal-based diet in broilers performance <i>J.H. Song, C.B. Lim, S. Biswas, Q.Q. Zhang, J.S. Yoo and I.H. Kim</i>	602
Veterinary coaching to stimulate biosecurity compliance <i>A. Amalraj, H. Van Meirhaeghe, M. De Gussem and J. Dewulf</i>	602
Establishing elevated perforated platforms in broiler chicken housing – is hygiene a barrier? <i>B. Sake, J. Müsse, F. May, J. Stracke, N. Kemper, J. Schulz and B. Spindler</i>	603
What's going on outside? Use of winter gardens by rearing hens of different genetics <i>A. Riedel, N. Kemper and B. Spindler</i>	603
Metabolomic analysis reveal the molecular mechanism related to leg disease in broilers <i>J. Zheng, G. Zhang, Q. Li and G. Zhao</i>	604
Housing conditions do not influence the effects of a nutritional challenge for broilers <i>V. Michel, C. Deschamps, N. Regrain, E. Devillard and J. Consuegra</i>	604
Compliance of biosecurity in poultry farms in France: remaining obstacles and levers for improvement <i>N. Rousset, A. Battaglia, J. Puterflam, J. Marguerie, R. Souillard, S. Le Bouquin-Leneveu and A.-C. Lefort</i>	605
Untrimmed beaks in turkey hens: Effect on injuries and mortality rate <i>M. Kramer, K. Skiba, P. Niewind, F. Von Rüden, N. Kemper and B. Spindler</i>	605
Habitat affects egg characteristics of Libyan local pigeon (domestic vs feral pigeon) <i>F. Akraim, M.F. Idrees and M.M. Sghieyer</i>	606
Effects of heat stress and spirulina on meat traits of two slow growth broiler strains <i>E.A. Fernandes, J.R. Sales, L.L. Martins, M. Lordelo, A. Raymundo and A.M. And Almeida</i>	606

How does broiler range use impact forage intake, outdoor excretion and gaseous emissions? <i>C. Bonnefous, B. Méda, K. Germain, L. Ravon, T. De Rauglaudre, J. Collet, S. Mignon-Grasteau, M. Reverchon, C. Berri, E. Le Bihan-Duval and A. Collin</i>	607
Heritability of the number of crossovers as proxy of recombination rate in chicken <i>V. Riggio, E. Tarsani and A. Kranis</i>	607
The potential of early warning system at health issues in poultry by sound <i>I. Halachmi, T. Lev-Ron, Y. Yitzhaky and S. Druyan</i>	608
Pre-slaughter fasting changes the <i>ante mortem</i> muscle proteolysis levels and <i>post mortem</i> meat quality <i>S. Katsumata, M. Kamegawa, A. Katafuchi, A. Ohtsuka and D. Ijiri</i>	608

Session 49. Monoguthealth – Part 1

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Bee / Trevisi

Theatre Session 49

invited Host-microbiota interactions in swine and poultry: disentangling causes and effects <i>J.F. Pérez</i>	609
Glutamine and glucose metabolism in suckling low birth weight piglets supplemented with glutamine <i>D. De Leonardis, Q.L. Sciascia, S. Goers, A. Vernunft and C.C. Metges</i>	609
Creep feeding (dry, liquid) and pen hygiene (low, high) impacts pre-weaning growth in pigs <i>S.R. Vasa, G.E. Gardiner, K. O'Driscoll, G. Bee and P.G. Lawlor</i>	610
The impact of early incubation temperature on broiler walking ability and final meat quality <i>T. Kettrukat and M. Therkildsen</i>	610
<i>In vitro</i> and <i>in vivo</i> analysis of bioactive substances growth and antioxidant activities <i>M. Mangan, C. Metges and M. Siwek</i>	611
Prophybiotics, a novel approach for <i>in ovo</i> gut microbiome reprogramming of broilers <i>R.N. Wishna-Kadawarage, R. Hickey and M. Siwek</i>	611
Antibacterial plant blends modulate gut microbiota in organic piglets challenged with <i>E. coli</i> F18 <i>K. Jerez-Bogota, M. Jensen, O. Højberg and N. Canibe</i>	612
Role of caecal microbiota in flock weight heterogeneity <i>M.Z. Akram, E.A. Sureda, L. Comer and N. Everaert</i>	612
¹ H-NMR metabolomics reveals alterations in the metabolism of ascarid-infected laying hens <i>O.J. Oladosu, B.S.B. Correia, B. Grafl, D. Liebhart, C.C. Metges, H.C. Bertram and G. Daş</i>	613
Validated machine-learning model to detect IUGR piglets <i>R. Ruggeri, G. Bee, P. Trevisi and C. Ollagnier</i>	613
<i>In vivo</i> validation of a non-invasive tool to collect intestinal content in pigs – CapSa- <i>I. García Viñado, F. Correa, P. Trevisi, G. Bee and C. Ollagnier</i>	614
Effect of creep feeding (liquid milk, dry and liquid diet) on pig growth and intestinal structure <i>E.A. Arnaud, G.E. Gardiner, M. Chombart, J.V. O'Doherty, T. Sweeney and P.G. Lawlor</i>	614
<i>In vitro</i> anthelmintic evaluation of Greek oregano against <i>Ascaridia galli</i> <i>I. Pouloupoulou, E. Sarrou, E. Martinidou, L. Palmieri, D. Masuero, S. Martens and M. Gauly</i>	615

Session 50. Insect genetics and reproduction

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Sandrock / Maya

Theatre Session 50

invited	Genetic diversity and improvement of the black soldier fly <i>C.D. Jiggins and T. Generalovic</i>	615
	Selection for larval weight in the black soldier fly – empirical evidence <i>K. Shrestha, E. Facchini, E. Van Den Boer, P. Junes, G. Sader, K. Peeters and E. Schmitt</i>	616
	Full-sib group records as a practical alternative to individual records in insect breeding <i>L.S. Hansen, A.C. Bouwman, H.M. Nielsen, G. Sahana and E.D. Ellen</i>	616
	Simulating breeding programs based on mass selection in black soldier fly (<i>Hermetia illucens</i>) <i>M. Slagboom, H.M. Nielsen, M. Kargo, M. Henryon and L.S. Hansen</i>	617
	Effects of artificial selection in the black soldier fly – a Pool-seq approach <i>E. Facchini, A. Vereijken, D. Bickhart, A. Michenet, K. Shrestha and K. Peeters</i>	617
	Adaptive responses of black soldier fly to simple low-quality diets <i>A. Gligorescu and J.G. Sørensen</i>	618
	Molecular sexing of black soldier flies <i>R.S.C. Rikkers, E. Van Der Valk, A.A.C. De Wit, L. Kruijt, E.D. Ellen, J. Van Den Heuvel and B.A. Pannebakker</i>	618
	Biomarker discovery for the black soldier fly (<i>Hermetia illucens</i>) <i>E.M. Espinoza</i>	619
	Improving black soldier fly genetics by CRISPR/Cas9 gene editing <i>I.N.Y. Nevo Yassaf, A.G. Goren, R.A. Adler and I.A. Alyagor</i>	619
	Expected response to selection on larval size and development time in the housefly (<i>Musca domestica</i>) <i>H.M. Nielsen, T.N. Kristensen, G. Sahana, S.F. Laursen, S. Bahrndorff, J.G. Sørensen and L.S. Hansen</i>	620
	ŸnFABRE: design of reference populations for genomic selection in <i>Tenebrio molitor</i> <i>E. Sellem, A. Donkpegan, Q. Li, K. Paul, A. Masseron, F. Gagnepain-Germain, K. Labadie, B. Vacherie, P. Garrabos, M.A. Madoui and T. Lefebvre</i>	620
	The potential of instrumental insemination for honeybee breeding <i>M. Du, R. Bernstein and A. Hoppe</i>	621
	Genetic analysis of production and behavioural traits of French honeybees <i>T. Kistler, C. Kouchner, C. Dumas, R. Dupain, A. Vignal, F. Mondet, P. Jourdan, B. Basso and F. Phocas</i>	621
	SimplyBee: R package for simulating honeybee populations and breeding programs <i>J. Obšteter, L.K. Strachan, J. Bubnič, J. Prešern and G. Gorjanc</i>	622
	Demonstrating the principles of genetic inheritance in honeybees using SIMplyBee <i>L. Strachan, J. Bubnič, G. Petersen, G. Gorjanc and J. Obšteter</i>	622
Poster Session 50		
	Exploring the potential for artificial selection in the black soldier fly, <i>Hermetia illucens</i> <i>T. Generalovic and C. Jiggins</i>	623

Weight of <i>Hermetia illucens</i> eggs from breeding and wild individuals <i>J. Lisiecka, Z. Mikołajczak, M. Dudek, K. Dudek, B. Kierończyk and D. Jóźefiak</i>	623
Paternity assignment tool in honey bees (<i>Apis mellifera</i>) <i>S. Andonov, G. Aleksovski, B. Dahle, M. Kovačič, A. Marinič, A. Moškrič, J. Prešern, B. Pavlov, Z. Puškadija and A. Uzunov</i>	624
Single-step genomic BLUP allows for the genetic evaluation of commercial honeybee queens <i>G.E.L. Petersen, F.S. Hely, M. Araujo, P.F. Fennessy and P.K. Dearden</i>	624
Deformed wing virus quantification: effect of selection and correlation with varroa related traits <i>M.G. De Iorio, S. Ottati, G. Molinatto, D. Bosco and G. Minozzi</i>	625
Monitoring the distribution of <i>Apis mellifera</i> genetic resources in Italy using mtDNA information <i>V. Taurisano, A. Ribani, K.E. Johnson, D. Sami, G. Schiavo, S. Bovo, V.J. Utzeri and L. Fontanesi</i>	625

Session 51. Leveraging the microbiome for resilience and sustainability in ruminant production – insights from H2020 HoloRuminant

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Kenny / Morgavi

Theatre Session 51

invited How does the cow's microbiome respond to physiological challenges? <i>J. Seifert</i>	626
Upper respiratory tract microbiota of dairy calves experimentally challenged with BRSV <i>S. O'Donoghue, B. Earley, M.S. McCabe, D. Johnston, K. Ní Dhúfaigh, S.L. Cosby, D.W. Morris and S.M. Waters</i>	626
Differential effects of <i>Ostertagia ostertagi</i> vaccination and infection on the rumen microbiome <i>J. Lima, T.N. McNeilly, P. Steele, M. Martínez-Álvaro, M.D. Auffret, R.J. Dewhurst, M. Watson and R. Roehe</i>	627
invited Novel ruminal microbiome solutions to reducing enteric methane emissions <i>T.A. McAllister, L.L. Guan and R.I. Mackie</i>	627
Relationship between feed efficiency and rumen microbiota in feedlot bulls fed contrasting diets <i>A. Ortiz-Chura, M. Popova, G. Cantalapiedra-Hijar and D. Morgavi</i>	628
Establishment and evolution of ruminotypes of lactating Lacaune ewes <i>T. Blanchard, C. Marie-Etancelin, Y. Farizon, C. Allain and A. Meynadier</i>	628
Effect of colostrum source and calf breed on diarrhoea incidents in pre-weaned dairy calves <i>S. Scully, P.E. Smith, B. Earley, C. McAloon and S.M. Waters</i>	629
invited Metagenome strain deconvolution and abundance estimation enabled by low-error long-read DNA sequence <i>D. Bickhart, M. Kolmogorov, E. Tseng, P. Pevzner and T. Smith</i>	629
Stakeholders views regarding new practices to control microbiomes <i>F. Bedoin, A. Ait-Sidhoum, E. Vanbergue, A. Stygar, T. Latvala, Á. MacKen-walsh, S. Waters, P. Smith and J.K. Niemi</i>	630

Poster Session 51

- Temporal establishment of the colon microbiota in angus calves from birth to post-weaning 630
M. Stafford, P. Smith, S. Waters, F. Buckley, E. O'Hara and D. Kenny
- Preliminary study of faecal microbiota in a selection experiment for birth weight variability in mice 631
L. El-Ouazizi El-Kahia, N. Formoso-Rafferty, J.P. Gutiérrez, C. Esteban Blanco, J.J. Arranz and I. Cervantes
- The effects of crude protein levels on rumen microbiome and CH₄ of the fattening Hanwoo steers 631
H. Kim, H. Cho, S. Jeong, K. Kang, S. Jeon, M. Lee, H. Kang, S. Lee, S. Seo and J. Seo
- Rumen metabolites of periparturient cows varying in SARA susceptibility modify fermentation *in vitro* 632
H. Yang, S. Heirbaut, J. Jeyanathan, X.P. Jing, N. De Neve, L. Vandaele and V. Fievez
- Prevalence of resistant *E. coli* and their transmission among dairy cattle in Swiss tie stalls 632
B. Köchle, V. Bernier Gosselin and J. Becker
- Stability of a *Bacillus*-based DFM following preparation of a milk replacer and premix 633
G. Copani, A. Segura, N. Milora, M. Schjelde and B.I. Cappellozza
- Effects of a *Bacillus*-based direct-fed microbial on performance and digestibility of lactating cows 633
M. Terré, N. Prat, D. Sabrià and B. Cappellozza
- Stability of a *Bacillus*-based direct-fed microbial post-palletisation under different temperatures 634
B. Cappellozza, C. Galschiet and G. Copani
- Microbial signals in peripheral blood mononuclear cells of Australian Angus cattle 634
P. Alexandre, A. Wilson, T. Legrand, R. Farr, S. Denman and A. Reverter
- Metabarcoding of milk, faeces and ruminal fluid of Sarda ewes fed with Alfalfa (*Medicago sativa*) 635
A. Vanzin, D. Giannuzzi, G. Zardinoni, A. Cecchinato, N. Macciotta, F. Correddu, A. Atzori, S. Carta, A. Ledda, S. Schiavon, L. Gallo and S. Pegolo
- An experimental approach for assessing causal microbes in early life diarrhoea in lambs 635
L. Voland, D. Graviou, K. Vazeille, A. Ortiz-Chura, D.P. Morgavi and M. Popova
- Mycotoxin-deactivating feed additive supplementation in dairy cows fed *Fusarium*-contaminated diet 636
A. Catellani, Y. Han, V. Bisutti, F. Ghilardelli, F. Fumagalli, E. Trevisi, A. Ceccinato, H. Swamy, S. Van Kuijk and A. Gallo
- Effects of 3-NOP on enteric methane production in growing beef cattle offered a forage based diet 636
S.F. Kirwan, L.F.M. Tamassia, N.D. Walker, A. Karagiannis, M. Kindermann and S.M. Waters

Session 52. Nitrogen management in the dairy supply chain and other tools to improve the efficiency and sustainability of cattle farming

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Righi / Tsiplakou

Theatre Session 52

- invited** COWFICIENCY project: a field attempt to increase nitrogen use efficiency of dairy cattle 637
A. Foskolos, A. Plomaritou, M.E. Hanlon and D. Kantas
- Dairy heifers intake capacity: are estimated values still correct? 637
J. Jurquet, Y. Le Cozler, D. Tremblais, F. Launay and L. Delaby

Current status of feed nitrogen use efficiency in dairy replacement heifers in Greece <i>A. Plomaritou, M.E. Hanlon, K. Gatsas, S. Athanasiadis, K. Droumtsekas, D. Kantas and A. Foskolos</i>	638
Impact of feed-grade and slow-release ureas on dairy cattle performance and nitrogen efficiency <i>M. Simoni, G. Fernandez-Turren, F. Righi, M. Rodríguez-Prado and S. Calsamiglia</i>	638
Current nitrogen status and management of dairy farms in Greece <i>M.E. Hanlon, A. Plomaritou, E. Tsiplakou, I. Vakondios, T. Michou, D. Kantas and A. Foskolos</i>	639
Dairy cattle holistic nutritional management for reduced nitrogen pollution <i>A. Foskolos, A. Plomaritou, M.E. Hanlon and D. Kantas</i>	639
Manure management practices of dairy farms in Greece <i>L. Makridis, D. Vouzaras, D. Kantas and A. Foskolos</i>	640
peNDF modulates chewing activity, rumen fermentation, plasma metabolites, performance in dairy cow <i>Y.C. Cao, L.M. Wang and J.H. Yao</i>	640
Impact on milk production of feeding organic acids during pre and post-partum period <i>L. Jansen and C. Gordon</i>	641
Peptide profile as fingerprinting of the ripening period of Alpine Asiago cheese <i>S. Segato, S. Khazzar, G. Galaverna, A. Caligiani, G. Riuzzi, L. Serva, F. Gottardo and G. Cozzi</i>	641
Producing sustainable milk in agroecology with Normande breed and grassland in Normandy <i>B. Rouillé, F. Lepeltier and L. Morin</i>	642
Hepatic metabolome of grazing dairy cows with or without feed restriction during early lactation <i>M. Carriquiry, M. García-Roche, A.L. Astessiano, D. Custodio, G. Ortega and P. Chilibroste</i>	642
Nitrogen balance of lactating cows from herds fed hay-based diets in Northern Italy <i>T. Danese, M. Simoni, R.G. Pitino, G. Mantovani, M.C. Sabetti, F. Righi and M.E. Van Amburgh</i>	643
Assessing sward managements on nitrogen fixation from a white clover high sugar grass mixture <i>M. Verbeeck, C. Segura, A. Louro-Lopez, N. Loick, P. De-Meo-Filho, S. Pulley, J. Hood, B.A. Griffith, L.M. Cardenas and D. Enriquez-Hidalgo</i>	643
Amino acid intake of hay-based diets and the relationship with milk production and urea content <i>M. Simoni, R. Pitino, T. Danese, G. Mantovani, E. Tsiplakou and F. Righi</i>	644

Poster Session 52

Does acidification affect urinary creatinine in dairy cattle? <i>T. Danese, M.C. Sabetti, M. Simoni, R.G. Pitino, G. Mantovani and F. Righi</i>	644
Effect of an alternative to sodium bicarbonate on performance of dairy cows <i>V. Leroux, C. Jaffres, A. Budan and N. Rollet</i>	645

Session 53. PLF for health and welfare – Part 1

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Maselyne / Calderon Diaz

Theatre Session 53

Evaluation of three measuring methods for the ammonia concentration for practical use in pig houses <i>J. Witt, J. Krieter, K. Schröder and I. Czycholl</i>	645

The information and communication technologies in livestock production – expectations and concerns <i>S. Opalinski, K. Olejnik, E. Popiela, A. Jankowska-Makosa, D. Konkol, M. Korczynski, D. Knecht, R. Kupczynski, I. Tikasz and T. Banhazi</i>	646
Implementation of a deep learning based system for monitoring farrowing in sows <i>M. Wutke, C. Lensches, A. Holzhauer, M.A. Lieboldt and I. Traulsen</i>	646
Who's biting? Detecting pig screams for identifying tail biting events <i>P. Hesecker, T. Bergmann, M. Scheumann, S. Ammer, I. Traulsen, N. Kemper and J. Probst</i>	647
Veterinarians' perceptions of using PLF technologies in pig husbandry in the Netherlands and Germany <i>M.F. Giersberg and F.L.B. Meijboom</i>	647
Automatic detection and quantification of ear biting in pigs <i>A. Odo, R. Muns, L. Boyle and I. Kyriazakis</i>	648
Installation modified carbon felt in pig house to control airborne pathogenic microorganisms <i>X.D. Zhao, F. Qi, H. Li and Z.X. Shi</i>	648
Benefit of caliper use at insemination on different genetic types: impact on farrowing performances <i>C. Teixeira Costa, C. Chevance, T. Nicolazo, G. Boulbria, V. Normand, J. Jeusselin and A. Lebret</i>	649
Combined effect of genetics, gut microbiota and environment on vaccine responses and welfare in hens <i>A. Lecoœur, F. Blanc, D. Gourichon, N. Meme, T. Burlot, V. Guesdon, V. Ferreira, L. Calandreau, L. Warin, F. Calenge and M.H. Pinard Van-Der-Laen</i>	649
Using triaxial accelerometers to monitor peripartum behaviour of Purebred Spanish mares <i>M.J. García García, F. Maroto Molina, C.C. Pérez Marín and D.C. Pérez Marín</i>	650
Relationships between direct and indirect genetic effects of RFI and feeding behaviour traits <i>M. Piles, M. Mora, M. Pascual and J.P. Sánchez</i>	650
Audio-based event detection and health monitoring in poultry <i>F. Hakansson and D.B. Jensen</i>	651

Poster Session 53

First approach of using sows' water consumption data to detect the onset of farrowing <i>J. Probst, N. Volkmann, C. Lensches, P. Hesecker, G. Thimm, M. Lieboldt, I. Traulsen and N. Kemper</i>	651
Social network analysis of cattle and horses inferred from sensor ear tag (SET) and GPS based data <i>U. Heikkilä, K. Ueda, N. Gobbo Oliveira Erünlü, M. Baumgartner, M. Cockburn, I. Bachmann, M. Roig-Pons and S. Rieder</i>	652

Session 54. Life Green Sheep and Farm management to adapt goat and sheep farming to climate change: solutions and experiments

Date: Wednesday 30 August 2023; 8.30 – 13.00

Chair: Throude / Satzori

Theatre Session 54

Modelling adaptation strategies to climate change in Mediterranean small ruminant systems <i>A. Lurette, S. Lobón, F. Douhard, M. Blanco-Alibes, D. Martin-Collado, A. Madrid, M. Curtil-Dit-Galin and F. Stark</i>	652
Feed365: Early findings for sheep grazing novel year-round forage systems <i>C.E. Payne, D. Real, A. Loi and C. Revell</i>	653

Quantifying responses to hot conditions in divergent sheep breeds in South Africa <i>S. Cloete, S. Steyn, J. Van Zyl and T. Brand</i>	653
Impacts of heat peaks in France on the performances of dairy goats housed in an insulated roof shed <i>K. Boissard, A. Fatet, M. Lambert, P. Sales and H. Caillat</i>	654
Cortisol level in sheep wool underwent to three different pasture management <i>L. Turini, A. Ripamonti, A. Silvi, E. Giua, A. Mantino, G. Conte, F. Bonelli and M. Mele</i>	654
How sheep sectors do face environmental, social and economic issues in French Pyrenees region? <i>A.-L. Jacquot, P.-G. Marnet and Y. Le Cozler</i>	655
Aligning carbon footprint estimates from different tools across Europe <i>A.S. Atzori, O. Del Hierro, B. Lyubov, R. Vial, C. Buckley, M.G. Serra, M. Habeanu, R. Ruiz, L. Lanzoni, M. Acciaro, T. Keady and S. Troude</i>	655
Determining carbon footprint of sheep farms in Europe: first results of the LIFE Green Sheep project <i>S. Throude, M. Acciaro, A. Atzori, R. Ruiz, O. Del Hierro, C. Buckley, L. Bragina, T.W.J. Keady, C. Dragomir, M.A. Gras and J.B. Dollé</i>	656
Greenhouse gas emission intensity of milk production in three Slovenian goat breeds <i>M. Bizjak, Ž. Pečnik and M. Simčič</i>	656
No difference in PAC methane emission corrected for milk yield in three Norwegian dairy goat farms <i>J.H. Jakobsen, T. Blichfeldt, K. Dodds and J.C. McEwan</i>	657
Sustainability of Irish sheep production <i>C. Buckley, L. Bragina and T. Keady</i>	657
Should animal welfare indicators be integrated into the environmental impact assessment of farms? <i>L. Lanzoni, L. Whatford, K. Waxenberg, R. Ramsey, R.M. Rees, J. Bell, E. Dalla Costa, S. Throude, A.S. Atzori and G. Vignola</i>	658
Testing mitigation actions to reduce GHG emissions from sheep farming in Europe <i>S. Throude, M. Acciaro, A. Atzori, R. Ruiz, O. Del Hierro, C. Buckley, L. Bragina, T.W.J. Keady, C. Dragomir, M.A. Gras and J.B. Dollé</i>	658
The effect of forage type on methane production from hill bred lambs grazing alternative forages <i>M. Dolan, T. Boland, N. Claffey, F. McGovern and F. Campion</i>	659
Poster Session 54	
Preliminary results of the LIFE Green Sheep project in Italy <i>M. Acciaro, M. Decandia, M.G. Serra, S. Picconi, V. Giovanetti, A. Atzori, D. Usai and S. Throude</i>	659
Carbon footprint assessment of a Pecorino cheese produced in central Italy <i>L. Lanzoni, L. Di Paolo, S. Abbate, M. Giammarco, M. Chincarin, I. Fusaro, A. Atzori, D. Di Battista, S. Throude and G. Vignola</i>	660
Grass management to adapt goat farming to climate change in western France <i>J. Jost, M.-G. Garnier, L. Robin, M. Proust, M. Bourasseau, R. Lesne, A. Villette, V. Tardif, T. Soulard, O. Subileau and O. Prodhomme</i>	660
Positive effects of grazing mulberry trees in summer on dairy goats' milk and cheese <i>C. Boyer, H. Le Chenadec, F. Noël, A. Stocchetti, J. Jost, A. Pommaret, S. Fressinaud and R. Delagarde</i>	661
Effects of heat stress and forage quality on feed intake and milk production of Sarda dairy ewes <i>M. Sini, F. Fulghesu, A. Ledda, A.S. Atzori and A. Cannas</i>	661

- Seasonal rainfall patterns modify summer energy balance and nutritional condition of grazing sheep 662
Y. Yoshihara, B. Choijilsuren, T. Kinugasa and M. Shinoda
- Effect of the inclusion of rumen-protected amino acids in the diet of high production dairy sheep 662
A. Cabezas, D. Martinez Del Olmo, J. Mateos, J. Matilla, M.T. Díaz, R. Bermejo-Poza, J. De La Fuente and V. Jimeno

Session 55. Breeding for climate change – adaptation

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Sell-Kubiak / Pszczola

Theatre Session 55

- Reaction norm model analysis for heat stress tolerance of growth performance in purebred pigs 663
Y. Fukuzawa, S. Ogawa, T. Okamura, N. Nishio, K. Ishii, K. Tashima, K. Akachi, H. Takahashi and M. Satoh
- Investigating the slick gene and its effects on heat stress in New Zealand grazing dairy cattle 663
G.M. Worth, E.G. Donkersloot, L.R. McNaughton, S.R. Davis and R.J. Spelman
- Use of sensors for the detection and genetic evaluation of heat stress in dairy cattle 664
P. Lemal, M.-N. Tran, M. Schroyen and N. Gengler
- Evaluation of heat stress effects on production traits and somatic cell score of Dutch Holstein cows 664
J. Vandenplas, M.L. Van Pelt and H. Mulder
- Multi-omics and multi-tissues data to improve knowledge of heat stress acclimation mechanisms 665
G. Huau, D. Renaudeau, J.L. Gourdine, J. Fleury, J. Riquet and L. Liaubet
- Should we consider fertility when improving thermotolerance in dairy cattle? 665
M.J. Carabaño, C. Díaz and M. Ramón
- Trade-off between fertility and production in French dairy cattle in the context of climate change 666
A. Vinet, S. Mattalia, R. Vallee, A. Barbat, C. Bertrand, B.C.D. Cuyabano and D. Boichard
- Genetic analyses of resilience indicator traits in German Holstein, Fleckvieh and Brown Swiss 666
F. Keßler, R. Wellmann, M. Chagunda and J. Bennewitz
- Estimating the heritability of nitrogen and carbon isotopes in the tail hair of beef cattle 667
M. Moradi, C. Warburton and L.F.P. Silva
- Changes in genetic correlations over generations due to selection and random drift 667
B.C.D. Cuyabano, S. Aguerre and S. Mattalia
- Longitudinal study of environmental effects for American Angus beef cattle over 30 years 668
G. Rovere, B.C.D. Cuyabano, B. Makanjuola and C. Gondro
- Characterization of environmental impact of 13,000 French dairy farms 668
R. Vial, A. Stocchetti, M. Mevel and C. Brocas

Poster Session 55

- Plateau-linear regression analysis of farrowing records on temperature data for pigs reared in Japan 669
S. Ogawa, T. Okamura, Y. Fukuzawa, M. Nishio, K. Ishii, M. Kimata, M. Tomiyama and M. Satoh

Genetic parameter of heat tolerance for reproductive traits in Landrace, Large White and Duroc pigs 669
T. Okamura, Y. Fukuzawa, M. Nishio, S. Ogawa, K. Ishii, H. Takahashi, K. Tashima, K. Akachi and M. Satoh

Breeding soundness evaluation of bulls in extensive systems in interior centre and south of Portugal 670
J. Várzea Rodrigues, L. Pinto De Andrade, S. Dias, J. Carvalho and M. Martins

Transcriptome analysis identifies genes affected by heat stress in hen uterovaginal junction 670
S. Kubota, P. Pasri, S. Okrathok, O. Jantasaeng, S. Rakngam, P. Mermillod and S. Khempaka

Session 56. Establishing breeding programs in extensive systems (including developing regions) with climate change in mind

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Leroy / Berg

Theatre Session 56

invited Establishing and scaling up breeding programs: a challenging, but not impossible task 671
M. Wurzinger

invited Development of a breeding programme for oysters 671
P. Haffray, R. Morvezen, F. Enez, L. Dégremonet and P. Boudry

Status of implementation of EU animal breeding legislation for endangered breeds 672
H. Göderz, L. Balzar, J. Wider, C. Danchin, M. Spoelstra, M. Schoon and S. Hiemstra

Spatial modelling improves genetic evaluation of Tanzanian smallholder crossbred dairy cattle 672
I. Houaga, R. Mrode, M. Okeyo, J. Ojango, Z. Nziku, A. Nguluma, A. Djikeng, E. Lavrenčič, G. Gorjanc and I. Pocrnic

Genetic parameters for grazing behaviour traits of Boutsko sheep 673
S. Vouraki, V. Papanikolopoulou, A. Argyriadou, V. Fotiadou, V. Tsartsianidou, A. Triantafyllidis, G. Banos and G. Arsenos

Research and development innovations for climate-smart beef production in subtropical countries 673
M.M. Scholtz, G.M. Pyoos, M.L. Makgahlela, M.C. Chadyiwa, M.D. MacNeil, M.M. Seshoka and F.W.C. Naser

Genetic and environmental factors influencing skin traits of South African farmed ostriches 674
K.R. Nemutandani, A. Engelbrecht, S.W.P. Cloete, K. Dzama and O. Tada

Genomic signatures of adaptive response driven by transhumant pastoralism in native Boutsko sheep 674
V. Tsartsianidou, S. Vouraki, P. Papanikolopoulou, G. Arsenos and A. Triantafyllidis

An Australian sheep genomic reference to meet the evolving breeding objectives of industry 675
S.F. Walkom, D.J. Brown and J.H.J. Van Der Werf

Poster Session 56

Evaluation of the perceptions of the functions of local breeds of domestic ruminants in Mayotte 675
J. Vuattoux, A. Lauvie, A. Giraud, E. Ozarak, J. Janelle, A. Rozier, T.T.S. Siqueira, M. Naves and E. Tillard

Signature of selection in South African Dexter cattle reveal resistance genes and genetic variations 676
E.D. Cason, J.B. Van Wyk, P.D. Vermeulen and F.W.C. Naser

Breed environment interaction and suitability of Dutch cattle breeds for low input systems 676
J.J. Windig, G. Bonekamp, M.A. Schoon, A.H. Hoving and S.J. Hiemstra

Session 57. Grassland management and grassland-based feeding systems for efficient and sustainable milk and meat production

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Berard / Probo

Theatre Session 57

- invited** Extensive permanent grasslands in Europe: multifaceted functions, threats and prospects 677
M. Bassignana
- The effect of establishment and grazing management on clover and herb establishment and persistence 678
L. McGrane, N. McHugh, T.M. Boland and P. Creighton
- Strategic concentrate supplementation in reducing slaughter age in pasture-based dairy-beef systems 678
J. O' Driscoll, D. Purfield, N. McHugh and N. Byrne
- Morphology and body composition of beef-on-dairy heifers along compensatory growth itinerary 679
I. Morel, A. Dieudonné, R. Siegenthaler, C. Xavier and S. Lerch
- In France, a new beef × dairy calf to steer production for the out-of-home consumers 679
M.A. Brasseur, C. Fossaert, F. Guy, J.J. Bertron, T. Dechaux and S. Brouard
- Behavioural and welfare responses of dairy cows learning a virtual fencing system 680
P. Fuchs, J. Stachowicz, M. Schneider, M. Probo, R. Bruckmaier and C. Umstätter
- Age does not affect the learning capacity of virtually fenced cows 680
A. Confessore, C. Aquilani, P. Fuchs, C. Pugliese, C.M. Pauler, M. Schneider, G. Argenti and M. Probo
- Integrating multiple data streams and models to inform precision grazing management in the U.S 681
J.R. Brennan, H. Menendez and K. Ehlert
- Yearly monitoring of soil ingestion by dairy cows in a grassland system with feed supply 681
C. Collas, A. Laffotte, C. Feidt and S. Jurjanz
- Pre-grazing sward height affects enteric methane emission during grazing 682
L. Koning, G. Holshof, A. Klop and C.W. Klotwijk
- Forage shortage affects performances, CH₄ emissions and cheese quality in grass- or corn-fed cows 682
M. Bouchon, I. Verdier-Metz, M. Eugene, C. Bord, B. Martin, J. Bloor, M.C. Michalski, B. Graulet and C. Delbès
- Variability of economic and GHG performance in dairy-beef systems at different stocking rates 683
M. Kearney, E. O'Riordan, J. Breen, R. Dunne, P. French and P. Crosson

Poster Session 57

- Feeding behaviour, methane emission and digestibility of crossbred heifers along compensatory growth 683
B. Hayoz, I. Morel, A. Dieudonné, M. Rothacher, R. Siegenthaler, F. Dohme-Meier and S. Lerch
- Involving farmers in the development of a grassland monitoring tool: sunshine's co-design approach 684
D.M. Mathy, C.L. Lucau-Danila, Y.C. Curnel, E.R. Reding, K.D. Dichou and S.L. Lagneaux
- Effects of increasing portion of grass-silage in dairy cow diet on carbon footprint of raw milk 684
S. Hietala, A. Vanhatalo, K. Kuoppala, T. Kokkonen, A. Reinikainen, K. Timonen and A.-L. Välimaa

Blood metabolite, hormone and $\delta^{13}\text{C}$ turnover kinetic during compensatory growth of crossbred heifers <i>S. Lerch, P. Silacci, G. Cantalapiedra-Hijar, R. Siegenthaler, S. Dubois, A. Delavaud, M. Bonnet and I. Morel</i>	685
Metabolic assessment of parasite dilution and forage niche sharing in sheep/cattle mixed-grazing <i>F. Joly, P. Nozière, P. Jacquet, S. Prache and B. Dumont</i>	685
Effects of different additives on the correlation between fermentation characteristics of wilted rye <i>Y.F. Li, L.L. Wang, Y.S. Yu, H.J. Kim and J.G. Kim</i>	686
Bite item selection by grazing suckler cows in multi-species grasslands <i>C. Siede, W. Pohlmann, A. Juch, D. Hamidi, J. Isselstein and M. Komanda</i>	686
Nutritional value of intramuscular fat of the muscle of Arouquesa weaners from different systems <i>L. Sacarrão-Birrento, C.A. Venâncio, A.M. De Almeida, L.M. Ferreira, M.J. Gomes, J.C. Almeida, J.A. Silva and S.P. Alves</i>	687
Prediction of nutritional parameters of naturalized grassland in the dry zone of Chile using NIRS <i>P.M. Toro-Mujica</i>	687
Effect of cutting length on fermentation dynamics of wilted Italian ryegrass silage <i>J. Kim, Y. Li, L. Waang, Y. Yu and H. Kim</i>	688
Grazing behaviour of energy-limited dairy cows and development of detection method by deep learning <i>Y. Shinoda, S. Asakuma, Y. Ueda, S. Tada and K. Sudo</i>	688
Evaluation of 3 equations based on grass height measurement for estimating grass stocks in pastures <i>F. Lessire, J.-L. Hornick and I. Dufrasne</i>	689
Breeding of native breeds as a chance for the development of livestock households in ecological sys <i>P. Radomski and P. Moskala</i>	689
Conceptual model for the analysis of energy allocation of cow-calf farms native grassland-based <i>V. Figueroa, I. Paparamborda, S. Scarlato and P. Soca</i>	690
Do botanically diverse pastures effect the meat eating quality of lamb? <i>S. Woodmartin, P. Creighton, T.M. Boland, E. Crofton, A. Monaghan and F. McGovern</i>	690
Altering milking frequency from 14 to ten milking's per week: effects on milk production of pasture <i>E. Kennedy, K. McCarthy, J.P. Murphy and M. O'Donovan</i>	691
Robustness of suckling cows at herd level is associated with cows' productive longevity <i>L. Barreto-Mendes, A. De La Torre, S. Ingrand and F. Blanc</i>	691

Session 58. The future of animal products: improved quality management, more alternatives or cell-based products?

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Ellies-Oury / Chriki

Theatre Session 58

Variability in consumer perception of meat and meat substitutes <i>E. Hocquette, J. Liu, S. Chriki, M.P. Ellies-Oury, M. Kombolo, J.H. Rezende-De-Souza, S.B. Pflanzner and J.F. Hocquette</i>	692
Bibliometric analysis of scientific articles related to 'cultured meat' <i>J.F. Hocquette, D. Fournier, M.P. Ellies-Oury and S. Chriki</i>	692

Addressing the challenges of animal-free meat using plant-based tissue engineering <i>M.O.R. Yahav</i>	693
Comparing the potential of meat alternatives for a more sustainable food system <i>T. Bry-Chevalier</i>	693
invited IMR3G Foundation, DATAbank software to facilitate collaborative data collection for mutual benefit <i>R. Polkinghorne, H. Cuthbertson, A. Neveu and J. Wierzbicki</i>	694
Beef processors experience large variation in yield and quality traits on a daily basis <i>W. Pitchford and S. Miller</i>	694
Introduction to plant-based, cultivated, and fermentation-made meat, eggs, and dairy <i>S. Kell</i>	695
Environmental impact of dairy alternatives: a case study of Hemp milk and other products <i>B. Queiroz Silva, J. Ferdouse and S. Smetana</i>	695
The tools of prediction of the sensory quality, the opinion of the French professionals <i>T. Fayet</i>	696
Limitations and challenges for the successful launch to market of cultured animal protein products <i>J.F. Fuentes-Pila</i>	696
Implementing advanced characterization methods and building a new reference for alt-meat development <i>M.O.R. Yahav</i>	697

Poster Session 58

Whey proteins as alternative supplement to FBS in C2C12 muscle cells for cultured meat production <i>T.S. Sundaram, D. Lanzoni, R. Rebucci, F. Cheli, A. Baldi and C. Giromini</i>	697
German consumers' attitudes towards cultured meat <i>A.-K. Jacobs, M.-P. Ellies-Oury, H.-W. Windhorst, J. Gickel, S. Chriki and J.-F. Hocquette</i>	698
Development of the beef eating quality management system in Poland <i>G. Pogorzelski, J. Wierzbicki, E. Pogorzelska-Nowicka, A. Jasieniak and A. Wierzbicka</i>	698

Session 59. Environmental challenges of cattle tropical grazing systems

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Dossa / Salgado

Theatre Session 59

Degradation of Amazonian grasslands by weeds, how to managing this situation? <i>V. Blanfort, C. Favale, S. Bazan, V. Petiot, D. Bastianelli and T. Le Bourgeois</i>	699
Analysing strategies adopted to cope the climate variability in pastoral zone of Burkina Faso <i>H.P. Yarga, A. Kiema, L. Ouedraogo and S. Ouedraogo</i>	699
How do changes in crop-livestock integration and specialisation affect farm performance in Vietnam? <i>A. Le Trouher, H. Le Thi Thanh, T. Dinh Khanh, T. Han Anh, C.-H. Moulin and M. Blanchard</i>	700
Problem of water supply in a context of climate variability in the pastoral zones of Burkina Faso <i>H.P. Yarga H Paul, S. Ouedraogo, A. Kiema and L. Ouedraogo</i>	700

Local feeding strategies allow to reduce enteric methane emission from cattle in Sahel <i>G.X. Gbenou, M.H. Assouma, C. Martin, D. Bastianelli, L. Bonnal, T. Kiendrebeogo, O. Sib, B. Bois, S. Sanogo and L.H. Dossa</i>	701
Development of a decision support tool to secure cattle production in chlordecone-contaminated areas <i>A. Fournier, C. Feidt, A. Fourcot, M. Saint-Hilaire, Y. Le Roux and G. Rychen</i>	701
Can tropical legume grass forage reduce enteric methane yield from suckler cows in the Sahel? <i>M.H. Assouma, A. Baro, G.X. Gbenou, O. Sib, S. Sanogo, H. Marichatou and E. Vall</i>	702
Agroforestry: an opportunity to improve the sustainability of livestock systems in Vietnam? <i>M. Blanchard, P. Tos, A. Le Trouher, A. Lurette and H. Le Thi Thanh</i>	702
Selection signatures of the indigenous Sanga cattle of Namibia <i>D.A. Januarie, E.D. Cason and F.W.C. Nesper</i>	703
<i>Diodelle sarmentosa</i> , an invasive plant in the rangelands of the sylvopastoral zone of Senegal <i>E.H. Traore and F. Sow</i>	703
invited Environmental challenges in dry tropical livestock systems: GHG emissions and carbon storage balance <i>M.H. Assouma, D. Bastianelli and P. Salgado</i>	704

Poster Session 59

Resilience analysis based on heifer productive and reproductive aspects <i>V.T. Rezende, G.R.D. Rodrigues, A.H. Gameiro, M.E.Z. Mercadante, R.C. Canesin and J.N.G.S. Cyrillo.</i>	704
Impact of GreenFeed protocols on cattle visitation and methane data collection <i>M.C. Parra, M.H. Dekkers, S.A. Cullen and S.J. Meale</i>	705
Effect of production system and season on composition of retail cow milk in Greece <i>G. Papatzimos, R.A. Stergioudi, V. Papadopoulos, Z. Basdagianni, M.A. Karatzia, P. Mitlianga and E. Kasapidou</i>	705
Influence of heifer resilience on the productive performance of calves <i>G.R.D. Rodrigues, V.T. Rezende, C. Raineri, M.E.Z. Mercadante, S.F.M. Bonilha and J.N.S.G. Cyrillo</i>	706
Feed autonomy and manure's recycling of dairy sheep farming systems in Roquefort (France) <i>W. Nasri, F. Stark, N. Amposta, M. Lamarque, C. Allain, D. Portes, S. Arles, S. Parisot, C. Corniaux, P. Salgado and E. González-García</i>	706
Metabarcoding study of the microbial dynamics in cheeses as a function of milk tank temperature <i>L. Giagnoni, C. Spanu, A. Tondello, S. Deb, A. Cecchinato, P. Stevanato, M. De Noni and A. Squartini</i>	707
Adaptive integumentary traits of cattle raised in a silvopastoral system in tropical region <i>A.R. Garcia, A.N. Barreto, M.A.C. Jacintho, W. Barioni Junior, L.N. Costa, F. Luzi, J.R.M. Pezzopane, A.C.C. Bernardi and A.M.F. Pereira</i>	707
Impact of fodder quality seasonality on enteric methane emission from cattle in Sub-Saharan Africa <i>G.X. Gbenou, M.H. Assouma, C. Martin, D. Bastianelli, L. Bonnal, T. Kiendrebeogo, O. Sib, B. Bois, S. Sanogo and L.H. Dossa</i>	708

Session 60. Minerals in animal nutrition: supplementation – Part 1

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Alvarez Rodriguez / Windisch

Theatre Session 60

invited	Variation in mineral content of feeds for dairy cows and how that can affect ration formulation <i>W.P. Weiss</i>	708
	Evolution of nutritional explorations in herds of dairy and beef cattle between 2013 and 2021 <i>L. Reisdorffer</i>	709
	Selenium supply in animal feeds, a powerful nutritional tool against cancer <i>M. López-Alonso, I. Rivas and M. Miranda</i>	709
	Effect of mineral source on 48-h <i>in vitro</i> fermentation <i>G.M. Boerboom, C.B. Peterson, L. Jansen, M.M. McCarthy, J.S. Heldt and J. Johnston</i>	710
	Feed phosphates market dynamics: does price influence demand? <i>G. Milochau</i>	710
	Reduction of trace mineral supplementation on performance and mineral status of fattening pigs <i>E. Gourlez, J.Y. Dourmad, F. Beline, A. Monteiro, A. Boudon, A. Narcy, P. Schlegel and F. De Quelen</i>	711
	Optimal level of dietary zinc for pigs between 10 and 30 kg <i>T.S. Nielsen, S.V. Hansen, J.V. Nørgaard and T.A. Woyengo</i>	711
	Administration of potentiated Zn and monovalent Cu in weanling piglets diet <i>L. Marchetti, R. Rebucci, P. Cremonesi, B. Castiglioni, F. Biscarini, A. Romeo and V. Bontempo</i>	712
	Unexpected Cu and Zn speciation patterns in the feed-animal-excreta system <i>S. Legros, M. Tella, A.N.T.R. Monteiro, A. Forouzandeh, F. Penen, S. Durosoy and E. Doelsch</i>	712
	Coarse limestone particles limit the formation of Ca-phytate complexes in laying hens <i>F. Hervo, M.-P. Létourneau-Montminy, B. Méda, M.J. Duclos and A. Narcy</i>	713

Poster Session 60

	The duration of efficacy of a single oral dose of selenium in sheep <i>S.E. Gallimore, E.J. Hall and N.R. Kendall</i>	713
	Dietary manganese impacts on growth, carcass and reproductive traits in angus bulls <i>J.R. Russell, E.L. Lundy-Woolfolk, A.S. Cornelison, W.P. Schweer, T.M. Dohlgan and D.D. Loy</i>	714
	Micronutrient supplementation for suckling calves <i>M.S.V. Salles, F.J.F. Figueiroa, A. Saran Netto, C.M. Bittar, F.F. Simili and H.N. Rios</i>	714
	Impacts of trace mineral source and ancillary drench on steer performance during backgrounding <i>K. Harvey, L. Rahmel, J. Cordero, B. Karisch, R. Cooke and J. Russell</i>	715
	Impact of trace minerals and water/feed deprivation on performance and metabolism of grass-fed beef <i>M.J.I. Abreu, I.A. Cidrini, D. Brito De Araujo, F.D. Resende and G.R. Siqueira</i>	715
	The impact of trace mineral sources of copper and zinc on performance and ruminal bacteria diversity <i>I.A. Cidrini, I.M. Ferreira, D. Brito De Araujo, G.R. Siqueira and F.D. Resende</i>	716

Are inorganic Mn sources soluble and improve rumen fermentation? <i>A. Vigh, C. Gerard and C. Panzuti</i>	716
Effect of diet type, Cu source and antagonists on rumen <i>in vitro</i> fermentation and Cu distribution <i>I. Bannister, J.A. Huntington, L.A. Sinclair, J.H. McCaughern and A.M. McKenzie</i>	717
Meta-analysis on zinc oxide's mode of action in reducing weaning stress in healthy piglets <i>C. Negrini, D. Luise, F. Correa, P. Bosi, A. Roméo and P. Trevisi</i>	717
Marine mineral complex reduces nutrient interactions and allows efficient use of Ca and P in broiler <i>M.A. Bouwhuis, R. Casserly, A. Craig, D. Currie and S. O'Connell</i>	718
Seaweeds in animal nutrition, a valuable source of minerals but in need of fine-tuning <i>S. Al-Soufi, J. García, E. Cegarra, A. Muñíos, V. Pereira and M. López-Alonso</i>	718
Online mislabelling of mineral and complementary feeds available in France <i>F. Toutiou, C. Marin, T. Blanchard, A. Meynadier and N. Priymenko</i>	719
Diversity of practices and advisors in mineral and vitamin supplementation of dairy farms <i>C. Manoli, G. Springer, L. Barbier, C. Chassaing, C. Sibra, G. Maxin, A. Boudon and B. Graulet</i>	719

Session 61. Resilient livestock farming systems in the face of climate and other global challenges – adaptation and mitigation

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Sturaro / Pouloupoulou

Theatre Session 61

invited How to improve resilience, from animal to system level <i>A. Mottet, R. Baumung, G. Velasco Gil, G. Leroy and B. Besbes</i>	720
On the link between climate change mitigation and adaptation in dairy cow farming in West of France <i>B. Godoc, E. Castellan, A. Madrid and C. Karam</i>	720
Resilience of ruminant organic systems to climatic hazards: a study model in a French grassland area <i>C. Boivent and P. Veyssset</i>	721
Resilgame: a game to experiment farm adaptation to climate change <i>G. Martel and S. Colombié</i>	721
Evolution of agroecology and associate indicators – looking for balance in farming systems <i>E. Benedetti Del Rio, A. Michaud and E. Sturaro</i>	722
Small ruminants farming systems of Spain: challenges and attributes for their resilience <i>J. Lizarralde, B. Soriano, A. Benhamou-Prat, P. Gaspar-García, Y. Mena-Guerrero, J.M. Mancilla-Leyton, A. Horrillo, R. Ruiz, D. Martín-Collado and N. Mandaluniz</i>	722
Building resilience in drylands' extensive livestock systems under climate uncertainty <i>A. Tenza-Peral, I. Pérez-Ibarra, A. Breceda, J. Martínez-Fernández and A. Giménez</i>	723
A thirty-year assessment of interactions between weather conditions and sheep milk yield and quality <i>A. Mantino, M. Milanesi, M. Finocchi, G. Conte, G. Vignali, G. Chillemi, L. Turini and M. Mele</i>	723
Indicators for animal health on agro-ecological dairy farms <i>A. Ceppatelli, M. Crémilleux, A. Michaud and E. Sturaro</i>	724

Exploring climate change adaptation strategies from the perspective of Mediterranean sheep farmers <i>D. Martín-Collado, S. Lobón, M. Joy, I. Casasús, A. Mohamed-Brahmi, Y. Yagoubi, F. Stark, A. Lurette, A. Abuoul Naga, E. Salah and A. Tenza-Peral</i>	724
Combining serious games in a process to support sustainable livestock farming systems <i>R. Etienne, S. Darnat, C. Rigolot and S. Ingrand</i>	725
Assessing how farm features and farmers' profile contribute to farm resilience <i>A. Prat-Benhamou, B. Soriano, D. Ondé, J. Lizarralde, J.M. Mancilla-Leyton, N. Mandaluniz, P. Gaspar-García, Y. Mena-Guerrero and D. Martín-Collado</i>	725

Poster Session 61

The difference between abnormal climate and extreme climate that cause yield damage to silage corn <i>M. Kim and K. Sung</i>	726
Causality in climate-soil-yield network for silage corn <i>M. Kim and K. Sung</i>	726
Can studying the health of livestock systems be a way to improve their resilience? <i>M. Cremilleux, B. Martin and A. Michaud</i>	727
Effect of heat stress on extensive beef cattle's calving percentage in the Central Bushveld Bioregio <i>S.M. Grobler, M.M. Scholtz, F.W.C. Naser, J.P.C. Greyling and L. Morey</i>	727
Contrasting rearing and finishing regimens on performance and methane emissions of Angus steers <i>J. Clariget, V. Ciganda, G. Banchemo, D. Santander, K. Keogh, D.A. Kenny and A.K. Kelly</i>	728
Energy and greenhouse gas emissions: tools to discuss sustainability of livestock systems in Amazon <i>D.C.C. Corrêa, R.J.M. Pocard-Chapuis, M. Lenoir, V. Blanfort, J.L. Bochu and P. Lescoat</i>	728
Microclimate and production of a tropical forage intercropped with pigeon pea <i>J.R.M. Pezzopane, P.P.A. Oliveira, A.F. Pedroso, W. Bonani, V.M. Gomes, C. Bosi, H.B. Brunetti, R. Pasquini Neto and A.J. Furtado</i>	729
Reducing energy consumption to dry alfalfa using organic acids – a field trial <i>T. Fumagalli and L.L.C. Jansen</i>	729
Carbon and energy footprint of dehydrated alfalfa production, from planting to factory output <i>D. Coulmier, P. Thiebeau, S. Recous and H. Labanca</i>	730
Impact of heat waves on the quality of milk and lactic farmhouse goat cheeses in the Aura region <i>S. Raynaud, E. Lemée, H. Le Chenadec, C. Laithier, P. Thorey, C. Boyer, M. Legris, S. Morge, S. Anselmet, V. Béroutle, S. Fressinaud, C. Delbès, M. Brocart, N. Morardet, J. Birkner and Y. Güzere</i>	730
Climate-smart practices can reduce GHG emissions intensity on smallholder dairy farms in Kenya <i>L. McNicol, M. Graham, M. Caulfield, J. Kagai, J. Gibbons, A.P. Williams, D. Chadwick and C. Arndt</i>	731

Session 62. Poultry and pig low-input and organic production systems' welfare

Date: Wednesday 30 August 2023; 15.00 – 18.30
Chair: Daş / Holinger

Theatre Session 62

invited Welfare barriers and levers for improvement in organic and low-input outdoor pig and poultry farms <i>C. Leterrier, C. Bonnefous, J. Niemi, PPILOW Consortium and A. Collin</i>	731

Range use relationship with welfare and performance indicators in four organic broilers strains <i>C. Bonnefous, A. Collin, L.A. Guilloteau, K. Germain, S. Mignon-Grasteau, M. Reverchon, S. Mattioli, C. Castellini, V. Guesdon, L. Calandreau, C. Berri and E. Le Bihan-Duval</i>	732
Case study of a newly-developed genotype for dual-purpose rearing of male chicks <i>H. Pluschke, S. Lombard, B. Desaint, M. Reverchon, A. Roinsard, O. Tavares, A. Collin-Chenot, M. Ferriz, S. Seelig and L. Baldinger</i>	732
Poultry production: using dual-purpose genotypes to reduce the culling of day-old male chicks? <i>J. Niemi, M. Väre, A. Collin, M. Almadani, M. Quentin, L. Baldinger, S. Steinfeldt, T.B. Rodenburg, F. Tuytens and P. Thobe</i>	733
Longitudinal assessment of health indicators in four organically kept laying hen flocks <i>L. Jung, M. Krieger, L. Matoni and D. Hinrichs</i>	733
invited Alternative pig housing systems with high welfare standards – status quo and perspectives <i>M. Holinger</i>	734
Characterising outdoor pig systems in Ireland <i>O. Menant, S. Mullan, F. Butler, L. Boyle and K. O'Driscoll</i>	734
Animal welfare and pork quality of intact male pigs in organic farming according to genotype <i>B. Lebre, S. Ferchaud, A. Poissonnet and A. Prunier</i>	735
Large White genetics in organic system: breeding for piglet survival <i>L. Canario, S. Ferchaud, S. Moreau, C. Larzul and A. Prunier</i>	735
Comparing animal welfare assessments by researchers and free-range pig farmers with the PIGLOW app <i>E.A.M. Graat, C. Vanden Hole, S. Nauta, M.F. Giersberg, T.B. Rodenburg and F.A.M. Tuytens</i>	736

Session 63. Monoguthealth – Part 2

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Bee / Trevisi

Theatre Session 63

Growth performance and digestive tract parameters in weaned piglets fed <i>Nannochloropsis limnetica</i> <i>A.A.M. Chaves, C.F. Martins, D.F. Carvalho, A.R.J. Cabrita, M.R.G. Maia, A.J.M. Fonseca, R.J.B. Bessa, A.M. Almeida and J.P.B. Freire</i>	736
Synbiotic administration to suckling piglets on health parameters at weaning and postweaning period <i>E.A. Sureda, M. Schroyen, J. Uerlings, F. Fannes, J. Liénart, A. Sabri, P. Thonart, V. Delcenserie, J. Wavreille and N. Everaert</i>	737
Fine characterisation of a standardized citrus extract and it's effect on weaned piglet performances <i>S. Cisse, J. Laurain and M.E.A. Benarbia</i>	737
Essential oils and butyric acid effects on growth performance, blood metabolites and health in pigs <i>U. Marume and R.B. Nhara</i>	738
The impacts of a spectrum of varied lifestyle factors on the porcine gut microbiota <i>L. Comer, E. Arévalo Sureda and N. Everaert</i>	738
<i>In vitro</i> inhibition of avian pathogenic <i>Enterococcus cecorum</i> isolates by probiotic <i>Bacillus</i> strains <i>M. Bernardeau, S. Medina-Fernandez and M. Cretenet</i>	739

Effects of breed and early feeding on intestinal microbiota, gene expression and welfare indicators <i>F. Marcato, D. Schokker, S.K. Kar, J.M.J. Rebel and I.C. De Jong</i>	739
Yogurt Acid Whey addition affects broiler caecal microbiota composition and metabolic activity <i>I. Palamidi, V.V. Paraskeuas, I. Politis and K.C. Mountzouris</i>	740
A richer gut microbiota is related to better feed efficiency and diet adaptability in laying hens <i>M. Bernard, A. Lecoeur, J.L. Coville, N. Bruneau, D. Jarret, S. Lagarrigue, F. Calenge, G. Pascal and T. Zerjal</i>	740
Gut microbiome variations during the productive lifespan of two high-yielding laying hen strains <i>C. Roth, J. Seifert, M. Rodehutschord and A. Camarinha-Silva</i>	741
A rabbit nutrition hypothesis to prevent digestive problems: 'Feed the fusus coli' <i>K.H. De Greef and M. Van Der Sluis</i>	741
Gut microbiota of growing rabbits fed diets with different fibre and lipid contents <i>G. Zardinoni, P. Stevanato, A. Trocino, M. Birolo, F. Bordignon and G. Xiccato</i>	742
Poster Session 63	
Gut microbiota-metabolome response to dietary porcine intestinal mucosa hydrolysate in piglets <i>S. Segarra, A. Middelkoop and F. Molist</i>	742
Effects of probiotics isolated from faeces of fast-growing pigs on growth performance of weaning pigs <i>Y.H. Choi, Y.J. Min, J.E. Kim, Y.D. Jeong, H.J. Park, C.H. Kim and S.J. Sa</i>	743
Effect of butyric acid salts on the palatability of feed for piglets <i>W. Kozera, A. Woźniakowska, K. Karpiesiuk, A. Okorski and G. Żak</i>	743
Synbiotics-glyconutrients enhance growth performance and fatty acid profile in finishing pigs <i>C.B. Lim, Q.Q. Zhang, S. Biswas, J.H. Song, O. Munezero, J.S. Yoo and I.H. Kim</i>	744
Impact of gut health product on appetite associated hormones using <i>ex vivo</i> porcine intestinal cells <i>N. Browne and K. Horgan</i>	744
Development of antimicrobial peptides against multidrug-resistant enterotoxigenic <i>Escherichia coli</i> <i>W.J. Chen, M.Y.W. Kwok, K.C. Wu, K.F. Hua, Y.H. Yu and Y.H. Cheng</i>	745
Influences of quercetin inclusion to corn-soybean-gluten meal-based diet on broiler performance <i>S. Biswas, Q.Q. Zhang, J.H. Song, C.B. Lim, I.H. Kim and J.S. Yoo</i>	745
Effects of <i>Bacillus</i> species – fermented products on growth performance and gut health in broilers <i>Y.H. Yu, S.H. Hsiao, Y.H. Cheng, W.J. Chen and K.F. Hua</i>	746
<i>Lactobacillus ingluviei</i> C37 improves gut health in lipopolysaccharide challenged broiler chickens <i>S. Khempaka, M. Sirisopapong and S. Okrathok</i>	746
Effects of different probiotics on laying performances, egg quality and gut health in laying hens <i>F. Barbe, L. Blanc, A. Sacy and E. Chevaux</i>	747
Simple methodology to evaluate faeces quality on farm and effect of <i>S. boulardii</i> on faecal scoring <i>A. Sacy, F. Barbé, S. Poulain, P. Belloir, C. Paes and E. Chevaux</i>	747
A comparison of yeast gut health products ability to limit attachment of <i>Salmonella</i> to IPEC-j2 cells <i>N. Browne, A. McCormack and K. Horgan</i>	748

Butyric acid and *Bacillus subtilis* 29784 improve cumulatively the intestinal barrier 748
A. Mellouk, D. Prévéraud, T. Goossens, O. Lemâle, E. Pinloche and J. Consuegra

Session 64. Project session: Farmyng

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Kihanguila / Gasco

Theatre Session 64

Safety of BSF larvae reared on substrates which are spiked or naturally contaminated with aflatoxins 749
K. Niermans, E.F. Hoek- Van Den Hil, N. Meijer, S.P. Salari, M. Gold, H.J. Van Der Fels-Klerx and J.J.A. Van Loon

Transfer of aflatoxin, lead and cadmium from larvae reared on contaminated substrate to laying hens 749
M. Heuel, M. Kreuzer, I.D.M. Gangnat, E. Frossard, C. Zurbrugg, J. Egger, B. Dortmans, M. Gold, A. Mathys, J. Jaster-Keller, S. Weigel, C. Sandrock and M. Terranova

Determination of minimal nutrient requirements of *Tenebrio molitor* larvae 750
B. Tamim, T. Parr, J. Brameld and A. Salter

FLAGship demonstration of industrial scale production of nutrient resources from mealworms 750
W. Kihanguila

Tailored vitamins and minerals premix for *Tenebrio molitor* farming 751
E. Barbier, V. Gerfault, T. Lefebvre, F. Peyrichou, C. Ricciardi and N. Tanrattana

Tenebrio molitor genomics revealed limited molecular diversity among available populations 751
L. Panunzi, E. Eleftheriou, B. Vacherie, K. Labadie, T. Lefebvre and M.A. Madoui

Assessing the quality of insect-derived products: methods and findings from the FARMYNG project 752
S. Gofflot, A. Pissard, F. Debode, A.C. Laplaize, B. Lorrette and J.F. Morin

Authentication of insect-derived products: methods and findings from the FARMYNG project 752
B. Dubois, A. Marien, S. Guillet, J.-F. Morin, B. Lorrette and F. Debode

More than an organic fertilizer: mealworm frass as a substitute to conventional fertilizers 753
E. Bohuon, D. Houben, G. Daoulas, M.-P. Faucon and A.-M. Dulaurent

The environmental life cycle assessment of Ynsect insect based proteins 753
K. Hsu, A. Eiperle and M. Jouy

Insects' nutrients – the Animal Frontiers special issue 754
T. Veldkamp and L. Gasco

Session 65. Remote sensing applied to livestock farming: discovering physiological and ethological clues to optimize productive performance and animal welfare

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Montanholi

Theatre Session 65

Time-course change in lamb composition and reflectance properties: implications for authentication 754
L. Rey-Cadilhac, D. Andueza, A. Prunier and S. Prache

Individual adaptive responses of meat ewes facing an abrupt nutritional challenge after lambing <i>E. González-García, M. Gindri, L. Puillet and N.C. Friggens</i>	755
Large variation in emission intensities from dual-purpose sheep production system <i>B.A. Åby, S. Samsonstuen and L. Aass</i>	755
Considering the morphology of cows for comfortable milking <i>J. Fazilleau, S. Guiocheau and J.L. Poulet</i>	756
Classification of honeybee flight activity patterns reveals impact of recruitment behaviours <i>G.E.L. Petersen, D. Gupta, P.F. Fennessy and P.K. Dearden</i>	756
Implementation of large-scale climate smart agriculture research on U.S. beef cattle grazing lands <i>K. Cammack, A. Blair, L.O. Tedeschi, H.M. Menendez Iii and J.R. Brennan</i>	757
Remote monitoring behaviour of bison in captivity: effects of gender, weather and daytime <i>R.R. Vicentini, D. Moya, J. Church, A.C. Sant'anna, W. Balan, W. Squair and Y.R. Montaholi</i>	757
Artificial intelligence for measuring the respiration rate in dairy cows <i>L. Dißmann, R. Antia, L. Chinthakayala, N. Landwehr, T. Amon and G. Hoffmann</i>	758
Using millimetre-wave radar for monitoring sow postural activity in individual pen: first results <i>D. Henry, J. Bailly, T. Pasquereau, W. Hebrard, J.F. Bompà, E. Ricard, H. Aubert and L. Canario</i>	758
The environmental variance on daily feed intake as a measure of resilience in pigs <i>C. Casto-Rebollo, P. Nuñez, S. Gol, J. Reixach and N. Ibáñez-Escriche</i>	759

Poster Session 65

Factors affecting somatic cell count in ewe milk and its effect on milk yield and composition <i>M. Oravcová, V. Tančin, L. Mačuhová and M. Uhrinčat'</i>	759

Session 66. Innovation in non-ruminant nutrition and feeding

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Alvarez Rodriguez / Stergiadis

Theatre Session 66

Digestibility of soybean meal vs toasted soybeans in newly weaned piglets <i>C. De Cuyper, P. Dubois and S. Millet</i>	760
Effect of variety and technological treatment on intake of lupin seed in pigs <i>E. Labussiere, H. Furbeyre, M. Guillevic and G. Chesneau</i>	760
Comparative energy values of 10 forages in finishing pigs <i>D. Renaudeau, J. Pirault, M. Dumesny, S. Lombard and F. Marie</i>	761
Implication of different amylose/amylopectin ratio on low protein diet on piglet's performance <i>P. Trevisi, D. Luise, F. Correa, S. Virdis, C. Negrini and S. Dalcanale</i>	761
Effects of two blends of phytoextracts on growth and gut health of weaning pigs to replace zinc oxide <i>D. Luise, F. Correa, C. Negrini, S. Virdis, M. Mazzoni, S. Dalcanale and P. Trevisi</i>	762

Effect of olive cake in growing pig diets on faecal microbiota fermentation and composition <i>D. Belloumi, P. García-Rebollar, P. Francino, S. Calvet, A.I. Jiménez-Belenguer, L. Piquer, O. Piquer and A. Cerisuelo</i>	762
Impact of increasing dietary sphingolipids on feed intake and growth performance of piglets <i>S. Chakroun, R. Larsen, J. Levesque, F. Cerpa Aguila, M.-P. Letourneau, J.E. Rico and D.E. Rico</i>	763
Faeces microbiota and metabolism correlated with reproductive capacity in early parity sow <i>J. Wang, Q. Xie and B. Tan</i>	763
Dehydrated sainfoin in rabbit feed: effects of high incorporation on the health and performances of <i>C. Gayrard, P. Gombault, A. Bretaudeau, H. Hoste and T. Gidenne</i>	764
Nutritional value of defatted larvae meal and whole larvae from black soldier fly <i>P. Belloir, F. Hervo, E. Gambier, L. Lardic, C. Guidou, C. Trespeuch, N. Mème, E. Recoules and B. Méda</i>	764
Poster Session 66	
Diet taste monotony decreases feed acceptability and preferences in nursery pigs <i>J. Figueroa, E. Huenul, R. Palomo and D. Luna</i>	765
Dietary taste variety improves performance in nursery pigs <i>J. Figueroa, T. Cabello, E. Huenul, R. Palomo and D. Luna</i>	765
Impact of some dietary agro-industrial by-products on the gut microbiota of finishing pigs <i>I. Skoufos, A. Nelli, C. Voidarou, I. Lagkouvardos, E. Bonos, K. Fotou, C. Zacharis, I. Giannenas and A. Tzora</i>	766
Effects of Greek aromatic/medicinal plants on health and meat quality characteristics of piglets <i>G. Magklaras, C. Zacharis, K. Fotou, E. Bonos, I. Giannenas, J. Wang, L.Z. Jin, A. Tzora and I. Skoufos</i>	766
Effects of mint leaf powder on performance and egg nutrient composition of laying hens <i>Y.H. Zhang, M.M. Bai, H.N. Liu, X.F. Kong and F.C. Wan</i>	767
Weaned piglets' gut microbiota regulation by dietary olive, winery, and cheese waste by-products <i>A. Tzora, A. Nelli, A. Tsinas, E. Gouva, G. Magklaras, S. Skoufos, B. Venardou, K. Nikolaou, I. Giannenas and I. Skoufos</i>	767
Effects of medium-chain fatty acids on feed intake, body weight and egg composition of laying hens <i>F. Cerpa Aguila, S. Chakroun, M.P. Letourneau Montminy, J.E. Rico and D.E. Rico</i>	768

Session 67. PLF for health and welfare – Part 2

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Pastell / Stygar

Theatre Session 67

Open-sourcing behavioural algorithms for ruminant welfare monitoring using raw wearable sensor data <i>D. Foy, T.R. Smith and J.P. Reynolds</i>	768
Evaluation of an automated cattle lameness detection system <i>N. Siachos, A. Anagnostopoulos, B.E. Griffiths, J.N. Neary, R.F. Smith and G. Oikonomou</i>	769
Breath analysis in dairy cattle: going beyond methane emission <i>I. Fodor, E. Van Erp-Van Der Kooij and I.D.E. Van Dixhoorn</i>	769

Dairy cow personality: correlations with age, weight, back fat thickness and activity <i>P. Hasenpusch, T. Wilder, A. Seidel, J. Krieter and G. Thaller</i>	770
Automatic behaviour assessment of young bulls in pen using machine vision technology <i>A. Cheype, J. Manceau, V. Gauthier, C. Dugué, L.-A. Merle, X. Boivin and C. Mindus</i>	770
Parity and lactation stage preserve a stable structure in the dynamic social networks in cattle <i>H. Marina, I. Hansson, I. Ren, F. Fikse, P.P. Nielsen and L. Rönnegård</i>	771
Application of rumen boluses to receive welfare parameters from fattening bulls <i>K. Fromm, J. Heinicke, T. Amon and G. Hoffmann</i>	771
Stepwise modelling for improved bovine health <i>C.M. Matzhold, K.S. Schodl, C.E. Egger-Danner, F.S. Steininger and P.K. Klimek</i>	772
Is milking order connected to social interactions? <i>I. Hansson, H. Marina and L. Rönnegård</i>	772
Combining ultra-wideband (UWB) location and accelerometer data for cattle behaviour monitoring <i>S. Benaissa, F. Tuytens, D. Plets, L. Vandaele, L. Martens, W. Joseph and B. Sonck</i>	773
FEMIR report – the new MIR advising tool <i>L.M. Dale, A. Werner, C. Natterer, E.J.P. Strang, Emissioncow Consortium, Remissiondairy Consortium and J. Bieger</i>	773
Heat stress relief of dairy cows by evaporative cooling under Mediterranean summer conditions <i>S. Pinto, C. Ammon, F. Estellés, A. Villagra, T. Amon and G. Hoffmann</i>	774
Poster Session 67	
Performance of subcutaneous thermochips implanted in dairy cows: preliminary report <i>A.R. Garcia, L.K. Zanetti, T.C. Alves, L.M. Neira, L.F. Pinho, A.N. Barreto, M.J. Moraes, G.G. Ramos, C.E. Grudzinski and G.N. Azevedo</i>	774
Dairy cow behaviour as proxy for heat stress sensitivity in dairy cows <i>I. Fodor, R.S.C. Rikkers, M. Taghavi and I. Adriaens</i>	775
Exploring the feeding behaviour of dairy calves: insights from automated milk feeders <i>K.J. Hemmert, M.H. Ghaffari, T. Förster, C. Koch and H. Sauerwein</i>	775
Characterization of behavioural anomalies of lameness in dairy cows using sensor technology <i>N.L. Mhlongo</i>	776
Test of Bluetooth low energy localization system for dairy cows in a barn <i>J. Maxa, D. Nicklas, J. Robert, S. Steuer and S. Thurner</i>	776
Integrating inline milk infrared spectra and genomics to predict metabolic profiling in dairy cattle <i>D. Giannuzzi, L.F. Macedo Mota, H. Toledo Alvarado, S. Pegolo, L. Gallo, S. Schiavon, E. Trevisi and A. Cecchinato</i>	777
Influence on the water intake of lactating dairy cows <i>J. Heinicke, C. Ammon, T. Amon, G. Hoffmann and S. Pinto</i>	777

Session 68. Small Ruminant Technologies (Sm@RT) and Thematic network EuroSheep

Date: Wednesday 30 August 2023; 15.00 – 18.30

Chair: Morgan-Davies / Grisot

Theatre Session 68

- Sm@RT: Identifying sheep and goats farmers' technological needs and potential solutions 778
C. Morgan-Davies, L. Depuille, J.M. Gautier, A. McLaren, T.W.J. Keady, B. McClearn, L. Grova, P. Piirsalu, V. Giovanetti, I. Halachmi, A. Bar-Shamai, R. Klein, F. Kenyon and I. Llach-Martinez
- EuroSheep: increasing flock profitability through improved sheep health and nutrition management 778
P.G. Grisot, B. Fança, A. Carta, S. Salaris, C. Morgan-Davies, I. Beltran De Heredia, R. Ruiz, S. Ocak Yetisign, T.W.J. Keady, B. McClearn, R. Klein, D. Tsiokos and C. Ligda
- Sm@RT: Innovative technologies training for small ruminant producers 779
L. Depuille, J.M. Gautier, A. McLaren, T.W.J. Keady, B. McClearn, L. Grøva, P. Piirsalu, V. Giovanetti, I. Halachmi, A. Bar-Shamai, R. Klein, F. Kenyon, I. Llach and C. Morgan-Davies
- EuroSheep: end-users assessments of flock health and nutrition best practices 779
P.G. Grisot, B. Fança, A. Carta, S. Salaris, C. Morgan-Davies, I. Beltran De Heredia, R. Ruiz, S. Ocak yetisign, T.W.G. Keady, B. McClearn, R. Klein, L. Perucho and C. Ligda
- Sm@RT: main lessons from New Zealand on PLF uptake in small ruminants 780
J.M. Gautier, C. Morgan-Davies, L. Depuille, A. McLaren, B. McClearn, L. Grøva, P. Piirsalu, V. Giovanetti, I. Halachmi, A. Bar-Shamai, R. Klein, F. Kenyon, E. Gonzalez-Garcia and T.W.J. Keady
- French regional project SO-PERFECTS: project methodology 780
C. Douine, L. Sagot, A.S. Thudor, M. Miquel, M. Bernard, M. Goyenette and D. Gautier
- French regional project SO-PERFECTS: trial results 781
M. Bernard, L. Sagot, A.S. Thudor, C. Douine, M. Miquel, M. Goyenette and D. Gautier
- Use of innovative and precision tools in research stations with small ruminants: the INRAE case 781
I. Llach, H. Caillat, A. Fatet, S. Breton, T. Aguirre-Lavin, D. Dubreuil, A. Eymard, J. Boucherot, T. Fassier, D. Marcon, S. Parisot, C. Durand, G. Bonnafe, D. Portes, C. Morgan-Davies and E. González-García
- FEC check: development of an online tool to aid farmer understanding of roundworm faecal egg counts 782
E. Geddes, A. Duncan, K. Lamont, J. Duncan, F. Kenyon and L. Melville
- Assessing sheep behaviour in an human-animal interaction test using infrared termography 782
M. Almeida, A. Afonso, C. Guedes and S. Silva

Session 69. Methods & genomic prediction

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Sell-Kubiak / El-Ouazizi

Theatre Session 69

- Detection of interchromosomal rearrangements in bulls using large genotype and phenotype datasets 783
J. Jourdain, H. Barasc, T. Faraut, C. Grohs, C. Donnadieu, A. Pinton, D. Boichard and A. Capitan
- Functional information embedded in the unmapped short reads of whole-genome sequencing 783
G.B. Neumann, P. Korkuć, M. Reißmann, M.J. Wolf, K. May, S. König and G.A. Brockmann

Expanding the capabilities of single-step GWAS with <i>P</i> -values for large genotyped populations <i>N. Galoro Leite, M. Bermann, S. Tsuruta, I. Misztal and D. Lourenco</i>	784
The Life-Functions Ratio: a new indicator trait of trade-offs to go beyond genetic correlations <i>N. Bedere, O. Cado, N.C. Friggens and P. Le Roy</i>	784
Impact of pedigree errors on the quality of predicted genetic merit from animal models <i>E.C.G. Pimentel, C. Edel, R. Emmerling and K.-U. Götz</i>	785
Bias in estimated variance components and breeding values due to pre-correction of systematic effect <i>P. Duenk and P. Bijma</i>	785
Improving computing performance of genomic evaluations by genotype and phenotype truncation <i>F. Bussiman, C. Cheng, J. Holl, A. Legarra, I. Misztal and D. Lourenco</i>	786
A single-step evaluation of functional longevity of cows including data from correlated traits <i>L.H. Maugan, T. Tribout, R. Rostellato, S. Mattalia and V. Ducrocq</i>	786
Expected values of genomic prediction validation parameters for non-random validation sets <i>M.P.L. Calus, M. Schrauf, T. Pook, L. Ayres, R. Bonifazi, J. Ten Napel and J. Vandenplas</i>	787
Unknown parent groups and metafounders in genomic evaluation of Norwegian Red cattle <i>T.K. Belay, A.B. Gjuvsland, J. Jenko, L.S. Eikje and T. Meuwissen</i>	787
Exploring non linear genetic relationships between correlated traits <i>F. Shokor, P. Croiseau, R. Saintilan, T. Mary-Huard, H. Gangloff and B.C.D. Cuyabano</i>	788
Single-Step Genomic Prediction in six German Beef Cattle Breeds <i>D. Adekale, H. Alkhoder, Z. Liu, D. Segelke and J. Tetens</i>	788

Poster Session 69

Incorporating QTL genotypes in the model to predict phenotypes and breeding values <i>J. Yang, T.H.E. Meuwissen, Y.C.J. Wientjes, P. Duenk and M.P.L. Calus</i>	789
Improving the efficiency of genomic evaluations with random regression models <i>A. Alvarez Munera, D. Lourenco, I. Misztal, I. Aguilar, J. Bauer, J. Šplíchal and M. Bermann</i>	789
Comparison of two software to estimate breeding value in cattle by single-step approach <i>M. Jakimowicz, D. Słomian, T. Suchocki and J. Szyda</i>	790
Estimating (co)variance components using Monte Carlo EM-REML in a multi-trait SNPBLUP model <i>H. Gao, M.H. Lidauer, M. Taskinen, E.A. Mäntysaari and I. Strandén</i>	790
Molecular phenotyping to predict neonatal maturity <i>L. Liaubet, N. Marty-Gasset, L. Gress, A. Bonnet, P. Brenaut and E. Maigné</i>	791
Comparison of genetic maps from different cattle breeds <i>X. Ding, H. Schwarzenbacher, F.R. Seefried and D. Wittenburg</i>	791
Genomic relationships across metafounders using partial EM algorithm and average relationships <i>A. Legarra, M. Bermann, Q. Mei and O.F. Christensen</i>	792
Impact of the correlation between SNP effects in different breeds on the accuracy of predictions <i>P. Croiseau, R. Saintilan, D. Boichard and B. Cuyabano</i>	792
Early prediction of lactation persistency of multiparous cows managed for extended lactation <i>C. Gaillard, M. Boutinaud, J. Sehested and J. Guinard-Flament</i>	793

Accuracy of genomic prediction by singular value decomposition of the genotype matrix <i>L. Ayres, M.P.L. Calus, J. Ødegård and T. Meuwissen</i>	793
Enhancing long-term genetic gain through a Mendelian sampling-based similarity matrix <i>A.A. Musa and N. Reinsch</i>	794
Mining the convergence behaviour of a single-step SNP-BLUP model for genomic evaluation of stature <i>D.S. Dawid Słomian, J.S. Joanna Szyda and K.Ž. Kacper Żukowski</i>	794
Increase in prediction accuracy can be achieved by combining multiple populations <i>A. Ajasa, S. Boison, H. Gjølén and M. Lillehammer</i>	795
Enhancing bovine genome SNP call accuracy with autoencoder analysis of nucleotide impact with AI <i>K. Kotlarz, M. Mielczarek, B. Guldbrandtsen and J. Szyda</i>	795
Efficient SNP calling: Nextflow vs Bash on the whole genome bovine sequence <i>P. Hajduk, M. Sztuka, K. Liu, K. Kotlarz, M. Mielczarek and J. Szyda</i>	796
Variant calling and genotyping accuracy of ddRAD-seq: comparison with WGS in layers <i>M. Doublet, F. Lecerf, F. Degalez, S. Lagarrigue, L. Lagoutte and S. Allais</i>	796
Performing single-step genomic evaluation for superovulatory response traits in Japanese Black cows <i>A. Zoda, R. Kagawa, H. Tsukahara, R. Obinata, M. Urakawa, Y. Oono and S. Ogawa</i>	797
Production traits in Nellore cattle classified by residual feed intake <i>J.A. Muñoz, R.H. Branco, R.C. Canesin, J.N.S.G. Cyrillo, M.E.Z. Mercadante and S.F.M. Bonilha</i>	797
Effect of paternal breeding values for residual feed intake on reproductive performance of heifers <i>T. Devincenzi, M. Lema, L. Del Pino, A. Ruggia and E.A. Navajas</i>	798
Species identification of animal/pig DNA in non-animal food <i>M. Natonek-Wiśniewska and P. Krzyścin</i>	798
Development of a proxy for feed efficiency prediction in dairy cows based on mid-infrared spectra <i>M. Raemy, T. Haak, F. Schori and S. Ampuero Kragten</i>	799
Improving taste and flavour in dairy product through analysis of free fatty acid by MIR spectroscopy <i>O. Christophe, R. Reding, J. Leblois, D. Pittois, C. Guignard and F. Dehareng</i>	799
Modelling growth curves in challenged mice lines divergently selected for birth weight variability <i>V. Mora-Cuadrado, I. Cervantes, J.P. Gutiérrez and N. Formoso-Rafferty</i>	800
Genomic prediction of commercial layers' bone strength <i>M. Sallam, H. Wall, P. Wilson, B. Andersson, M. Schmutz, C. Benavides, M. Checa, E. Sanchez, A. Rodriguez, I. Dunn, A. Kindmark, D.J. De Koning and M. Johnsson</i>	800
Variability of daily milk yield during the first 100 days of lactation in Holstein cows <i>E. Kašná, L. Zavadilová and J. Vařeka</i>	801

Session 70. Genetic parameters & GWAS

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Egger-Danner / Martin

Theatre Session 70

Single-step GBLUP for growth and carcass traits in Nordic beef cattle <i>A. Nazari Ghadikolaei, F. Fikse and S. Eriksson</i>	801

Genetic parameters of pig birth weight variability <i>Y. Salimiyekta, S.B. Bendtsen, K.V. Riddersholm, M. Askov and J. Jensen</i>	802
Disentangling paternal and maternal components of within litter birth weight variability in mice <i>N. Formoso-Rafferty, L. El-Ouazizi El-Kahia, I. Cervantes and J.P. Gutiérrez</i>	802
(Co)variances between anogenital distance and fertility in Holstein-Friesian dairy cattle <i>M.A. Stephen, C.R. Burke, N. Steele, J.E. Pryce, S. Meier, P.R. Amer, C.V.C. Phyn and D.J. Garrick</i>	803
Genetic relationships between productive and reproductive traits on Friesian cows <i>S. Abomselem, A. Badr and A. Khattab</i>	803
Heritabilities of the mid-infrared spectra of sheep milk throughout the lactation <i>C. Machefert, C. Robert-Granié, J.M. Astruc and H. Larroque</i>	804
Genetic parameters for the composition of milk fatty acid of Holsteins <i>Y. Masuda</i>	804
External and genetic factors influencing fertility in Latxa dairy sheep breed <i>C. Pineda-Quiroga, I. Granado-Tajada, E. Ugarte and A. Basterra-García</i>	805
Single-step genome-wide association for milk urea concentration in Walloon Holstein <i>H. Atashi, Y. Chen, C. Bastin, S. Vanderick, X. Hubin and N. Gengler</i>	805
Genome-wide association study for milk production traits in the Cyprus Chios sheep <i>A.N. Georgiou, G. Maimaris, S. Andreou, A.C. Dimitriou and G. Hadjipavlou</i>	806
Characterization of additive, dominance, and runs of homozygosity effects inbreeds of dairy cattle <i>H. Ben Zaabza, M. Neupane, M. Jaafar, K. Srikanth, S. McKay, A. Miles, H.J. Huson, I. Strandén, H. Blackburn and C.P. Van Tassell</i>	806
A genome-wide association study identified a major QTL affecting the red colour in nitrate free hams <i>J. Vegni, M. Zappaterra, R. Davoli, R. Virgili, N. Simoncini, C. Schivazappa, A. Cilloni and P. Zambonelli</i>	807
Poster Session 70	
Genetic relationships between milk fatty acids at early lactation and fertility in Holstein cows <i>T. Yamazaki, A. Nishiura, S. Nakagawa, H. Abe, Y. Nakahori and Y. Masuda</i>	807
Genetic parameters for early-life racing performance in pigeons <i>P. Duenk and D. Shewmaker</i>	808
Genetic parameters for milk urea in Swiss dairy cattle breeds <i>A. Burren and S. Probst</i>	808
Estimation of genetic correlations between predicted energy balance and fertility in Holsteins <i>A. Nishiura, O. Sasaki, S. Yamaguchi, Y. Saito, R. Tatebayashi and T. Yamazaki</i>	809
Comparison of random regression test-day models for production traits of South African Jersey cattle <i>M.G. Kinghorn, E.D. Cason, V. Ducrocq and F.W.C. Naser</i>	809
Application of single-step genomic method in routine evaluation of Czech Holstein cattle <i>J. Bauer, J. Šplíchal, D. Fulínová and E. Krupa</i>	810
A meta-analysis of the genetic parameter estimates for lamb survival <i>S. Fernandes Lazaro, H. Rojas De Oliveira and F. S. Schenkel</i>	810

Survival analysis in the conservation program of an endangered wild ungulate (<i>Nanger dama mhorri</i>) <i>S. Domínguez, I. Cervantes, E. Moreno and J.P. Gutiérrez</i>	811
Genetic parameters of maturing rate index and asymptotic adult weight in French beef cattle <i>A. Lepers, S. Aguerre, J. Promp, S. Taussat, A. Vinet, P. Martin, A. Philibert, A. Laramée and L. Griffon</i>	811
Genetic architecture of the persistency of production, quality, and efficiency traits in laying hens <i>Q. Berger, N. Bedere, P. Le-Roy, T. Burlot, S. Lagarrigue and T. Zerjal</i>	812
On the potential of improving daily milk yield by extending productive lifespan <i>A. Bieber, F. Hediger, F. Leiber, C. Pfeifer and M. Walkenhorst</i>	812
Genetic trends in a selection process using electronic feeders to improve feed efficiency in rabbit <i>J.P. Sánchez, M. Pascual and M. Piles</i>	813
Maturity, a heritable trait in French dairy goat <i>M. Arnal, M. Chassier, V. Clément and I. Palihière</i>	813
Multivariate genome-wide associations for immune traits in two maternal pig lines <i>C. Große-Brinkhaus, K. Roth, M.J. Pröhl-Cornelissen, A.K. Appel, H. Henne, K. Schellander and E. Tholen</i>	814
Estimation of heritability for digital dermatitis in Polish Holstein-Friesian cows <i>M. Graczyk-Bogdanowicz, K. Baczkiewicz and K. Rzewuska</i>	814
Genetic parameters for β -hydroxybutyrate concentration in milk in Spanish dairy cows <i>I. Cervantes, M.A. Pérez-Cabal, N. Charfeddine and J.P. Gutiérrez</i>	815

Session 71. Building on a resilient dairy sector – from animal, farm and regional perspective – Part 2

Date: Thursday 31 August 2023; 8.30 – 12.00
Chair: Brocard / Klopčič

Theatre Session 71

Comparison of self-assessment and objective indicators of attributes driving farms resilience <i>D. Martín-Collado, B. Soriano, J. Lizarralde, J.M. Mancilla-Leyton, N. Mandaluniz, P. Gaspar-García, Y. Mena-Guerrero and A. Prat-Benhamou</i>	815
Inventory and analysis of needs towards resilient dairy farming in 15 EU countries <i>A.M. Menghi and C.S.S. Soffiantini</i>	816
Assessment of solutions for resilient dairy farming in fifteen European countries <i>A. Kuipers, J. Zijlstra, R. Loges and S. Østergaard</i>	816
Knowledge needs and solutions related to resilience in the European dairy sector <i>K. Kuoppala, M. Rinne, N. Browne and V. Brocard</i>	817
Resilience of contribution to food security of specialized Walloon dairy systems <i>C. Battheu-Noirfalise, E. Froidmont, D. Stilmant and Y. Beckers</i>	817
Innovative solutions supporting resilience of dairy farms in Netherlands <i>P.J. Galama, J. Zijlstra and A. Kuipers</i>	818
Needs of the dairy sector: a Hungarian overview <i>L. Czeglédi, B. Béri, I. Komlósi and E. Török</i>	818

Eco-efficient low-cost pasture based dairy production on a mixed farm in Northern Germany <i>R. Loges and F. Taube</i>	819
Factors contributing to the financial resilience of spring-calving pasture-based dairy farms <i>G. Ramsbottom, B. Horan, K.M. Pierce, D.P. Berry and J.R. Roche</i>	819
Planning for resilient dairy farms in the USA <i>A. De Vries</i>	820
Towards a socially sustainable dairy sector with cow-calf contact systems <i>H.W. Neave, M. Bertelsen, E.H. Jensen and M.B. Jensen</i>	820
Resilient, healthy or efficient? The ideal animal according to breeders of small ruminants in Europe <i>E. Janodet and M. Sautier</i>	821

Poster Session 71

Strategies and cases of resilience from dairy farming community in Slovenia <i>M. Klopčič</i>	821
How farm management influences the longevity of dairy cows: a comparative study of Swiss dairy farms <i>R.C. Eppenstein, A. Bieber, M. Lozano-Jaramillo and M. Walkenhorst</i>	822
High herd exit rates existence of small herds: a case study from North West Province, South Africa <i>M.D. Motiang and E.C. Webb</i>	822
Building on a resilient dairy sector- highlights and discussion <i>A. Kuipers, V. Brocard and M. Klopčič</i>	823
Economic and environmental impacts of cattle longevity extension by altered reproductive management <i>R. Han, A. Kok, M. Mourits and H. Hogeveen</i>	823

Session 72. What are the stakeholder and societal expectations of intrinsic and extrinsic quality of animal products?

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Martin

Theatre Session 72

Economic sustainability of different levels of extensiveness in fattening pig farms <i>P. Ferrari, C. Montanari and L. Giglio</i>	824
How to characterise the European livestock production systems? <i>E. Bailly-Caumette, S. Moakes, C. Pfeifer and D.R. Yáñez-Ruiz</i>	824
The IntaQt project's stakeholders' involvement: impact on the research work? <i>F. Bedoin, C. Couzy, C. Laithier, C. Berri and B. Martin</i>	825
EU policy impacts on the sustainability of the livestock sector, insights from the PATHWAYS project <i>N. Roehrig, A. Sans, K.-E. Trier-Kreutzfeldt, M.A. Arias Escobar, F.W. Oudshoorn, N. Bolduc, E. Regnier, P.-M. Aubert and L.G. Smith</i>	825
Stakeholders' perception of pig and chicken local breeds – a broad survey by the GEroNIMO project <i>M.J. Mercat, A.J. Amaral, R. Bozzi, M. Čandek-Potokar, P. Fernandes, J. Gutierrez Vallejos, D. Karolyi, D. Laloë, Z. Luković, H. Lenoir, G. Restoux, A. Vicente, V. Ribeiro, T. Rodríguez Silva, R. Rouger, D. Škorput and M. Škrlep</i>	826

Responding to stakeholder needs and consumer-driven demands in the dairy goat and poultry sectors <i>C. Bonardi and M. Gerevini</i>	826
The INTAQT project: stakeholders' opinions on future multicriteria scoring tools for animal products <i>I. Legrand, A. Nicolazo De Barmon, F. Albert, M. Berton, M. Bourin, V. Bühl, A. Cartoni Mancinelli, R. Eppenstein, D.A. Kenny, E. Kowalski, S. McLaughlin, G. Plesch, F. Bedoin, C. Couzy, C. Berri, B. Martin and C. Laithier</i>	827
Co-designing Agroecology farming concepts to increase food sovereignty in the Global South <i>M. Simataa, R. Valkenburg and H. Romijn</i>	827
Mapping of value chains in the Italian bovine sector <i>M. Finocchi, M. Moretti, A. Mantino, A. Ripamonti, G. Conte and M. Mele</i>	828
The INTAQT project: stakeholders' expectations on husbandry systems and innovative practices <i>R.C. Eppenstein, V. Bühl, I. Legrand, A. Nicolazo De Barmon, B. Martin, F. Albert, M. Berton, M. Bourin, A. Cartoni Mancinelli, D.A. Kenny, E. Kowalski, S. McLaughlin, G. Plesch, F. Bedoin, C. Couzy, C. Berri and C. Laithier</i>	828
The INTAQT project: stakeholders' perceptions and points of view on products quality <i>C. Laithier, F. Bédoin, F. Albert, I. Legrand, A. Nicolazo De Barmon, M. Bourin, M. Berton, V. Bühl, R. Eppenstein, A. Cartoni Mancinelli, D.A. Kenny, E. Kowalski, S. McLaughlin, G. Plesch, C. Couzy, C. Berri and B. Martin</i>	829
Life cycle assessment of different pig production systems around Europe: mEATquality project <i>C. Reyes-Palomo, A. Pignagnoli, S. Sanz-Fernández, P. Meatquality Consortium and V. Rodríguez-Estévez</i>	829

Poster Session 72

Consumer expectations for beef in the French region Auvergne-Rhône-Alpes <i>S. Chriki, J. Normand, C. Brosse, L. Hallez, L. Vallet, V. Payet and J.F. Hocquette</i>	830
Analysis of preferences and perception of cheese products by Portuguese consumers <i>V.M. Merlino, M. Renna, M. Tarantola, A. Ricci, A.S. Santos, A. Monteiro and J. Nery</i>	830
How a risk-based strategy could contribute to a more sustainable agri-food system? <i>B. Grossiord and M.P. Elies-Oury</i>	831
Perceptions of meat quality of UK stakeholders: from intrinsic to extrinsic factors <i>S. McLaughlin, F. Bedoin, C. Couzy, I. Legrand, A. Nicolazo De Barmon, C. Laithier and N. Scollan</i>	831
Transforming livestock practices by federating around common values <i>S. Nade</i>	832

Session 73. Molecules in animal nutrition: over and above building blocks

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Van Milgen / Geraert / Mercier

Theatre Session 73

Genetic response of red yeast supplementation in feed to mycotoxin contamination in laying hens <i>S. Hosseini, B. Brenig, W. Tapingkae and K. Gatphayak</i>	832
Faecal starch content as an indicator of starch digestibility by fattening Japanese Black cattle <i>M. Matamura, S. Uzawa and M. Kondo</i>	833

Impact of isoacids on performance and digestibility in gilts fed different dietary fibre sources <i>W. Schweer, B. Kerr, M. Socha, A. Cornelison and L. Rodrigues</i>	833
The enterotype is associated with the phenotype variation in the pigs treated with dietary fibre <i>H. Li and B.E. Tan</i>	834
A high rumen degradable starch modulates jejunum microbiota and bile acids in dairy goats <i>L.M. Wang, J.H. Yao and Y.C. Cao</i>	834
Development of a novel endolysin, Rallys8, for the specific inhibition of <i>Ruminococcus albus</i> <i>J. Moon, H. Kim and J. Seo</i>	835
Dietary microalgae (<i>Nannochloropsis limnetica</i>) and probiotic on performance and intestine of piglets <i>M.F. Pedro, D.F.P. Carvalho, A.M. Almeida, R.J.B. Bessa, A.J.M. Fonseca, A.R.J. Cabrita and J.P.B. Freire</i>	835
Muramidase inclusion reduces gut inflammation in weaned piglets, especially in high protein diets <i>U.M. McCormack, J. Schmeisser, E. Bacou, P. Jenn, F. Amstutz and E. Perez Calvo</i>	836
Utilization of tryptophane by kynurenine, indoles and serotonin pathways are modified by fructose <i>A. Gual-Crau, M. Jarzaguet, D. Dardevet, D. Rémond, A. Lefèvre, A. Bernalier-Donadille, P. Emond and I. Savary-Auzeloux</i>	836
Regulation of glucose metabolism in rumen epithelium of cows transitioned from forage to high-grain <i>S. Kreuzer-Redmer, A. Sener, C. Pacífico, F. Dengler, S. Ricci, H. Schwartz-Zimmermann, E. Castillo-Lopez, N. Reisinger and Q. Zebeli</i>	837
Altering nutrients supply modified dynamics of milk components synthesis in dairy cows <i>J.C. Anger, C. Loncke, R. Bidaux and S. Lemosquet</i>	837
Phytogenic effects on layer performance, egg quality and cytoprotective response in the ovaries <i>I.P. Brouklogiannis, E.C. Anagnostopoulos, V.V. Paraskeuas, E. Griela, G. Kefalas and K.C. Mountzouris</i>	838
Poster Session 73	
Phytogenic effects on layer performance, and cytoprotective response in the ceca <i>E.C. Anagnostopoulos, I.P. Brouklogiannis, V.V. Paraskeuas, E. Griela, G. Kefalas and K.C. Mountzouris</i>	838
Effects of guanidinoacetic acid supplementation on growth performance in Nellore cattle <i>O.R.M. Neto, I.M.S.C. Farias, R.N.S. Torres, R.V. Ribeiro, W.A. Baldassini, R.A. Curi, L.A.L. Chardulo and G.L. Pereira</i>	839
In feed histidine supplementation improves muscle carnosine content and meat quality in pigs <i>M. Paniagua, B. Saremi, B. Matton and S. De Smet</i>	839
Impact of functional amino acids on performance parameters in post-weaning piglet <i>A. Simongiovanni, K. Fenske, F. Witte, H. Westendarp and T. Chalvon-Demersay</i>	840
Phytobiotics from <i>Thymus</i> species in poultry feed – thymol, carvacrol and rosmarinic acid <i>M. Taghouti</i>	840
Dietary microalgae (<i>Chlorella vulgaris</i>) and probiotic on performance and intestine of piglets <i>M.F. Pedro, D.F.P. Carvalho, A.M. Almeida, R.J.B. Bessa, A.J.M. Fonseca, A.R.J. Cabrita and J.P.B. Freire</i>	841

Session 74. Balancing the feed for the economy, the environment, and society

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: De Campeneere / Bruggeman

Theatre Session 74

- Effects of linseed oil, a brown seaweed and seaweed extract on methane emissions in beef cattle 841
E. Roskam, D.A. Kenny, V. O'Flaherty, M. Hayes, A.K. Kelly and S.M. Waters
- Effect of whey on methane emission and systemic comparison of *in vivo* and *in vitro* methane formation 842
H. Luisier-Sutter, M. Terranova, S.L. Amelchanka, K. Schweingruber, S. Hug, K. Müller, L. Isele, K. Sommer and M. Schick
- Effects of feeding fresh white clover on digestibility and methane emission in lambs 842
X. Chen, S. Ormston, S. Stergiadis, K. Theodoridou, O. Cristobal-Carballo and T. Yan
- Algae for reducing methane from dairy cows: what expectation with French local resources? 843
B. Rouillé, H. Marfaing, F. Dufreneix, S. Point, M. Gillier, R. Boré, J. Jurquet and N. Edouard
- Managing the rumen microbiome to reduce methane emissions through dietary interventions 843
G. Pugh, O. Cristobal Carballo, T. Yan, C. Creevey and S. Huws
- Production and enteric methane emissions in grazing dairy cows fed flaxseed-based supplement 844
M.A. Rahman, K.V. Almeida, D.C. Reyes, A.L. Konopoka, M.A. Arshad and A.F. Brito
- Effect of feeding brown seaweed and its extract on methane emissions and performance in dairy cattle 844
K.D. Barnes, S. Huws, T. Yan, X. Chen, M. Hayes and K. Theodoridou
- Establishing conclusive links between the gastrointestinal microbiota and feed efficiency in cattle 845
M.M. Dycus, U. Lamichhane, C.B. Welch, K.P. Feldmann, T.D. Pringle, T.R. Callaway and J.M. Lourenco
- Variations in bulk milk urea content on dairy farms in Flanders, Belgium in 2019-2021 845
J. Vandicke, K. Goossens, Z. Lipkens, T. Vanblaere and L. Vandaele
- Impact on environment and performance of the replacement of soybean meal in post-weaning pig diets 846
E. Royer, P. Pluk, J. De Laat, G. Binnendijk, K. Goris and P. Bikker
- Simulating pig multiperformance in contrasted breeding systems using an individual-based model 846
E. Janodet, F. Garcia-Launay and H. Gilbert
- Environmental impacts of substituting soybean with rapeseed or haemoglobin meal in broiler diets 847
V. Wilke, J. Gickel, A. Abd El-Wahab and C. Visscher

Poster Session 74

- Manipulating dietary degradable protein and starch to increase nitrogen efficiency in dairy cows 847
P. Piantoni, Y. Roman-Garcia, C. Canale, M. Messman and G. Schroeder
- Substitution of soybean meal with canola meal in dairy cow diets: effect on enteric methane emission 848
C. Benchaar and F. Hassanat

Session 75. Livestock based circularity for health and sustainable land use

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Siqueira / De Olde

Theatre Session 75

invited	Does better circularity in livestock require a paradigm shift? <i>A. Mottet and M. Benoit</i>	848
	More or better to obtain sustainable food production? <i>H.F. Olsen, H. Møller, S. Samsonstuen, M.T. Knudsen, L. Mogensen and E. Rös</i>	849
	Satisfying meat demand and avoiding excess manure nitrogen at the regional scale in China <i>F. Accatino, Y. Li and Z. Sun</i>	849
	Role of livestock in the nutrient and carbon metabolism of the agri-food system of a tropical island <i>M. Alvanitakis, V. Kleinpeter, M. Vigne, A. Benoist and J. Vayssières</i>	850
	State and regional nitrogen and phosphorus balances to assess manure sheds in New York State <i>O.F. Godber, K. Workman and Q.M. Ketterings</i>	850
invited	Circularity in livestock production: from theory to practice <i>E.M. De Olde, O. Van Hal, A. Groenewoud and I.J.M. De Boer</i>	851
	The perspective of young farmers on circular agriculture: definition, implementation and barriers <i>A.G. Hoogstra, H. Geerse, I.J.M. De Boer, M.K. Van Ittersum, A.G.T. Schut, C.J.A.M. Termeer and E.M. De Olde</i>	851
	Companion modelling approach for collective nitrogen management in a French municipality <i>G. Martel, F. Garcia-Launay and V. Souchère</i>	852
	Historical transformation of crop-livestock integration and its drivers in a French region <i>R. Pedeches, C. Aubron, S. Bainville and O. Philippon</i>	852
	Livestock: option or necessity? Changes of energy flows in an Indian village, 1950-2022 <i>C. Hemingway, C. Aubron and M. Vigne</i>	853

Poster Session 75

	Developing livestock-based circularities for healthy and sustainable territories: the CLiMiT project <i>T.T.S. Siqueira, J.-M. Sadaillan, M. Vigne, J. Veyssières, A. Benoist and M. Miralles-Bruneau</i>	853
	Co-design of a scenario of biomass valorisation within a circular approach on Reunion Island <i>R. Youssouf, E. Cavillot, A.-L. Payet, T.T. Da Silva Siqueira and J.-P. Choisis</i>	854
	Barriers for farmers to 'sustainabilize' their farm: the example of nematode control management <i>M. Sautier, A. Somera, R. Rostellato, P. Ly, Y. Labrunne, J.M. Astruc and P. Jacquet</i>	854
	Benefits and limits of an organic agroforestry system associating rabbits and apple trees <i>D. Saviotto, V. Fillon, S. Simon, E. Lhoste, M. Grillot, A. Dufils, L. Lamothe, F. Derbez, M. Fétiveau and S. Drusch</i>	855
	INOSYS livestock farming systems network: benchmarks for advisors, trainers and policy makers <i>P. Sarzeaud, J. Seegers, O. Dupire and T. Charroin</i>	855
	APIVALE scientific consortium: integrated approach for organic effluent recycling and valorisation <i>F. De Quelen, E. Jarde, C. Le Marechal, T. Lendormi, S. Menasseri and F. Beline</i>	856

Progress made in whole-farm nitrogen and phosphorus mass balances on New York dairy farms <i>O.F. Godber, K. Workman and Q.M. Ketterings</i>	856
Measuring greenhouse gas emission from pretreatment and liquid composting storage in biogas facility <i>G.W. Park, M. Ataallah, N. Eska and K.H. Park</i>	857
Effect of yoghurt acid whey on quality characteristics of corn silage <i>I. Palamidi, V.V. Paraskeuas, I.P. Brouklogiannis, E.C. Anagnostopoulos, I. Politis, I. Hadjigeorgiou and K.C. Mountzouris</i>	857

Session 76. Humans and horses: from One Health to One Life perspectives

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Evans / Montovani

Theatre Session 76

How do horses perceive human emotions? <i>P. Jardat, C. Parias, F. Reigner, L. Calandreau and L. Lansade</i>	858
Sensorimotor empathy in horse-human interactions: a new way to understand inter-species performance <i>M. Leblanc, B. Huet and J. Saury</i>	858
Rethinking horse work <i>R. Evans</i>	859
Humans and equines: shared working conditions <i>V. Deneux - Le Barh and C. Lourd</i>	859
invited Working horses: humanities and social sciences approach <i>V. Deneux - Le Barh</i>	860
Web based dissemination of research to support human knowledge and understanding for horse welfare <i>A.-L. Holgersson, K. Lagerlund and G. Gröndahl</i>	860
Comparison of ethological & physiological indicators in headshakers & control horses in riding tests <i>L.M. Stange, T. Wilder, D. Siebler, J. Krieter and I. Czycholl</i>	861
Relationship between hay botanical diversity and faecal bacterial diversity in horses <i>C. Omphalius, P. Grimm, V. Milojevic and S. Julliand</i>	861
invited Thoroughbreds in equine assisted services programmes: selection, living and working conditions <i>C. Neveux, S. Mullan, J. Hockenhull, J. Barker, K. Allen and M. Valenchon</i>	862
The role of gender in the worldwide Pura Raza Español equestrian sector <i>M. Ripolles, A. Encina, M. Valera and M.J. Sánchez-Guerrero</i>	862
Anthelmintic activity of chicory (<i>Cichorium intybus</i>) in grazing horses <i>J. Malsa, G. Sallé, L. Wimel, J. Auclair-Ronzaud, B. Dumont, L. Boudesocque-Delaye, F. Reigner, F. Guégnard, A. Chereau, D. Serreau and G. Fleurance</i>	863

Poster Session 76

Does pain condition influence the human-horse relationship? <i>L. Sobrero, M.G. Riva, M. Minero, A. Cafiso, A. Gazzonis and E. Dalla Costa</i>	863

Saliva steroidome and metabolome in mare during anoestrus, oestrus cycle and gestation 864
S. Beauclercq, C. Douet, A. Piano, L. Haddad, F. Reigner, P. Liere, L. Nadal-Desbarats and G. Goudet

Session 77. Trade-offs between health, production and welfare in pigs and poultry: which tools do we have and which research is needed?

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Nilsson / Millet

Theatre Session 77

invited The future of genetic selection in pigs and poultry 864
L. Verschuren and P.W. Knap

invited The future of nutrition research in pigs and poultry 865
S. Vigors and J.V. Milgen

invited Economically sustainable and animal welfare friendly animal production: what is the role of research 865
A. Silveira and H.A.M. Spoolder

Group discussion 866
K. Nilsson and S. Millet

Session 78. Insect nutrition (substrates) & insect health

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Biasato / Lefebvre

Theatre Session 78

invited Farmed insects to create a circular bio-economy in the food and feed industry 866
A. Vilcinskis

Amino acid requirements of mealworm and black soldier fly larvae 867
T. Spranghers, A. Moradei and M. Boudrez

Evaluation of the suitability of hemp production side-streams for the rearing of edible insects 867
A. Kolorizos, G. Baliota, C. Adamaki-Sotiraki, I. Malikentzos, C.I. Rumbos and C.G. Athanassiou

Dietary fat sources impact black soldier fly larvae performance 868
R. Zheng, S. Karanjit and A. Hosseini

Hermetia illucens production parameters and the effect of dietary energy source 868
E.Y. Gleeson and E. Pieterse

Starch digestion in *H. illucens* conversion: exploring the role of amylases from larvae and substrate 869
J.B. Guillaume, S. Mezdoor, F. Marion-Poll, C. Terrol, C. Brouzes and P. Schmidely

Investigating the nutritional requirements of black soldier fly larvae using artificial substrates 869
L. Broeckx, L. Frooninckx, A. Wuyts, S. Berrens, M. Van Peer and S. Van Miert

Km0 diets for black soldier fly larvae: the link between insect rearing and biogas systems 870
S. Bellezza Oddon, I. Biasato, Z. Loiotine, A. Resconi, C. Caimi and L. Gasco

Sugar processing by-products for black soldier fly farming: does the rearing scale matter? 870
I. Biasato, S. Bellezza Oddon, A. Resconi, Z. Loiotine and L. Gasco

Optimization of a hatchery residues fermentation process to feed black soldier fly larvae <i>M. Dallaire-Lamontagne, G.W. Vandenberg, L. Saucier and M.H. Deschamps</i>	871
Fish side residues as a substrate for <i>Hermetia illucens</i> <i>M.G. Zhelezarova</i>	871

Poster Session 78

Black soldier fly larvae production is optimized by the presence of HMTBa <i>K. Luyt, G. Crielaard, M. Briens, J.A. Conde-Aguilera and M. Ceccantini</i>	872
Black soldier fly larvae production is optimized by the presence of a multi-carbohydrase <i>K. Luyt, G. Crielaard, M. Briens, J.A. Conde-Aguilera and M. Ceccantini</i>	872
Effect of water-soluble complementary feed on performance in nursery of black soldier fly <i>L. Schneider, M. Brake, A. Heseke, W. Westermeier and G. Dusel</i>	873
Digestibility in <i>H. illucens</i> larvae: resolving faeces collection and ingesta quantification issues <i>J.B. Guillaume, S. Mezdour, F. Marion-Poll, C. Terrol and P. Schmidely</i>	873
Black soldier fly larvae as tools for the bioconversion of sludge from wastewater treatments <i>C. Ligeiro, I. Lopes, T. Ribeiro, I. Rehan, K. Silvério, M. De Fátima and D. Murta</i>	874
Mediterranean agricultural by-products as insect diet ingredients: the ADVAGROMED perspective <i>C.G. Athanassiou, S. Bellezza Oddon, V. Zambotto, T. Ribeiro, R. Rosa García, A. El Yaacoubi, C. Adamaki-Sotiraki, I. Biasato, A. Resconi, D. Murta, C.I. Rumbos and L. Gasco</i>	874
Multigenerational and nutritional traits of BSF reared on seaweed or selenium enriched substrates <i>M. Ottoboni, L. Ferrari, A. Moradei, F. Defilippo, P. Bonilauri and L. Pinotti</i>	875
Bacterial biomass improves performance and antibacterial activity of black soldier fly larvae <i>N. N. Moghadam, K. Dam Nielsen, A. Simongiovanni and T. Chalvon-Demersay</i>	875
Impact of zinc supply on black soldier fly larvae growth, bioconversion and microbiota <i>L. Froominckx, L. Broeckx, D. Vandeweyer, C. Keil, M. Maeres and S. Van Miert</i>	876

Session 79. Improved insight into the reproductive physiology of livestock

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Kenny

Theatre Session 79

Review: recent outcomes associating time to PSPB increase with pregnancy loss in dairy cows <i>T. Minela, A. Santos and J.R. Pursley</i>	876
Improving cow fertility by immunizing against inhibin and P4 supplementation <i>Z.D. Shi, F. Chen and R.H. Guo</i>	877
Characterization of sex chromosomes-linked lncRNAs in Holstein spermatozoa under stress conditions <i>A. Yousif, G. Thaller and M. Saeed-Zidane</i>	877
Inbreeding affects the freezing ability in sperm samples of Pura Raza Español stallions <i>Z. Peña, M. Valera, A. Molina, N. Laseca and S. Demyda-Peyrás</i>	878
Sperm transcripts and seminal plasma metabolome reveal the regulatory mechanism of bull semen quality <i>W.L. Li and Y. Yu</i>	878

Application of an oligo-based FISH method in fertility assessment of boars by chromosomal analysis <i>W. Poisson, J. Prunier, A. Bastien, A. Carrier, I. Gilbert and C. Robert</i>	879
Artificial insemination success: a new trait for French dairy goats <i>V. Clément, A. Piacère and M. Chassier</i>	879
The male effect as an alternative to eCG in oestrus induction and synchronization treatment in ewes <i>N. Debus, G. Besche, S. Fréret, A. Hardy, M.T. Pellicer-Rubio, A. Tesniere and J.-B. Menassol</i>	880
Circulating anti-Müllerian hormone from 5-month old Merino ewe lambs predicts first birthing rates <i>J. Daly, J. Kelly, K. Kind and W. Van Wettere</i>	880

Poster Session 79

Impact of pinecone oil on reproductive performance, milk composition and serum parameters in sows <i>Q.Q. Zhang, J.H. Song, C.B. Lim, S. Biswas, J.S. Yoo and I.H. Kim</i>	881
Maternal <i>Forsythia suspensa</i> extract alleviated oxidative stress and improved gut health in sows <i>S. Long, Z. Chen and T. He</i>	881
Effects of PGF2 α on luteal tissue morphology, expression of relative genes in Hu sheep <i>Y.Q. Liu, Y. Li, C.H. Duan and Z.P. Song</i>	882
Relationship between some micronutrients in serum and their effect on the seminal quality of bulls <i>A. Benito-Díaz, A.S. Sarmiento-García, M. Montañes-Foz, R. Bodas-Rodríguez and J.J. García-García</i>	882
Genetic correlations on kinetic sperm parameters in a closed population of PRE stallions <i>Z. Peña, A. Molina, C. Medina, M. Valera and S. Demyda-Peyrás</i>	883
Gestation length in Braunvieh cows <i>M. Fanger, A. Burren and H. Jörg</i>	883
Distribution of adipokines in reproductive tract and embryonic annexes in hen <i>O.B. Bernardi, A.E. Estienne, M.R. Reverchon, A.B. Brossaud, C.R. Rame and J.D. Dupont</i>	884
The effects of PROK 1, alone or in combination with IFN gamma on endometrial immune response in pig <i>S.E. Song and J. Kim</i>	884

Session 80. Animal behaviour

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Dantas / Boyle

Theatre Session 80

Creating a culture of openness for the responsible use of video observation in animal sciences <i>M.F. Giersberg and F.L.B. Meijboom</i>	885
Salivary oxytocin and lachrymal caruncle temperature as indicators of anticipation in growing pigs <i>G.A. Franchi, L.R. Moscovice, H. Telkänranta and L.J. Pedersen</i>	885
Pig oxidative stress model: behaviour as a potential indicator of oxidative stress in pigs <i>R.D. Guevara, J.J. Pastor, S. López-Vergé, X. Manteca, G. Tedo and P. Llorch</i>	886
Comparison of aversiveness of 8 different inert gas (mixtures) to CO ₂ for stunning pigs at slaughter <i>I. Wilk, J. Gelhausen, T. Friehs, T. Krebs, D. Mörlein, J. Tetens and J. Knöll</i>	886

Detecting onset of farrowing using CUSUM-charts based on sows' activity <i>T. Wilder, B. Baude and J. Krieter</i>	887
Impact of environmental enrichment on the behaviour and immune cell transcriptome of pregnant sows <i>M.M. Lopes, C. Clouard, J. Chambeaud, M. Brien, N. Villain, C. Gerard, F. Hérault, A. Vincent, I. Louveau, R. Resmond, H. Jammes and E. Merlot</i>	887
The knowns and unknowns about feather pecking in laying hens <i>A. Harlander and N. Van Staaveren</i>	888
Lower redness of the facial skin is a marker of a positive human-hen relationship <i>D. Soulet, A. Jahoui, M.-C. Blache, B. Piégu, G. Lefort, L. Lansade, K. Germain, F. Lévy, S. Love, A. Bertin and C. Arnould</i>	888
Do sheep differentiate emotional cues conveyed in human body odour? <i>I. Larrigaldie, F. Damon, S. Mousqué, B. Patris, L. Lansade, B. Schaal and A. Destrez</i>	889
Evaluation of inter-observer reliability of dichotomous and four-level animal-based indicators <i>B. Torsiello, M. Giammarino, L. Battaglini, M. Battini, S. Mattiello, P. Quatto and M. Renna</i>	889
Social network analysis of dairy cows' group structure at the feeding trough <i>T. Wilder, P. Hasenpusch, A. Seidel, G. Thaller and J. Krieter</i>	890
Roughage and type of dispensers: what consequences on horses' feeding behaviour? <i>M. Roig-Pons and S. Briefer</i>	890
Poster Session 80	
Caudectomy effect on the severity of tail lesions and abscesses' frequency in pig carcasses <i>P. Trevisi, D. Luise, S. Virdis, S. Dalcanale and U. Rolla</i>	891
Characterising cattle daily activity patterns using accelerometer data <i>S. Hu, A. Reverter, R. Arablouei, G. Bishop-Hurley and A. Ingham</i>	891
Effects of olfactory exposure to twelve essential oils on behaviour and health of cows with mastitis <i>R. Nehme, C. Michelet, E. Vanbergue, O. Rampin, S. Bouhallab, A. Aupiais and L. Andennebi-Najar</i>	892
Assessment of stress in dairy cattle industry via analysis of cortisol residue in commercial milk <i>M. Ataallah, G.W. Park, E. Nugrahaeningtyas, M. Dehghani, J.S. Lee and K.H. Park</i>	892
The physiological and behavioural effects of COVID-19 restrictions on lactating dairy cows <i>S.J. Morgan and D. Barrett</i>	893
Effects of the living environment on the behaviour of rabbits <i>M. Fétiqueau, M. Besson, V. Fillon, M. Gunia and L. Fortun-Lamothe</i>	893
Behaviour test and study of sheepdogs' abilities <i>B. Lasserre, B. Ducreux, M. Chassier, L. Joly, T. Le Morzadec, P. Cacheux and C. Gilbert</i>	894
Innovative evaluation method of behavioural reactivity for 'foie gras' ducks <i>C.M. Monestier, A.W. Warin, S.L. Lombard, S.L.M. Laban-Mele and W.M. Massimino</i>	894
Use of scaring devices to avoid roe deer fawns getting injured or killed during mowing <i>J. Mačuhová, T. Wiesel and S. Thurner</i>	895

Session 81. Precision feeding

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Druyan / Bloch

Theatre Session 81

- Precision feeding, recent advances for gestating sows and dairy cows 895
C. Gaillard, C. Ribas and M. Durand
- Individual ingestion time prediction with RGB-D cameras in beef cattle: a machine learning approach 896
P. Guarnido-Lopez, F. Ramirez-Agudelo, S. Tomozyk, A. Kjørvel, A. Carvalho, F. Jezegou-Bernard, P. Gauthier and M. Benaouda
- Using image classification to estimate feed intake in weaned piglets under commercial conditions 896
T. Van De Putte, J. Degroote and J. Michiels
- invited** The value of precision feeding technologies: economic, productivity and environmental aspect 897
J.K. Niemi
- Precision feeding in dairy cows: what do professionals in ruminant nutrition think about it? 897
A. Igier, A. Petillon-Pronk, J. Martin, E. Hertault, N. Gaudillière, J. Jurquet, A. Fischer and Y. Le Cozler
- Characterizing dairy cow's individual reaction to a decrease in production concentrate distribution 898
A. Fischer, R. Lehuraux and J. Jurquet
- Longitudinal patterns for feeding traits in the two parental populations of the mule duck 898
H. Chapuis, C. Ribas, H. Gilbert, M. Lagüe and I. David
- Models predicting methane emissions and methane conversion factor of Finnish Nordic Red dairy cows 899
J.S. Adjassin, A. Guinguina, M. Eugène and A.R. Bayat
- Use of automated head-chamber systems as exclusive concentrate dispensers during bulls fattening 899
N. Lorant, E. Henrotte, Y. Beckers, F. Forton, A. Vanlierde, M. Mathot and A. Mertens

Poster Session 81

- On-farm nutritional supplementation to improve sows and piglets' performances: field report 900
P. Engler, G. Gemo, S. Cissé and J.M. Garcia
- Effects of monosaccharides on *in vitro* NDF and starch digestibility, pH and volatile fatty acids 900
E. Raffrenato, G. Esposito and L. Bailoni
- Benefit of full matrix application for a novel phytase using a phased-dosing or fixed dosing strateg 901
B.C. Hillen, S. Gilani, R.D. Gimenez-Rico, K.M. Venter, P. Plumstead and Y. Dersjant-Li
- Use of fodder beets in French dairy diets: farmers points of views and experimental results 901
V. Brocard, A. Marsault, L. Vivenot, E. Tranvoiz and J. Jurquet
- Effect of wilting grass silage on milk production of dairy cows fed two concentrate protein levels 902
M. Grøseth, L. Karlsson, H. Steinshamn, M. Johansen, A. Kidane and E. Prestlækken
- Zootechnical performance of dairy cattle fed ensiled Italian ryegrass or winter rye 902
L. Vandaele, J.L. De Boever, T. Van Den Nest and K. Goossens
- Performance of NIR spectrometry to predict amino acids content in forages 903
L. Bahloul, V. Larat, P. Riche and B. Sloan

Estimation of feed weight of dairy cows using computer vision <i>M. Taghavi, T. Izquierdo and I. Fodor</i>	903

Session 82. Product quality and efficiency of small ruminant production systems

Date: Thursday 31 August 2023; 8.30 – 12.00

Chair: Hernández-Castellano / Tsiplakou

Theatre Session 82

The performance of cross fostered lambs from birth to weaning on commercial sheep flocks in Ireland <i>F.P. Campion, J. Molloy and M.G. Diskin</i>	904

Latent factors analysis of protein profile, composition, and cheese-making traits of goat milk <i>N. Amalfitano, G. Secchi, M. Pazzola, G.M. Vacca, M.L. Dettori, F. Tagliapietra, S. Schiavon and G. Bittante</i>	904

Pyrenean wools: how improving the organisation of the upstream and downstream sectors in the massif <i>C. Viguié, S. Fichot and G. Brunschwig</i>	905

The Gentile di Puglia merino sheep breeds preliminary wool quality assessment <i>V. Landi, E. Ciani, G. Molina, R. Topputi, F.M. Sarti, A. D'Onghia, G. Mangini, F. Pilla, S. Grande, A. Maggolino and P. De Palo</i>	905

Using indoor and outdoor finishing systems to finish hill lambs to carcass weights between 12-16 kg <i>M. Dolan, T. Boland, N. Claffey and F. Campion</i>	906

Influence of climatic disturbances on the lactation curve in dairy goats <i>A. Harnois Gremmo, N. Gafsi, F. Bidan, O. Martin and L. Puillet</i>	906

Genetic parameters for fleece uniformity in Alpacas <i>J.P. Gutiérrez, A. Cruz, R. Morante, A. Burgos, N. Formoso-Rafferty and I. Cervantes</i>	907

Farmers' competitions: stimulating new management practices by Peruvian alpaca and llama farmers <i>E. Quina, T. Felix, M. Aguilar, G. Gutierrez, J. Candio, J. Gamarra, M. Mamani, A. Mejía and M. Wurzinger</i>	907

YoGArt project: milk quality and oxidative status of ewes fed microalgae blend <i>A. Mavrommatis, P. Kyriakaki, F. Satolias and E. Tsiplakou</i>	908

Goat AI programs based on the male effect using less or no hormones progress with suitable results <i>A. Fatet, L. Johnson, L. Jourdain, F. Bidan and P. Martin</i>	908

Fiber characteristics of cashmere goat in Mongolia <i>S.B. Baldan, M.P. Purevdorj, G.M. Mészáros and J.S. Sölkner</i>	909

Poster Session 82

Anco fit improves feed efficiency, milk production and milk solids in lactating ewes <i>C. Panzuti, R. Breitsma and C. Gerard</i>	909

No effect of meslin flattening on dairy ewes <i>B. Fañça, A. Hardy, M. Rinn and L. Buisson</i>	910

Quality of cheeses made from the milk of native breeds of goats <i>A. Kawęcka, M. Pasternak, J. Sikora and M. Puchała</i>	910

The impact of live-weight and body condition score on reproductive success in ewes <i>P. McCarron, N. McHugh, N. Fetherstone, H. Walsh and F.M. McGovern</i>	911
Genetic parameters of medullation types in alpaca fibre <i>A. Cruz, Y. Murillo, A. Burgos, A. Yucra, M. Quispe, E. Quispe and J.P. Gutiérrez</i>	911
Blood and gastrointestinal nematode profile of sheep-fed diets supplemented with fossil shell flour <i>O.O. Ikusika and C.T. Mpendulo</i>	912
Synchrotron FTIR microspectroscopy investigation on the sperm cryopreservation of Sanan goat <i>S. Ponchunchoovong, F. Suwor, K. Tammanu and S. Siriwong</i>	912
A need for knowledge on the utilisation of forage by goats according to the distribution methods <i>B. Fança and B. Bluet</i>	913
Changes in fattening and slaughter traits of old-type Polish merino between 2010 and 2020 <i>M. Puchała, A. Kawęcka, J. Sikora and M. Pasternak</i>	913
Milk fat nutritional indices – a comparative study between retail goat and cow milk <i>G. Papatzimos, P. Mitlianga, M.A. Karatzia, Z. Basdagianni and E. Kasapidou</i>	914
Mountain caprine milk – the higher the better? <i>M.A. Karatzia, M. Amanatidis, G. Papatzimos, E. Kasapidou, P. Mitliagka and Z. Basdagianni</i>	914
Results of milk performance of Carpathian goats <i>J. Sikora, A. Kawęcka, M. Puchała and M. Pasternak</i>	915
Barley in concentrates for dairy goats – effects of alkaline and mechanical treatments <i>A. Martinsen, D. Galméus, H. Volden, K. Hove, M. Silberberg and M. Eknæs</i>	915

Session 83. Genetic diversity

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Neumann / Schiavo

Theatre Session 83

The effect of population history, mutation and recombination on genomic selection <i>D. Adepoju, T. Klingström, A.M. Johansson, E. Rius-Vilarasa and M. Johnsson</i>	916
The detection of putative recessive lethal haplotypes in Irish sheep populations <i>R. McAuley, N. McHugh, T. Pabiou and D.C. Purfield</i>	916
Assessing the impact of inbreeding on mastitis and digital dermatitis in German dairy cattle <i>J. Mugambe</i>	917
Genomic inbreeding in the Austrian Turopolje pig population <i>G. Mészáros, B. Berger, C. Draxl and J. Sölkner</i>	917
A genetic diversity study of a local Belgian chicken breed using the new IMAGE SNP array <i>R. Meyermans, W. Gorssen, J. Bouhuijzen Wenger, O. Heylen, J. Martens, S. Janssens and N. Buys</i>	918
Genetic diversity in Dutch sheep breeds shaped by geography, history, use and genetic management <i>J.N. Hoorneman, W.J. Windig and M.A. Schoon</i>	918
Genetic diversity and population structure of the Cyprus Chios sheep and Damascus goat breeds <i>A.C. Dimitriou, G. Maimaris, A.N. Georgiou and G. Hadjipavlou</i>	919

Genome-wide analysis of Greek goats with global breeds revealing population structure and diversity <i>E. Tosiou, V. Tsartsianidou, S. Vouraki, V. Papanikolopoulou, L.V. Ekateriniadou, E. Boukouvala, I.G. Bouzalas, I. Sakaridis, G. Arsenos and A. Triantafyllidis</i>	919
Genome-wide scan for runs of homozygosity in South American camelids <i>S. Pallotti, M. Picciolini, M. Antonini, C. Renieri and V. Napolioni</i>	920
Exploring global cattle genealogy with tree sequence <i>G. Mafra Fortuna, J. Obsteter, A. Kranis and G. Gorjanc</i>	920
Which diversity measures are important for small breeds like German Black Pied Cattle (DSN)? <i>G.A. Brockmann, G.B. Neumann, P. Korkuc, M.J. Wolf, K. May and S. König</i>	921
Characterisation of free-living and exotic animal species at species and individual level <i>M. Zorc, M. Cotman, A. Dovč, J. Zabavnik-Piano and P. Dovc</i>	921
Comparative analysis of heterozygosity-enriched regions in two autochthonous Italian cattle breeds <i>G. Schiavo, S. Bovo, F. Bertolini, A. Ribani, V. Taurisano, S. Dall'olio, M. Bonacini and L. Fontanesi</i>	922
Recovering latent population stratification using ADMIXTURE and metafounders in Brown Swiss <i>C. Anglhuber, C. Edel, E.C.G. Pimentel, R. Emmerling, K.-U. Götz and G. Thaller</i>	922

Poster Session 83

Genomic diversity analysis of the Swedish Landrace goat <i>B. Hegedüs, A.M. Johansson and P. Bijma</i>	923
Effect of interpopulation distance on average heterosis in crosses <i>A. Legarra, D. Gonzalez-Dieguez, A. Charcosset and Z.G. Vitezica</i>	923
Genome of the extinct Gotland cattle breed <i>M. Johnsson and A.M. Johansson</i>	924
Genetic variability in Italian Mediterranean buffalo: implications for conservation and breeding <i>M.M. Gómez, R. Cimmino, D. Rossi, G. Zullo, G. Campanile, G. Neglia and S. Biffani</i>	924
A comparative genome analysis across pig breeds can help to identify putative deleterious alleles <i>M. Ballan, S. Bovo, G. Schiavo, F. Bertolini, M. Bolner, M. Cappelloni, S. Tinarelli, M. Gallo and L. Fontanesi</i>	925
The effect of recessive genetic defects on pregnancy loss in Swedish dairy cattle <i>P. Ask-Gullstrand, E. Strandberg, R. Båge, E. Rius-Vilarrasa and B. Berglund</i>	925

Session 84. EuroFAANG: genotype-to-phenotype research across Europe and beyond

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Clark / Kuhn

Theatre Session 84

EuroFAANG – an infrastructure for farmed animal genotype to phenotype research in Europe and beyond <i>E.L. Clark, E. Giuffra, A. Granados-Chapette, M. Groenen, P.W. Harrison, C. Kaya, S. Lien, M. Tixier-Boichard and C. Kuehn</i>	926

GENE-SWitCH: improving the functional annotation of pig and chicken genomes for precision breeding <i>E. Giuffra, H. Acloque, A.L. Archibald, M.C.A.M. Bink, M.P.L. Calus, P.W. Harrison, C. Kaya, W. Lackal, F. Martin, A. Rosati, M. Watson and J.M. Wells</i>	926
Genome-wide association studies for body weight in broilers using sequencing and SNP chip data <i>E. Tarsani, V. Riggio and A. Kranis</i>	927
Using methylation annotation to improve genomic prediction of gene expression in pigs <i>B.C. Perez, J. De Vos, D. Crespo-Piazzuello, M.C.A.M. Bink, M. Ballester, M.J. Mercat, O. Madsen and M.P.L. Calus</i>	927
The path from functional annotation towards improved genomic prediction in cattle <i>C. Kühn</i>	928
Biology-driven genomic predictions for dry matter intake within and across breeds using WGS data <i>R. Bonifazi, G. Plastow, M. Heidaritabar, A.C. Bouwman, L. Chen, P. Stothard, J. Basarb, C. Li, Bovreg Consortium and B. Gredler-Grandl</i>	928
Newly annotated genomic features for biology-driven genome selection: the BovReg contribution <i>G.C.M. Moreira, L. Tang, S. Dupont, M. Bhati, H. Pausch, D. Becker, M. Salavati, R. Clark, E.L. Clark, G. Plastow, C. Kühn, C. Charlier and The Bovreg Consortium</i>	929
AQUA-FAANG: decoding genome function to enhance genotype-to-phenotype prediction in farmed finfish <i>D. MacQueen and S. Lien</i>	929
Integrating functional annotation data in genomic prediction of VNN resistance in European sea bass <i>S. Faggion, R. Mukibi, L. Peruzza, M. Babbucci, R. Franch, G. Dalla Rovere, S. Ferraresso, D. Robledo and L. Bargelloni</i>	930
GEroNIMO (Genome and Epigenome eNabled breeding in MOnogastrics) <i>S. Lagarrigue, F. Pitel and T. Zerjal</i>	930
RUMIGEN: new breeding tools in a context of climate change <i>S. Mattalia, A. Vinet, M.P.L. Calus, H.A. Mulder, M.J. Carabaño, C. Diaz, M. Ramon, S. Aguerre, J. Promp, R. Vallée, B.C.D. Cuyabano, D. Boichard, E. Pailhoux and J. Vandenplas</i>	931
The genetic basis of ruminant microbiomes – contribution of the HoloRuminant project <i>Y. Ramayo-Caldas, I. Mizrahi, P. Pope, C. Creevey, J.P. Sanchez, R. Quintanilla and D. Morgavi</i>	931

Poster Session 84

The effect of production systems on adipose tissue gene expression in Krškopolje pig <i>K. Poklukar, M. Čandek-Potokar, N. Batorek-Lukač, M. Vrecl, G. Fazarinc and M. Škrlep</i>	932
A lncRNA gene-enriched atlas for GRCg7b chicken genome using Ensembl, RefSeq and two FAANG databases <i>F. Degalez, M. Charles, S. Foissac, H. Zhou, D. Guan, L. Fang, C. Klopp, F. Lecerf, T. Zerjal, F. Pitel and S. Lagarrigue</i>	932

Session 85. Climate care dairy farming: herd management – Part 3

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Cieślak / Kuipers

Theatre Session 85

Effect of the Rumitech in a high-forage diet on methane production and performance of dairy cows 933

A. Cieślak, H. Huang, B. Nowak, M. Kozłowska, D. Lechniak, P. Pawlak, M. Szumacher-Strabel and J. Dijkstra

invited Sorghum hybrids as viable forage alternative to corn silage when water availability is limited 933

D. Duhatschek, J. Bell, D. Druetto, L.F. Ferraretto, K. Raver, J. Goeser, J. Smith, S. Paudyal, G.M. Schuenemann and J.M. Piñeiro

Feed intake and milk production of dairy cows fed with a ration with ensiled tall fescue 934

M. Cromheeke, L. Vandaele, D. Van Wesemael, J. Baert, M. Cougnon, D. Reheul and N. Peiren

Effect of supplementing live bacteria on methane production in lactating dairy cows 934

O. Ramirez-Garzon, D.G. Barber, J. Alawneh, L. Huanle and M. Soust

Greenhouse gas emissions from dairy cows fed best practice diets 935

M. Managos, C. Lindahl, S. Agenäs, U. Sonesson and M. Lindberg

Effects of cashew nutshell liquid on milk production and methane emission of dairy cows 935

R.J.F. Gaspe, T. Obitsu, T. Sugino, Y. Kurokawa and Y. Kuroki

In vivo testing of a methane-suppressing feed additive that acts by altering rumen redox potential 936

C. O'Donnell, C. Thorn, A.C.V. Montoya, S. Nolan, M. McDonagh, E. Dunne, F. McGovern, R. Friel, S. Waters and V. O'Flaherty

Diurnal variation and repeatability of CO₂ production in GreenFeed studies with lactating cows 936

A. Guinguina and P. Huhtanen

Repeatability and correlations of residual carbon dioxide and feed efficiency in Nordic Red cattle 937

A. Chegini, M.H. Lidauer, T. Stefanski, A.R. Bayat and E. Negussie

Methane emission from purebred Holstein, Nordic Red and F1 crossbred cows of the two breeds 937

A.L.F. Hellwing, M. Vestergaard and M. Kargo

How does a beef × dairy calving affect the dairy cow's following lactation? 938

R.E. Espinola Alfonso, W.F. Fikse, M.P.L. Calus and E. Strandberg

Extended lactation and milk yield – a randomized controlled trial in high yielding older cows 938

A. Hansson, C. Kronqvist, R. Båge and K. Holtenius

Effect of usage BWB sire on Holstein cow performances 939

K. Elzinga, C. Schrooten, G. De Jong and P. Duenk

Combined analysis: genetic and phenotypic trends in German Holstein dairy cattle 939

L. Hüneke, J. Heise, D. Segelke, S. Rensing and G. Thaller

Poster Session 85

Whole-crop maize forage preservation improvement with silage additives 940

I. Nikodinoska, E. Wambacq, G. Haesaert and C.A. Moran

Gallic acid alleviates the negative effect of <i>Asparagopsis armata</i> on milk yield in dairy cows <i>R. Huang, P. Romero, C. Martin, E.M. Ungerfeld, A. Demeter, A. Belanche, D.R. Yáñez-Ruiz, M. Popova and D. Morgavi</i>	940
Milk production in primiparous cows with customized voluntary waiting period <i>A. Edvardsson Rasmussen, E. Strandberg, R. Båge, M. Åkerlind, K. Holtenius and C. Kronqvist</i>	941
Association of nisin and <i>Cymbopogon citratus</i> against <i>S. aureus</i> isolated from bovine mastitis <i>L. Castelani, T.M. Mitsunaga, L.C. Roma Jr. and L.E.F. Zadra</i>	941

Session 86. How to address stakeholder and societal expectations of intrinsic and extrinsic quality of animal products?

Date: Thursday 31 August 2023; 14.00 – 18.00

Theatre Session 86

Quick sustainability scan calculator for intensive and extensive pig farms <i>S. Sanz-Fernández, C. Reyes-Palomo, P. Meatquality Consortium and V. Rodríguez-Estévez</i>	942
Bulk milk and farms characterization in the Parmigiano Reggiano Consortium area: the INTAQT project <i>M. Berton, M.A. Ramirez Mauricio, N. Amalfitano, L. Gallo, A. Cecchinato and E. Sturaro</i>	942
Bridging environmental sustainability and intrinsic quality traits of pork <i>M. Gagaoua, F. Gondret, F. Garcia-Launay and B. Lebret</i>	943
Improving milk intrinsic quality: considering synergies and antagonisms of farming practices <i>L. Rey-Cadilhac, A. Ferlay, M. Gelé, S. Léger and C. Laurent</i>	943
Imagining futures of husbandry farming: new business models for the sustainable transition? <i>B. Smulders, R. Valkenburg and M. Anastasi</i>	944
Current prediction and authentication tools used and needed in EU livestock product chains <i>S. McLaughlin, F. Albert, F. Bedoin, C. Couzy, I. Legrand, A. Nicolazo De Barmon, C. Laithier, C. Manuelian, F. Klevenhusen, S. De Smet, E. Sturaro and N. Scollan</i>	944
Milk quality assessment for intensive and extensive goat farming of the Skopelos breed in Greece <i>Z. Basdagianni, I. Stavropoulos, G. Manessis, C.G. Biliaderis and I. Bossis</i>	945
Rheological evaluation of rennet-induced curdling of goat milks from different farming systems <i>K. Kotsiou, M. Andreadis, A. Lazaridou, C.G. Biliaderis, Z. Basdagianni, I. Bossis and T. Moschakis</i>	945
invited Technological tools for authentication assessment of animal products <i>C.L. Manuelian</i>	946
Potential of milk infrared spectroscopy to discriminate farm characteristics: the INTAQT project <i>M.A. Ramirez Mauricio, D. Giannuzzi, L. Gallo, M. Berton, A. Cecchinato and E. Sturaro</i>	946
A longitudinal cohort study of health and welfare status in extensively and intensively reared goats <i>V. Korelidou, A.I. Kalogianni and A.I. Gelasakis</i>	947
New tool for accurate analysis of gas concentrations in barns <i>O. Bonilla-Manrique, A. Moreno-Oyervides, H. Moser, J.P. Waclawek, B. Lendl and P. Martín-Mateos</i>	947

Poster Session 86

Implementation of husbandry practices improving quality and sustainability: a living lab approach 948
E. Sturaro, C. Berri, D. Berry, R. Eppenstein, C. Laithier, A. Cartoni Mancinelli, B. Martin and F. Leiber

Muscle proteomics towards molecular understanding of colour and water-holding biochemistry in meat 948
S. Yigitturk

Exploring YOLO deep learning model for goat detection in animal welfare and behavioural monitoring 949
A. Temenos, A. Voulodimos, D. Kalogeras and A. Doulamis

The association between body condition score and the udder skin surface temperature in goats 949
V. Korelidou, A.I. Kalogianni and A.I. Gelasakis

Session 87. Carbon sources and sinks within global livestock systems

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Salami / Pouloupoulou

Theatre Session 87

invited Leveraging the measuring and managing of livestock farms on the journey towards Net Zero 950
J. Gilliland

The role of carbon sequestration in organic dehesas ruminant farms 950
R. Casado, M. Escribano, P. Gaspar and A. Horrillo

Estimating soil carbon sequestration gaps for ruminant systems across the globe 951
Y. Wang, I. Luotto, Y. Yigini, R. Vargas, D. Wisser, T.P. Robinson, U.M. Persson, C. Cederberg, R. Ripoll-Bosch, I.J.M. De Boer and C.E. Van Middelaar

Agronomic and environmental impacts of sheep integration in cover crop management in Wallonia 951
N. Lorant, B. Huyghebaert and D. Stilmant

Carbon footprint assessment of Korean native beef cattle and options to achieve net-zero emissions 952
R. Ibdhi, T. Kim, J. Byun, R. Bharanidharan, Y. Lee, S. Kang and K. Kim

Carbon Footprint of organic beef from dairy male calves 952
L. Mogensen, T. Kristensen, C. Kramer, A. Munk, P. Spleth and M. Vestergaard

Model to calculate the impact of interventions on the carbon footprint of dairy 953
A. Esselink

Tools to optimise the carbon footprint of milk production 953
D. Schwarz

Evaluation of feed additives under varying diets of dairy cows on performances and enteric emissions 954
M.E. Uddin, M.R.A. Redoy, S. Ahmed, M. Bulness, D.H. Kleinschmit, J. Lefler and C. Marotz

Supplementation with a calcium peroxide additive mitigates enteric methane emissions in beef cattle 954
E. Roskam, D.A. Kenny, V. O'Flaherty, A.K. Kelly and S.M. Waters

Methane emission from rosé veal calves feed a corn cob silage-based or grass silage-based ration 955
A.L.F. Hellwing and M. Vestergaard

Feeding a starch and protein binding agent for mitigating enteric methane emissions in sheep 955
P. Prathap, S.S. Chauhan, J.J. Cottrell, B.J. Leury and F.R. Dunshea

Poster Session 87

- Neutralization of bovine enteric methane emission by the presence of trees in a silvopastoral system 956
J.R.M. Pezzopane, H.B. Brunetti, P.P.A. Oliveira, A.C.C. Bernardi, A.R. Garcia, A. Berndt, A.F. Pedroso, A.L.J. Lelis and S.R. Medeiros
- Dairy goat farms in Extremadura: carbon sources and sinks in several management systems 956
L. Madrid, M. Escribano, P. Gaspar and A. Horrillo
- Life cycle assessment of IntelliBond on the carbon footprint of a dairy farm 957
D. Brito De Araujo, K. Perryman and J.G.H.E. Bergman
- Effects of supplementation of *Asparagopsis taxiformis* as a means to mitigate methane emission 957
M. Angellotti, M. Lindberg, M. Ramin, S.J. Krizsan and R. Danielsson

Session 88. Minerals in animal nutrition: basal diet – Part 2

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Alvarez Rodriguez / Windisch

Theatre Session 88

- invited** Trace element concentrations in feed ingredients: previously overlooked, now under the spotlight 958
M. López-Alonso
- Review on native Se concentrations in feed ingredients 958
D. Cardoso and A. Hachemi
- Does USEtox predicts adequately Cu and Zn ecotoxicity in soils amended with animal effluents? 959
E.P. Clement, M.N. Bravin, A. Avadi and E. Doelsch
- Challenges in establishing the mineral composition of feed materials 959
G. Tran and V. Heuzé
- Swiss feed database: mineral and trace element composition of feedstuffs 960
M. Lautrou, E. Manzocchi and P. Schlegel
- Overview of international aquaculture feed formulation database with reference to mineral nutrition 960
D.P. Bureau, L. Manomaitis and F.M. Damasceno
- invited** Mineral analysis: opportunities and limitations 961
P. Berzaghi, R. Fornaciari, M. Dorigo and G. Cozzi
- Determination of forage mineral analysis with portable X-ray Fluorescence device 961
R. Balegi, F. Penen, M. Lemarchand and A. Boudon
- A new phosphorus feeding system for the sustainability of swine and poultry production 962
M.P. Létourneau Montminy, M. Lautrou, M. Reis, C. Couture, N. Sakomura, B. Meda, C.R. Angel and A. Narcy
- Phosphorus digestibility of porcine processed animal proteins (PAPs) in broiler diets 962
J. Van Harn and P. Bikker
- Prediction of magnesium absorption in dairy cows: An update 963
R. Khiaosa-Ard and Q. Zebeli
- Se and Co balance in dairy cows: longitudinal study from late lactation to subsequent mid-lactation 963
J.B. Daniel and J. Martín-Tereso

Poster Session 88

Mineral analysis in feed using a new automated analytical method <i>D. Schwarz and D. Aden</i>	964
Trace mineral trends in British and Irish forages <i>A.H. Clarkson and N.R. Kendall</i>	964
Does size matter? Comparing liver sample sizes for trace element status <i>A.H. Clarkson, J. Angel and N.R. Kendall</i>	965
Investigation on the variation in phosphorus of wheat bran: effect in diets of fattening pigs <i>R. Puntigam, P. Riesinger, A. Honig, M. Schaeffler, W. Windisch and H. Spiekers</i>	965
Swiss Feed Database: a closer look at minerals and trace elements in 10 years of roughage surveys <i>E. Manzocchi, M. Lautrou and P. Schlegel</i>	966
Mineral forage value in the INRAE feeding system for ruminants <i>A. Boudon and G. Maxin</i>	966
Minerals in cattle nutrition – meet the needs! <i>A.C. Honig, V. Inhuber, H. Spiekers, W. Windisch, K.-U. Götz, G. Strauß and T. Ettle</i>	967
Ruminant feed rations rich in clay minerals may induce Zn deficiency <i>M. Schlattl, M. Buffler and W. Windisch</i>	967
Zn, Cu, Mn and Fe balance in dairy calves fed milk replacer or whole milk at two feeding allowances <i>T. Chapelain, J.B. Daniel, J.N. Wilms, L.N. Leal and J. Martín-Tereso</i>	968
Impact of drinking water salinity on lactating cows <i>A. Iritz and Y. Ben Meir</i>	968
Seasonal variation of trace essential and toxic minerals in milk and blood of dairy ewes <i>A. Nudda, M.F. Guiso, G. Sanna, A. Cesarani, M. Deroma, G. Pulina and G. Battacone</i>	969

Session 89. Explainable models and artificial intelligence supporting farming decisions

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Foy / Odintsov

Theatre Session 89

Measuring the behaviour of lambs in an isolated environment with artificial intelligence methods <i>B. Benet and R. Lardy</i>	969
Estimating sow posture from computer vision: influence of the sampling rate <i>M. Bonneau, J.A. Vayssade and L. Canario</i>	970
Estimating pig mass in a high-density pig group during transportation <i>V. Bloch, A. Valros, C. Munsterhjelm, M. Heinonen, M. Tuominen-Brinkas, H. Koskikallio and M. Pastell</i>	970
Assessment of piglet maturity at birth using computer vision <i>L. Maignel, R. Mailhot, A. Carrier and P. Gagnon</i>	971
Validation of new software (r-Algo) for predicting meat chemical composition from ultrasound images <i>B. Ahmadi, T. Schwarz and P.M. Bartlewski</i>	971

Coupling a sow herd model with a bioclimatic model of gestation rooms: development and evaluation <i>E. Dubois, F. Garcia-Launay, N. Quiniou, M. Marcon, J.Y. Dourmad, D. Renaudeau and L. Brossard</i>	972
Supervised machine learning as a tool to improve farrowing monitoring and stillborn rate in sows <i>C. Teixeira Costa, G. Boulbria, C. Dutertre, C. Chevance, T. Nicolazo, V. Normand, J. Jeusselin and A. Lebreton</i>	972
Use of accelerometers to predict the behaviour of growing rabbits <i>M. Piles, J.P. Sánchez, L. Riaboff, I. David and M. Mora</i>	973
Use of accelerometry data to detect kidding in goats <i>P. Gonçalves, M.R. Marques, A.T. Belo, A. Monteiro and F. Braz</i>	973
FTIR milk fatty acids quantification for non-invasive monitoring of rumen health in dairy cows <i>F. Huot, S. Claveau, A. Bunel, D. Warner, D.E. Santschi, R. Gervais and E.R. Paquet</i>	974
Optimizing breeding performance through algorithmic approaches to maximize meat quality in livestock <i>J. Albechaalany, M.P. Ellies-Oury, J.F. Hocquette, C. Berri and J. Saracco</i>	974
Detection of multiple feeding behaviours in calves using noseband and accelerometer sensors <i>S. Addo, K.A. Zipp, M. Safari, F. Freytag and U. Knierim</i>	975
Numerical detection of productive anomalies induced by heat stress in dairy cows <i>M. Bovo, M. Ceccarelli, C. Giannone, S. Benni, P. Tassinari and D. Torreggiani</i>	975

Poster Session 89

Using existing slaughterhouse data to assist detection of boar taint <i>B. Callens, M. Aluwé, R. Klont, M. Bouwknecht and J. Maselyne</i>	976
Evaluation of SARA risk prediction models based on non-invasive measurements in dairy cows <i>V. Leroux, C. Jaffres, A. Budan and N. Rollet</i>	976

Session 90. Genetics in horses

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Stock / Cox

Theatre Session 90

Use of linear data for characterization and selection of sport horses with highest genetic potential <i>K.F. Stock, A. Hahn, I. Workel and W. Schulze-Schleppinghoff</i>	977
Effect of mitochondrial genetic variability on performance of endurance horses <i>A. Ricard, S. Dhorne-Pollet, C. Morgenthaler, J. Speke Katende, C. Robert and E. Barrey</i>	977
Early life jumping traits' potential as proxy for jumping performance in Belgian Warmblood horses <i>L. Chapard, R. Meyermans, W. Gorssen, N. Buys and S. Janssens</i>	978
Genetic covariance components of conformation, movement and athleticism traits in Irish Sport Horses <i>J.L. Doyle, S. Egan and A.G. Fahey</i>	978
Start status in Swedish Warmblood horses <i>Y. Blom, S. Eriksson and Å. Gelinder Viklund</i>	979
Genetic analysis of the precocity potential in trotting races of Spanish Trotter Horses <i>M. Ripollés-Lobo, D.I. Perdomo-González, M.D. Gómez, M. Ligeró and M. Valera</i>	979

Is the ability to race barefoot a heritable trait in Standardbred trotters? <i>P. Berglund, S. Andonov, A. Jansson, T. Lundqvist, C. Olsson, E. Strandberg and S. Eriksson</i>	980
Searching for genomic regions associated with conformation traits in the Pura Raza Español horse <i>N. Laseca, C. Ziadi, D.I. Perdomo-González, M. Valera, P. Azor, S. Demyda-Peyrás and A. Molina</i>	980
Successful genotype imputation from medium to high density in Belgian Warmblood horses <i>L. Chapard, R. Meyermans, W. Gorssen, B. Van Mol, F. Pille, N. Buys and S. Janssens</i>	981
Inbreeding in the Belgian equine warmblood population: current degree and evolution <i>B. Van Mol, H. Hubrechts, R. Meyermans, L. Chapard, W. Gorssens, M. Oosterlinck, N. Buys, F. Pille and S. Janssens</i>	981
Population structure assessment using genome wide molecular information in Martina Franca donkey <i>V. Landi, E. Ciani and P. De Palo</i>	982
Unravelling genomic regions with transmission ratio distortion in horse <i>N. Laseca, A. Cánovas, M. Valera, S. Id-Lahoucine, D.I. Perdomo-González, P.A.S. Fonseca, S. Demyda-Peyrás and A. Molina</i>	982
Microsatellite-based detection of transmission ratio distortion in the Pura Raza Española horse <i>D.I. Perdomo-González, S. Id-Lahoucine, A. Molina, A. Cánovas, N. Laseca, P.J. Azor and M. Valera</i>	983

Poster Session 90

Estimation of the genetic parameters for temperament in Haflinger horses <i>T.H. Zanon, B. Fürst Waltl, S. Gruber and M. Gauly</i>	983
Estimation of the genetic propensity to suffer hock osteochondrosis in Pura Raza Española horses <i>M. Ripollés, A. Molina, M. Novales, C. Ziadi, E. Hernández and M. Valera</i>	984
Genetic characterization of white facial marking in Pura Raza Español horses depending on coat colour <i>A.E. Martínez, M.J. Sánchez Guerrero, A. López, M. Ligeró and M. Valera Córdoba</i>	984
Climate effects on foaling event: genotype-by-environment interactions in horse fertility <i>C. Sartori, E. Mancin, G. Gomez-Proto, B. Tuliozi and R. Mantovani</i>	985

Session 91. Nitrogen excretion and ammonia emission in pig and poultry production

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Millet / Brodziak

Theatre Session 91

Impact of raw and digested pig manure on ammonia volatilization after land application <i>F.M.W. Hickmann, R. Rajagopal, N. Bertrand, I. Andretta, M.-P. Létourneau-Montminy and D. Pelster</i>	985
Influence of housing manure management on ammonia emissions from broiler and laying hen productions <i>E. Caron, P. Le Bras and M. Hassouna</i>	986
NH ₃ , N ₂ O and CH ₄ emission from piggeries: comparison of several manure management techniques <i>N. Guingand and P. Le Bras</i>	986
Feeding pigs with low-protein diets: impact of pig manure nitrogen content on biogas production <i>F.M.W. Hickmann, I. Andretta, L. Cappelaere, B. Goyette, M.-P. Létourneau-Montminy and R. Rajagopal</i>	987

A tool to reduce worker exposure from ammonia and particles in swine and poultry housing <i>N. Guingand, S. Lagadec, K. Amin, D. Bellanger, A.L. Boulestreau-Boulay, C. Delaqueze, C. Depouvent, L. Gabriel, E. Koulete, V. Le Gall, P. Lecorguille, L. Leroux, G. Manac'h, S. Roffi and M. Ruch</i>	987
Methodological redesign of the poultry mass-balance excretion and variability of nitrogen excretion <i>V. Blazy, E. Caron, D.D. Djenontin-Agossou and Y. Guyot</i>	988
Access to bedding and an outdoor run for growing-finishing pigs and their impact on the environment <i>A.K. Ruckli, S. Hörtenhuber, S. Dippel, P. Ferrari, M. Gebeska, J. Guy, M. Heinonen, J. Helmerichs, C. Hubbard, H. Spoolder, A. Valros, C. Winckler and C. Leeb</i>	988
Reduction of protein and potassium to improve welfare and environmental footprint in broilers <i>T. De Rauglaudre, B. Méda, W. Lambert, S. Fournel and M.P. Létourneau-Montminy</i>	989
Effects of reducing protein content in broiler diets on environmental impacts <i>J. Gickel, V. Wilke, C. Ullrich and C. Visscher</i>	989
Effect of reduced-crude protein diets on performance, meat yield, and nitrogen production in broiler <i>C. Gayraud, T. Wise, J.D. Davis, J.C. De Paula Dorigam, V.D. Naranjo and W.A. Dozier, Iii</i>	990
Effect of reducing dietary protein content on performance and environmental impact of pig production <i>E. Gonzalo, A. Simongiovanni, C. De Cuyper, B. Ampe, M. Aluwe, W. Lambert and S. Millet</i>	990
Impact of genotype×feed-interactions in nitrogen- and phosphorus-reduced ration on fattening pigs <i>C. Große-Brinkhaus, B. Bonhoff, I. Brinke, E. Jonas, S. Kehraus, K.H. Südekum and E. Tholen</i>	991
Pig performance, carcass composition and meat quality can be maintained with high CP reduction <i>L. Cappelaere, F. Garcia-Launay, W. Lambert, A. Simongiovanni and M.-P. Létourneau-Montminy</i>	991

Poster Session 91

Alpha mannan polysaccharide supplement increase growth performance and reduce gas emission in pig <i>J.H. Song, C.B. Lim, M.D.M. Hossain, S. Biswas, J.S. Yoo, I.H. Kim and Q.Q. Zhang</i>	992
Characteristic of odour substances from broiler farms <i>S.Y. Seo, J.S. Park, S.Y. Park and M.W. Jung</i>	992
Environmental assessment of layer-type male chicks breeding <i>E. Dubois and M. Quentin</i>	993

Session 92. Inflammation and energy metabolism in young and adult livestock

Date: Thursday 31 August 2023; 14.00 – 18.00
Chair: Sauerwein

Theatre Session 92

Milk metabolites differ with feed efficiency during early lactation but not during feed restriction <i>J. Pires, T. Larsen, S. Bes, I. Constant, D. Roux, M. Tourret, A. De La Torre, I. Ortigues-Marty, F. Blanc and I. Cassar-Malek</i>	993
Dairy cow inflammatory status is modulated by physiological stage and feed restriction <i>C. Delavaud, A. De La Torre, D. Durand, S. Bes, D. Roux, A. Thomas, M. Tourret, I. Ortigues-Marty, I. Cassar-Malek, M. Bonnet and J. Pires</i>	994

Energy balance clusters in relation to metabolic and inflammatory status and disease in dairy cows <i>J. Ma, A. Kok, R. Bruckmaier, E. Burgers, R. Goselink, J. Gross, T. Lam, A. Minuti, E. Saccenti, E. Trevisi and A. Van Kneghsel</i>	994
Effects of parity on metabolism, redox status and cytokines in early lactating dairy cows <i>A. Corset, A. Boudon, A. Remot, S. Philau, P. Poton, O. Dhumez, B. Graulet, P. Germon and M. Boutinaud</i>	995
Tissue distribution and pharmacological characterization of bovine free fatty acids-sensing GPCRs <i>T.C. Michelotti, M. Bonnet, V. Lamothe, S. Bes and G. Durand</i>	995
Maternal nutrition carry-over effects on beef cow colostrum but not on milk fatty acid composition <i>N. Escalera-Moreno, B. Serrano-Pérez, E. Molina, L. López De Armentia, A. Sanz and J. Álvarez-Rodríguez</i>	996
Different types and doses of colostrum to optimize the passive immune transfer and health in lambs <i>A. Belanche, F. Canto and O. Calisici</i>	996
Oxidative status in female Holstein calves fed with or without transition milk <i>C.S. Ostendorf, M. Hosseini Ghaffari, B. Heitkönig, C. Koch and H. Sauerwein</i>	997
Effects of concentrate feeding and hay quality on adipogenesis and inflammation in dairy calves <i>R. Khiaosa-Ard, A. Sener-Aydemir, S. Kreuzer-Redmer and Q. Zebeli</i>	997
Synergistic benefits of marine derived bioactives to maintain the gut barrier in an <i>ex vivo</i> model <i>M.A. Bouwhuis, I. Nooijen, E. Van Der Steeg and S. O'Connell</i>	998
Effects of milk replacer diets on the intestinal development of suckled piglets <i>G.Y. Duan, C.B. Zheng, J. Zheng, P.W. Zhang, M.L. Wang, J.Y. Yu, B. Cao, M.M. Li, F. Cong, Y.L. Yin and Y.H. Duan</i>	998
The impact of early thermal manipulation on the hepatic energy metabolism of mule duck <i>C. Andrieux, M. Morisson, V. Coustham, S. Panzerat and M. Houssier</i>	999
Poster Session 92	
Feed efficiency and responses of plasma and milk isotopic signatures in Charolais beef cows <i>A. De La Torre, J. Pires, I. Cassar-Malek, I. Ortigues-Marty, F. Blanc, L. Barreto-Mendes, G. Cantalapiedra-Hijar and C. Loncke</i>	999
How the composition of Holstein cow colostrum differs according to the immunoglobulins G level <i>A. Goi, A. Costa and M. De Marchi</i>	1000
An educational kit for effective prevention and management of energy deficit in dairy cows <i>M. Gelé, M. Boutinaud, A. Bouqueau, M. Marguerit, J. Jurquet, Y. Le Cozler and J. Guinard-Flament</i>	1000
Inflammation status weakly modulated by short-term feed restriction in lactating beef cows <i>C. Delavaud, J. Pires, M. Barbet, I. Ortigues-Marty, I. Cassar-Malek, M. Bonnet and A. De La Torre</i>	1001
Metabolic profiles of grazing dairy cows with or without feed restriction during early lactation <i>A.L. Astessiano, M. Garcia-Roche, D. Custodio, G. Ortega, P. Chilibroste and M. Carriquiry</i>	1001
Hepatic mitochondrial function in grazing dairy cows with or without feed restriction <i>M. Garcia-Roche, D. Custodio, A. Astessiano, G. Ortega, P. Chilibroste and M. Carriquiry</i>	1002
On-farm emergency slaughtered dairy cows: causes and haematological biomarkers <i>F. Fusi, I.L. Archetti, S.M. Chisari, V. Lorenzi, C. Montagnin, R. Salonia, L. Bertocchi and G. Cascone</i>	1002

The effect of early feed restriction of ewe lambs on milk miRNAome of the filial generation <i>A. Martin, F. Cecilian, F.J. Giráldez, R. Calogero, C. Lecchi and S. Andrés</i>	1003
Quercetin supplementation in perinatal sows diet influencing suckling piglets and its mechanism <i>Y. Li, Q.L. Yang, Y.X. Fu, S.S. Zhou, J.Y. Liu and J.H. Liu</i>	1003
Development of muscle injury in weanling piglets under chronic immune stress <i>Y. Duan</i>	1004

Session 93. Recent advances on *in vitro* systems (from cell culture to *in vitro* digestion methods): relevance as alternatives to animal experimentation for livestock research

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Louveau

Theatre Session 93

invited The great power of being tiny: <i>in vitro</i> gut systems in livestock research <i>S.K. Kar</i>	1004
Comparison of adult intestinal stem cell derived organoids between different ages and sex in pigs <i>R.S.C. Rikkers, O. Madsen, S.K. Kar, L. Kruijt, A.A.C. De Wit, E. Van Der Valk, L.M.G. Verschuren, S. Verstringe and E.D. Ellen</i>	1005
Butyric glycerides directly and indirectly enhance chicken enterocyte resistance to pathogens <i>A. Mellouk, N. Vieco-Saiz, V. Michel, O. Lemâle, T. Goossens and J. Consuegra</i>	1005
invited Spheroid and organoid models to study animal reproduction <i>K. Reynaud, M. Ta, C. Pucéat, M. Billet, C. Mahé, L. Schmaltz, L. Laffont, P. Mermillod and M. Saint-Dizier</i>	1006
3D-cell culture systems; a breakthrough to improve the human and animal disease research <i>E.S. Smirnova, K.A. Adhimoolam and T.M. Min</i>	1006
Slurry chemical characteristics and ammonia emissions assessed by different methods <i>L. Sarri, E. Fuertes, E. Pérez-Calvo, A.R. Seradj, R. Carnicero, J. Balcells and G. De La Fuente</i>	1007
<i>In vitro</i> protein fractionation methods for ruminant feeds <i>B.Z. Tunkala, K. Digiacomo, P.S. Alvarez Hess, F.R. Dunshea and B.J. Leury</i>	1007
Storage conditions of rumen inoculum: impact on gas productions in mini dual flow fermenters <i>V. Berthelot, M. Charef-Mansouri, A.-M. Davila and L.P. Broudiscou</i>	1008
Dynamics of rumen microbiome and methane emission during <i>in vitro</i> rumen fermentation <i>R. Dhakal, R. Sapkota, P. Khanal, A. Winding and H.H. Hansen</i>	1008
Effects of <i>Asparagopsis armata</i> inclusion on methane production in semi-continuous fermenters <i>P. Romero, S.M. Waters, D.R. Yañez-Ruiz, A. Belanche and S.F. Kirwan</i>	1009
Calcium propionate mitigated adverse effects of incubation temperature shift on <i>in vitro</i> fermentation <i>T. He, S. Long and Z. Chen</i>	1009

Poster Session 93

<i>In vitro</i> generation of ovine monocyte-derived macrophages for SRLV infection studies <i>E. Grochowska, M. Ibrahim, M. Wu and K. Stadnicka</i>	1010

Resistance of probiotics to antibiotics and antagonism to poultry pathogens <i>N. Akhavan, K. Stadnicka, D. Thiem and K. Hryniewicz</i>	1010
Metabolic footprint of prebiotics and probiotics in Chick8E11 and Caco-2 intestinal cell lines <i>S. Zuo, W. Studziński, K. Stadnicka and P. Kosobucki</i>	1011
Cellular imagery evaluation of butyric acid biological activities in Caco-2 cell line <i>D. Gardan-Salmon, B. Saldaña, J.I. Ferrero and M. Arturo-Schaan</i>	1011
Effect of silage sample preparation on rumen fermentation (<i>in vitro</i>) <i>J.A. Huntington, T. Snelling, L.A. Sinclair, H. Warren, D.A. Galway and D.R. Davies</i>	1012
Repeatability of fermentation kinetics using <i>in vitro</i> gas fermentation <i>B. Jantzen and H.H. Hansen</i>	1012
Evaluation of rumen bypass protein in processed soybean meal products <i>A. Chariopolitou, A. Plomaritou, A. Tzamourani, K. Droumtsekas and A. Foskolos</i>	1013
Effect of rumen inoculum on predicted <i>in vivo</i> methane production from barley and oats <i>P. Fant, M. Ramin and P. Huhtanen</i>	1013
Comparison of <i>in vitro</i> and <i>in vivo</i> methane production in dairy cows <i>D.W. Olijhoek, É. Chassé, M. Battelli, M.V. Curtasu, M. Thorsteinsson, M.H. Kjeldsen, W.J. Wang, G. Giagnoni, M. Maigaard, C.F. Børsting, M.R. Weisbjerg, P. Lund and M.O. Nielsen</i>	1014

Session 94. Free communications in animal health and welfare

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Boyle / Calderon Diaz

Theatre Session 94

What impairs laying hens' foot health? A retrospective German study <i>N. Volkmann, A. Riedel, N. Kemper and B. Spindler</i>	1014
Pododermatitis in broilers: prevalence and risk factors present in reused beddings <i>J. Montalvo, M. Cevallos and M. Cisneros</i>	1015
Digital dermatitis in French young bulls fattening farms <i>A. Waché, M. Petitprez, E. Dod Ioan, M. Delacroix and C. Guibier</i>	1015
Prevalence and factors associated with teat-end hyperkeratosis in dairy cows <i>F.G. Silva, C. Antas, A.M.F. Pereira and C. Conceição</i>	1016
Milk calcium content to detect hypocalcaemia in dairy cows at the onset of lactation <i>T. Aubineau, R. Guatteo and A. Boudon</i>	1016
PRRSV stabilisation programs in French farrow-to-finish farms: a way to reduce antibiotic use <i>C. Teixeira Costa, G. Boulbria, V. Normand, C. Chevance, J. Jeusselin, T. Nicolazo and A. Lebret</i>	1017
Monitoring of antimicrobial use on French pig farms from 2010 to 2019 using INAPORC panels <i>A. Poissonnet, I. Correge, C. Chauvin and A. Hemonic</i>	1017
Digital drug registration and its relation to veterinary slaughter findings <i>H. Gorge, I. Dittrich, N. Kemper and J. Krieter</i>	1018
A critical lens to regulations around veterinary antimicrobial use across countries and species <i>G. Olmos Antillón and I. Blanco-Penedo</i>	1018

An approach of the place of animal health and role of veterinarian in sustainable farming systems <i>A. Scholly-Schoeller and G. Brunschwig</i>	1019
Developing an animal welfare benchmarking framework for Australian lot-fed cattle <i>T. Collins, E. Taylor, A. Barnes, E. Dunston-Clarke, D. Miller, D. Brookes, E. Jongman and A. Fisher</i>	1019
H2020 mEATquality: on-farm animal welfare assessment in slaughter pigs <i>T. Rousing, L.D. Jensen, M.L.V. Larsen and L.J. Pedersen</i>	1020
Variability in pig hair cortisol concentrations at the end of the fattening period <i>P. Levallois, M. Leblanc-Maridor, S. Gavaud, B. Lieubeau, G. Morgant, C. Fourichon, J. Hervé and C. Belloc</i>	1020
Identification and characterization of IUGR piglets <i>C. Ollagnier, R. Ruggeri, J. Bellon and G. Bee</i>	1021
Poster Session 94	
Investigating the association between sole ulcers and sole temperature in dairy cattle using IRT <i>A. Russon, A. Anagnostopoulos, M. Barden, B. Griffiths, C. Bedford and G. Oikonomou</i>	1021
Osteopathic manipulative treatment: a complementary approach to promote milk production in cows <i>C. Omphalius, A. Hardouin, M. Launay Ventelon and S. Julliard</i>	1022
The relationship between stress levels and skin allergy or atopy problem by analysing hair cortisol <i>G.W. Park, M. Ataallah and K.H. Park</i>	1022
SECURIVO: self-assessment tools for biosecurity in veal calves' farms <i>M. Chanteperdrix, M. Drouet, M. Mounaix, M. Tourtier, D. Le Goic, C. Jaureguy, P. Briand, M. Coupin, A. Hemon and N. Rousset</i>	1023
Temporally synchronized ruminal vs reticular fluid pH and short chain fatty acids in dairy cows <i>A. Kidane, K.S. Eikanger and M. Eknæs</i>	1023
Antimicrobial use and main causes of treatment in Italian buffalo farms <i>G. Di Vuolo, F. Scali, C. Romeo, V. Lorenzi, C.D. Ambra, M. Serrapica, G. Cappelli, F. Fusi, E. De Carlo, G.L. Alborali, L. Bertocchi and D. Vecchio</i>	1024
Herd factors associated with levels of parasitism in alternative pig farms <i>M. Delsart, N. Rose, B. Dufour, J.M. Réperant, R. Blaga, F. Pol and C. Fablet</i>	1024
Biosecurity and Animal Welfare relationship on buffalo farms through ClassyFarm assessments <i>D. Vecchio, G. Santucci, V. Lorenzi, C. Caruso, C.D. Ambra, M. Serrapica, G. Di Vuolo, G. Cappelli, F. Fusi, E. De Carlo, C. Romeo, F. Scali, G.L. Alborali, A.M. Maisano and L. Bertocchi</i>	1025
Immune function of pre-weaned calves fed a fortified milk replacer under heat stress conditions <i>A.A.K. Salama, S. Serhan, L. Ducrocq, M. Biesse, A. Joubert and G. Caja</i>	1025
The effect of udder health on milk composition <i>Z. Nogalski and M. Sobczuk-Szul</i>	1026

Session 95. Happy Delivering innovative and holistic milk based monitoring and decision-making PLF tools – collaboration with HappyMoo

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Gengler / Knijn

Theatre Session 95

- An attempt to predict dairy cows chronic stress biomarkers using milk MIR spectra 1026
C. Grelet, H. Simon, J. Leblois, M. Jattiot, C. Lecomte, R. Reding, J. Wavreille, E.J.P. Strang, F.J. Auer, Happymoo Consortium and F. Dehareng
- Prediction of body condition score for the entire lactation in Walloon Holstein cows 1027
H. Atashi, J. Chelotti and N. Gengler
- Conditions to develop successful mid-infrared (MIR) based BCS and BCS change predictions 1027
J. Chelotti, H. Atashi, C. Grelet, M. Calmels, J. Leblois and N. Gengler
- Large-scale analysis of chronic stress in dairy cows using hair cortisol and blood fructosamine 1028
H. Simon, C. Grelet, S. Franceschini, H. Soyeurt, J. Leblois, M. Jattiot, C. Lecomte, R. Reding, J. Wavreille, E.J.P. Strang, F.J. Auer and F. Dehareng
- Calculation of dry matter intake and energy balance based on MIR spectral data at European level 1028
V. Wolf, L. Dale, M. Gelé, U. Schuler, U. Müller, N. Gengler, J. Leblois and M. Calmels
- Validation of HappyMoo MIR energy balance models on external datasets with feeding restriction 1029
M. Calmels, J. Pires, M. Boutinaud, A. Leduc, C. Leroux, J. Chelotti, L. Dale, C. Grelet, A. Tedde, J. Leblois and M. Gelé
- Genetic analyses of principal components of milk mid-infrared spectra from Holstein cows 1029
Y. Chen, P. Delhez, H. Atashi, H. Soyeurt and N. Gengler
- MastiMIR – MIR prediction for udder health 1030
L.M. Dale, A. Werner, E.P.J. Strang, Happymoo Consortium and J. Bieger
- Prediction of lameness and hoof lesions using MIR spectral data 1030
M. Jattiot, L.M. Dale, M. El Jabri, J. Leblois, M.-N. Tran and HappyMoo Consortium
- MIR spectral prediction based on heat stress in dairy cattle 1031
L.M. Dale, M. Jattiot, A. Werner, E.J.P. Strang, P. Lemal, Happymoo Consortium, Klimaco Consortium and N. Gengler
- Use of MIR spectra-based indicator for genetic evaluation of heat stress in dairy cattle 1031
P. Lemal, L.M. Dale, M. Jattiot, J. Leblois, M. Schroyen and N. Gengler
- A unique overview of enteric methane emissions by dairy cows in Bretagne, France 1032
S. Mendowski, O. Garcia, C. Bruand, M. Tournat, T. Viot and L. Meriaux
- Genetic parameters analysis of milk citrate for Holstein cows in early lactation 1032
H. Hu, Y. Chen, C. Grelet and N. Gengler

Poster Session 95

- Milk fluctuations in daily milk yield associated with diseases in Chinese Holstein cattle 1033
A. Wang, D.K. Liu, C. Mei and Y.C. Wang

Session 96. ERANET-funded 'Grass To Gas' and EU-funded 'SMARTER' projects

Date: Thursday 31 August 2023; 14.00 – 18.00

Chair: Conington / Vouraki

Theatre Session 96

- Impact of genomic selection for methane emissions in a high performance sheep flock 1033
S.J. Rowe, T. Bilton, P. Johnson, S. Hickey, A. Jonker, N. Amyes, K. McRae, S. Clarke and J. McEwan
- Improving feed efficiency in meat sheep increases CH₄ emissions measured indoor or on pasture 1034
F. Tortereau, J.-L. Weisbecker, C. Coffre-Thomain, Y. Legoff, D. François, Q. Le Graverand and C. Marie-Etancelin
- Effects of sire and diet on rumen volume and relationships with feed efficiency 1034
N.R. Lambe, A. McLaren, K.A. McLean, J. Gordon and J. Conington
- Evaluating the effect of herbage composition on methane output in sheep 1035
F.M. McGovern, P. Creighton, E. Dunne and S. Woodmartin
- Dry matter intake across life stages in sheep 1035
E. O'Connor, N. McHugh, E. Dunne, T.M. Boland and F.M. McGovern
- Selecting feed-efficient sheep with concentrates alters their efficiency with forages and behaviour 1036
C. Marie-Etancelin, J.L. Weisbecker, D. Marcon, L. Estivalet, Q. Le Graverand and F. Tortereau
- Genome-wise association study of footrot and mastitis in UK Texel sheep 1036
K. Kaseja, S. Mucha, J. Yates, E. Smith, G. Banos and J. Conington
- Genetic parameters of nematode resistance in dairy sheep 1037
B. Bapst, K. Schwarz, S. Thüer and S. Werne
- Contrasting genetic resistance to GIN on growth performance and feed efficiency of Corriedale lambs 1037
E.A. Navajas, G. Ciappesoni and I. De Barbieri

Poster Session 96

- Australian Merino: animal welfare and resilience in extensive systems 1038
M. Del Campo, J.L. De Araújo Pimenta, I. De Barbieri, P. Lorenze, F. Rovira and J.M. Soares De Lima
- Prediction of feed efficiency related traits from plasma NMR spectra 1038
A. Marquisseau, F. Tortereau, N. Marty-Gasset, C. Marie-Etancelin and Q. Le Graverand
- Metabolism in lambs from two feed-efficiency genetic lines subjected to different early rearing practices 1039
G. Cantalapiedra-Hijar, M.M. Milaon, S. Parisot, C. Durand, M. Vauris, F. Tortereau and C. Ginane
- Genetic link between fertility and resilience in sheep and goat divergent selection experiments 1039
R. Rupp, C. Oget-Ebrad, S. Parisot, T. Fossier, G. Tosser Kloppe and S. Freret
- Phenotypic and genetic variability of health and welfare traits in French dairy goats 1040
I. Palhiere, A. Bailly-Salins, A. Gourdon, M. Chassier, R. De Cremoux, M. Berthelot and R. Rupp
- Assessment of phenotypic and genetic variability of rumen temperatures in goats 1040
I. Palhiere, C. Huau, T. Fossier, R. Rupp and L. Bodin
- Heritability of novel metabolite-based resilience biomarkers in dairy goat 1041
M. Ithurbide, T. Fossier, M. Turret, J. Pires, T. Larsen, N.C. Friggens and R. Rupp

Rumen size of sheep: difference between a modern and a native Norwegian sheep breed <i>B.A. Åby, M.A. Bhatti and G. Steinheim</i>	1041
Diurnal feed intake pattern of two sheep breeds fed different silage qualities <i>I. Dønnem, B.A. Åby and G. Steinheim</i>	1042

The real place of livestock in GHG emissions and their control for climate change*K. Johnson**Washington State University, Animal Sciences, 126 ASLB, P.O. Box 646351, Pullman, WA 99164-6351, USA; johnsoka@wsu.edu*

Climate change presents multiple challenges to the livestock industry including the need to examine animal and environmental management practices to enhance efficiency, reduce greenhouse gas emissions from animals and manure, reduce water and other resource use, and pressure to eliminate meat and livestock products from diets. This pressure is because methane is a relatively short-lived greenhouse gas and reductions in methane emissions now will benefit concentrations in 10 years. This argument does not necessarily take into consideration the role of ruminant livestock across many different cultures across the world and the benefits grazing livestock have to regenerative agriculture. Additionally, the role and benefits livestock provide through up-cycling byproducts of human consumption can be lost in the discussion but will have significant environmental consequences if they are not used. There is a recent body of literature that describes different alternatives for livestock management that address some of the concerns while maintaining the positive attributes ruminants provide. Examination of the ideas in that literature and associated data can benefit livestock managers, scientists who study livestock and society in general as important public policy decisions are debated and enacted.

Session 01

Theatre 2

Global emissions from livestock systems: updated baselines, projections, and mitigation options*D. Wisser, G. Tempio, A. Falcucci and G. Cinardi**Food and Agriculture Organization of the United Nations (FAO), Animal Production and Health Division, Viale di Terme di Caracalla, 00153 Roma, Italy; dominik.wisser@fao.org*

Livestock provide valuable nutritional benefits as well as supporting livelihoods and the resilience of families and communities. Though growth has slowed, demand for animal products is projected to grow by 34% by 2050 globally, mostly as a result of demand growth in low and middle income countries. Livestock systems contribute to a considerable fraction of all anthropogenic greenhouse gas emissions but can contribute to climate change mitigation through gains in efficiency along the production chain as well as through specific interventions aiming at reducing greenhouse gases, in particular methane. We present an updated assessment of global emissions associated with livestock using FAO's Global Livestock Environmental Assessment Model (GLEAM). GLEAM adopts a Tier 2 methodology to estimate detailed and spatially explicit emissions for a specified base year and uses a lifecycle assessment (LCA) approach, including both direct emissions from animals as well indirect emissions upstream and downstream. This approach differentiates key stages within livestock agrifood systems, such as land use change, feed production, processing and transport; animal production, animal feeding and manure management; and the processing and transport of products. We will present an overview of the approach and updated estimates of emissions from all species and production systems globally and highlight major sources. These results are made available through a recently released dashboard (<https://www.fao.org/gleam/dashboard/en/>). Using a business-as-usual scenario, we will then illustrate pathways of future emissions taking into account improvements in productivity as well as specific mitigation interventions. Results suggest that emissions from livestock systems currently account for about 11% of all anthropogenic GHG emission but considerable reductions in emission intensity (emissions per unit of output) and in total emissions can be achieved through efficiency gains along the production chain through interventions in animal health, feed, breeding, and others, while meeting projected future demand for animal products.

Genetic control of ruminant methane emissions in livestock

A.E. Van Breukelen¹, M.N. Aldridge¹, R.F. Veerkamp¹ and Y. De Haas²

¹Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands,

²Wageningen University & Research, Animal Health & Welfare, P.O. Box 338, 6700 AH Wageningen, the Netherlands; anouk.vanbreukelen@wur.nl

Animal agriculture is a large contributor to anthropogenic greenhouse gas emissions. The main source is enteric methane (CH₄) produced by ruminants, with emissions increasing due to growing livestock numbers and increased productivity of individual animals. By mitigating CH₄ emissions, short-term wins can be made towards meeting the 1.5 °C Paris agreement temperature target, due to the short lifetime of CH₄. There is a world-wide interest in applying animal breeding as a mitigation strategy, because the effect is permanent, cumulative, and cost-effective. Initial studies have shown that there is natural variation in CH₄ emissions of cows, that it is heritable, and that theoretical genetic gains will have a significant mitigation effect. Nevertheless, practical implementations that mitigate CH₄ emissions in breeding programs are still limited, which is largely because enteric CH₄ emissions of individual cows are challenging and costly to record. Although phenotyping with sniffers makes large scale recording easier, this technology is still at its infancy and therefore genetic correlations with key production traits are yet still unknown or uncertain, whereas they are essential to ensure that all trait changes are in the desired direction. Furthermore, incentives to apply CH₄ in breeding programs need to be found as the economic value of mitigating CH₄ emissions is uncertain. Nonetheless, many countries are working towards applications in national breeding programs, or have recently started implementing breeding values for CH₄. First implementations confirmed that animal breeding could deliver a substantial mitigation towards Paris agreement targets, ideally when combined with other dietary and management approaches.

Session 01

Theatre 4

Effective strategies to mitigate enteric methane emissions by ruminants

C. Arndt

ILRI, Naivasha Rd, 00100 Nairobi, Kenya; claudia.arndt@cgiar.org

Agricultural methane emissions must be decreased by 11 to 30% of the 2010 level by 2030 and by 24 to 47% by 2050 to meet the 1.5 °C target. A meta-analysis identified strategies to decrease product-based (PB; CH₄ per unit meat or milk) and absolute (ABS) enteric CH₄ emissions while maintaining or increasing animal productivity (AP; weight gain or milk yield). Next, the potential of different adoption rates of one PB or one ABS strategy to contribute to the 1.5 °C target was estimated. The database included findings from 430 peer-reviewed studies, which reported 98 mitigation strategies that can be classified into three categories: animal and feed management, diet formulation, and rumen manipulation. A random-effects meta-analysis weighted by inverse variance was carried out. Three PB strategies – namely, increasing feeding level, decreasing grass maturity, and decreasing dietary forage-to-concentrate ratio – decreased CH₄ per unit meat or milk by on average 12% and increased AP by a median of 17%. Five ABS strategies – namely CH₄ inhibitors, tanniferous forages, electron sinks, oils and fats, and oilseeds – decreased daily methane by on average 21%. Globally, only 100% adoption of the most effective PB and ABS strategies can meet the 1.5 °C target by 2030 but not 2050, because mitigation effects are offset by projected increases in CH₄ due to increasing milk and meat demand. Notably, by 2030 and 2050, low- and middle-income countries may not meet their contribution to the 1.5 °C target for this same reason, whereas high-income countries could meet their contributions due to only a minor projected increase in enteric CH₄ emissions.

Tannins, legumes and methane production by ruminants*H.H. Lardner**University of Saskatchewan, Department of Animal and Poultry Science, 51 Campus Drive, Saskatoon, Saskatchewan, Canada, S7N 5A8, Canada; bart.lardner@usask.ca*

Methane (CH₄) is a greenhouse gas (GHG) with a global warming potential 28 times that of carbon dioxide. Due to methane's contribution to the agriculture emission footprint, investigating mitigation strategies are needed. Condensed tannins (CT) are secondary plant polyphenol compounds, when fed at low levels (5-10 g/kg DM) to ruminants can increase rumen by-pass protein, enhance animal performance and reduce enteric methane production. Several CT legumes in pasture grazing systems include sainfoin (*Onobrychis viciifolia* Scop.), white prairie clover (*Dalea candida* Michx. ex Willd), purple prairie clover (*Dalea purpurea* Vent.), and birdsfoot trefoil (*Lotus corniculatus*). Fermentation of carbohydrates in ruminant diets results in volatile fatty acids, microbial protein synthesis, accompanied by the release of gases such as carbon dioxide and CH₄. Methane is synthesized by anaerobic archaea coupled with bacteria, protozoa and fungi in the rumen ecosystem. Several studies have reported the effects of tannins as alternative feed additives to modify rumen fermentation, improve animal production and mitigate CH₄ production. Opportunities for reducing rumen methanogenesis through dietary inclusion of tannins will be discussed.

Session 01

Theatre 6

Enteric methane reduction in ruminants by early-life interventions*D.P. Morgavi**INRAE, Centre Auvergne-Rhône-Alpes, Theix, 63122 Saint Genès Champanelle, France; diego.morgavi@inrae.fr*

Modulating the microbial colonisation of the developing rumen towards communities that produce less methane is gaining attention as a way to reduce the carbon hoofprint of ruminants. The rationale is that in the first days and weeks after birth, when the gastrointestinal tract is colonised and microbial consortia are installed, inducing changes in the rumen microbiota can have a lasting effect later in life. The rumen microbiota in early life can be modulated by management and targeted interventions that favour phenotypes of interest, such as decreased methane emissions. Modulation options include: allowing contact with dams or mature conspecifics with a desirable microbiota, inoculation with gastrointestinal contents (engraftment) obtained from mature conspecifics, diet and supplementation with direct-fed microbials, prebiotics and feed additives. To modulate methane emissions, the use of nutritional strategies such as feed additives and supplements have been most studied. Two different types of approach can be distinguished in terms of their mechanisms of action: one using feed supplements or additives that affect the microbial ecosystem in a general way, and the other using specific inhibitors of methanogens or the methanogenesis pathway. The presentation will provide an update on the latest information in this field, focusing on its potential and the challenges ahead.

Sustainable intensification of animal production with silvopastoral systems*J. Chára**CIPAV, Centre for Research on Sustainable Agriculture, Carrera 25 # 6-62, 760046. Cali, Colombia; julian@fun.cipav.org.co*

Livestock production has the challenge of generating more food and protein to fulfil the global growing demand and, at the same time, reducing its climatic and environmental footprint. Animal production occupies a great portion of the ice-free land both directly in grazing areas, and indirectly to generate feed and other inputs. Silvopastoral systems (SPS) have been proposed as part of nature-based solutions to reverse the negative environmental impact of cattle ranching and increase animal production and economic performance at the same time. SPS are agroforestry arrangements that combine trees, shrubs, forage production and animal grazing on the same land. The trees in SPS provide shade, shelter, and fodder for animals, and generate income from the sale of products, such as fruits, nuts or timber. SPS produce more edible dry matter and nutrients per hectare and increase milk or meat production while reducing the need of chemical fertilizers and concentrate feeds, thus improving profitability. In addition to the improved production, the presence of shrubs and trees in these arrangements have demonstrated effects on biodiversity by creating more complex habitats for wild animals and plants, harbouring a richer soil biota and increasing landscape connectivity. In farmed landscapes, SPS provide food and cover for birds and other organisms, serving as wildlife corridors where unique species assemblages can be found. The tree component has also demonstrated effects on soil physical, chemical and microbiological properties since they provide more layers of vegetation that transform solar energy into biomass that is deposited on the soil in the form of leaves, branches, fruits, legumes and exudates. They contribute also to increase carbon sequestration, reduce enteric methane emissions due to improved nutrition and the presence of fodder legumes, and reduce GHG emission from soil due to the reduction of fertilizer use and enhanced soil microbiota. SPS have gained interest in several parts of the world where they are used for improving animal welfare and comfort of livestock combined with fruit or timber production. The improved efficiency of the system provides an opportunity to release land for restoration and production of other crops thus contributing to sustainability.

Session 01**Theatre 8****Sustainability of low-input livestock systems***A. Mottet**FAO, Viale delle Terme di Caracalla, 00153, Italy; anne.mottet@fao.org*

Livestock farming is found in most ecosystems around the world. Thanks to the diversity of animal genetic resources, livestock farmers have been able to live in areas where there is no alternative livelihood. Hundreds of millions of families rely on small-scale and low-input livestock production and pastoralism. They provide food and essential nutrition, manure, animal traction, transport and income. They have a key role to play in particular for women's empowerment and youth employment, both in rural and urban areas. While demand for meat, milk and eggs is increasing, low-input livestock systems have a key role to play for the sustainable development of the sector. Five main areas of environmental priority and inputs can be considered: biodiversity, water, land use, soils and climate change. The type of feeding system is arguably one of the most important drivers for the sustainability of livestock in all five areas. Livestock have the ability to convert grass and swill into protein and the efficiency in this conversion varies between production systems. For example, grazing systems in non-OECD countries need an average 200 g of edible plant protein to produce 1 kg of edible animal protein. The entire livestock sector uses about 2.5 billion hectares, 77% of which are grasslands, and a large part of this can be considered non-cultivable and therefore only valuable if grazed by animals. While low-input livestock systems contribute to GHG emissions, they also have significant potential for climate change mitigation through the adoption of best practices for the reduction of emissions, in feed management but also herd and manure management. However, while most of the sector's growth has so far benefited rather large-scale production systems, access to technologies, services and markets is essential if small holders are to make a bigger contribution. Targeted innovative public policies are required to enhance this access, and social sustainability should be considered as important as economic and environmental sustainability in this development.

Agroecological transformation of tropical livestock production through integrating improved forages*A.M.O. Notenbaert**Alliance of Bioversity and CIAT, Shinyalu Road 88, 00100, Kenya; a.notenbaert@cgiar.org*

Livestock production systems play a crucial role in meeting the global demand for animal protein, but they also contribute to global warming, deforestation, biodiversity loss, water use, pollution and land/soil degradation. This paper argues that, although the environmental footprint of livestock production presents a real threat to planetary sustainability, also in the global south, this is highly contextual. Under certain context-specific management regimes livestock can deliver multiple benefits for people and planet. We provide evidence that a move towards sustainable livestock production is possible and could mitigate negative environmental impacts and even provide critical ecosystem services, such as improved soil health, carbon sequestration and enhanced biodiversity on farms. To facilitate the agroecological transformation, it is suggested that cultivated forages – consisting of grasses, legumes, and trees – many of which have been enhanced through selection or breeding, be utilized within integrated crop-tree-livestock systems. However, to realize this, a multi-stakeholder approach is needed, involving farmers, researchers, policymakers, and consumers.

Session 01

Theatre 10

Livestock-wildlife conflicts: a struggle for land use and conservation in the U.S. Mountain West*J.B. Taylor and H.N. Wilmer**Agricultural Research Service, U.S. Department of Agriculture, 19 Office Loop, Dubois, Idaho 83423, USA; bret.taylor@usda.gov*

The upper Mountain West of the United States (U.S.) is home to nearly one-third of the national sheep inventory and generates one-third and one-half of the total U.S. lamb crop and wool revenue, respectively. Unfortunately, the Mountain West breeding ewe inventory has declined 37% since 2002 compared with a 26% decline experienced in the remaining states. To date, this sheep depopulation trend has not slowed, indicating obstacles unique to the Mountain West which are not experienced elsewhere. Most sheep production in the Mountain West is transhumant and largely depends on grazing access to U.S. government-owned ('public') rangelands. These rangelands consist of mainly indigenous vegetation, are managed as natural ecosystems, and provide distinct, critical ecosystem services. Specifically, of great interest to the public, is the provisioning of abundant wildlife habitat. However, over the last 100 years, extensive conversion of rangelands to croplands, exurban or energy development, and fire suppression have resulted in a substantial loss of wildlife habitat, thus creating competing ideologies for how remaining rangelands should be managed with regard to wildlife conservation. Some wildlife-focused paradigms embraced by a vocal public minority explicitly exclude livestock grazing on all public lands. Such exclusion negatively impacts the operational capacity of Mountain West sheep ranches and land management capability of government agencies, thus posing serious threats to the U.S. sheep industry and its contributions towards national food security, rural community viability, and rangeland conservation. Unfortunately, in the debate surrounding public land use and wildlife-livestock conflicts, a common foe to all – climate change – is somewhat overlooked. Accordingly, opposing groups must come together to consider the 'real' issues and collectively work towards developing agroecological solutions that perpetuate resilient, multi-use rangelands in U.S. Mountain West.

Community-based breeding programs (CBBP): platforms for genetic improvement and biological discoveryJ.M. Mwacharo^{1,2}, A. Haile² and B. Rischkowsky²¹SRUC and CTLGH, Roslin Institute Building, Midlothian, EH25 9RG, United Kingdom, ²ICARDA, Small Ruminant Genomics, P.O. Box 5689, Ethiopia; j.mwacharo@cgiar.org

One major constraint facing smallholder farmers in developing countries has been low farmgate productivity attributed to lack of fit-for-purpose breeding programs and technical knowhow. Scientific discovery in smallholder low-input systems has also lagged behind due to dearth of quality data. Conventional breeding programs with centralised nucleus flocks have been implemented as a mitigating strategy but have had limited or no success due to small flock sizes and limited resources, while providing data only from the nucleus flocks. CBBPs are low-cost operations that are implemented by farmers who set their breeding objectives collectively and have proved to be a sustainable alternative to conventional breeding and are gaining popularity among smallholder farmers in developing countries. CBBPs have resulted in increased productivity and profitability in the target breeds without undermining their resilience and genetic integrity, and in household income in the absence of expensive interventions. A key element of CBBPs is that farmers are trained on better and alternative selection approaches, farmers are organised in groups and pool their flocks to broaden the genetic base, a constant interaction between farmers and scientists to evaluate genetic progress and, performance recording that allows for genetic evaluations to select individuals of high genetic merit to sustain genetic progress. CBBPs are making it possible to obtain datasets that have been challenging and almost impossible to collect in smallholder farms. They are also providing the infrastructure that makes it possible to test the application of cutting-edge genomic tools and technologies in smallholder farms in developing countries. CBBPs therefore are offering a blueprint for learning and knowledge exchange between farmers and, between farmers and researchers for the improvement of animal productivity in smallholder farms and in generating information that enrich the existing body of scientific knowledge. In our talk, we shall discuss and demonstrate using real-world data and studies how CBBPs have been a cornerstone of breeding improvement and scientific discovery.

Session 02

Theatre 1

'Sustainable livestock systems': what does this mean? – welcome and introductionF. O'Mara¹ and M. Lee²¹Animal Task Force, 149 rue de Bercy, 75012 Paris, France, ²Harper Adams University, Newport, Shropshire, TF10 8NB, United Kingdom; mail@animaltaskforce.eu

The EU will introduce a Framework Law on Sustainable Food Systems in 2023. In this context, what are sustainable livestock systems, which common ground could they have and how will they differ from region to region? Policymakers, civil society, NGOs, consumers, the agri-food sector and scientists all want to better define and contribute to more sustainable livestock systems. However, there is no clear definition of what a sustainable livestock system is, how to assess the state of existing systems, and the direction in which they must evolve. In the meanwhile, food security has grown in importance because of the recent crisis occurring in Europe. How to combine food security, resilience and sustainability should be at the centre of research and innovation and policy initiatives. This topic will explore the key attributes of sustainable livestock systems, the trade-offs and synergies between different aspects of the systems and their interactions with other parts of the food system. It will also explore how current livestock systems can evolve to be more sustainable and will examine methodologies to assess the sustainability of livestock systems: (1) the benefits and trade-offs of livestock systems from an economic, social and environment viewpoint; (2) Assessing the sustainability of livestock systems and its different levels; (3) barriers for young farmers to enter livestock farming systems; (4) The role of livestock systems in rural economies and job creation; (5) the role of livestock systems in providing nutrient-rich and affordable foods; (6) sustainability and healthy and robust livestock; (7) livestock systems in the context of climate change and the effects of heat and water shortage; (8) intrinsic qualities of livestock products in food and non-food uses; (9) the place of animal welfare concerns in sustainable livestock systems and benefits/trade-offs with the three main pillars of sustainability; (10) contribution to culture; (11) tools to assess and improve sustainability; e.g. development of new metrics, feeding and breeding.

Friend or Foe? The role of animal-source foods in healthy and environmentally sustainable dietsL. Merbold¹, T. Beal², C. Gardner³, M. Herrero⁴, L. Iannotti⁵, S. Nordhagen² and A. Mottet⁶¹Agroscope, Reckenholzstrasse 191, 8046 Zürich, Switzerland, ²GAIN, Rue Varembe 7, 1202 Geneva, Switzerland, ³University of California, 2201 North Hall, Santa Barbara, USA, ⁴Cornell University, 340 Tower Road, Ithaca, USA, ⁵Washington University, One Brooking Drive, St. Louis, USA, ⁶FAO, Viale delle Terme di Caracalla, 00153 Roma, Italy; lutz.merbold@agroscope.admin.ch

Discussions around the role of animal-source foods (ASFs) in healthy and environmentally sustainable diets are often polarizing. Our study reviews the evidence on the environmental and health benefits and risks of ASFs, focusing on primary trade-offs and tensions. We further aim at summarizing the evidence on alternative proteins and protein-rich foods in such diets. ASFs are rich in bioavailable nutrients commonly lacking globally and can make important contributions to food and nutrition security. Populations in Sub-Saharan Africa and South Asia could benefit from increased consumption of ASFs through improved nutrient intakes and reduced undernutrition. In areas where consumption is high, processed meat should be limited, and red meat and saturated fat should be moderated to lower noncommunicable disease risk – this could also have co-benefits for environmental sustainability. Evidence shows that ASF have a large environmental impact; yet, when produced at the appropriate scale and in accordance with local ecosystems and contexts, ASFs can play an important role in circular and diverse agroecosystems. Under these circumstances, they can be beneficial for restoring biodiversity and degraded land and mitigate greenhouse gas emissions from food production. In summary, the amount and type of ASF that is healthy and environmentally sustainable will depend on the local context and health priorities. This will change over time as populations develop, nutritional concerns evolve, and alternative foods from new technologies become more available and acceptable. Efforts by governments and civil society organizations to increase or decrease ASF consumption should be considered in light of the nutritional and environmental needs and risks. Policies, programs, and incentives are needed to ensure best practices in production, curb excess consumption where high, and sustainably increase consumption where low.

Session 02

Theatre 3

The economic sustainability of dairy production systems in the EU and beyondF. Thorne¹, E. Dillon¹, T. Donnellan¹, P. Jeanneaux², R. Jongeneel³ and L. Latruffe⁴¹Teagasc, Department of Agricultural Economics and Farm Surveys, Ashtown, Dublin. D15 KN3K, Ireland, ²VetAgroSup, UMR Territoires, 89 avenue de l'Europe, 63370 Lempdes, France, ³WUR, Department of Social Sciences, Wageningen Economic Research, Hollandseweg 1, 6706 KN Wageningen, the Netherlands, ⁴INRAE, Univ. Bordeaux, CNRS, BSE, UMR 6060, 33600 Pessac, France; fiona.thorne@teagasc.ie

The economic sustainability of farming is one of the core objectives of the Common Agricultural Policy (CAP), as set out in the objectives of the Treaty on the Functioning of the EU (TFEU). Whilst a number of TFEU provisions lay down objectives pertaining to the multi-dimensional aspects of sustainability, the purpose of this paper is to examine the current economic sustainability of EU livestock production systems, using the dairy sector as a case study. Whilst economic sustainability is identified as a clear policy objective, the means to measure this term are not clearly identified in policy or literature. Almost all contributions to date, define the concept in a different manner. Hence, the literature relating to defining the theory and practise of measuring farm level economic sustainability across countries or regions will be reviewed in this paper. Based on an agreed set of indicators, harmonised data sources will be consulted to examine the situation with regards to comparative economic sustainability, both within the EU and internationally. A mix of primary and secondary data sources will be reviewed to draw inferences regarding the drivers of economic sustainability. Whilst seminal papers in the literature relating to the drivers of performance will be reviewed, key case study regions where farm level data is available will also be examined using parametric and non-parametric approaches. Finally, the potential role of policy reform in impacting economic sustainability and the evolving role of policy direction will be considered.

Methods to assess the sustainability of livestock systems: challenges and opportunities*E. De Olde^{1,2}**¹Wageningen University & Research, Wageningen Economic Research, P.O. Box 29703, 2502 LS The Hague, the Netherlands, ²Wageningen University & Research, Animal Production Systems group, P.O. Box 338, 6700 AA Wageningen, the Netherlands; evelien.deolde@wur.nl*

Assessing the sustainability performance of livestock systems is becoming increasingly important, not only in response to pressure from NGOs or consumers, but because of a variety of reasons. First of all, given the substantial environmental impact of the livestock sector, sustainability assessments are seen as a key step to identify possible pathways for improving the environmental as well as economic and social performance of livestock systems. Research into the trade-offs and synergies of (interventions in) livestock systems plays an important role in this. Second, gaining insight into the sustainability practices and performance of farms is increasingly part of corporate sustainability programs and certification schemes which aim to differentiate themselves and establish a market for more sustainable products. In fact, actors in the agri-food sector are increasingly formulating sustainability goals, for instance with regard to the reduction of greenhouse gas emissions. Meanwhile, the use of sustainability indicators in policy (for instance through payments based on sustainability performance) and finance (through discounts on land rent or interest rates) is becoming more prominent. Despite this increased interest, there are certain persistent challenges in the development and use of sustainability methods and indicators. This talk gives insight into these challenges as well as the key characteristics and trade-offs of a variety of methods. Which sustainability issues and indicators are generally included, and which tend to be ignored? What are opportunities for methods to be improved, and options for harmonizing methods? The talk concludes with a reflection on the implication of these challenges and opportunities for future directions in the field of sustainability assessments of livestock systems.

Session 02

Theatre 5

SustAinimal – a multi-actor knowledge centre for livestock in future Swedish food systems*M. Hetta¹, S. Agenäs², D.J. De Koning², H. Oscarsson³, P. Peetz Nielsen⁴ and A. Wallenbeck²**¹Swedish University of Agricultural Sciences, 901 83 Umeå, Sweden, ²Swedish University of Agricultural Sciences, Box 7023, 750 07 Uppsala, Sweden, ³Vreta Kloster AB, Klustervägen 11, 585 76, Vreta kloster, Sweden, ⁴Research Institutes of Sweden, Scheelevägen, 17, 223 63 Lund, Sweden; marten.hetta@slu.se*

SustAinimal is a novel knowledge centre created to identify and develop the future role of livestock production for increased sustainable and competitive food production in Sweden. The activities aim to evaluate the potential contributions to ecosystem services and loads as well as enhancing the competitiveness and resilience of the sector. The organization is a resource for decision-makers and stakeholders. The focus areas include grazing and fodder production, digitalization, governance for transition, and regional applications. The partners in the project include academia, research institutes, companies, industry organizations and governing authorities, working together along the value chain from farm to fork. SustAinimal has its own academy with special focus on PhD students and post-docs to ensure that the next generation of livestock scientists are well equipped to contribute to transdisciplinary research processes and knowledge for future challenges. Sweden is a relatively large and long country from North to South and thereby there are different settings for food production, depending on local conditions and differences in proximity to consumers. The work in SustAinimal focuses on three geographical regions for investigations of the importance of local conditions for sustainability and competitiveness in future food systems. An important part of Sweden's agricultural land is currently used for production of animal feed. The intersection between plant cultivation, land use and animal husbandry is therefore highlighted in the regional activities. The centre monitors the supply of food and ecosystem services and evaluate their impact on climate, environment and social sustainability. The project SustAinimal includes different regional living labs for co-creation of innovative future land management practices. The living labs will provide new biodiversity assessment tools and aims to increase the awareness of the role of grazing animals in future food systems.

At least five of the UN's 17 Sustainable Development Goals (SDG) can be supported by animal breeding. SDG2: 'achieve food security and improve nutrition': produce more cost-efficient animals, which makes animal source food (ASF) an affordable source of essential amino acids and micronutrients for a wider group of consumers. SDG3: 'Ensure healthy lives for all': produce leaner and more resilient animals that produce food with a lower fat content, and that need fewer antibiotics. SDG12/13: 'ensure sustainable consumption and production patterns; combat climate change and its impacts': improve the efficiency of ASF production by creating animals that are more feed-efficient and produce more high quality protein, and by improving animal health to reduce losses; all of this results in reduced greenhouse gas emission. SDG15: 'halt biodiversity loss': implement responsible management and conservation of genetic resources. From another point of view, sustainability of livestock production follows the same Triple Bottom Line 'PPP' pattern as any other production system: People, Planet & Profit – but there is a fourth element, representing the animals themselves (so, Pigs-Poultry-Puminants-Phish production follows a PPPP pattern). Note that this element does not feature in the UN's SDGs. Animal breeding can contribute significantly to the interests of all P elements, and we discuss two of these: 'Planet' is about: (1) biodiversity; and (2) environmental load and climate change, 'Pigs-etc' is about: (3) animal health; and (4) animal welfare. 'People' is about social justice, with little connection to livestock breeding technology; a possible case would be biopiracy which is more a political and economic issue than a technical one, and more relevant in the plant breeding sector. Influencing 'Profit' by breeding has been covered intensely since selection indexes were designed – there is no need to repeat that here apart from the imminent role of carbon shadow prices in livestock production. It must be borne in mind throughout that 'sustainability will always be a matter of more or less: it can never be an absolute goal'.

Session 02

Theatre 7

Panel discussion (morning)

A. Granados and A.S. Santos

Animal Task Force, 149 rue de Bercy, 75012 Paris, France; mail@animaltaskforce.eu

Panel discussion with speakers and the audience, moderated by Ana Granados & Ana Sofia Santos, ATF Vice-Presidents (45 min.).

Use of grazing with dairy goats to design sustainable food systems*H. Caillat, E. Bruneteau and B. Ranger**INRAE UE FERLus, Les Verrines, 86600 Lusignan, France; hugues.caillat@inrae.fr*

France is the largest producer of goat's milk in Europe with about 550 million litres collected. Today, French goat farms have a low feed self-sufficiency (61%), increasing economic risks and feeding costs. To improve sustainability, a larger use of grazing, in particular of legume-based pastures, might be a solution. FERLus-PATUCHEV is an experimental farm of INRAE based in Lusignan (New Aquitaine- 46.43°N, 0.12°E) whose objective is to assess and propose innovative, low input and sustainable goat farming systems by a greater use of grazing. This platform aimed at evaluating 2 independent farmlets about of 60 Alpine goats differing in kidding period: February (F) or September (S). The area for each farmlet was of 10.4 ha and was divided between temporary multi-specific pastures (7.4 ha) and a cereal-protein crops mixture (3 ha). The study period was from 2020 to 2022. Dairy goats number was higher for the F farmlet (62.3 vs 59.8). Average days of grazing was 150 days/year for the F goats, i.e. +19 days/year than the S goats. Average feed self-sufficiency of F farmlet was 83.6%, i.e. +3.9% than S farmlet. Average concentrates quantities were higher for the S (340 vs 286 kg/goat/year), despite a large fodder proportion in the ration for the 2 farmlets (68.4 vs 70.2%). Average milk production per goat and average milk solids per hectare were higher for the F farmlet (818 vs 739 l/year; 365 vs 319 kg). This pasture-based farms are net producers of protein because 82% of the proteins and 81% of the energy consumed by the goats were not edible by humans. Other complementary studies have demonstrated that bulk milk from goats eating fresh grass was richer in nutriment for humans (fatty acids and B6 B12 E vitamins). By limiting the use of resources and producing food for human, these grazing dairy goat farms, in particular with kidding in February, make it possible to realise more sustainable food systems by limiting the feed/food competition. However, the main limit of these systems is the parasitism management because we have observed a continue increase of the annual excretion of strongyles (+24.8% per year since 10 years). The second point is the lack of attractiveness in France for the consumption of kid meat, which would however improve the efficiency indicators of feed-food competition.

Session 02

Theatre 9

Benefits and limits of farm animals to control herbage mass, pests and weeds in orchards: a review*G. Maillet¹, A. Dufils², F. Angevin³, S. Ramonteu¹, J.L. Peyraud⁴ and R. Baumont⁵**¹ACTA, 149 rue de Bercy, 75012 Paris, France, ²INRAE, UMR ECODEV, 84000 Avignon, France, ³INRAE, UR Info&Sols, 45000 Orléans, France, ⁴INRAE, UMR Pegase, 35590 Saint-Gilles, France, ⁵INRAE, UMR Herbivores, 63122 Saint-Genès-Champagnelle, France; rene.baumont@inrae.fr*

One of the levers of the agroecological transition is the diversification of systems, in particular by reintroducing animals into systems specialised in field crops or arboriculture. In this study, we focus on the introduction of animals into fruit and vineyard plots. One of the assumed benefits of introducing animals into the plots is the management of pests through biological regulation. The objective of our study, which analysed 66 documents (23 scientific and 18 technical articles, 25 other documents), was to make a comparative synthesis of the effects of the introduction of different animals (sheep, goats, cattle, poultry, pigs and rabbits) on the control of herbage mass, weeds and pests in vineyards and orchards. Sheep is a traditional and efficient solution for managing grass cover in orchards and vines; and cows are traditionally used in high-stem orchards like 'pré-vergers' or coconut plantations. Geese are herbivorous poultry that are easy to introduce into vines or orchards and chickens or guinea fowl a possible solution but which can lead to the appearance of bare soil. In contrast, goats and pigs are not very well recommended for managing grass cover because of the damage they cause to trees and soil respectively. Several benefits can be expected from the introduction of animals on pest and disease management. For rodent management, the destruction of rodent burrows by trampling is the most frequently reported mechanism. Animals can also have a direct or indirect effect on the management of insects and other invertebrates. For example, some animals, in particular poultry are heavy consumers of larvae, insects or mollusks. The introduction of animals into orchards can also play a prophylactic role. For example, the consumption or trampling of dead leaves or fallen fruits can reduce the scab inoculum. Introducing animals can be a solution for managing weed, pest and diseases and lead to reduction of chemical treatments. However, not all species can be equally used and some mechanisms of pest and disease control remain unknown.

A new concept for agro-ecological efficiency at different scales of ruminant production systems*H. Nguyen-Ba, P. Veyssset and A. Ferlay**Université Clermont Auvergne, INRAE, VetAgro Sup, UMR 1213 Herbivores, Theix, 63122 Saint-Genès-Champanelle, France; hieu.nguyen-ba@inrae.fr*

Improving efficiency of ruminant production systems is deemed essential to achieve their sustainability. But does efficiency *per se* really mean sustainability? The efficient high-input systems that intensively breed high-performing animals in confined housing and use nutrient-dense diets are increasingly criticized for accelerating feed-food competition, waterbody contamination, biodiversity loss, animal welfare concerns and rural unemployment, etc. Agroecology has emerged as a promising alternative for current farming. Applying principles of ecology on agriculture such as relying on biodiversity and interactions among components of agroecosystems allows to close nutrient cycle and boost production capacity. It aims to reduce dependencies on synthetic and fossil resources and brings more added values to farmers, society and nature. However, under the simplistic view of current efficiency concept (defined as a mere ratio between outputs and inputs), agroecological ruminant systems are less efficient and have more environmental impacts per kg of products than conventional counterparts. Moreover, numerous studies had showed that it is difficult to maintain at higher scales of ruminant farming systems the efficiency's gains obtained at animal scale. The aim of this study was thus to conceptualize a more holistic criteria for efficiency at different scales of agroecological ruminant systems (i.e. agroecological efficiency). Based on literature review and expert's counsels, we propose that agroecological efficiency at the system scale is a combination of production, environment, economy and farmer's work. More precisely, agroecological efficiency can be improved based on 5 principles: (1) reduce the use of intermediate consumptions (purchased goods and services), (2) reduce pollution and losses by closing the nutrient cycle within the system, (3) reduce feed-food competition, (4) increase the added value and the remuneration of the farm workers in relation to the gross value of the production and (5) increase the 'net' labour productivity. We then adapt this concept to define specific criteria for improving efficiency at herd and animal scales that can potentially avoid the potential losses of efficiency due to changing scales.

Session 03

Theatre 1

Issues and perspectives in genomic selection in limited size breeds: the case of Italian Simmental*N.P.P. Macciotta¹, L. Degano², D. Vicario² and A. Cesarani¹**¹Università di Sassari, Dipartimento di Agraria, Viale Italia 39, 07100 Sassari, Italy, ²ANAPRI, Via Ippolito Nievo n. 19, 33100 Udine, Italy; macciott@uniss.it*

Genomic selection has had a huge impact in the dairy cattle breeding industry, particularly in large breeds as Holsteins, with strong effects on the genetic trend and on the reduction of the generation interval. However, small size breeds like dual purposes or local breeds have already implemented GS programs although they have to cope with specific issues. A case is the Italian Simmental (IS) cattle breed that has started genomic evaluations in 2011. A first main issue was represented by the curse of dimensionality, i.e. the marked unbalance between animals genotyped and markers (usually the medium density 50K panel). In the original two-step approach, this issue has been addressed by reducing the prediction dimensionality through the Principal Component Analysis. This approach allowed to reduce the dimensionality of predictors of about 90% maintaining the same GEBV accuracy of the whole SNP panel. A further strategy to overcome this issue has been the exchange of genotypes with related cattle bred as the German and Austrian Simmental populations. The next step has been the implementation of the single step GBLUP procedure, that was carried out with a project that involved the main cattle breeds farmed in Italy in order to harmonize genomic evaluations. The ssGBLUP is currently implemented in the GS of IS. The GS has impacted the accuracy of GEBV and the genetic trend. Other co-products of the GS breeding program of the IS are biodiversity studies, in particular the comparison of its genomic structure with other breeds of the Simmental group farmed in Europe. Genomic inbreeding has been also investigated. Future challenges will be represented by the consideration of novel phenotypes and the improvement of sustainability. Among them, feed efficiency (i.e. residual feed intake) and environmental adaptation are under investigation. Proxies provided by precision livestock farming, such as milk infrared spectra, could help to predict phenotypes on large scale that can be used in the breeding program. Finally, the role of epigenetics in the mechanisms of adaptation, in particular for thermotolerance, and its possible consideration in the genetic model, is an emerging topic.

Impact of genomic selection on genetic diversity in five European local cattle breedsJ.J. Winding¹, T.H.E. Meuwissen², P. Croiseau³, G. Restoux³ and R. Bonifazi¹*¹Wageningen University & Research, Animal Breeding and Genomics, Droeendaalsesteeg 1, Radix, 6700 AH Wageningen, the Netherlands, ²Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Oluf Thesens vei 6, 1433 Ås, Norway, ³Université Paris-Saclay, INRAE, AgroParisTech, Jouy-en-Josas, 78350, France; jack.winding@wur.nl*

Genomic selection (GS) has revolutionized animal breeding and in general accelerated genetic gains in cattle breeding programs. However, in Holstein and Jersey cattle, the implementation of GS was accompanied by increases in inbreeding rates. Similarly to these popular breeds, GS has been implemented also for smaller populations and local breeds. In this study, we investigated inbreeding trends in five local cattle breeds from three European countries and evaluated the possible impact of implementing GS on breeds' genetic diversity. The five breeds evaluated were: Abondance, Tarantaise, Vosgienne (from France), Norwegian Red (from Norway), and MRIJ (from the Netherlands). We estimated trends in inbreeding and kinship based on pedigree and genomic information (available as medium or high-density SNP genotypes), before and after the introduction of GS. The number of available genotyped animals for each breed was 16,478, 8,589, 4,474, 51,799, and 4,997, for Abondance, Tarantaise, Vosgienne, Norwegian Red, and MRIJ, respectively. Results show that inbreeding trends did not differ between pedigree-based or DNA-based estimates. In all five breeds, periods with higher and lower inbreeding rates occurred across time. However, no clear trend could be observed after the introduction of GS in any of the breeds. Inbreeding rates either slightly increased (MRIJ, Abondance), remained stable (Tarantaise, Vosgienne), or decreased (Norwegian Red). Such small deviations could be due to GS allowing for shorter generation intervals, screening for a larger number of individuals compared to traditional breeding schemes, and preselection of a smaller number of sires. Ultimately, our results suggest that the genetic management of these breeds is more important in determining inbreeding rates than the implementation of GS per se. This project has received funding from the European Union's Horizon 2020 Programme for Research & Innovation under grant agreement n°101000226.

Accounting for sequential genomic selection in broiler breedingJ. Hidalgo¹, D. Lourenco¹, S. Tsuruta¹, V. Breen², W. Herring² and I. Misztal¹*¹The University of Georgia, Animal and Dairy Science Department, 425 River Rd, Athens, GA 30602, USA, ²Cobb-Vantress Inc., 4703 US-412 E, Siloam Springs, AR 72761, USA; jh37900@uga.edu*

Sequential selection occurs in broiler breeding; in the first selection stage, the best individuals for growth are selected for reproduction. These birds are later evaluated for reproductive traits in a separate evaluation for time efficiency; however, excluding data from the broiler phase can yield inaccurate and biased predictions. This study aimed to find the most accurate, unbiased, and time-efficient approach for jointly evaluating broiler and reproductive traits. Broiler data was incorporated sequentially into the evaluation for reproductive traits to assess the impact on accuracy, bias, and dispersion (computed using the Linear Regression method) of predictions for hens from the last two breeding cycles and their sires. Data included a pedigree with 577K birds (146K genotyped), phenotypes for three reproductive (R1, R2, R3; 9K each), and four broiler traits (up to 467K). To find the most time-efficient approach, we evaluated three core definitions for the algorithm of proven and young: a core set with 19K, including parents and young animals, and two random core sets with 7K and 12K animals. The reproductive evaluation (RE) included pedigrees, genotypes, and phenotypes for reproductive traits of selected animals; in RE2, we added their broiler phenotypes; in RE_BR, broiler phenotypes of non-selected animals, and in RE_BR_GE, their genotypes. From RE to RE_BR_GE, accuracy changes were null or negligible for R1 (0.51 in hens, 0.59 in roosters) and R3 traits (0.47 in hens, 0.49 in roosters) that had heritability close to 0.3. For R2 trait (heritability=0.02), accuracy increased in hens (roosters) from 0.4 (0.49) to 0.47 (0.53). The bias of GEBV for hens (roosters), in additive SD units, decreased from 0.69 (0.7) to 0.04 (0.05) for R1, 1.48 (1.44) to 0.11 (0.03) for R2, and 1.06 (0.96) to 0.09 (0.02) for R3. The dispersion was stable in hens (roosters) at ~ 0.93 (~ 1.03) for R1, improved from 0.57 (0.72) to 0.87 (1.0) for R2 and from 0.8 (0.79) to 0.88 (0.87) for R3. Using data from all selection phases is advised in breeding programs with sequential selection. A random core with 7K birds halves computing time, maintaining the quality of predictions.

Changes in the genome due to genomic selection in two pig populationsY.C.J. Wientjes¹, M.P.L. Calus¹, P. Bijma¹, A.E. Huisman² and K. Peeters²¹Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands,²Hendrix Genetics B.V., P.O. Box 114, 5830 AC Boxmeer, the Netherlands; yvonne.wientjes@wur.nl

The implementation of genomic selection in breeding programs has resulted in more genetic gain. However, it has also resulted in faster changes in the genome compared to pedigree selection. Our aim here was to investigate the changes in allele frequency and in the results of genome-wide association studies (GWAS) from 2015 to 2021 in two commercial sow lines undergoing genomic selection. For line A, genotypes of 44,054 segregating markers were available for 2,616 to 7,689 animals per birth year, with a total of 40,075 animals. For line B, genotypes of 44,000 segregating markers were available for 921 to 4,995 animals per birth year, with a total of 23,487 animals. Moreover, phenotypes for eight traits under selection were available on a subset of the genotyped animals (Line A: 738-6,423 animals per trait per birth year; Line B: 406-3,965 animals per trait per birth year), including general production and reproduction traits. Over the seven birth years included in the dataset, absolute allele frequency changes up to 0.35 were observed in each line, with a few clear peaks. The regions with the largest changes in allele frequency did not overlap between lines. In each line, GWAS were performed separately for each birth year-trait combination. Results showed that the most significant peaks were present across birth years. This suggests that the changes in the genetic architecture (allele frequencies and allele substitution effects) were relatively limited over the seven years. Some significant GWAS regions overlapped between the two lines. Surprisingly, the largest changes in allele frequency were in regions where no significant markers were found related to any of the traits. Moreover, the correlation between significance levels of markers and changes in allele frequency was close to zero. Additional analyses will be performed to investigate whether the observed allele frequency changes were larger than expected due to drift in those populations. Altogether, those results indicate that the genome changes over the years, however, it is not yet clear to what extent this is due to genomic selection vs drift.

Session 03

Theatre 5

Practical approaches to managing increased homozygosity caused by genomic selectionC. Baes^{1,2}, C. Obari², B. Mäkinen², C. Rochus², C. Maltecca³, F. Schenkel² and F. Miglior^{2,4}¹University of Bern, Institute of Genetics, Vetsuisse Faculty, Bremgartenstrasse 109a, 3012 Bern, Switzerland, ²University of Guelph, Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, 50 Stone Road East, N1E 2W1 Guelph, Canada, ³North Carolina State University, Department of Animal Science, Polk Hall, 120 W Broughton Dr, NC 27607 Raleigh, USA, ⁴Lactanet Canada, Genetics, 660 Speedvale Ave W, N1K 1E5 Guelph, Canada; cbaes@uoguelph.ca

The mating of related animals is unavoidable in most breeding programs, but the rate of inbreeding in livestock populations has increased sharply since genomic selection, and will continue to increase. Intense directional selection, coupled with novel technologies, have allowed the industry to recognize and identify recessive disorders associated with increased homozygosity. Although the economic gains of intense directional selection strategies currently outweigh negative effects of inbreeding, long-term consequences of this approach are unclear. Several approaches have been proposed for estimating, monitoring and controlling inbreeding, including those using pedigree and genomic information, but these methods do not consider genetic relationships at the herd level. The objective of this study was to investigate the average genetic and genomic relationships of individual sires to the active cow population within each herd (within-herd R-value), and across herds (across-herd R-value). The active sire population had an average relationship ranging from 1 to 8.5% with the active cow population for the across-population pedigree-based R-value. In addition to this, pedigree-based R-values showed the average sires' relationship with cows ranged from 0.43 to 32.38% across herds. By quantifying the R-value on a within-herd basis, more meaningful herd-level information can be used by breeders in selection and mating programs to control inbreeding. Future work will focus on developing a monitoring system to rapidly identify, understand, and manage detrimental haplotypes in dairy. A rapid-response feedback system will be developed in which detrimental haplotypes will be identified before their frequency in the population increases.

Positive and negative effects of genomic selection

I. Misztal

University of Georgia, Animal and Dairy Science, Athens, GA 30605, USA; ignacy@uga.edu

Initial reports on genomic selection indicated strong improvement for major traits and even successful selection for antagonistic traits. Lately, mostly unofficial reports, indicate increased frequency of problems mostly related to fitness traits. The change can be explained by treating the genetic selection as a form of optimization according to a resource allocation theory. Traits in explicit or implicit selection index are improved while other traits change according to genetic correlations among the traits. After long selection, usually production traits improve while fitness traits deteriorate. At the gene level, genes associated with positive effects on major traits tend to fixation, and remaining genes with large effect exhibit pleiotropy. Strong negative effects of genetic selection on fitness traits were noted before the genomic selection, however, adding some of those traits in the index and constantly improving management counterbalanced the deterioration. Under genomic selection, the generation interval declined, and management modifications are not fast enough to alleviate the problems. If problematic traits are recorded in sufficient volume, an obvious solution is a stronger weight for these traits in the selection index. Otherwise, a stronger selection can be implemented for already recorded trait(s) that include problematic traits, e.g. productive life or survival. Setting up an appropriate selection index required to implement the changes requires current genetic parameters. Reports indicate that such parameters are changing: heritabilities for strongly selected traits decline while genetic correlations between production and fitness traits become more antagonistic. An accurate selection index would require new methods to estimate changing genetic parameters with large genomic data as current methods are not applicable. The genomic selection enters a new phase where possible negative effects need to be considered.

Theatre 7

Storing and analysing a million genomes on a desktop computerG. Gorjanc¹, J. Obsteter¹, G. Mafrá Fortuna^{1,2}, R. Ros-Freixedes³, M. Johnsson⁴ and I. Pocrnic¹

¹The Roslin Institute, University of Edinburgh, Easter Bush, EH259RG, Edinburgh, United Kingdom, ²Agricultural Institute of Slovenia, Hacquetova ulica 17, 1000 Ljubljana, Slovenia, ³Universitat de Lleida, Pl. de Víctor Siurana, 1, 25003 Lleida, Spain, ⁴Swedish University of Agricultural Sciences, Ultuna campus, 750 07 Uppsala, Sweden; gregor.gorjanc@roslin.ed.ac.uk

Whole-genome sequence data holds promise for a more informed and accurate study of genetic and phenotypic variation than the established SNP array genotypes. To deliver on this promise, we must efficiently manage and analyse this ultimate source of genomic variation. We describe a plan to manage the whole-genome sequence data from Roslin and Genus/PIC projects – almost a million haploid whole-genome sequences by leveraging pedigrees, SNP array genotypes, strategic sequencing, phasing, and imputation. The data includes 440,610 pigs and 46+ million sequence variants. Storing this data in a rectangular format in double precision requires ~150 TB of memory. While we can lower precision, storing and analysing such data has at least a quadratic complexity. By leveraging pedigree structure and inferred haplotypes, we can succinctly encode the data with tree sequence format in only ~15 GB. The tree sequence contains four key tables: haplotype identifications (nodes), relationships between ancestor-descendant haplotypes (edges), sequence variant loci (sites), and sequence variant alleles (mutations). We estimate the node table will contain ~170M haplotype identifications (~2.5 GB), the edge table will contain ~334M haplotype relationships (~10 GB), and the sites table will contain 46M sequence variant loci (~1 GB). These tables describe whole-genome sequences within the pedigree, while extending the tables with a deep ancestry beyond the pedigree will recapitate the tree sequence up to the most recent common ancestor for every genome region. For this last part, we expect the mutations table to contain ~46M biallelic mutations with ~1.4 GB. While this is a work in progress, we have already successfully inferred tree sequence from the 1000 bull genome data, where we have observed a more than 90% reduction in data storage. This novel way of storing and analysing whole-genome sequence data will pave the way for future biological discovery and more informed breeding.

Large scale screening for genetic defects in Holstein cattle using transmission disequilibrium test

F. Besnard^{1,2}, M. Boussaha¹, H. Leclerc³, J. Jourdain³, D. Boichard¹ and A. Capitan¹

¹INRAE, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²IDELE, 149 Rue de Bercy, 75012 Paris, France, ³ELIANCE, 149 Rue de Bercy, 75012 Paris, France; florian.besnard@idele.fr

In this study, we exploit the bovine population structure with large paternal progeny groups to detect loci with transmission disequilibrium, corresponding to multiple determinism defects frequently overlooked by other approaches. Transmission disequilibrium test (TDT) in large genotyped families is an efficient tool to detect these conditions. In a healthy progeny group, both haplotypes are expected to be inherited equally from the parent. In contrast, if the parent carries a deleterious abnormality, a deficit is expected in the surviving progeny carrying the haplotype associated with the mutation. For a recessive defect, this disequilibrium increases with the frequency of the deleterious allele in the population. For a defect with incomplete penetrance or mosaicism, the disequilibrium depends on these parameters. To conduct this study, we selected 401 Holstein bulls with at least 500 genotyped calves, resulting in a total of 532,864 calves. In each progeny, we observed the transmission of 20-SNP haplotypes and selected the haplotypes in significant transmission disequilibrium. The minimum number of calves required for a disequilibrium to be considered significant was determined from a binomial distribution adjusted for multiple testing. Of the 401 bulls tested, 321 bulls had at least one haplotype in disequilibrium. We then grouped all significant identical haplotypes and, for each 10 MB window, selected the most unbalanced haplotypes shared by at least five bulls. This resulted in a subset of 33 significant haplotypes. To detect candidate variants, we used whole genome sequences of 301 bulls. We selected 56 candidate variants (SNPs or structural variants in a 20 MB window around the peak) on the basis of their correlation with the haplotype status of each animal and their Sift score. We propose candidate variants for the previously known QTL in BTA 18 associated to viability and suggest candidate variants in BOLA region that could partly explain early mortality. The functional impacts of these variants are currently under investigation. FB is a recipient of a CIFRE grant with the financial support of ANRT and APIS-GENE.

Genomic selection strategies and their potential to maintain rare alleles and de-novo mutations

M.F. Schrauf, Y.C.J. Wientjes, H.A. Mulder and J. Vandenplas

Wageningen University and Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands; matias.schrauf@wur.nl

Sustainable breeding programs need to balance short-term genetic improvement with the conservation of genetic diversity. While genomic selection has considerably increased the genetic gain for many breeding programs, consequences on diversity can be less desirable. This is particularly the case for rare alleles and de-novo mutations, as markers used in genomic selection are generally not strongly associated to rare alleles. Moreover, genomic selection allows for the selection of young individuals without records, thereby ignoring the effects of de-novo mutations. To study possible solutions, we simulated populations of 1000 individuals subject to 50 generations of selection. We evaluated four selection strategies to identify the ones which best conserve favourable rare variants and de-novo mutations in the presence of additive and non-additive gene action. The genomic selection strategies represent a variety of approaches to balance between genetic improvement and diversity management and were: truncation selection, which only focuses on short-term gain; optimal contribution selection, which balances that gain with a constraint in the relatedness of the selected individuals; allele-reweighted selection, which upscales the effect of rare alleles in the breeding values; and constrained allele loss selection, a novel strategy which balances short-term gain with a constraint on the reduction in frequency of rare alleles estimated to be favourable. Systematic differences between the strategies were not observed for traits with non-additive gene action. For the trait under additive gene action, allele-reweighted selection obtained a higher genetic gain than truncation selection while preserving a similar level of genetic variance. Meanwhile, constrained-allele-loss selection obtained a similar genetic gain than truncation selection while accumulating a higher number of favourable de-novo mutations. These and similar strategies may contribute to the sustainable long-term use of genomic selection. This project has received funding from the European Union's Horizon 2020 Programme for Research & Innovation under grant agreement n°101000226.

Genomic prediction with selected sequence variants in gestation length of New Zealand dairy cattle

Y. Wang, K.M. Tiplady, E.G.M. Reynolds, M.A. Nilforooshan, C. Couldrey and B.L. Harris

Livestock Improvement Corporation, Research and Development, Private Bag 3016, Hamilton 3240, New Zealand; yu.wang@lic.co.nz

The increasing availability of whole genome sequence (WGS) data has opened up new opportunities for improving genomic prediction in livestock breeding. The aim of the study was to investigate the performance of genomic prediction combining a filtered Illumina50k single nucleotide polymorphism (SNP) panel, with a subset of informative sequence variants selected from a large genome-wide association study (GWAS). The study used gestation length phenotypes for 97,522 New Zealand admixed dairy cattle, where the gestation length for each calf was calculated as the difference between its dam's calving and mating dates in days. The animals were genotyped and imputed up to whole-genome sequence level with 16,122,291 variants. BOLT-LMM software was used for the iterative GWAS analysis, then a subset of significant variants were selected and added to the filtered Illumina50k markers in the prediction models. The prediction analyses were performed using BayesR methods implemented in the GCTB software. Compared to other scenarios, the approach that estimated the effects of selected SNPs in the same training population from which they were chosen resulted in the highest number of significant sequence variants been selected (783), the greatest amount of explained genetic variance (0.518), and the highest prediction accuracy (0.570). However, a relatively high degree of bias (0.887) was also observed. When animals were separated by birth year into GWAS and prediction populations, a relatively high prediction accuracy (0.556) and low bias (0.927) were achieved, compared to the scenarios with either separate animals of equal number for GWAS and prediction, or more animals for GWAS. In conclusion, including informative sequence variants can improve the performance of genomic prediction, offering not only biological insights but also practical applications such as the development of customized SNP arrays or the use of imputation in existing industry SNP panels.

Theatre 11

Novel runs of homozygosity islands in the Finnish Ayrshire population

K. Sarviaho, P. Uimari and K. Martikainen

University of Helsinki, Department of Agricultural Sciences, P.O. Box 28, 00014 Helsinki, Finland; katri.sarviaho@helsinki.fi

Artificial selection and inbreeding increase autozygosity and result in long homozygous stretches, runs of homozygosity (ROH), in the genome. In particular, genomic selection may increase ROHs around quantitative trait loci (QTL). High frequency of ROHs at certain genomic regions in a population form 'ROH-islands' – population-specific indicatives of selection pressure. ROH-islands have revealed selection signatures in range of livestock breeds (e.g. cattle, pig, and sheep). The aim of our study was to identify differences in ROH-island patterns, Δ ROH-islands, in the Finnish Ayrshire (FAY), that have emerged after genomic selection (GS) was introduced. Our data included genotypes for 45,834 SNPs from 53,469 FAY cows. Cows were divided into two populations; cows born between 1980-2011, before GS was introduced (6,108 cows), and cows born between 2015-2020 (47,361 cows), after GS was introduced. First, ROHs were identified using PLINK version 1.90b6.20. We calculated difference in the occurrence of each SNP in a ROH between the two populations (Δ H-score). Next, the top 1% of SNPs with the largest Δ H-scores were considered significant, and if separated by a maximum of two non-significant SNPs formed a Δ ROH-island. We listed genes under positive selection within the Δ ROH-islands based on UCSC Table browser (ARS-UCD1.2/bosTau9 assembly, April 2018). Finally, overlap of Δ ROH-islands with QTL identified in previous studies were studied using CattleQTLdb version 14 release 47. We detected a total of 1,237 SNPs (including the conjunctive SNPs) within 22 Δ ROH-islands in ten *Bos Taurus* autosomes. Δ ROH-island length ranged from 45.4 Kbp to 9.23 Mbp and encompassed 61.4 Mbp in total. The Δ ROH-islands identified in our study included 424 annotated genes. A total of six Δ ROH-islands in BTAs 2, 14, 16, 18, 25, and 26 completely or partially overlapped 777 QTL previously identified in Nordic Red cattle (FAY, Swedish Red, and Danish Red). The QTL were related to milk fat yield, fertility index, somatic cell score, and stature. In conclusion, we identified signatures of selection in genomic regions with previously identified dairy QTL that have appeared after genomic selection was introduced in the Finnish Ayrshire population.

Sometimes we win, sometimes we lose: the consequences of genomic selection

Since implementing genomic selection (GS), the dairy industry has seen faster genetic progress because of the rapid turnover of genomic bulls. Generation intervals for Holsteins bulls have decreased from 7 years in 2008 to 2.2 years in 2020, and the genetic gain has more than doubled for some traits in Holstein and Jersey. The yearly changes in average predicted breeding values nine years after the implementation of genomics are greater than in the nine years before for several traits like fat, protein, and daughter pregnancy rate. In fact, the overall increase in genetic gain for Holstein and Jersey resulted from the higher level of implementation and early adoption of genomics compared to breeds like Ayrshire, Brown Swiss, and Guernsey. Besides the increase in genetic gain per generation, GS was supposed to help reduce rates of inbreeding; however, this is not the reality. Right before genomics, the pedigree and genomic inbreeding levels for Holstein bulls were both 6%, but after genomics, they increased to 10.9 and 12.7%, respectively. In Jersey, the increase in inbreeding levels was only 1 to 2%, probably because of different selection decisions. Although pedigree and genomic inbreeding levels are similar, the genetic trends based on pedigree and genomic-based models differ. Once GS started being used, breeding values from BLUP became biased because this method does not account for genomic information that is used for selection; therefore, deregressed breeding values based on BLUP are questionable. Before genomics, predictions based on BLUP were stable and, therefore, trusted by the industry; however, genomic predictions are less stable, and top-ranked animals can easily drop in subsequent evaluations, generating concerns about GS. Another issue related to GS is the ever-increasing computational cost because of the amount of genomic data available. In this talk, we will review the advantages and disadvantages of GS after almost 15 years of its first implementation and discuss how to leverage the positive and overcome the negative aspects.

Session 04

Theatre 1

Old, native cattle breeds; from critically endangered to successfully utilized in niche productions

N. Svartedal¹ and O. Vangen²

¹NIBIO, PB 115, 1431 Aas, Norway, ²NMBU, PB 5003, 1432 Aas, Norway; nhs@nibio.no

Around 1990 the old cattle breeds native to Norway were critically endangered. There was little information on where these breeds might be found or if breeds had gone extinct. Thus, two actions were taken by the Committee on animal genetic resources. Recording remaining animals of these breeds showed that the population sizes varied between 11 and 113 breeding cows. Additionally, frozen semen from a few bulls from most of the breeds was made available. The semen was collected by Geno, the breeding organisation for the main producing commercial cattle breed, Norwegian Red (NRF). GENO was the only organisation which had facilities to collect and store bull semen. The recorded animals were registered in a pedigree database generated specifically for these breeds. Access to semen, free participation in the pedigree database and public support when establishing breed societies were the only extra support the owners of these breeds had access to up to 2000. Thereafter, subsidies for native endangered cattle breeds were introduced. Slowly the number of breeding animals increased in numbers, and by 2022 the population sizes varied between 307 and 1965 breeding and none of the breeds were any longer characterized as ‘critically endangered’, only ‘endangered’. The different public actions to support the farmers with these breeds have been of crucial importance for the breeds’ survival and growth. Still, no cattle breed can be sustainably maintained without being utilized in a production system. Traditionally the breeds were kept in dairy production. However, as the average milk yield of these breeds are approx 4,000 kg/year, only a few farmers manage to make a living as dairy farmers. Some farmers have extended their profit by producing local cheese and other dairy products. However, during the last ten years the growth in population sizes have exclusively been linked to meat production. Direct sale of meat from farmers to consumers, at farmers’ market, etc. has been a great success. As seen in many other European countries as well, there is a future for the old, local breeds in alternative low-input production systems, both linked to product quality, local adaptation, different grazing- and plant preferences and local production close to consumers.

Kenyan pastoralists and climate change: breeding as a possible adaptation strategy?J. Jandl¹, M. Wurzinger¹, L. Gichuki², B. Habermann², R. Siamito² and T.A. Crane²¹BOKU-University of Natural Resources and Life Sciences, Vienna, Gregor-Mendel-Str. 33, 1180 Vienna, Austria, ²ILRI-International Livestock Research Institute, P.O. Box 30709, 00100 Nairobi, Kenya; maria.wurzinger@boku.ac.at

Pastoralists in the semi-arid areas of Kenya are grappling with the impacts of climate change, yet livestock is at the centre of the pastoralists' livelihood strategies. Therefore, this study aims at analysing the current management and breeding strategies of Maasai pastoralists to adapt to the changing conditions. The study was carried out in Kajiado county, which has an annual rainfall between 500-700 mm and a bi-modal rainfall pattern. Qualitative interviews and focus group discussions were conducted to gather general information on livelihood strategies and breeding strategies for the different livestock species, cattle, goats and sheep. Data were recorded, transcribed and analysed using NVIVO software. Income diversification by combining livestock keeping with other agricultural activities is a common management strategy. However, livestock remains the primary source of income, provides milk and meat for home consumption and plays an important cultural role. Thus, improving livestock productivity by making strategic breeding decisions is critical to pastoralists' mainstay. In all three species, breeding animals are selected based mainly on their physical appearance. Crossbreeding is the standard approach for cattle. Non-local bulls (Sahiwal, Borana) are mated with local Zebu cattle. Pastoralists aim for large animals, which can fetch a reasonable price on the market. In addition, resistance to drought and diseases, early puberty and good fertility are essential traits. Migration, herd splitting, destocking (applied by some), controlled matings and cultivated pasture on fenced land for breeding bulls are other adaptation mechanisms. Short-term economic aspects are more important in breeding decisions than adaptation to climate change. While this strategy is essentially important, it could be disadvantageous in the long term, as the animals may not have enough adaptive potential for difficult environmental conditions.

Session 04

Theatre 3

Adapting climate-smart breeding practices for small ruminants in pastoral communities of KenyaJ.M. Ojango¹, E. Oyieng¹, J.W. Gitau¹, N. Ndiwa¹, J. Gachora² and A.W.T. Muigai³¹ILRI, Bioscience, 30709, Nairobi, Kenya, ²Min Agric. Liv. Fish. & Coop, Livestock, 34188 Nairobi, Kenya, ³National Defence Univ., AA & Research, 370 Nakuru, Kenya; j.ojango@cgiar.org

Changing climatic conditions with high frequencies of droughts have increased the vulnerability of pastoral communities in the Northern rangelands of Kenya and necessitate prompt interventions in sheep and goat breeding practices. Sheep and goats in the arid areas are locally adapted indigenous breeds with low potential for meat and milk production. The animals are reared in large numbers by pastoral families who individually own small flocks (5 to 10 animals) that are herded in large communal groups. Since 2018, the International Livestock Research Institute in collaboration with the Ministry of Agriculture, Livestock and Fisheries and Cooperatives in Kenya commenced a program to build the resilience of pastoralists to the changing climatic conditions using their small ruminant assets rather than depending on humanitarian emergency responses. Interventions necessitated changes in traditional management practices related to sheep and goat production in each community. Core Innovation Groups (CIG), each comprising 30 pastoral households, were established to adopt and model new practices using participatory processes in Isiolo, Marsabit and Turkana Counties of Kenya. The CIG members underwent a three-year phased training program on breeding management practices for more efficient, resilient, and productive animals aligned to a collaboratively pre-designed impact pathway. Data collated over three years by extension personnel engaged to monitor the CIG was analysed using logistic regression techniques to assess household-level adoption of livestock breed improvement, feeding and disease control interventions. All CIG adopted more than one of the introduced technologies concurrently. Prevention of diseases was the most readily adopted, followed by crossbreeding using indigenous breeds of sheep and goats from other arid areas. The study shows that pastoral communities are open to adapting technological interventions that will positively impact animal productivity. The adoption of the technologies was enhanced by the experiential capacity development activities adapted to different socio-economic parameters within the communities.

Zooarchaeology for conservation biology: introducing ARETIA. Spyrou¹, G. Hadjipavlou² and D. Bradley³¹The Cyprus Institute, STARC, 20 Konstantinou Kavafi Street, Nicosia, 2121, Cyprus, ²The Agricultural Research Institute, Athalassa Area, 1011, Cyprus, ³Trinity College Dublin, The Smurfit Institute of Genetics, College Green, Dublin 2, Ireland; a.spyrou@cyi.ac.cy

Animals REsilient in Time (ARETI) is an interdisciplinary research project that explores the genetic, economic and cultural history of cattle on the island of Cyprus from the prehistoric times to the present. By weaving together evidence from Zooarchaeology, a subfield of archaeology that studies the remains of animals, cattle iconography and palaeogenomics, ethnography and folklore studies, the project's main aim is to unearth vital information about the last 8,000 years of human-cattle interactions on the island and highlight the historical value of an animal that has accompanied Cypriot rural societies for many centuries. One of the core elements of the project is to demonstrate the physical presence of the thermotolerant *Bos indicus* or zebu cattle (or hybrids) on the island and its potential link to past climatic shifts and human migrations. Our genomic analysis focused so far on 15 prehistoric cattle samples (petrous bone) from key archaeological sites, spanning the early Neolithic-Iron Age, while blood samples from 100 unrelated cattle belonging to the Cyprus local breed have also been selected to be genotyped by using a high density bovine 800K beadchip microarray. Archaeological findings are combined and compared with contemporary DNA mapping of the local Cyprus cattle breed to look for long-lasting signatures of selection, conservation and historical adaptation and contribute to the development, promotion and implementation of sustainable strategies for conserving and further improving the adaptive genetic traits of the Cyprus' indigenous cattle breed. Overall, through the main concepts and methodologies of ARETI as well as our public outreach plan (e.g. documentary, educational activities for children, etc.), we demonstrate what can be achieved when different disciplines such as archaeology, animal genomics and conservation biology join forces.

Session 04

Theatre 5

A robustness proxy based on variations in energetic allocation to growth in Duroc fattening pigsG. Lenoir^{1,2,3}, L. Flatres-Grall², R. Muñoz-Tamayo³, I. David¹ and N.C. Friggens³¹GenPhySE, Université de Toulouse, INRAE, ENVT, Auzeville Tolosane, 31326 Castanet Tolosan, France, ²Axiom, La Garenne, 37310 Azay-sur-Indre, France, ³Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 place de l'Agronomie, 91120 Palaiseau, France; glenoir@axiom-genetics.com

In the context of global warming, livestock, especially pigs, evolve in an increasingly changing and challenging environment. The ability of an animal to cope with these changes while ensuring the expression of its production potential can be associated with its robustness. Our objective was to develop a robustness proxy on the basis of modelling of longitudinal energetic allocation coefficient to growth for fattening pigs, from 75 to 150 days of age. A total of 3,710 pigs from Duroc paternal line were raised at the AXIOM boar testing station (Azay-sur-Indre, France) from 2015 to 2023. This farm was equipped with automatic feeding system, recording individual weight and feed intake at each day t of the fattening period. We used a dynamic linear regression model to characterize the daily evolution of the allocation coefficient (α_t) between cumulative net energy available for growth and cumulative weight gain during fattening period. The cumulative net energy available for growth at day t was estimated as the difference between the net energy intake and the net energy requirement for maintenance. Longitudinal energetic allocation coefficients were analysed using a two-step approach. In a first step, the repeated trait α_t was analysed using a linear random regression animal model (RR). The residuals at day t for each animal of the RR model was used to compute log transformed squared residuals (LSR _{t}). In a second step, the heritability of LSR was estimated using a multi-traits animal model including LSR and the four traits under selection. The LSR trait, which could be interpreted as an indicator of the response of the animal to perturbations/stress, showed low heritability (0.06 ± 0.01). The trait LSR had high favourable genetic correlations with average daily growth (-0.79 ± 0.07) and unfavourable with feed conversion ratio (-0.54 ± 0.10). In this study, we proposed an approach for characterizing the robustness through the variability in the allocation.

Genetic architecture of skin histology with implications for heat tolerance in beef cattle

R.G. Mateescu¹, F.M. Rezende¹, K.M. Sarlo Davila², A. Hernandez¹, A.N. Nunez Andrade¹, G.A. Zayas¹, E.E. Rodriguez¹ and P.A. Oltenacu¹

¹University of Florida, Animal Science, 2250 Shealy Dr, Gainesville, FL 32611, USA, ²ORISE/NADC, 1920 Dayton Ave, Ames, IA 50010, USA; raluca@ufl.edu

Development of effective strategies to improve the ability to cope with heat stress is imperative to enhance productivity of the livestock industry and secure global food supplies. However, selection focused on production and ignoring adaptability results in beef animals with higher metabolic heat production and increased sensitivity to heat stress. Cattle lose heat predominantly through cutaneous evaporation at the skin-hair coat interface when experiencing heat stress. Sweating ability, sweat gland properties, and hair coat properties are a few of the many variables determining the efficacy of evaporative cooling. Sweating is a significant heat dissipation mechanism responsible for 85% of body heat loss when temperatures rise above 86 °F. This is, to our knowledge, the first study reporting an extensive investigation of skin histology properties in a multibreed Angus-Brahman heifer population. Heat loss adaptations at the skin level are anticipated to have a negligible impact on productivity and thus provide an excellent opportunity to select for animals with superior thermal adaption and food production abilities. The breed group had a statistically significant effect on all skin properties in this study except dermis thickness. Brahman cattle had significantly thinner and longer epidermis, thinner dermis, larger sweat gland areas, longer sweat glands closer to the skin surface, smaller sebaceous gland area and more sebaceous glands compared to Angus cattle. Equally important, these differences are also accompanied by significant levels of variation within each breed, which is indicative that selection for these skin traits would improve the heat exchange ability in beef cattle. Single-trait GWAS were used to investigate the relevance of direct additive genetic effects on each trait. Genomic windows explaining more than 1% of direct additive genetic variance were considered to be associated with the analysed trait. Several quantitative trait loci (QTLs) were identified by GWAS for sweat gland area with a large QTL explaining over 1.4% of the genetic variance.

Session 04

Theatre 7

Ewe-lamb allocation trade-offs shape ewe lifetime production depending on dietary energy scarcity

M. Hiltbold and F. Douhard

GenPhySE, Université de Toulouse, INRAE, ENVT, 31326 Castanet-Tolosan, France; maya.hiltbold@inrae.fr

Pasture-based production systems strongly depend on weather and seasonal conditions and are potentially facing limits in climate change adaptation without sufficiently robust animals. Robustness likely involves the balanced allocation of the mother's limited resources between her own survival and future reproduction and her offspring's survival and growth until weaning. Thus, we expect that the optimal resource allocation strategies exist depending on the available resources in the animal's environment. To study the effect of different priorities between mother and offspring traits, we applied a mathematical model of energy acquisition and allocation to suckler sheep. Our dynamic model predicts the whole lifetime production trajectory of an ewe with a given energy allocation strategy between growth, maintenance, reproduction and body reserves in response to dietary energy. Model outputs include the changes of ewe body weight and condition across successive reproduction cycles as well within each cycle, the number of lambs and their growth from birth to weaning. Importantly, the model predictions are based on direct energy transfers from the ewe to her lambs during pregnancy and lactation. The predicted ewe and lamb conditions were assumed to affect ewe and lamb survival, prolificacy and conception rates. We explored the consequences of various allocation strategies on ewe lifetime production for a range of grazing scenarios (schematically described in terms of seasonal energy availability) under fixed management conditions (one lambing per year, winter period). First results suggest that individual variation in energy allocation leads to trade-offs among the components of lifetime production. Comparable lifetime production levels might be achieved with strategies emphasizing either early first lambing and large litter sizes over a short ewe life or moderate litter sizes over a long ewe life. However, prudent allocation strategies were preferred in energy scarce environments. Our work contributes to understanding the optimum ewe performance in contrasting environments by identifying not only the best animal for a given environment, but also the most robust ewe which can deal with a variable environment.

System performance of three dairy-beef genotypes divergent in carcass merit

N. Byrne, D. Fahy, M. Kearney and N. McHugh

Teagasc, Animal & Grassland Research and Innovation Centre, Grange, Dunsany, Co. Meath, C15 PW93, Ireland; nicky.byrne@teagasc.ie

The proportion of beef output originating from the dairy herd in many countries, such as Ireland, is increasing. Compared to suckler origin beef, dairy-beef systems has the potential for greater carbon efficiency; however, in Ireland there is an increasing proportion of dairy-beef animals failing to meet minimum carcass specifications, limiting profitability. The objective of this study was to compare the physical, financial and environmental performance of three dairy-beef genotypes, within an efficient grass-based steer production system. These genotypes consist of male Holstein Friesians (HF) and two Angus (AAX) genotypes, sired by bulls of divert genetic merit for carcass weight and conformation (Low and High AAX). The effect of early-life calf nutrition on lifetime performance was also evaluated, whereby half of each genotype group received either 4 or 8 litres (L) of milk replacer/day from 30 days of age until weaning. Milk feeding level had no effect on lifetime growth and carcass performance ($P>0.05$), however, calves on the 4 L treatment consumed significantly more concentrate during the rearing phase (+21 kg DM, $P<0.01$). Genotypes achieved the same lifetime growth performance ($P>0.05$), except for the first grazing season where HF had significantly higher growth. Terminal performance differed between genotypes for age at slaughter, conformation and carcass value ($P<0.001$). Although numerically in favour of the High AAX genotype, pairwise comparisons indicated non-significant ($P>0.05$) differences between AAX genotypes for individual carcass traits. Using coefficients generated from each genotypes physical performance their contribution to overall farm economic and environmental efficiency was modelled using the Grange Dairy Beef Systems Model. The High AAX genotype achieved a €728/ha net margin, €121 and €266 greater than Low AAX and HF genotypes, respectively. Both AAX groups had a reduced carbon footprint, producing 9% less CO₂ eq per carcass kg and were net producers of human edible protein compared to the HF genotype, who consumed 25% more protein than they produced. From this study, dairy-beef genotypes of reduced slaughter age, increased carcass weight and conformation have the best overall farm system performance.

Session 04

Theatre 9

Characterization and main factors of variation of milk production in suckler cowsB. Sepchat¹, M. Barbet¹ and A. De La Torre²*¹INRAE, Herbipôle, Theix, 63122 Saint-Genès-Champanelle, France, ²UCA, INRAE, VetAgro Sup, UMRH, Theix, 63122 Saint-Genès-Champanelle, France; bernard.sepchat@inrae.fr*

The improvement of conformation and muscular development in suckling herd results in a decrease in milk production (MP) leading to an increase of concentrate consumption by calves. In a tense economic, environmental and societal context, it is necessary to maintain or even improve the MP of beef cows to support calves' growth. Assessment of MP is indirect and consists to calculate milk drunk by the calf as the difference of its weight after and before suckling. The objectives of this work were to acquire knowledge on MP and determine the main factors of variation. For that, MP measured in Herbipôle unit (more than 12,000 measures over 1000 cows controlled at least 7 times per cow and lactation) over the last 15 years in Charolais (C), Salers (S) and Limousin (L) cattle were analysed. Breed is the main factor of variation of MP (29% difference between S and L): 1,600±313 kg milk / lactation in L, 1,840±355 in C and 2,250±470 in S as well as parity ±10% difference between primiparous and multiparous regardless of breed. In a 'classic' system of weanling's production, characterized by a winter calving and semi-extensive pasture, two peaks are observed across the lactation. The first occurs one-month post-calving and the second largest at turn-out. This peak is ranged from 0.8 to 2.3 kg of milk according to the breed, parity and calving date. In this study, the persistence of lactation and its variability were quantified, (-17 to -27 g drunk milk / day). Persistence is higher for low-producing cows (-0.5 against -0.9 kg milk / day less per month) than for high-producing cows. High MP supports high growth rate of calf. Throughout lactation, this gain is 60 g/l of milk drunk in more, either 70 kg of live weight gain for a lactation of 2,300 vs 1,200 kg. The composition of milk from suckler cows is very poorly known, a first approach was performed in a subset of Charolais cows. The average composition (in g/kg of milk) in protein, fat and lactose is respectively 35.4±2.2, 39.1±10.2 and 49.9±1.8. In suckler cows, a better characterization of milk production and its composition is required to improve feed autonomy and contribute to animal selection strategies in a context of climatic deregulation.

Mediterranean Baladi cattle presents adaptive traits to cope with climate change in the Near East

A. Shabtay¹, E. Lipkin², M. Soller², F. Garcia-Solares¹, J. Sölkner³, E. Shor-Shimoni¹, A. Bagnato⁴, M.G. Strillacci⁴ and M. Cohen-Zinder¹

¹Agricultural Research Organization, Sustainable Ruminant Production Lab; Model Farm for Sustainable Agriculture, Neve Ya'ar Research Center, P.O. Box 1021, Ramat Yishay 30095, Israel, ²The Hebrew University of Jerusalem, Dept. of Genetics, Silberman Life Sciences Institute, Givat Ram Campus, Israel, ³University of Natural Resources and Life Sciences, Gregor-Mendel-Strasse 33/II 1180, Vienna, Austria, ⁴Università degli Studi di Milano, Milan, Italy, Via Dell'Università, 6. Facoltà Medicina Veterinaria 26900 Lodi, Italy; shabtay@volcani.agri.gov.il

The Near East is amongst the driest and water-scarce regions in the world. Moreover, in light of the global climate changes, it is expected to become even hotter and drier, and hence, to experience a reduction in crop yields and quality and turn more vulnerable to geographical redistribution of pests and diseases. It is, therefore, recommended to accelerate the buildup of resilient agri-food systems, which in case of the livestock sector, would lean on breeds under adaptive selection to harsh environment, that can maintain sustainable production. The Baladi is an indigenous cattle, known for its hardiness, disease resistance, and ability to utilize feedstuffs of low nutritious quality. Located at the centre of the three major cattle domestications events, its genome contains relatively similar proportions of the three ancestral components, implying a rich pool of genetic diversity and selection signatures for adaptation to the Near East environment. At physiological level, the capability to maintain lower energy expenditure enable Baladi animals to retain improved energy balance over the productive Simmental breed, under poor diets. Moreover, intrinsic features of Baladi erythrocytes imply an improved resistance to tick borne diseases. Although bearing relatively low dressing percentage comparing to traditional beef breeds, preliminary analysis mark Baladi meat qualitative, in terms of physical and organoleptic characteristics. The current presentation will screen the bio-agricultural advantages described above, and discuss the biological and economic efficiency of Baladi cattle breeding program, as part of future sustainable resilient agri-food system in the Near East.

Session 04

Theatre 11

Effect of some environmental variables on milk traits in dairy sheep

F. Correddu¹, A. Cesarani¹, G. Gaspa², I. Peana³, G. Fois³, C. Dimauro¹ and N.P.P. Macciotta¹

¹Università di Sassari, Dipartimento di Agraria, viale Italia, 39, 07100 Sassari, Italy, ²Università di Torino, Dipartimento di scienze agrarie, forestali e alimentari – DISAFA, Largo Braccini, 2, 10095 Grugliasco (TO), Italy, ³Agenzia Regionale per la Protezione dell'Ambiente della Sardegna, Dipartimento MeteoClimatico – Servizio Meteorologico, Agrometeorologico ed Ecosistemi, Viale Porto Torres, 119, 07100 Sassari, Italy; macciott@uniss.it

Due to the climate changes, livestock sector will face the possibility of farming more resilient animals. This is particularly true for the extensive dairy sheep farming systems of the Mediterranean area. Aim of this work was to evaluate the impact of the Temperature Humidity Index (THI) and Wind Chill Index (WCI) on milk traits in Sarda dairy sheep. Data consisted of 2,695 test day records from 555 Sarda breed ewes. Maximum THI and minimum WCI registered the same day (0d), one day (1d), two days (2d) or three days (3d) before each test, respectively, were retrieved from the closest meteorological stations of the ARPAS (Sardinian Regional Agency for the Environment Protection). A total of 7 and 5 classes were created for THI and WCI, respectively. The considered traits were milk yield (MY), fat (FP), protein (PP) and lactose (LC) contents, and somatic cells count (SCC). Each trait was analysed using a linear mixed model with sampling date, days in milk (DIM) class, parity, climate variable (THI or WCI) and the interaction between DMI and climate variable as fixed effects and flock and animal as random effects. Both THI and WCI were negatively correlated with MY and LC, and positively with FP and PP. THI class was always highly significant ($P < 0.001$) for all traits except SCC. According to the F-values, the largest effects of THI were found at 3d, 2d, 1d, and 0d for MY, FP, PP, and LC, respectively. The negative effect of THI on MY was evident at almost each class of DIM, with lower production observed at THI > 72. WCI class was significant for MY only at 3d, whereas for LC only at 1d; it was always significant for PP and at 0d, 1d, and 2d for FP. The largest effects of WCI class were observed at 0d for FP and PP and at 1d for LC. Results of the present work evidenced an effect of the climate variables on the temporal evolution of milk production traits in dairy sheep.

Genomic tolerance to harsh climate conditions in beef cattle as a result of cross-breeding program*R. Tian and H. Asadollahpour Nanaei**Inner Mongolia Academy of Agricultural & Animal Husbandry Sciences, Animal science, 010031, Hohhot, 7521325, China, P.R.; tiannky@163.com*

Understanding the evolutionary forces related to climate changes that have been shaped genetic variation within species has long been a fundamental pursuit in biology. In this study, we generated whole-genome sequence (WGS) data from 65 cross-bred and 45 Mongolian cattle. Together with 62 whole-genome sequences from world-wide cattle populations, we estimated the genetic diversity and population genetic structure of cattle populations. In addition, we performed comparative population genomics analyses to explore the genetic basis underlying variation in the adaptation to climate change and immune response in cross-bred cattle located in the cold region of China. To elucidate genomic signatures, we performed three statistical measurements, fixation index (FST), log2 nucleotide diversity ($\theta\pi$ ratio) and cross population composite likelihood ratio (XP-CLR), and further investigated the results to identify genomic regions under selection for cold adaptation and immune response-related traits. Analysis of population structure demonstrated evidence of shared genetic ancestry between studied cross-bred population and both Red-Angus and Mongolian breeds. Among all studied cattle populations, the highest and lowest levels of linkage disequilibrium (LD) per Kb were detected in Holstein and Rashoki populations. Our search for potential genomic regions under selection in cross-bred cattle revealed several candidate genes related with immune response and cold shock protein on multiple chromosomes. We identified some adaptive introgression genes with greater than expected contributions from Mongolian ancestry into Mongolian $\times$ Red Angus composites such as TRPM8, NMUR1, PRKAA2, SMTNL2 and OXR1 that are involved in energy metabolism and metabolic homeostasis. In addition, we discovered some candidate genes probably associated with immune response-related traits. The identification of these genes may clarify the molecular basis underlying adaptation to extreme environmental climate and as such they might be used in cattle breeding programs to select more efficient breeds for cold climate regions.

Session 04

Theatre 13

Expected selection responses in breeding plans aiming to limit environmental impacts of trout farming*S. Pouil¹, J. Aubin² and F. Phocas¹**¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²INRAE, Institut-Agro, SAS, 65 rue de Saint-Brieuc, 35042 Rennes, France; simon.pouil@inrae.fr*

With the growing societal concerns about the sustainability of food production systems, there is increasing interest in considering not only economic gains but also environmental impacts in the selective breeding of farmed species. In this study, we compared expected selection responses for alternative breeding programs aiming to limit the environmental impacts of the production of rainbow trout, one of the most important farmed fish species in Europe. The consequences of genetic improvement based on optimal selection indexes derived to minimize various environmental impacts were investigated in a theoretical rainbow trout farm producing constant annual fry production volumes. A cradle-to-farm-gate life-cycle assessment was performed to evaluate the environmental value (ENV) of each trait that has been used in the breeding goals. The tested breeding goals included three different traits: the body weight (BW), the feed conversion ratio (FCR) measured through the feed conversion ratio and the fry survival rate (SR). Due to a lack of knowledge about the genetic links across these traits, we tested several correlation scenarios between the traits. We explored different impact categories as various environmental breeding goals, such as acidification, climate change, cumulative energy demand, eutrophication, land occupation and water dependence. Annual genetic gains ranged from 0.9 to 1.4% for the different impact categories, while the annual genetic gains ranged from 0.4 to 4.6% for BW, 0.0 to 2.8% for FCR and -11 to 0.9% for SR. We demonstrated interest in using ENV in breeding goals to minimize environmental impacts at the farm level, while maintaining high genetic improvements in growth and feed efficiency-related traits. Nevertheless, another selection strategy should be considered to avoid negative consequences on SR when considering possible negative correlations between survival and production traits. Although our results are promising, their interpretations have to be qualified by the consideration of the economic repercussions of such a selection strategy.

Defining resilience traits in sheep from fibre diameter variation of wool

E.G. Smith¹, S.F. Walkom², D.J. Brown² and S.A. Clark¹

¹University of New England, School of Environmental and Rural Science, University of New England, Elm Avenue, 2351 Armidale NSW, Australia, ²Animal Breeding and Genetics Unit, University of New England, Elm Avenue, 2351 Armidale NSW, Australia; esmith76@myune.edu.au

The capacity to measure and select livestock that are more resilient to environmental fluctuation is of increasing importance amidst climate change, labour shortages and increasing production demand. Currently, however, there is no consensus on how to quantify resilience, particularly in extensive sheep populations. In this study, we explored the ability to derive resilience indicator traits from fibre diameter variation measured longitudinally (5 mm increments) along the wool staple. Fibre diameter varies in relation to the supply of nutrients to the wool follicles and thereby provides a stable archive of the animal's physiological status across the preceding wool growth period. From this fibre diameter variation, ways to detect and characterise an animal's ability to withstand or be minimally affected by its environment were explored. The heritability estimates of these traits were shown to be low to moderate (0.10 to 0.31), indicating that genetic variation exists for fibre diameter variation measured along the wool staple which may be interpreted as a measure of resilience. The inclusion of such measures in sheep breeding programs has the potential to improve the resilience of sheep to environmental challenges, which may have positive implications for sheep enterprise profitability, health and welfare.

Session 04**Theatre 15****Evaluating the impact of uncertainty in estimated breeding values on optimal contribution selection**

I. Pocrnic, J. Ortiz and G. Gorjanc

The University of Edinburgh, The Roslin Institute, Easter Bush Campus, EH25 9RG Edinburgh, United Kingdom; ivan.pocrnic@roslin.ed.ac.uk

Many livestock breeding programmes have a closed nucleus and therefore have to manage the conversion of genetic variation into genetic gain with care. Consequently, these breeding programmes use some methods for managing genetic variation. One such method is the optimal contribution selection (OCS), which aims to maximise genetic gain for a given loss in genetic variation. The accuracy of this optimisation depends on the accuracy of its input parameters; the estimated breeding values (EBV) and the relationship matrix. In OCS, we typically assume that EBV are true values, that is, that they have no associated uncertainty, which is seldom the case. The aim of this study was to evaluate how uncertainty in EBV impacts optimised contributions and success of OCS. To this end, we have stochastically modelled a small breeding programme and obtained 1,000 posterior samples of EBV from either the pedigree (BLUP) or genomic (GBLUP) evaluations. We then ran OCS for each EBV sample (probabilistic OCS), for the posterior mean of EBV (naïve OCS), as well as for the true breeding values (true OCS). We finally evaluated the distribution of optimised contributions for the selected parents and of genetic mean and genetic variation of their progeny. We compared scenarios with OCS that aimed for an effective population size of 50 and 100. Results have shown considerable underestimation of optimised contributions for naïve OCS compared to probabilistic OCS, which were closer to the true OCS. Future work includes the use of robust optimisation that can work with a full distribution of estimated breeding values, thereby enabling probabilistic OCS for routine use.

Increasing genetic gain without compromising diversity by selection based on mating qualities

T.A.M. Niehoff, J. Ten Napel, P. Bijma, T. Pook, Y.C.J. Wientjes, B. Hegedűs and M.P.L. Calus

Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands; tobias.niehoff@wur.nl

Selection decisions traditionally rely on expected offspring performance, hence breeding values. By also considering the expected Mendelian sampling variance of a mating pair, the probability to produce animals with high performance can be increased, which means a shift in the planning horizon of the breeding objective by one generation. We extended this idea to multiple generations. Thus, by extending the planning horizon, our criterion allows to maximize genetic gain in several generations ahead. We tested our newly developed criterion against previously developed criteria, namely selection based on: (1) breeding values; (2) the probability to select top offspring; (3) the expected breeding value of selected offspring; and (4) a recently published index that describes the linearized probability to produce top offspring. Comparisons were based on a simulated recurrent selection breeding scheme using the software MoBPS. We explored our new criterion in an ideal breeding program with known QTL effects and linkage information to test the theoretical benefit without errors induced by estimating QTL effects and haplotypes. Our criterion achieved higher genetic gain compared to all other criteria while maintaining more genetic variance and achieving lower inbreeding levels relative to selection based on breeding values, both after 5 and 20 generations. This is because our criterion allows to consider the diversity that is present in the current generation to project how it can be turned into genetic gain in a certain generation in the future. In conclusion, our criterion allows faster genetic progress without compromising diversity.

Session 05

Theatre 1

Holistic perspectives on climate care cattle farming

G. Van Duinkerken

Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, the Netherlands; gert.vanduinkerken@wur.nl

The EU 'Green Deal' includes a commitment to reach a climate neutral economy by 2050. European agreements indicate that greenhouse gas (GHG) emissions from EU agriculture should be reduced with 30% by 2030, compared with 2005 levels. However, with unchanged policies and efforts, and based on projections per member state, it is expected that a reduction of only 2% is expected in the time span 2005 to 2030. Moreover, individual member states are focusing on integrated solutions to mitigate GHG emissions, and simultaneously optimise nitrogen management to reduce ammonia emission and nitrate leaching. Because the cattle chain is a large contributor to EU agricultural emissions, especially methane and ammonia, there is a strong need for applicable measures to reduce emissions along this chain. About two thirds of cattle GHG-emissions have an on-farm origin. For example enteric methane, and emissions related to manure management and crop cultivation. One-third has an off-farm origin, such as the production of fertilizers and concentrates, and processing and transport of farm products. The EU-project Climate Care Cattle Farming ('CCCFarming') focuses on reducing GHG and ammonia emissions while maintaining socio-economic farm performance. Processes within the farm itself are being studied, and emission reducing innovations are being developed and implemented. Potential trade-offs with off-farm emissions are being evaluated. Trade-offs can also occur on-farm. For example an increased maize cultivation, and higher share of maize silage in the animal diet, can reduce enteric methane emissions and increase nitrogen use efficiency at animal level, but the associated reduction of permanent grassland will reduce biodiversity and grazing possibilities and will increase the risk of nitrate leaching from farm land. In this presentation emission mitigation strategies, their interactions, and their relevance for integral sustainable dairy farming will be highlighted.

Climate care farming aspects in China*W. Wang**China Agricultural University, No.2 Yuanmingyuan West Road, 100193, Beijing, China, P.R.; wei.wang@cau.edu.cn*

China is the world's largest emitting economy and the world's largest emitter of greenhouse gases from agriculture. President Xi Jinping announced at the 75th United Nations General Assembly in September 2020 that China strives to peak its carbon dioxide emissions by 2030 and become carbon neutral by 2060. The commitment made by President Xi gives national strategic importance to carbon reduction efforts in all sectors. With the growth of China's population and economic level, China's livestock industry is still rapidly developing to meet the growing demand for animal products. Major livestock animals such as pigs, chickens, dairy cattle, and beef cattle are among the top in the world and still maintain a high growth rate. With the continuous improvement of scale, automation, and intelligence, China's livestock industry has undergone radical changes in livestock breeds, breeding methods, and feed types. Under such dramatic changes, some basic parameters of greenhouse gas emissions have also changed a lot. However, compared with developed countries, there is still much room for improvement in China's livestock and poultry production level, livestock and poultry waste treatment technology, and the breeding cycle implementation. There is an urgent need to conduct long-period greenhouse gas emission monitoring of the livestock industry to determine the emissions baseline.

Session 05

Theatre 3

Producer adoption of climate-smart agriculture practices on U.S. grazing lands*A. Blair, K. Cammack, H. Menendez, J. Brennan and K. Ehlert**South Dakota State University, Animal Science, 711 N Creek Dr, Rapid City, SD 57703, USA; amanda.blair@sdstate.edu*

Today's livestock producers face increasing public scrutiny because animal agriculture is often cited as a major contributor to greenhouse gas (GHG) emissions. Despite proven ecosystem benefits associated with grazing, range livestock and land managers are typically overlooked in GHG reduction and carbon sequestration incentive programs. South Dakota State University, along with ten external partners, was recently awarded a commodity development grant for grazing beef cattle and bison. A primary goal of this project is to provide economic incentives to beef and bison producers to implement land practices that have carbon and GHG benefits. Furthermore, this project will develop producer-friendly carbon and GHG measuring and monitoring technologies. The long-term goal of this project is to develop sustainable market opportunities for producers that employ climate-smart practices on their operations. Such opportunities can include not only emerging carbon markets, but commodity markets with premiums assigned to responsibly raised beef and bison. Accessible measuring and monitoring technologies are needed by producers to verify the impacts of their practices and successfully enter into these emerging market opportunities. Producer partnership is key to the success of this project and long-term market sustainability. We will work with specific groups of producers to ensure widespread participation, including: (1) established and early practice adopters; (2) late practice adopters; and (3) underserved groups, including indigenous producers. Through this project, we will work with producers that manage more than 970,000 ha of grazing lands. To accomplish this, we have developed a multi-tiered approach between academia, governmental agencies and industry to facilitate sustainable and effective climate-smart practice implementation. Providing economic incentives to producers for adopting climate-smart practices will help overcome transactional entry barriers often associated with new practice implementation and will position producers to merge into new market opportunities aligned with consumer preferences and demand.

Assessing impacts of new legislation on Dutch dairy farms using a revised linear programming model

A. Van Der Linden¹, L.M. Alderkamp¹, C.W. Klootwijk², G. Holshof², N. Van Eekeren³, F. Taube^{1,4} and C.E. Van Middelaar¹

¹Wageningen University, Animal Production Systems group, De Elst 1, 6708 WD Wageningen, the Netherlands, ²Wageningen Livestock Research, Animal Nutrition, De Elst 1, 6708 WD Wageningen, the Netherlands, ³Louis Bolk Institute, Kosterijland 3-5, 3981 AJ Bunnik, the Netherlands, ⁴Christian Albrechts University, Grass and Forage Science/Organic Agriculture, Hermann-Rodewald Str. 9, 24118 Kiel, Germany; aart.vanderlinden@wur.nl

The Dutch agricultural sector is not eligible for derogation anymore in 2023, which affects dairy farmers because the application room for nitrogen (N) in animal manure is reduced to the European standard of 170 kg/ha. The objective of this study is to quantify the impacts of new legislation, including the loss of derogation, on the economic and environmental performance of Dutch dairy farms. An existing linear programming model for Dutch dairy farms was revised. During revision, the model was written in the R programming language, input parameters were updated, and new legislation was included. As a potential measure to deal with the new legislation, parameters of grass-white clover and grass-white red clover sward were added to the model. Labor income of a typical farm on a sandy soil in the Netherlands (50 ha, Holstein-Friesian cows) was maximized given legislation and available resources on-farm. Due to new legislation, the annual labour income decreased by € 18,350, and nitrogen (N) surplus decreased by 63 kg/ha. The number of cows decreased from 101 to 93, and the percentage maize land increased from 20 to 31% of the total area. Artificial N fertilizer use decreased by 18 kg/ha. New legislation and adoption of grass-white clover (66% land area) decreased income only by € 5,900 and decreased N surplus by 77 kg/ha. Grass with white and red clover (21% land area) decreased income by € 8,700 and decreased N surplus by 48 kg/ha. In conclusion, model results indicated that labour income and N surplus will both decrease under the new legislation. Fewer animals are kept and more maize is cultivated. Adopting grass clover-swards could mitigate the decrease in labour income and reduce N surplus depending on the sward type, which shows their potential to improve environmental and economic performance of dairy farms.

Session 05

Theatre 5

Gaseous emissions (building, storage, pasture) of dairy systems combining or not grazing and housing

N. Edouard¹, X. Vergé², C. Flechard³, Y. Fauvel³ and A. Jacotot³

¹INRAE, Institut Agro, Pegase, 35590 Saint-Gilles, France, ²Institut de l'élevage, Monvoisin, 35650 Le Rheu, France, ³INRAE, Institut Agro, SAS, 35000 Rennes, France; nadege.edouard@inrae.fr

Sustainable dairy farms need to make better use of feed resources, reduce the use of inputs and their environmental impacts, particularly in terms of nitrogen (N) losses. Dairy cattle are largely fed on grazed grass in Western Europe but, at certain times of the year, conserved forages and concentrates may be added to the animal diet. Few studies have investigated the consequences of this combination on the animal's N use and manure composition. Moreover, in these situations, animals divide their time between grazing, where urine and solid excreta fall directly onto the soil, and the building, where manure need to be managed and stored, leading to contrasted impacts on the environment. Our project focuses on strategies combining grazed and conserved forages in dairy systems and their consequences on N flows and environmental impacts. Several experiments were conducted to compare animal performance, N use efficiency and gaseous emissions (ammonia and greenhouse gases) of full-housing (FH) vs half-housing-half-grazing (HH-HG) vs full grazing (FG) management systems in spring and autumn 2022. In the FH treatment, cows were housed in mechanically ventilated rooms where they were fed a basic diet of maize silage and concentrates *ad libitum*. Manure was scraped, collected and transferred to controlled pens. Gaseous emissions were measured in the house and during manure storage by spot air samples, with several methods. In the FG treatment, cows grazed a temporary pasture equipped with an eddy covariance flux tower and several trace gas infrared analysers (NH₃, N₂O, CH₄, CO₂, H₂O), and ALPHA passive diffusion samplers for NH₃ coupled with short-range atmospheric dispersion modelling for the determination of field-scale gaseous emissions. Cows on the HH-HG treatment were housed in a mechanically ventilated room at night (receiving 8 kg DM of the basic diet) and grazed on a temporary pasture during the day (8 hours). The results will contribute to the acquisition of new knowledge on these mixed systems especially in terms of gaseous losses over the whole continuum of cattle feeding and manure management.

Agri-food and net zero: a science-policy-society perspective

R. McGuire¹, S. Huws¹, C. Foyer², P. Forster³, M. Welham⁴, L. Spadavecchia⁵, D. Curry⁶ and N. Scollan¹

¹Queen's University Belfast, Belfast, BT9 5DL, United Kingdom, ²University of Birmingham, Birmingham, B15 2TT, United Kingdom, ³University of Leeds, Leeds, LS2 9JT, United Kingdom, ⁴UK Research and Innovation Biotechnology and Biological Sciences Research Council, Swindon, SN2 1FL, United Kingdom, ⁵The Department for the Environment, Food and Rural Affairs, London, SW1P 4DF, United Kingdom, ⁶House of Lords, London, London, SW1A 0PW, United Kingdom; r.mcguire@qub.ac.uk

Globally, agriculture is responsible for up to 8.5% of all greenhouse gas emissions – whilst in the UK, the agri-food system produces ~23% of UK emissions. Despite this significance, mitigations must be based on scientific knowledge, technological innovation, and the socio-economic capacities of industry and society. Hence, the need for a science-policy-society interface. Using the UK as a case study, through a series of multi-stakeholder workshops, the key policy, political and scientific challenges to a net zero agri-food system were scrutinised, whilst demonstrating farmer's views to a net zero strategy. Overall, in terms of effective mitigation, it is essential that agri-food does not wait for 'perfection'. Indeed, rapid advances to net zero are possible using existing knowledge and technology, supported by targeted policies. The most significant barrier is the lack of plausible road maps that enjoy widespread support and confidence. Such road maps must detail feasible emission mitigation targets for farmers. This sector's ability to translate scientific knowledge into practical application is poor and the knowledge-exchange processes are fragmented. Governments must urgently outline their export strategy, sustain national production standards (particularly animal health and welfare) and outline how they plan to work in partnership with their own farmers. There is a view among some stakeholders that governmental regulation should be the last resort, because it can compromise innovation. The key challenge for a net zero strategy is to create the conditions that initiate industry buy-in, controls for the different capacities of farm systems and delivers the evidence of climate-friendly food production to consumers.

Theatre 7

Testing the effects of grassland swards for yield, greenhouse gas emissions and soil health

P.R. Hargreaves¹, D.Z. Kreismane², A. Dorbe², K. Klumpp³, J. Bloor³, A. Cieślak⁴, M. Szumacher⁴, A. Szejner⁴ and R.M. Rees¹

¹SRUC, Kings Buildings, West Mains Road, Edinburgh, EH9 3JG, Edinburgh, United Kingdom, ²Latvia University of Life Sciences and Technologies, Faculty of Agriculture, Institute of Soil and Plant sciences, 2 Liela Street, Jelgava, 3001, Latvia, ³INRAE, VetAgro Sup, Grassland Ecosystem Research Unit, Université Clermont Auvergne, 5 Chemin de Beaulieu, Clermont Ferrand, France, ⁴Poznan University of Life Sciences, Department of Animal Nutrition, 60-637 Poznań, Wołyńska 33, Poland; paul.hargreaves@sruc.ac.uk

As part of the Climate Care Cattle Farming mixtures of red clover and other species were tested to assess their contribution to the mitigation of greenhouse gas (GHG) emissions (carbon dioxide (CO₂), nitrous oxide (N₂O) and methane (CH₄)) and the promotion of soil health, whilst retaining yield. Four countries (France, Latvia, Poland, Scotland) established experiments. Treatments were: red clover + perennial ryegrass with fertiliser, red clover + perennial ryegrass, red clover + chicory and red clover + tonic plantain. Plots were cut and the yield calculated as dry matter (t/ha). The experiments ran for two years (2021 to 2022). Soil samples were taken on establishment, at the end of the first year and twice in the second year and analysed for pH, nutrients, N and C. Soil structure was assessed using a visual method and bulk density. Gas samples were taken weekly during the growing seasons, using static chambers and analysed for CO₂, N₂O and CH₄. Results showed variations in dry matter (DM) with the perennial ryegrass + red clover providing similar amounts of DM even with the addition of the fertiliser. The tonic plantain + red clover provided similar yield as the perennial ryegrass mixtures however, the chicory gave the lowest yields for most of the experiments (France, Poland and Scotland). The emissions of N₂O varied across the sites but were lower for the tonic plantain (France and Scotland) and greatest for the perennial ryegrass (fertilised). The tonic plantain gave similar yield to the perennial ryegrass and produced less N₂O emissions. That the two perennial ryegrass mixtures with and without fertiliser produced comparable yield indicated inorganic fertiliser use could be reduced, saving costs on farm and GHG emissions.

How to mitigate methane and ammonia emissions at the farm level with innovative approaches

P.J. Galama, H.J. Van Dooren, H. De Boer and C. Schep

Wageningen University and Research, Livestock research, De Elst 1, 6700 AH Wageningen, the Netherlands; paul.galama@wur.nl

Complying with intensive societal discussions, the Dutch Dairy chain has set goals for 2030 to increase the sustainability on the topics of climate, welfare, grazing, biodiversity, environment, new business model and land based farming. Also, a coalition of several Dairy organizations have set management goals about dilution of manure, grazing and protein in ration together with the Ministry of Agriculture to reduce the nitrogen losses, especially ammonia emission. The potential to reduce ammonia and greenhouse gas emissions with these management measures and investment in housing systems like floor types to separate faeces and urine, daily removal of manure from the barn, different freewalk housing systems, Cow-toilet and air extraction systems will be shown. The challenge is to design a cow barn that improves animal welfare, manure quality and reduces emissions. These indicators were studied in case control studies with groups of 16 cows at research station Dairy Campus. The Cowtoilet is an automatic urinal that cows use voluntarily in a concentrate feeder. It collects 35% of the urine production and reduced the ammonia emission by around 35-45%. A permeable plate on a slatted floor improves the walkability of the cows and collects all the urine underneath the floor. The ammonia emission can be reduced between 35-50% by acidification of the urine, flushing the plates with the urine or by spraying 20 litre water per cow per day on the floor in combination with a urease inhibitor. A freewalk housing system with woodchips bedding material decreased the ammonia emission with 32% but did increase methane emission with 30%. A new development is a freewalk system with sand bedding that separates the urine by drains at the bottom of the bedding. The faeces are picked up by a bedding cleaner behind the tractor. The data of 12,000 dairy farmers using the Annual Nutrient Cycle Assessment tool (ANCA) were analysed and show the importance of fertilizing, feeding and housing systems on the emissions of ammonia and greenhouse gasses. It illustrates that low emissions of ammonia can go hand-in-hand with low emissions of greenhouse gasses.

Effect of mitigation measures on GHG and ammonia emissions of pilot farms in European countries

Zebenkos, 1282317 Baisogala, Lithuania; diana.ruska@lbtu.lv

A large number of solutions to reduce greenhouse gas (GHG) and ammonia emissions have been proposed for the dairy sector, but their suitability and impact may be strongly influenced by local conditions and characteristics of farming systems. The aim of this research, therefore, was to choose mitigation measures with farmers and simulate effects of measures on GHG and ammonia emissions based on actual farm situations. First, a group of experts from eight countries summarised promising mitigation measures for simulation in carbon footprint tools, and chose options from them that were most suitable for the conditions in their country. In total thirteen mitigation measures for dairy farms were chosen. Second, the list of mitigation measures was discussed with project pilot farmers, who chose measures more suitable for their farm. Expectations of the most effective measures for the simulation process from farmers' and experts' points of view were renewable energy sources on farm, methane blockers as a feed additive, and improve of feed efficiency. Third, measures were simulated using two carbon footprint calculation tools. Simulated results were discussed with the farmers involved, and a farm plan prepared from the suggested measures, estimated reductions, and economic evaluation.

Economic aspects of mitigation practices on pilot dairy farms in Europe

K. Naglis-Liepa, D. Ruska, A. Lenerts and D. Kreismane

Latvia University of Life Sciences and Technologies, Svētes iela 18, 3001, Latvia; kaspars.naglis@lbtu.lv

The EU has taken a leading role in mitigating climate change and preserving the environment, where farmers also have an important role to play. EU countries are responsible for implementing measures to reduce GHG emissions, which would ensure the achievement of the EU Green Deal objectives. The practical implementation of GHG reducing measures differs significantly both in terms of practical implementation and their impact on emission reduction potential as well as farm economics. One of the tasks of the Climate Care Cattle Farming Systems study is to assess the socio-economic impact of GHG emission reduction practices. A pilot farm from 8 EU countries participates in the study, where the impact of GHG measures on emission reduction is simulated and the costs of implementing and maintaining the measures are determined. This information is used to construct the Marginal Abatement Cost Curve, which allows the evaluation of the effectiveness of these measures. The results provide interesting insights into the impact of equal GHG and ammonia measures on European farmers.

Session 05

Theatre 11

Specialized or integrated systems: on-farm eco-efficiency of dairy farming in northern Germany

R. Loges, T. Reinsch, I. Vogeler, C. Kluss and F. Taube

Kiel University, Grass and Forage Science/Organic Agriculture, Hermann-Rodewald-Str. 9, 24118 Kiel, Germany; rloges@email.uni-kiel.de

Potential advantages with regards to ecosystem services of alternative systems such as full-grazing (FG) or integrated dairy/cash-crop (IFG) systems compared to intensive all year indoor feeding (IC) systems for dairying are widely discussed. To investigate performance and environmental impacts, we compared four prevailing dairy systems in an on-farm study. The farm types differed in their quantity of resource inputs and access to pasture: (1) an IC with high import of supplements and mineral fertilizers; (2) a semi-confinement (SC) with daytime grazing during summer and moderate import of supplementary feeds (3) FG based on grazed grass-clover with no purchased N-fertilizers and low quantities of supplementary feeds; and (4) an IFG comparable to FG based on grass-clover leys integrated in a cash-crop rotation. Results revealed highest milk productivity (16 t energy-corrected-milk (ECM)/ha) and a farm-N-balance of 230 kg N/ha in IC; however, the highest product carbon footprint (PCF; 1.2 CO₂eq/kg ECM) and highest N-footprint (13 g N/kg ECM) were found in the SC system. The PCF in FG were comparable to IC (0.9 vs 1.1 kg CO₂eq/kg ECM) but at a lower N-footprint (9 vs 12 g N/kg ECM). However, the farm-N-surplus in the FG system exceeded 90 kg N/ha. A further reduction was possible in the IFG by accounting for a potential N-carry-over from N-rich plant residues to the cash-crop unit, leading to the lowest PCF (0.6 kg CO₂eq/kg ECM) for the IFG. According to this study based on field data, improved integrated grazing systems could provide an important opportunity to increase the ecosystem services from dairy farming.

Modelling methane emission from dairy cows, barn, and storageS. Lashkari¹, F.R. Dalby² and C.F. Børsting¹¹Aarhus University, Department of Animal and Veterinary Sciences, 8830 Tjele, Denmark, ²Aarhus University, Department of Biological and Chemical Engineering, Environmental Engineering, 8000 Aarhus, Denmark; saman.l@anivet.au.dk

There is a large variation among dairy farms in the productivity, feed intake, feed composition, and slurry management in the barn and in outside storage, which affect emissions. The aim of the present study was to develop a model to quantify enteric methane emission and emission from barn and storage based on diet composition, performance level and farm management. The annual emission was modelled for a dairy farm with 200 cows (11.2 tons milk/cow/year and 8,480 kg DMI/cow/year based on the Danish Manure Normative System). Slurry was removed every 28 d from a barn with a ring-channel slurry storage under a slatted floor. Slurry was stored in an outside slurry storage with a natural crust and without tent cover until field application (avg. ret. time of 3.2 months). Nutrient composition of feedstuffs was obtained from Norfor feed table. Enteric methane was estimated based on DMI, fat (g/kg DM), and NDF (g/kg DM). Nutrient composition of faeces was calculated based on feedstuff composition and digestibilities of organic matter, sugar, starch, protein, and fat. Methane emission from slurry was estimated with the anaerobic biodegradation model, which tracks organic matter conversion to methane in two steps: (1) hydrolysis of organic matter to VFA; and (2) VFA conversion to methane and CO₂ by methanogens. Hydrolysis rate constants were applied individually for each organic matter component in the slurry (protein, fat, fibre, etc.). The hydrolysis rate constants were derived from laboratory experiments with pig slurry incubated at different temperatures and are preliminary. Three diets with a wide range of concentrate to forage ratios (49:51%; diet 1, 70:30%; diet 2, and 91:9%; diet 3) were used to investigate the effect of extremely different diet compositions on emissions. Enteric methane emission was 55, 51, and 47 (tons/year) in diets 1, 2, and 3, respectively, and methane emission from the barn was 6.0, 6.1, and 6.2, and it was 9.8, 9.4, 9.0 (tons/year) from the storage in diets 1, 2, and 3, respectively. These preliminary modelling results indicate that feed composition has an impact on the total emission of methane, mainly due to differences in enteric methane.

Session 05

Theatre 13

Impact of sorbent application on NH₃ and CO₂ and CH₄ gas emissions from dairy cattle manure

V. Juskiene, R. Juska, G. Kadziene, D. Stankeviciene and R. Juodka

Lithuanian University of Health Science, Animal Science Institute, R. Žebenkos 12, Baisogala, 82317, Lithuania; violeta.juskiene@ismuni.lt

Livestock manure storage is a significant source of gas emissions. Application of various manure additives is one of possible ways to reduce gas emissions. Therefore, this study was conducted to evaluate the effectiveness of sorbents for NH₃, CO₂ and CH₄ emissions from dairy cattle manure. The study was carried out on laboratory scale, using 90-litter tanks. Three treatments, including biochar, peat and dolomite were applied to stored fresh cow liquid manure. The manure was stored for 42 days under a constant ambient temperature of 14 °C and 60-62% relative humidity. The emission reductions were evaluated by the treatments as compared to the control group without sorbents. The results of the study showed that average NH₃ emission without using sorbents during all study period was 9.2±1.6 mg/m²/h, using biochar – 8.7±1.4 mg/m²/h, peat 9.3±21.7 mg/m²/h, and dolomite 9.1±1.5 mg/m²/h. The addition of biochar reduced NH₃ emissions from manure by 5.9%, dolomite – by 0.6%, however, peat increased the emission by 0.8%. The highest average CO₂ emission was fixed from manure with dolomite treatment – 155.1±8.2 mg/m²/h, and the lowest from biochar treatment – 120.5±8, 0 mg/m²/h (*P*=0.03). CO₂ emissions from manure without sorbents and manure with peat were 133.1±8.2 and 147.5±9.8 mg/m²/h, respectively. It was found that the highest emission values in all groups were observed in the first week, then they gradually decreased and at the end of the study were negligible and the differences between the various treatments were the most insignificant. The highest positive correlation (0.973) between NH₃ and CO₂ emissions was determined for manure treated with dolomite. Sorbents reduced CH₄ emissions from manure on average by 33.6%. In summary, it can be concluded that sorbents most efficiently reduced gas emissions in the first week after adding the sorbents to manure, then this effect decreased. The most effective emission reduction was achieved using biochar. However, at the same time, it can be stated that the ability of sorbents to reduce gas emissions from liquid cow manure is not high, perhaps due to the specific property of cattle manure to form a natural crust during storage.

Greenhouse gas emissions on dairy farms in Slovenia

M. Klopčič, T. Perčič, M. Bric, S. Rogina, G. Šen, T. Kramer, J. Klopčič, D. Drašler and A. Dolinar

University of Ljubljana, Biotechnical Faculty, Department of Animal Science, Groblje 3, 1230, Slovenia; marija.klopac@bf.uni-lj.si

Greenhouse gas emissions on dairy farms are influenced by various management-related factors such as animal nutrition (feed ratio and feeding regime), housing of dairy cattle, disposal and storage system and application of animal excreta, barn ventilation. In addition, breed of the animal, the level of milk yield, the micro-climate of the barn, and local weather conditions also have an important influence. As part of the EIP-AGRI project 'Innovative environmental-climate farm management systems on dairy cattle farms', greenhouse gas concentrations are measured monthly on 11 farms with dairy cows in Slovenia in connection with different housing systems (tied-in housing system, free barn with cubicles, compost bedded pack barn, barn with artificial floor), with different farming system (conventional / organic) and depending on the season. Measurements of greenhouse gases (CH₄, CO₂, N₂O) and NH₃ concentrations on selected dairy farms has been performed once a month with the use of an FTIR analyser for ambient air measurements, with the possibility of measuring 25 gases at different, predetermined locations inside and outside the barn. Simultaneously with these measurements, we also perform measurements of the micro-climate parameters of the barn (temperature, humidity, air flow) at these same locations. Based on numerous measurements over the past year, we have identified large differences already in the barn itself - different places where the measurements are taken, big differences between farms and large differences between months.

Session 06

Theatre 1

'Greenanimo' – green future through research

S.Y. Georgieva

Trakia University, Faculty of Agriculture, Students campus, 6000 Stara Zagora, Bulgaria; svetlana.georgieva8888@abv.bg

Project 'GREENANIMO' aims to significantly strengthen the competencies of Trakia University, an institution of excellence in Bulgaria, in agro-ecological herbivores productivity and meat quality, by creating a strong collaborative link with two scientific institutions INRAE, France, and SRUC, Scotland that are international leaders in this field. The target areas and fields of tasks of the project are as follows: 'Enhancing meat quality'; 'Increasing feed efficiency'; 'Improving animal welfare'; 'Designing sustainable ruminant farming systems'. The challenge for the Bulgarian researchers is to bridge the gap between sciences, business and education-training, which will enable the livestock sector and rural areas to become more sustainable and competitive. By working with the researchers from the internationally-leading partners INRAE and SRUC, knowledge transfer and successful integration into new networks is being achieved. The project clearly addresses all instruments as active measures in the project implementation: scientific exchanges; expert visits and medium and short-term on-site and virtual training; conference attendance, workshops; training courses for students and farmers, etc. Dissemination activities and promotion of newly-developed modules, knowledge, and experiences are oriented to the young and early career researchers and business through a multidimensional interdisciplinary system for scientific and popular media activity, and publications, as well as social demonstration and programmes. Addressing the problems of the primary production from ruminants and the needs for a thematic University centre interacting with the meat quality and productivity systems is a core challenge for the present project. Integration of the project in the University life and educational future is optimized by the students' activity and post graduate programs and individual courses with a practical training set.

PLS-DA analysis on hand-held spectrometer for on-line prediction of beef marbling in slaughterhouses

M. Kombolo¹, A. Goi², M. Santinello², N. Rampado², S. Atanassova³, J. Liu¹, P. Faure⁴, L. Thoumy⁵, A. Neveu⁶, D. Andueza¹, M. De Marchi² and J.-F. Hocquette¹

¹INRAE, UMR1213, Rte de Theix, 63122 Saint-Gènes-Champanelle, 63122, France, ²University of Padova, Viale dell'Università 16, 35020 Legnaro, Italy, ³Trakia University, Faculty of Agriculture, Stara Zagora, 6000, Bulgaria, ⁴INRAE, Herbiopôle, Rte de Theix, 63122 Saint-Gènes-Champanelle, 63122, France, ⁵IDELE, Boulevard des Arcades, 87000 Limoges, France, ⁶IMR3GF, Smulikowskiego St. 4/217, 00-389 Warsaw, France; moise.kombolo-ngah@inrae.fr

Few studies have used near infrared (NIR) spectroscopy to assess meat quality traits directly in the chiller. This study aimed to predict marbling scores with a handheld NIR spectrometer operating in the 740-1,070 nm region on intact meat muscles in the chiller in France and Italy. Marbling was assessed according to the 3G (Global Grading Guaranteed) protocol. The scores ranged from 100 to 1,190 with a mean of 330. Five scans were performed at different points of the *Longissimus thoracis* muscle. Two PLS-DA models were used with or without sex and breed included. The first dataset was made of 677 samples (with sex and breed known), the second dataset was made of all of the 829 samples. The models were developed using an external validation set. Both models gave similar outcomes. The models were first evaluated using a confusion matrix which describes the classification performance. The overall accuracy for both confusion matrices was 61%. The model was also assessed with receiver operating characteristic (ROC) curves where AUROC corresponds to the area under a ROC curve and a single value indicates the overall performance of a binary classifier. It ranges from 0.5 to 1 where the lowest value represents a random classifier and the maximum value represents a perfect classifier. AUROC values were higher for the low and high classes (ranging between 0.8 and 0.7). Finally, permutation plots were obtained for each class, using 100 permutations. Values of the permuted R^2 (the explained variance) and Q^2 (the predictive capability of the model) indicated that only the medium class prediction could be built randomly. In conclusion, results did provide a moderate prediction of the marbling scores which can be useful in the European industry context to predict low and high classes of MSA marbling.

Application of computed tomography and hyperspectral images for enhanced meat quality evaluation

T. Stoyanchev¹, I. Penchev², S. Georgieva², A. Daskalova¹ and S. Atanassova²

¹Trakia University, Faculty of Veterinary Medicine, Students Campus, 6000 Stara Zagora, Bulgaria, ²Trakia University, Faculty of Agriculture, Students Campus, 6000 Stara Zagora, Bulgaria; todor.stoyanchev@trakia-uni.bg

Meat quality is difficult to determine because it is a combination of microbiological, nutritional, technological, and organoleptic components. Classical methods for measuring meat quality require the destruction of samples. Recently, X-ray computed tomography (CT) and hyperspectral imaging (HSI) have been investigated as tools for non-contact inspection and monitoring of meat and whole carcasses. This study aimed to evaluate the capabilities of CT and HSI to assess the quality of beef cuts. Different steaks (Ribeye steak; Denver steak; Rump steak; Top-sirloin steak) were purchased from the city market in Stara Zagora. The meat samples were analysed by CT tomography Somatom Go (Siemens-Healthcare, Germany) and Hyperspectral camera AVT Goldeye CL-008, (Specim, Spectral Imaging Ltd. Oulu, Finland) in the spectral range 900-1,700 nm. Spectronon software (Resonon Inc. Bozeman, MT, USA) was used for processing hyperspectral images. Fat; protein; dry matter and ash content of meat samples were determined by classical laboratory methods. PLS regression was used for the quantitative determination of the chemical content of meat. The percentage of lean meat and fat was estimated on the base of CT and HSI images. A comparison of the determination accuracy of the two investigated methods was made. Equations for estimation of the chemical composition of meat samples based on spectral information in the near-infrared range provide good accuracy of the determination. In conclusion, results show the capabilities of the CT and HSI for fast and non-destructive estimation of meat quality, which can be useful in the meat industry.

Effect of husbandry factors on marbling depositionA. Nicolazo De Barmon¹, I. Legrand¹, J. Normand¹ and J.J. Bertron²¹Institut de l'Élevage, Service qualité des carcasses et des viandes, 149, rue de Bercy, 75012 PARIS, France, ²Institut de l'Élevage, Service production des viandes, 149, rue de Bercy, 75012 PARIS, France; aubert.nicolazodebarmon@idele.fr

Various studies confirm the positive impact of marbling on the overall palatability of meat. Thus, this criterion has been chosen by the French beef interbranch organization (INTERBEV) as a priority to better answer to consumers expectations. However, husbandry practices that enhance marbling deposition are partially known. The objective of the present study is to identify practices which allow to produce marbled meat from beef breeds females (Limousines and Charolaises). Measurements on carcasses were made in slaughterhouses with the new French marbling grid (from 1: no marbling, to 6: very high marbling). Then, two farm's groups were separated: a group producing carcasses with low marbling (LM – marbling score 2.2 ± 0.8) and another group with high marbling carcasses (HM – marbling score 3.7 ± 0.9). Interviews of breeders were conducted to collect husbandry practices to try to explain marbling levels. First, they had to define the major genetic type of their livestock between: 'beefy type' selected on muscle deposition, 'livestock type' chosen for maternal qualities and body size or 'mixed type', which is intermediate. 'Beefy type' is largely represented in LM group and 'livestock type' in HM group. Results indicate two important nutrition periods that may affect marbling: between 5 and 12 months, a period embracing the 'marbling windows' already identified for Anglo-Saxon breeds, and during finishing. Differences between the two extreme groups are important during these two periods. Between 5 and 12 months, the HM group distribute concentrate during a longer period (5.1 ± 2.4 months) than LM (2.6 ± 2.0 months). Moreover, HM distribute more concentrate than LM (around 30% of HM breeders give it *ad libitum* vs 0% for LM). Fattening periods are longer for HM group (5.7 ± 1.4 months) than for LM (2.9 ± 0.9 months). In addition, energetics levels during fattening are more important in the HM group ($+1.3$ UFV/d compared to LM group). The efficiency, technical and economical feasibility of the practices identified in this study must be confirmed in experimental farms to make them operational.

Session 06**Theatre 5****Effect of birth type on meat quality in Ile-de-France lambs**E. Achkakanova¹, I. Penchev² and S. Georgieva³¹Institute of Animal Science – Kostinbrod, Spirka Pochivka, 2232, Kostinbrod, Bulgaria, ²Trakia University, Faculty of Agriculture, Department of Animal husbandry – Ruminant animals and animal products technologies, Students campus, 6000, Stara Zagora, Bulgaria, ³Trakia University, Faculty of Agriculture, Department of Fundamental sciences in animal husbandry, Students campus, 6000, Stara Zagora, Bulgaria; ivan.penchev@trakia-uni.bg

The aim of the present study was to investigate the influence of the factor 'birth type' in lambs on the performance of the meat obtained from them. The studied lambs were of the Ile de France breed and were divided into two groups: the first group is *Single* and the second group *Multiple*. The lambs were slaughtered at 120 days of age, with 4 lambs from each group slaughtered. Samples were taken at 24 hours *post mortem* from the following muscles: m. longissimus thoracis et lumborum (LTL), m. iliopsoas (IP) and m. semimembranosus (SM). The research of the samples for the chemical composition and technological qualities of the meat was carried out 48 h *post mortem*, stored at 4 °C. Regarding the total chemical composition of the meat, no significant difference was observed between the two study groups. There was also no significant difference between the groups in terms of technological qualities (pH value, colour, roasting losses, brittleness). Only a significant difference ($P < 0.01$) was found in the indicator of water-holding capacity between the groups in the studied LTL and IP muscles.

Relationships between lamb feed efficiency, rumen volume and carcass quality measured by CT scanning

N.R. Lambe, A. McLaren, K.A. McLean, J. Gordon and J. Conington

SRUC, SRUC Hill and Mountain Research Centre, FK20 8RU, United Kingdom; nicola.lambe@sruc.ac.uk

There is mixed evidence in the literature about the relationships between feed intake or efficiency and body composition of sheep. In cattle there is some evidence that selection for feed efficiency may reduce fatness at a fixed age or weight. These relationships require further investigation before sustainable strategies to breed for improved efficiency and reduce methane can be proposed. Across two years, Texel × Scotch Mule lambs (n=236 in total) from 10 sires were recorded through individual feed intake recording equipment, after weaning, for a total of six weeks (~14-20 weeks old), following a two week adaptation period. Lambs were CT scanned at the end of the feeding trial and a number of carcass quality traits were calculated from the resulting images, as well as reticulo-rumen volume (RRvol; known to be linked to methane emissions). Residual feed intake (RFI) was calculated for each lamb, by adjusting average daily dry matter intake for live weight, average daily liveweight gain and fixed effects (sex, litter size). Residual values for the CT traits were calculated, after adjusting for fixed effects (sex, year, litter size in which the lamb was reared, age of dam) and live weight at CT scanning. Low to moderate negative correlations between residuals imply that reduced RFI is favourably associated with increased carcass muscle weight, eye muscle area and depth. No significant correlations with RFI were observed for fat traits (carcass fat weight or CT-predicted intramuscular fat), spine traits (length or vertebra number), or RRvol. Low to moderate negative correlations were observed between RRvol and most of the carcass traits, suggesting poorer carcass yield and quality (but reduced fatness) in lambs with higher RRvol, which has previously been associated with higher methane emissions. Larger data sets are being amassed to allow genetic relationships among these traits to be further investigated.

Theatre 7

Do biomarkers of residual feed intake in beef cattle remain consistent regardless of feeding level?G. Cantalapiedra-Hijar¹, K. Nedelkov², P. Crosson³ and M. McGee³

¹INRAE, UMR Herbivores, 63122, France, ²Trakia University, Faculty of Veterinary Medicine, 6000, Stara Zagora, Bulgaria, ³TEAGASC, Animal & Grassland Research and Innovation Centre, Grange, Dunsany, Ireland; gonzalo.cantalapiedra@inrae.fr

The use of novel blood biomarkers to predict residual feed intake (RFI) has been proposed as a cost-effective technology to identify feed efficient cattle. However, it is unclear whether these biomarkers are linked to RFI because they reflect the metabolic efficiency of the animal or simply co-vary with the inherent differences in feeding level. This study aimed to determine if plasma biomarkers of RFI, identified under *ad libitum* feeding conditions, remain consistent when animals are feed-restricted on the same grass silage-based diet. Sixty Charolais crossbred young bulls divided into two groups of 30 animals were used in a cross-over design study with two 70-day test periods. Group 1 was fed *ad libitum* in period 1 (A1) and then restricted during period 2 (R2), while the opposite occurred for Group 2 (R1 and then A2). Animals in R1 and R2 were restricted at a level of 1.45% of their body weight. Blood samples were collected from the 12 most divergent RFI (6 Low-RFI, efficient; 6 High-RFI, inefficient) animals in both groups at the end of the first test period, and again on the same animals after the second test period (n=48). Plasma samples were analysed by LC-tandem mass spectrometry and colorimetric methods for quantifying a total of 74 targeted metabolites. Repeated measurements analysis was conducted with the fixed effects of RFI, feeding level and their interaction and the random effect of animal; RFI was considered as either a categorical (Group 1; Low vs High) or continuous (Group 2) variable. Fourteen plasma metabolites had a moderate-to-high repeatability ($0.55 \leq r \leq 0.91$) across both feeding levels. In Group 1, the plasma concentration of α -aminoacidic acid was lower in Low-RFI compared to High-RFI cattle for both feeding levels (FDR=0.02). In Group 2, 5-aminovaleric acid concentration was positively correlated ($r=0.72$) with RFI across both feeding levels (FDR=0.01). These two metabolites belong to the lysine degradation pathway. Results suggest that metabolic regulations associated with RFI are not solely driven by differences in feeding levels.

Practical application of Observer XT software for behaviour and welfare research in sheep and cattle*N.A. Bozakova and M. Halil**Trakia University, Students campus, 6000 Stara Zagora, Bulgaria; nadiab@abv.bg*

In modern scientific research with animals, it is especially relevant to synchronize and combine various vital signs to obtain a complete picture of their welfare. Observer XT software provides detailed and refined data on animal behaviour, but also provides the ability to visualize physiological data, as well as export and synchronize ethological data with other physiological indicators. The aim of the present study is to review the practical use of Observer XT software for synchronizing and integrating ethological observations in sheep and cattle with different physiological parameters in relation to their welfare. To achieve the goal, we reviewed over 250 official documents, and scientific publications through electronic networks – PubMed, Research Gate, and Elsevier, related to the use of Observer XT software to integrate data from video recordings of various behavioural reactions of cattle, calves, sheep, lambs, and goats with their physiological, hormonal, biochemical, immunological and other indicators related to their welfare. As a result, we summarized and systematized the scientific data from the practical use of Observer XT software to synchronize and integrate indicators from ethological observations in sheep and cattle with other multimodal data. This makes it possible to establish relationships and regularities between the various vital indicators and, as a result, to obtain a more complete picture of animal welfare, as well as to significantly improve the quality of scientific research. Based on established data, the Observer XT software is an optimal method for integrating and synchronizing ethological data in research with different physiological parameters in sheep and cattle in relation to their welfare.

Session 06

Theatre 9

Software tools and technologies used to study animal behaviour-benefits and capabilities of Observer*M. Halil, N. Bozakova and S. Georgieva**Trakia university, Animal husbandry, Student campus, Stara Zagora, 6000, Bulgaria; mehmed.halil@trakia-uni.bg*

Some behaviours can be used to gain insight into the emotional state and welfare of the animals. It is important to be able to recognize abnormal behaviours, equally important to understand which typical behaviours could be indicative of poor welfare when performed in excess, and which behaviours can indicate positive welfare. Using recording methods to quantitatively assess behaviours related to positive and negative welfare can be a powerful tool for professionals working with farm animals. Welfare assessment methods have evolved significantly in recent decades in terms of both behavioural and physiological indicators. Modern ethological studies require a good knowledge and precise measurements and synchronization of video data of behaviour with the physiological parameters of the studied animals in this scientific field. Nowadays, applications are using that support these processes, such as software for studying animal behaviour – Observer XT. The aim of this research is to investigate the benefits and capabilities of Observer XT in analysing and study of farm animal behaviour, as well as its practical application in teaching students. After numerous observations, trainings and specialized literature searches for the application of this unique software, in the present scientific study, we present that the Observer XT software offers a wide range of possibilities for simultaneous integration and synchronization of video – data from ethological observations, with physiological indicators such as heart rate, abdominal movements, respiratory rate in animals. Due to its flexibility, the application can be successfully used in various fields such as Ethology, Zoology, Veterinary Hygiene and Technology, both for scientific purposes and for training of future specialists.

Animal welfare: from research to practice

I. Veissier¹, V. Brunet¹, D. Ledoux² and A. De Boyer Des Roches²

¹INRAE, UMR Herbivores INRAE-VetAgro Sup, Centre de Clermont-Ferrand Theix, 63122 Saint Genes Champanelle, France, ²VetAgro Sup, UMR Herbivores INRAE-VetAgro Sup, 1 avenue Bourgelat, 69280 Marcy l'Etoile, France; alice.deboyordesroches@vetagro-sup.fr

In the second half of the 20th century, research on animal welfare began. Initially, most research aimed at identifying and reducing suffering; e.g. research helped to define minimum space allowances per animal or to identify the need for social interactions. Then research focused on what would make animals comfortable; e.g. preferences between lying surfaces have been studied. More recently, the concept of positive welfare has been introduced, which goes beyond the mere satisfaction of needs by providing a rich environment and promoting positive emotions (expressed through play behaviour, positive interactions, exploration, etc.). Much is now known about animal welfare, at least in theory. On the basis of this knowledge, legislation has been adapted in many countries, at least in the EU, to guarantee minimum standards of animal welfare, i.e. essentially to avoid poor welfare. Quality standards have also been developed by several production chains, some of which offer a higher level of welfare than the legislation. To bridge the gap between theory and practice, researchers need to work with stakeholders to define best practices that can be applied on farms (or during transport and slaughter) to ensure a high level of animal welfare. These recommendations should not be seen as an addition to farming practices, but as an integral part of those practices. In other words, the latest knowledge on animal behaviour, sensory and cognitive abilities, health, physiology, etc. should be considered when defining husbandry practices that meet the needs of animals and farmers. We believe that good practices should cover animal needs (basic needs, comfort) and best practices should promote positive welfare. We illustrate this approach with the CARE4DAIRY project, which is developing good and best practice guidelines for the dairy cattle sector. The scientific and technical knowledge will be used to define these practices which will be discussed with stakeholders (farmers, farm advisors, policy makers) before final guidelines are produced. The project covers dairy calves, heifers and cows, including cows at the end of their productive lives.

Session 06

Theatre 11

Effects of warm climatic periods on dairy cow behaviour and welfare in a maritime European climate

M.J. Haskell, I. Sullivan, M. March and L. Shewbridge-Carter

SRUC, West Mains Road, EH9 3JG Edinburgh, United Kingdom; marie.haskell@sruc.ac.uk

Global warming is resulting in an overall increase in temperatures and in the frequency of extreme weather events. In dairy cattle, thresholds within the temperature-humidity index (THI) have been used to indicate points at which cattle will likely experience thermal stress (e.g. a THI threshold of 75 predicts thermal stress). However, high-yielding dairy cows that reside in temperate maritime climates may experience some degree of thermal discomfort below this threshold particularly when they are housed. Housing often results in high levels of humidity. The use of technology such as activity monitors and automated intake measures allow us to monitor responses. The aim of this study was to use technological solutions to assess behavioural changes in response to moderate increases in THI levels. Data from dairy cattle on an experimental unit were used. Data on daily lying times, lying bout frequency, step count, feed and water intake were extracted for 10 pairs of warmer (THI<65) and ten matching cooler (THI=43 to 60) periods. Each period was 3 or more days each, and warm and cooler periods were no more than 5 weeks apart to ensure that the data from the same animals were being compared. Results showed that total daily lying time was shorter during warmer periods than cooler periods ($P<0.05$; means and SEMs (h): warm: 11.4±0.04; cool: 12.0±0.04) with a tendency for cows to have more daily lying bouts in warm periods ($P=0.08$; (counts): warm: 12.1±0.1; cool: 11.9±0.1). However, there was no effect of THI level on the no. of steps taken by cows ($P>0.05$ (counts): warm: 858±6; cool: 856±6). Water intake was higher during warm periods ($P<0.05$: (l) = warm: 79.4±0.6; cool: 71.5±0.5). Milk yield was lower during warm periods than cool periods ($P<0.05$; (l): warm: 30.3±0.2; cool: 30.7±0.2). This suggests that behaviour and milk yield are adversely affected even in conditions that are not traditionally regarded as exceeding cows' ability to cope with thermal challenge. Technological solutions aid in detection on cow thermal distress and may be used as a routine monitoring system.

Behavioural and hormonal effects of intensive sheep farming on milking behaviour in a milking parlour

I. Nedeva, T. Slavov, V. Radev, S. Georgieva and I. Varlyakov

Trakia University, Faculty of Agriculture, Department of Fundamental Sciences in Animal Husbandry, Students campus, 6000 Stara Zagora, Bulgaria; ivelina.nedeva@trakia-uni.bg

The aim of the present study was to evaluate how intensive dairy sheep farming influenced their behaviour during milking in a milking parlour. The sheep ($n=633$) were divided into groups according to milk yield (high- and low-yielding) and stage of lactation (beginning, middle, end). Using video surveillance and data from morning and evening milking of the automated system installed in the milking parlour, an analysis of ethological parameters order of entry in the milking parlour (EMI) and milking parlour side preference (SMI) was made. The calculated EMI and SMI indices served for individual scoring of each animal for evaluation of studied factors. The blood concentrations of thyroid hormones (T_3 and T_4) and cortisol were assayed during three different seasons (summer, autumn, winter). The daily milk yield of studied sheep was 2.451 l, with a peak of 3.967 l in mid-lactation. The sheep built a stable hierarchical order in the group throughout the entire lactation period, manifested with high values of the EMI index: 668.62. The milk yield had no effect on both the order of entry in the parlour and side preference. The established milking parlour side preference (SMI=69.38%) was not accompanied with preference to the milking place, which facilitate the technological process of milking. A statistically significant effect of the season ($P<0.001$ in the autumn) on blood cortisol, triiodothyronine and thyroxine concentrations was demonstrated with no relation with milk yields. Regardless of the established seasonal changes in adrenal and thyroid gland hormones, they had no effect on the health and welfare of sheep reared in intensive systems, but point out to a more difficult adaptation to this farming system.

Combining cattle and sheep in a grassland-based system: which effects for system multiperformance?

S. Prache, K. Vazeille, B. Sepchat, P. Note, P. Veyssset and M. Benoit

INRAE, Theix, 63122 Saint-Genès-Champagnelle, France; sophie.prache@inrae.fr

The association of beef cattle and sheep shows benefits at the grazing season level, but a comprehensive assessment at system level is lacking. Three grassland-based organic systems were managed for 4 years as separate farmlets, with similar surface area and stocking rate: one mixed system combining beef cattle and sheep (MIX, 60:40 cattle:sheep livestock units (LU)) and two specialised systems, beef cattle (CAT) and sheep (SH). Calving and lambing were adjusted to grass growth to optimise grazing. Calves were pasture-fed from 3 months old until weaning in October, fattened indoors with haylage and slaughtered at 12-15 months. Lambs were pasture-fed from 1 month old until slaughter; if lambs were not ready for slaughter when the ewes mated, they were stall-finished with concentrates. The decision to supplement adult females with concentrate was based on the achievement of a target body condition score (BCS) at key periods. The decision to treat animals with anthelmintics was based on mean faecal egg excretion remaining below a certain threshold. A higher proportion of lambs were pasture-finished in MIX vs SH due to a higher growth rate which led to a lower age at slaughter. Ewe prolificacy and productivity were higher in MIX vs SH. The level of concentrate consumption and number of anthelmintic treatments in sheep were lower in MIX vs SH. Cow productivity, calf performance, carcass characteristics and the level of external inputs used did not differ between MIX and CAT. However, cow BW gain during the grazing season was higher in MIX vs CAT. These outcomes validated our hypothesis that the association of beef cattle and sheep promoted the self-sufficient production of grass-fed meat in sheep. It also promoted better female BCS and BW at key stages of the reproduction cycle and better development of the females used for replacement, which may enhance animal and system resilience. It improved economic and environmental performance and feed-food competition in the sheep enterprise, due to better animal performance and reduced inputs use, but not in the beef cattle enterprise.

Milking temperament and its relation with test day milk yield in Bulgarian Murrah buffaloes

T. Stepancheva, I. Marinov and Z. Gergovska

Trakia University, Faculty of Agriculture, Department of Animal husbandry – Ruminant animals and animal products technologies, Students campus, 6000 Stara Zagora, Bulgaria; ivaylo.marinov@trakia-uni.bg

The aim of the study was to assess temperament during preparation for milking and the milking itself of Bulgarian Murrah buffaloes reared in Bulgaria. The study included 91 buffalo cows that were between 30 and 240 Days in milk (DIM). Cows were housed under the conditions of tie-stall housing system and milked with a milking pipeline. The average milk yield of cows for standard lactation was 2245.37 kg with 7.77% fat and 4.34% protein content in milk. The average score for temperament during attaching the milking cluster was 1.83, and for milking temperament – 1.93. The highest was the percentage of cows that reacted by leg lifting (18.9%), followed by animals that were moving on the stall bed during milking (10%), cows that definitely kick (9.9%), and 13.3% managed to remove the milking cluster during milking. A higher percentage of cows responded by leg lifting and kicking during the milking cluster attaching compared to milking itself, 27.8 and 13.3%, respectively. During milking, 72.2% of the buffaloes stood still or only have stepped from foot to foot (scores 1 and 2), and 14.5% have shown undesirable behaviour (scores 4 and 5). A significant difference between the first and second temperament scores during preparation for milking and during milking was not reported. With the highest LS-means for test day milk yield (TDMY) were cows with the most undesirable behaviour during milking, scores 5 (8.18 kg) followed by those with a score of 4 (7.65 kg). The milk yields of cows with milking temperament scores from 1 to 3 were almost the same and lower than that of aggressive and nervous cows, respectively from 7.21 to 7.37 kg. In cows with scores 1, 2 and 3, the lactation curves were similar in both shape and variation. In all cows, the maximum milk yield was 7.5 to 8.0 kg and was maintained for several months with small variation. The lactation curve in cows with a score 5 had the most fluent shape and the highest maximum milk yield – over 8.5 kg. The lactation curve in cows with a temperament score 4 was with the most undesirable shape – steep reaching the peak and a sharp decrease in milk yield after the peak.

Over the last decade, the EU has been focused on solving its dependency on imported soybean for livestock feeding, which means Mediterranean legumes species may represent a local solution and possible replacement candidate. The objective of this preliminary study was to evaluate the effects of partial replacement of soybean meal by lupins on portuguese autochthonous Churra da Terra Quente lambs' diets, on the carcass traits, meat characteristics, and meat fatty acid profile. Two trials were conducted: on trial 1, the soybean meal (control; C) was partially replaced by *Lupinus albus* or *Lupinus luteus* (50 g/kg; LA5 and LL5, respectively); on trial 2, lambs were fed four diets with graded levels of *Lupinus luteus* (0, 100, 150 and 200 g/kg; C, LL10, LL15, LL20, respectively). At the end of the feeding trials, animals were slaughtered to evaluate carcass characteristics and meat composition, including fatty acids. Carcass composition in tissues was not affected ($p>0.05$) by diet in both trials. Also, no significant ($P<0.05$) differences were observed in meat quality attributes between diets on trials 1 and 2. Overall, the *Longissimus* muscle's fatty acid content was not affected by diet ($p>0.05$) in both trials. Carcass and meat quality was overall comparable between lambs fed with soybean meal and lupins, indicating the latter as a potential alternative protein source. However, the lack of significant differences could also be attributed to the small sample size. This work was supported by the projects UIDP/CVT/00772/2020 and LA/P/0059/2020 funded by the Portuguese Foundation for Science and Technology (FCT).

Lipid composition of dromedary camels (*Camelus dromedarius*) raised in extensive and intensive system

M. Lamraoui¹, J. Pestana^{2,3}, M. Costa^{2,3}, C. Alfaia^{2,3}, Y. Khelef⁴, N. Sahraoui⁵, A.M. Almeida⁶ and J.A.M. Prates^{2,3}

Although camel meat is a valuable source of protein for human consumption, it remains relatively understudied. In this study, we investigated the effect of production systems on the fatty acid profile and fat-soluble compounds of Sahraoui dromedary camel meat. We collected meat samples from 12 healthy male camels of similar age from both extensive (EPS, n=6) and intensive (IPS, n=6) production systems for analysis. Meat from camels raised in IPS had higher lipid content (3.1 g/100 g fresh weight) than meat from those raised in EPS (1.2 g/100 g). The primary fatty acid present in camel meat was oleic acid, which accounted for 28.7 and 23.9% of the fatty acid composition in meat from IPS and EPS, respectively. Additionally, meat from EPS had higher percentages of saturated fatty acids (53.7%) compared to meat from IPS (44.7%). Moreover, polyunsaturated fatty acids content was higher in meat from animals raised in EPS (19.2%) compared to those raised in IPS (6.6%). Interestingly, cholesterol levels were higher in the meat from camels raised in EPS (0.7 mg/g) than those from IPS (0.52 mg/g). However, there were no significant differences in α -tocopherol content between the two production systems. Results suggest that the observed differences in fatty acid profile and fat-soluble compounds in camel meat could be attributed to variations in animal feeding, which can ultimately affect the growth and development of the animals. The insights gained from this study are highly relevant to camel producers and consumers, as it provides an understanding of its suitability for human diets and could help in improving feeding strategies.

Effective application of UAVS in modern livestock agriculture

T. Petrova¹, Z. Petrov² and M. Marinov³

¹Trakia University, Faculty of Agriculture, Department of Agricultural Engineering, Students campus, 6000 Stara Zagora, Bulgaria, ²Rakovski National Defence College, Defence Advanced Research Institute, 82 Evlogi i Hristo Georgievi Blvd., 1000 Sofia, Bulgaria, ³Georgi Benkovski Air Force Academy, 1 Sv. sv. Cyril and Methodius str., 5855 Dolna Mitropolia, Bulgaria; zhpetrov@gmail.com

This article examines the effectiveness of aerial photography using unmanned aerial vehicles (UAVs) in free-ranging livestock. The goal is to analyse the effectiveness of applying algorithms for contrast enhancement and histogram analysis in image processing. The results of the study of three algorithms for contrast enhancement and histogram analysis of digital images are shown. All studied algorithms can also be used on colour images. The results show that it is very important to use appropriate computational image processing methods to achieve the objectives.

Effects of dietary beet pulp on rumen fermentation, beef quality, and intramuscular adiposity

M. Baik, S.H. Lee and S.Y. Kim

Seoul National University, Department of Agricultural Biotechnology, College of Agriculture and Life Sciences, Gwanak-ro 1, Gwanak-gu, Seoul, Republic of Korea, 08826, Korea, South; mgbaik@snu.ac.kr

Beet pulp is a byproduct of sugar beet processing and contains abundant neutral detergent fibre and pectin, which are readily fermentable in the rumen. We investigated the effects of partial replacement of corn flake in the diet with beet pulp on growth performance, ruminal volatile fatty acid profiles, lipogenic gene expression, adipocyte cellularity, and carcass traits in Hanwoo (Korean cattle) steers. The eighteen steers (body weight, 636 ± 10.9 kg; age, 25.9 ± 0.25 months) were equally divided into the corn flake (CF) and beet pulp (BP) groups. Approximately 89% of dry matter of the requirement was offered as a concentrate portion, and the remaining 11% was offered as tall fescue hay. The 78 and 72% of concentrate portion was provided by the pelleted basal concentrate to CF and BP groups, and the remaining 22 and 28% were supplemented with corn flake or beet pulp, respectively. Dietary crude protein and energy levels of two groups were similar. The experiment was conducted for 25 weeks, including a 5-week adaptation period. Average daily gain and feed efficiency were not affected ($P \geq 0.79$) by beet pulp feeding. The proportion of ruminal acetate was higher ($P < 0.001$) in the BP group than in the CF group, whereas proportion of ruminal propionate was lower ($P < 0.001$) in the BP group. The beef yield grade ($P = 0.10$), quality grade ($P = 0.10$), and beef price per kg ($P < 0.001$) were tended to be higher or higher in the BP group than in the CF group. Intramuscular adipocyte size of longissimus thoracis (LT), which was determined by image analysis of histological section of the LT, was larger ($P < 0.001$) in the BP group than in the CF group. Fatty acid synthase mRNA levels determined by qPCR were higher ($P = 0.03$) in the BP group than in the CF group. The increased lipogenic gene expression may, in part, contribute to the increased adipocyte size of the LT by beet pulp feeding. In conclusion, beet pulp could be used as a lipogenic energy source for improving beef quality grade without affecting growth performance of cattle.

The identification of high-quality *Perilla frutescens* Tan lamb meat by multi-metabolomics analyses

Y. Yu, B.Y. Zhang, X.Z. Jiang, Y.M. Cui, H.L. Luo and B. Wang

China Agricultural University, State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, 2 Yuanmingyuan west road, Haidian District, 100193, Beijing, China, P.R.; wangb@cau.edu.cn

Consumers are paying increasing attention to eating healthily, thus, food enriched with omega-3 polyunsaturated fatty acids (n-3 PUFAs) is admired worldwide. *Perilla frutescens* seeds and *P. frutescens* oil are widely used in the food market and livestock due to their abundance of α -linolenic acid. This study aimed to investigate effects of dietary *P. frutescens* seed supplementation on animal growth, meat quality, muscle fatty acid profiles, and volatile, lipophilic, and hydrophilic metabolome of Tan-lambs. Forty-five Tan-lambs (approximately 6 months old) were randomly divided into three groups with HC (a high-grain based control diet), LC (a low-grain based control diet) and PFS (a low-grain based control diet with supplemented 3% *P. frutescens* seed). Longissimus dorsi was collected for this study. Both HC and PFS showed a significantly increased growth performance compared to the LC. The PFS modified the 24h meat colour than LC. Compared to the HC and LC, the PFS increased n-3 PUFA content, resulting in the upregulated ratio of PUFA to saturated fatty acid. The ratio of n-6 PUFA to n-3 PUFA was significantly different among the three groups, with the highest value in the HC and lowest value in the PFS. Untargeted high-resolution LC-MS and untargeted GC-MS metabolomics were further used to analyse muscle volatile, lipophilic, and hydrophilic metabolome in the PFS and LC. In total, 68 differential metabolites and 7 volatile compounds were screened between PFS and LC based on LC-MS and GC-MS, respectively. Among them, 18 lipid molecules, 23 hydrophilic molecules and 4 volatiles were significantly increased. Most of the differential metabolites were mainly enriched in the pathways related to antioxidant function and branched-chain amino acid synthesis. Together, this study demonstrated that dietary *P. frutescens* seed supplementation improved the meat colour and fatty acids profiles, and increased the antioxidant capacity of Tan-lambs, indicating the *P. frutescens* seed can be used to enhance lamb meat quality with enriched contents of healthy and flavour compounds for populations.

Effect of feeding garlic-citrus supplement on carcass characteristics and fatty acid profile of beef

M.E. Eckhardt¹, T. Brand², S.A. Salami³, B.M. Tas³, J.F. Legako⁴, T.E. Lawrence¹ and L.W. Lucherk¹

¹West Texas A&M University, Canyon, TX 79016, USA, ²Mootral GmbH, Waldseeweg 6, 13467 Berlin, Germany, ³Mootral Ltd, Roseheyworth Business Park North, Abertillery, United Kingdom, ⁴Texas Tech University, Lubbock, TX 79409, USA; ssalami@mootral.com

Several studies have shown that feeding garlic- and citrus-extract-based supplement (GCE; Mootral Ruminant) reduces enteric methane emissions in ruminants. However, there is limited information on the impact of feeding this supplement on beef quality. This study evaluated the carcass characteristics, proximate composition, and fatty acid (FA%) profile of beef from cattle supplemented with GCE. Twenty feedlot cattle were randomly assigned to 4 groups (5 cattle/group). Two groups were fed for 9 months (control vs GCE) and the other two groups were fed for 12 months (control vs GCE). All animals were fed a typical feedlot diet while the GCE-fed cattle were supplemented with 27 g of GCE/head/day and top-dressed on the ration. At the end of each feeding duration, all animals were slaughtered, and carcasses were evaluated according to the USDA beef grading measures. Strip loin steaks and ground beef patties were prepared at 14- and 15-days *post-mortem*, respectively. Data were statistically analysed using SAS and treatment effects were considered significant when $P < 0.05$. Marbling score, backfat, hot carcass weight and dressing percentage were similar between the control and GCE groups. Cattle fed for 9 months had higher backfat compared to those fed for 12 months. Relative to the control, the ribeye area was lower in cattle fed GCE for 9 months but did not differ after 12 months of feeding GCE. Proximate analysis of beef steaks and patties showed that fat, moisture, protein, and collagen were similar between the control and GCE diets. In general, feeding GCE and duration of feeding did not exhibit substantial changes in FA% of beef steaks and patties. Dietary GCE decreased C20:2 in steaks and increased C15:0 and C17:1 in patties. Compared to 9-month feeding, the 12-month steaks had higher C18:2 *n*-6, C20:4 *n*-6 and total polyunsaturated FA whereas only higher C18:2 *n*-6 was observed in 12-month patties. Overall, these results indicate that feeding GCE had minimal or no effect on carcass characteristics and FA profile of beef regardless of the feeding duration.

Main microclimatic indicators in a milking parlor for dairy cows

D. Dimov¹, T. Penev¹, I. Marinov², J. Mitev¹, T. Miteva¹ and M. Stoyanov¹

¹Trakia University, Faculty of Agriculture, Department of Ecology and Zoohygiene, Students campus, 6000 Stara Zagora, Bulgaria, ²Trakia University, Faculty of Agriculture, Department of Animal husbandry – Ruminant animals and animal products technologies, Students campus, 6000, Stara Zagora, Bulgaria; toncho.penev@trakia-uni.bg

The study was conducted in the milking parlour of a cattle farm with a capacity of 400 cows of the Holstein-Friesian breed. The milking installation was a double 8 'Herringbone' type without windows, and the roof was constructed of glass. The reporting of temperature, air humidity and temperature-humidity index (THI) was performed three times during each milking (at the start, in the middle and at the end of milking) with measurements repeated during the morning, midday and evening milking. The highest mean and maximum daytime air temperature values were recorded in summer and spring. Although the average values for the spring season were lower than those for summer (by about 4 °C), the maximum values reached were equally high – 31.4 °C. In terms of relative air humidity, the highest mean values were reported for the winter season – 82.39%. For the other seasons, the relative humidity values were on average high and close in value – from 62.51 to 67.46%. At THI, the highest mean daily and maximum values were reported in the summer months – 73.41 and 80, respectively.

Estimation of rib composition and intramuscular fat from DXA or smartphone imaging in crossbred bullC. Xavier^{1,2}, B. Meunier³, I. Morel², Q. Delahaye³, Y. Le Cozler¹, M. Bonnet³ and S. Lerch²¹INRAE-Institut Agro, PEGASE, 35590 St-Gilles, France, ²Ruminant Nutrition and Emissions, Agroscope, 1725 Posieux, Switzerland, ³INRAE, Université Clermont Auvergne, Vetagro Sup, UMRH, 63122 Saint-Genès-Champagnelle, France; xaviercaroline@orange.fr

Aim was to compare dual X-ray absorptiometry (DXA) or smartphone-derived picture for estimating the 11th beef rib tissue composition and intramuscular fat content (IMF). Forty-nine beef-on-dairy crossbred bulls (♀ Swiss Brown × ♂ Angus, Limousin or Simmental) were slaughtered at 519.6±8.5 kg body weight. Left 11th rib was DXA scanned (iLunar, GE Med. Syst., 'Right Arm' mode) and DXA total mass, lean and fat proportions were recorded. An open-access computer image analysis method based on smartphone pictures of both faces of the rib was used to estimate the total rib area, from which bone, muscle (longissimus and others) and adipose tissue (subcutaneous, inter- and longissimus intra-muscular) proportions were recorded. As gold standard measures, rib was dissected, and *longissimus* IMF determined by Soxhlet after acid-hydrolysis. Estimative equations of rib composition from DXA or smartphone data were set-up by linear regressions (R 4.2.2). Rib contained 42.6±3.3% longissimus and 63.5±3.3% total muscles, 12.6±1.8% intermuscular and 18.9±3.0% total adipose tissues, and *longissimus* 1.6±0.5% IMF. Rib longissimus and total muscle proportions were precisely estimated by DXA [root mean square error (RMSE) 1.7 and 1.3%, R²=0.72 and 0.85], as well as intermuscular and total adipose tissues (RMSE=1.0 and 0.9%, R²=0.69 and 0.90, respectively). Precision was similar for smartphone cranial ribs cross-section estimations (RMSE=1.1, 1.4, 1.0 and 1.1%, R²=0.88, 0.82, 0.64 and 0.86, for longissimus, total muscles, intermuscular and total adipose tissues). Longissimus IMF was estimated less precisely, but still satisfactorily by either DXA or smartphone (RMSE=0.28%, R²=0.58 for both). For smartphone, precision was comparable when based on caudal or the average of both faces. At the exception of intermuscular adipose tissue, crossbreed effect was included (P<0.05) in DXA and smartphone models. A single rib DXA scan or cross-section picture seem promising methods to estimate rib composition in a simple, quick, precise, and non-destructive way.

Perception of beef by the Algerian consumerM. Sadoud¹ and J.F. Hocquette²¹H. Benbouali Chlef University, Faculty of Science, 0200 Chlef, Algeria, ²INRAE, UMR1213 Herbivores, 63122, Theix, France; mh.sadoud@univ-chlef.dz

Meat consumption is often the symbolic marker of prosperity of a society and/or of specific socio-economic groups. While meat consumption has decreased in the North of the Mediterranean, it has increased in North Africa (Tunisia, Morocco and Algeria) from 23.5 to 39 kg/year/person during the last decade. The development of cattle breeding has always been a priority for Algeria to meet the needs of its population in animal proteins, particularly in the north where meat is mostly consumed. The cattle population of Algeria is around 2 million heads. The beef self-sufficiency rate is 55%, the rest coming from imports. This communication aims to analyse the perception of beef by Algerian consumers according to their socio-demographic profiles. The survey took place in 2018, with 300 consumers from four different age groups. The questionnaire was sent to heads of households, who are mainly responsible for purchasing meat. This survey made it possible to draw up an inventory of consumer preferences in order to know their perceptions of beef. The surveys comprised 24 questions targeting regular consumers of beef. Different factors were studied: household size, family situation, level of education, income, type of the most purchased meat, frequency of purchase, cut, colour, smell, taste and juiciness of the meat, consumption preferences, cooking time, diet, cuts purchased and consumed. Many factors, such as psychological factors and sensory factors, influence consumer behaviour towards beef. First, the majority of consumers go to the butcher for meat purchases. About 60% of them choose beef due to its perceived high nutritional value due to its richness in proteins. Most of them think it is of satisfactory quality. Second, consumers put importance on specific attributes, namely colour, taste and price, and a lower interest in fat content. In addition, this analysis of meat perception by consumers in the Algerian region shows very different behaviours towards beef. In conclusion, beef is well consumed in Algeria despite a great variability mainly due to different socio-demographic and economic conditions of the population in the studied region resulting in specific consumption patterns.

Effect of intramammary infection on milk protein profile measured at the quarter level in dairy cowsV. Bisutti¹, D. Giannuzzi¹, A. Vanzin¹, A. Toscano¹, M. Giancesella², S. Pegolo¹ and A. Cecchinato¹¹University of Padova, DAFNAE, viale dell'Università 16, 35020, Italy, ²University of Padova, MAPS, viale dell'Università 16, 35020, Italy; alessio.cecchinato@unipd.it

Subclinical mastitis is an impactful disease affecting, other than animal health and welfare, also milk productivity, composition, and technological traits. This work evaluated the impact of subclinical intramammary infection (sIMI) induced by four pathogens (*Staphylococcus aureus*, *Streptococcus agalactiae*, *Streptococcus uberis* and *Prototheca* spp.) on the detailed milk protein profile of Holstein cows from three Italian dairy farms. After an initial bacteriological screening (T0) performed on all animals (n=450) to detect cows with sIMI, only the positive ones (n=78) were followed up at a quarter level after two (T1) and six weeks (T2) from T0. In total, 529 quarter milk samples were collected, on which a validated RP-HPLC method was used to identify and quantify 4 caseins (CN; κ -, α -_{s1}-, α -_{s2}-, and β -CN), and 3 whey proteins (β -LG, α -LA, and lactoferrin). Traits were analysed using a hierarchical linear mixed model including as fixed effects: cows' DIM, parity, herd, somatic cell count (SCC) in classes, bacteriological status (BACT, negative and positive), and the interaction SCC×BACT. As random effect, we used the individual cow/replicate nested within herd, DIM, and parity, that is the error line on which the latter effects were tested. At T1, sIMI decreased β -CN (-6%, $P<0.01$) but increased κ -CN (+5%, $P<0.05$) and α -_{s2}-CN (+6%, $P<0.01$) content, while at T2 we observed an increase of lactoferrin (+7%, $P<0.05$), an antimicrobial peptide, in positive animals. Somatic cell count affected most protein fractions, especially at T2. Increases in SCC were associated with a reduction in β -CN ($P<0.001$) and with increases in κ - and α -_{s2}-CN ($P<0.001$ and $P<0.05$, respectively). At T2, the interaction SCC×BACT was associated with α -_{s1}-CN ($P<0.05$), with the highest proportion of α -_{s1}-CN found in positive samples with SCC $\geq$ 50,000 and <200,000 cells/ml, while the lowest in positive animals with SCC>400,000 cells/ml. This study added new insights on the alteration driven by sIMI of the milk protein profile, at quarter level. Acknowledgments: This study was part of the LATSAN project funded by MIPAAF.

Antioxidant and anti-hypertensive properties of acid whey from Greek yoghurt

E. Dalaka, A. Vaggeli, G.C. Stefanos, I. Palamidi, A. Savvidou, I. Politis and G. Theodorou

Agricultural University of Athens, Animal Science, Iera Odos 75, 11855, Athens, Greece; gtheod@aua.gr

Greek yoghurt has gained immense popularity due to its high nutritional value. However, acid whey (AW) is produced in enormous volumes and its disposal has a negative environmental impact. Fermentation releases antioxidant (AO) and anti-hypertensive (AH) compounds, supporting that AW can be upcycled to develop value-added products. The aim of this study was to evaluate *in vitro* AO and AH activity of AW derived from yogurts before and after a simulated *in vitro* digestion model. AO activity was measured by ORAC, FRAP, ABTS and reducing power assays for AW, digested AW and the <3 kDa fraction. *In vitro* digestion improves the AO activity as assessed by all assays. Within each fraction, animal origin (cow, sheep, goat), season (winter-summer), region and straining method were studied. Regarding animal origin statistical differences were observed in ORAC and FRAP assays. Season influenced the AO properties of samples as assessed by the ORAC method. Regarding region statistical differences were noted in ABTS and FRAP assays. Finally, samples from different straining methods exhibited statistically different AO properties as assessed by ABTS and reducing power assays. AH properties of AW samples and post-digestion fractions of <10 kDa and <3 kDa were evaluated by measuring their ability to inhibit the angiotensin converting-enzyme using the same factors as above. *In vitro* digestion improves the AH activity of samples. No differences were observed between samples of different animal origin and samples of different region. On the other hand, season and straining method affected the AH activity of samples. This research is co-financed by Greece and the European Union through the Operational Programme 'Human Resources Development, Education and Lifelong Learning' in the context of the project 'Strengthening Human Resources Research Potential via Doctorate Research' (MIS-5000432), implemented by the State Scholarships Foundation (IKY). This research is co-financed by the European Regional Development Fund of the European Union and Greek national funds through the Operational Program Competitiveness, Entrepreneurship and Innovation, under the call RESEARCH – CREATE – INNOVATE (project code: T2EDK-00783).

Recent developments in aquaculture feeds – an industry perspective

A. Obach

Skretting, Aquaculture Innovation, Sjøhagen 3, 4016 Stavanger, Norway; alex.obach@skretting.com

Fish meal and fish oil have traditionally been the main ingredients in aquaculture feeds. These are excellent raw materials; however, they are finite. The Food and Agriculture Organisation (FAO) published an update on the state of the World Fisheries and Aquaculture in 2022. According to the FAO, aquaculture is expected to grow by close to 20% in the next 10 years. This means another 18 million tonnes of seafood to be produced in 2030. Today more than 70% of the world production of fish meal and fish oil goes into aquafeeds. In order for aquaculture to grow we need to eliminate our dependence on marine ingredients and to find alternative sources that could provide all the benefits, without the limitations. Fish meal and fish oil replacement have been one of the main focus in fish nutrition research for the last two decades, and several EU-funded projects involving major research institutions and other industry stakeholders have addressed the issue. Due to this extensive research, since 2016, diets without fish meal have become commercially available for Atlantic salmon. A significant proportion of the fish oil in aquafeeds had already been replaced by alternative fat sources, both of vegetable and animal origin. However, complete substitution of fish oil has been difficult due to the lack of alternative sources providing the long-chain n-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Today new ingredients with EPA and/or DHA are available, such as algae meals and oils or genetically modified plant oils, although in relatively small volumes and at a higher cost. In recent years, marine ingredients have been replaced by ingredients of both vegetable and animal origin. Reducing our dependence on fish meal and fish oil has also opened an ocean of opportunities to develop new raw materials that can contribute to make our industry even more sustainable. The so-call novel ingredients such as insect meals and microbial proteins and oils are becoming a commercial reality.

Theatre 2

Nutritive value of soybean meals from different origins fed to Nile tilapiaN.V. Nguyen¹, H. Le¹, V.K. Tran¹, D.H. Pham¹, T.L.T. Tran¹, J.M. Hoof² and D.P. Bureau²

¹Research Institute for Aquaculture (RIA2), Research Center for Aquafeed Nutrition & Fishery Post-Harvest Technology, 116 Nguyen Dinh Chiet St, District 1, Ho Chi Minh City, Viet Nam, ²University of Guelph, Dept of Animal Biosciences, 50 Stone RD East, N1G2W1, Guelph, Canada; dbureau@uoguelph.ca

Soybean meal is an important protein source in aquaculture feeds. However, few studies have examined the impact of the origin of the soybeans on the nutritive of SBM to aquaculture species. In this study, batches of soybeans of Argentinian (ARG), Brazilian (BRA) or American (USA) origin were purchased and characterized. USA soybeans contained less damage bean (1.1%) compared to ARG (3.2%) and BRA (4.6%) soybeans. These soybeans were then processed to produce three SBMs and used to produce eight (8) extruded diets formulated to contain 21% (basal diet), 26, 31 or 36% crude protein (CP) using either ARG, BRA or USA SBM. These diets were fed to four replicate groups of Nile tilapia in a 12-week growth trial. A digestibility trial with the same eight (8) diets fed to triplicate groups of tilapia was carried out in parallel. Growth performance of the fish increased linearly ($P < 0.0001$) or quadratically ($P < 0.05$) with increasing levels of CP in the diet. Moreover, linear ($P < 0.0001$) and quadratic ($P < 0.001$) decreases in FCR (feed:gain) were associated with increasing CP content of the diet regardless of the origin of the SBM. Fish fed the diets containing USA SBM appeared to have significantly better ($P < 0.05$) growth performance than did fish fed the diets containing ARG or BRA SBM. Nutrient retention and nutrient retention efficiencies increased significantly ($P < 0.05$) with increasing CP content of the diets. A multiple regression approach was used to estimate apparent digestibility of nutrients of the SBMs of different origins. The apparent digestibility coefficient (ADC) of CP of USA SBM was estimated to be 91% while that of ARG SBM and BRA SBM were observed to be significantly lower at 88 and 85%, respectively. Overall, SBM produced from USA soybeans appeared to support better growth performance of Nile tilapia compared to SBM produced from ARG or BRA soybeans, possibly due to their lower degree of damage and higher nutrient digestibility.

EcoXtract® green solvent increases rainbow trout performances and decreases susceptibility to VHSV

D. Rigaudeau¹, N. Abdedaim¹, T. Rochat², L. Jep³, F. Terrier³, P. Boudinot², S. Skiba-Cassy³, L. Jacques⁴ and C. Langevin¹

¹INRAE, IERP, Domaine de Vilvert, 78350 Jouy en Josas, France, ²INRAE, VIM, Domaine de Vilvert, 78350 Jouy en Josas, France, ³INRAE, NuMeA, Aquapôle INRAE, 64310 Saint Pée-sur-Nivelle, France, ⁴Pennakem Europa, 224 avenue de la Dordogne, Dunkerque 59944, France; christelle.langevin@inrae.fr

The Farm to Fork Strategy of the European Green Deal strategy aims to make food systems fair, healthy and environmentally-friendly. The sustainability of aquaculture production has to face several challenges among which the maintenance of fish health and welfare, the fight against outbreaks of infectious diseases and the need to develop alternative fish feeds protecting the environment and the biodiversity. Soybean meal (SBM) is a common alternative, whose processing is based on hexane extraction. In 2021, 2-methyloxolane (EcoXtract®) was described as an alternative green solvent for production of soybean oil and defatted meal. Our study aims to evaluate the impact of the solvent used and SBM inclusion level on rainbow trout. Fish were monitored for survival, growth performance, digestibility of SBMs and diets, metabolism, gut health and robustness to infectious challenges. The results showed that fingerlings fed EcoXtract-extracted SBM presented statistically higher performance than those fed hexane-extracted SBM, with higher increasing at 15% inclusion rate. No significant effect was detected on the growth in juveniles, although, differences in gene expression were revealed for glycolytic and lipogenesis pathways in fish fed diets containing 40% SBM, likely related to the lower level of starch in these diets. Experimental infections of fingerlings by immersion with *Flavobacterium psychrophilum* did not reveal difference in fish susceptibility for the inclusion rates and the extraction methods. In contrast, fingerlings fed EcoXtract-extracted SBM showed significantly lower susceptibility to the viral haemorrhagic septicaemia virus compared to those fed hexane-extracted SBM, with a stronger phenotype at 15% inclusion rate. Analyses are in progress to evaluate the impact of these diets on the microbiota and the intestinal health of fingerlings by using innovative 3D histology method.

Session 07

Environmental impact of aquafeed for rainbow trout containing alternative protein meals

M. Berton¹, C. Fanizza^{1,2}, V. Stejskal³, M. Prokešová³, M. Zare³, H.Q. Tran³, F. Brambilla⁴, E. Sturaro¹, G. Xiccato¹, A. Trocino¹ and F. Bordignon¹

¹University of Padova, 35020, Legnaro, Italy, ²Universitat Politècnica de València, 46022, València, Spain, ³University of South Bohemia, 37005, České Budějovice, Czech Republic, ⁴NaturAlleve (VRM s.r.l.), 37044, Cologna Veneta, Italy; francesco.bordignon@unipd.it

The study analysed the effect on global warming potential (Life Cycle Assessment) of the partial replacement of fishmeal (from by-products) by alternative protein meals in diets for rainbow trout. A total of 1,020 trout (17±7.5 g) were fed four diets (three tanks per diet) with fishmeal being partially substituted by alternative protein meals: a control diet (FM) with 307 g/kg fishmeal and three alternative diets where about 40% of fishmeal was replaced with poultry by-product meal (diet PBM), feather meal (diet FeM), or feather + rapeseed meals (diet FeM+RM). All diets contained also rapeseed oil, soybean protein concentrate and bacterial protein meal, among other ingredients. Final weight (191 g) and feed conversion ratio (1.05) did not differ among diets. The system boundaries included the impact of aquafeed production; 1 kg increase of fish was used as functional unit. Global warming potential, without (GWP) and with (GWP_LUC) emissions due to land-use change were calculated. Impact values were analysed by ANOVA with diet as a fixed effect. No differences among diets were found in term of GWP (1.74±0.07 kg CO₂-eq, on average) and GWP_LUC (2.75±0.10 kg CO₂-eq). In all diets, the major contribution to global warming was due to ingredients different from the four protein meals tested, i.e. rapeseed oil (25 and 31% of the total impact for GWP and GWP_LUC), followed by soybean protein concentrate (10 and 23%) and bacterial protein meal (20 and 12%). Among the protein meals tested, fishmeal provided the highest contribution (14% GWP and 9% GWP_LUC), while the contribution of the three alternative protein meals was limited (0.3 and 0.3% for poultry by-product meal; 2.8 and 1.8% for feather meal; 1.7 and 1.4% for rapeseed meal). In conclusion, the tested alternative protein meals are promising and sustainable ingredients for trout aquafeeds guaranteeing good growth rates and, compared to fishmeal from by-products, a lower contribution to global warming.

New strategies for fish nutrition

S. Skiba-Cassy, J. Roy, L. Marandel, E. Cardona and F. Medale

INRAE, NuMÉA, Aquapôle INRAE, 64310 Saint Pée sur Nivelle, France; sandrine.skiba@inrae.fr

Global fish production has been growing rapidly for several decades and is expected to increase by a further 14% over the next ten years, reaching 203 million tons in 2031. This increase will be mainly due to the growth of aquaculture, which is expected to overtake capture fisheries by 2023 and account for 53% of global fish production in 2031. For fish, as for other species of agronomic interest, feed plays a central role, as it determines the performance of the animals and the economic profitability of the farm. The expectations of feed are therefore numerous and go beyond the strict coverage of nutritional requirements. In aquaculture, it is now expected that a feed will be multi-performing, i.e. that it will provide essential nutrients for the growth and the development of the products, but also functional elements that can improve the robustness of the fish in the light of global changes. Aquafeeds are also a potential lever for reducing the environmental footprint of aquaculture. Fish feeds have undergone a strong evolution mainly to reduce the reliance of aquaculture on the use of fishmeal and fish oil. However, total substitution of these marine ingredients by plant protein and oil sources, especially in carnivorous species, has not yet been achieved. One of the limitations rely on the regulation of feed intake. Research efforts have therefore expanded. They are now focusing on the use of new ingredients and micro-ingredients (insects, yeasts, microalgae, by-products of the food industry, pre or probiotics, etc.) and the consideration of the environmental impact of the feed. Selection for adaptation of fish to new aquafeeds is also considered and more exploratory approaches based on the principle of early programming are on ongoing.

Session 07

Theatre 6

Rainbow trout hepatic cell lines reveal differences of DL-Methionine and DL-HMTBa functionM. Klünemann¹, K. Pinel², K. Masagounder¹, I. Seiliez² and F. Beaumatin²

¹Evonik Operations GmbH, Animal Nutrition Research, Rodenbacher Chaussee 4, 63457 Hanau, Germany, ²Université de Pau et des Pays de l'Adour, E2S UPPA, INRAE, NUMEA, 173, RD 918 Route de St Jean de Luz, 64310 Saint-Pée-sur-Nivelle, France; martina.kluenemann@evonik.com

The replacement of fishmeal by plant protein sources in aquafeeds requires the use of added methionine (MET) sources to balance the amino acid composition and to meet the metabolic needs of fish of agronomic interest such as rainbow trout (RT; *Oncorhynchus mykiss*). There are different MET products commercially available, DL-MET and DL-2-Hydroxy-4-(methylthio) butanoate (HMTBa), and there is a debate if one product is used more efficiently than another by fish. To address this question, we used hepatic cell lines to control cell growth conditions by fully depleting MET from the media and studied whether DL-Met and HMTBa are capable to restore cell growth and metabolism when supplemented back. We evaluated DL-MET and DL-HMTBa based on their effects on targeted cell proliferation, MET-related intracellular metabolites and specific amino acid sensing pathways. The results of cell proliferation assays, Western blots, qPCR and liquid chromatography analyses from two RT liver-derived cell lines revealed a better absorption and metabolization of DL-MET than DL-HMTBa with the activation of the mechanistic Target Of Rapamycin (mTOR) pathway for DL-MET and the activation of integrated stress response (ISR) pathway for DL-HMTBa. In detail, DL-MET treated cells proliferated significantly more than DL-HMTBa treated cells, independent of cell line ($P < 0.05$). We observed a significantly higher expression of the MET related enzymes and a significantly higher concentration of MET related metabolites like glutathione in DL-MET treated cells vs DL-HMTBa treated cells ($P < 0.05$). We found no significant differences between DL-HMTBa supplemented cells and cells grown in MET deprived media for any of the measured parameters ($P > 0.05$) except intracellular DL-HMTBa concentration, which was higher in DL-HMTBa treated cells. Altogether, our study results in hepatic cell lines clearly showed that DL-Met and HMTBa are not biologically equivalent, suggesting similar effects to be found in RT liver and, accordingly metabolic advantages of DL-Met over HMTBa.

Millennial salmon – sustainable salmon feed using black soldier fly meal

M.L. Lefranc¹, H.B. Bergoug¹ and K.K. Kousoulaki²

¹Innovafeed, 85 Rue de Maubeuge, 75010, France, ²Nofima, Nutrition and feed technology, Kjerreidvika 16, 5141 Fyllingsdalen, Norway; maxime.lefranc@innovafeed.com

Millennial Salmon Project is a strategic partnership along the value chain of salmon production between leading research institutes (Nofima, Sintef Ocean) and commercial actors including leading microalgae (Corbion) and insect producers (Innovafeed), feed producer (Cargill), salmon producer (MOWI), processor (Labeyrie) and retailer (Auchan). This collaboration aims at developing sustainable farmed salmon using novel ingredients. DHA-rich *Schizochytrium limacinum* biomass and black soldier fly insect meal are combined to satisfy large parts of the nutritional requirements of salmon in high quality proteins and long chain omega-3 polyunsaturated fatty acids, allowing for sustainable future growth in salmon industry without the need of further deforestation or compromising wild fish biodiversity. The project focuses on optimally maximising dietary inclusion of heterotrophic microalgae and insect meal substituting large part of fish meal, soy protein concentrate and fish oil without negative effects on salmon health, animal welfare, growth performance and feed physical properties. Life cycle analysis of feed ingredients was also conducted to demonstrate the environmental aspects of the suggested innovation.

Session 07

Theatre 8

Digestibility of ingredients derived from food by-products (insect and single-cell) in Asian seabass

R. Le Boucher, W. Chung, J. Ng Kai Lin, L. Tan Shun En, C.S. Lee and C. Wu

Temasek Life sciences Laboratory, 1 Research Link National University of Singapore, 117604, Singapore; richard@tll.org.sg

Food by-products transformation could become a more sustainable source of ingredients for aquaculture but only little is known yet about their digestibility for marine species. This study gathers the learning of two trials conducted on 2,700 (48.2 g) and 840 (591.3 g) Asian seabass (*Lates calcarifer*) grown in large-scale RAS and fed with experimental diets containing 30% of two types of black soldier fly meal (BSF), and two types of single cell protein meal (SCP). Diets were produced with a twin-screw extruder and 0.1% Yttrium oxide was added to estimate digestibility. In small and large fish trials, thermal-unit growth coefficient (TGC), feed conversion rate (FCR) and nutrient retention efficiency were measured. Fish faeces were collected in each tank, diet and ingredient digestibility were estimated for protein, energy and amino acids. TGC of fish fed with BSFM and SPC was never significantly lower than TGC of fish fed with the control diet ($P < 0.05$). FCR of fish fed with BSFM (1.05) was higher ($P < 0.05$) than the FCR of fish fed with the control diet. Apparent digestibility coefficients (ADC) of BSFM were high for protein (90.2-91.9), energy (87.7-89.9) when ADC of SCP were moderate. The impact of extrusion parameters and water temperature on digestibility is discussed, together with the role these new ingredients could play in future Asian seabass feed formulation.

Specialty feeds to enhance the health value of farmed fishJ. Dias¹, A. Ramalho-Ribeiro², A. Gonçalves³, M.T. Dinis⁴ and P. Rema⁵¹SPAROS LDA, Area Empresarial de Marim, Lote C, 8700-221 Olhao, Portugal, ²Politécnico de Coimbra, ESAC, Bencanta, 3045-601 Coimbra, Portugal, ³Instituto Português do Mar e Atmosfera, Av. Alfredo Magalhães Ramalho, 6, 1495-165 Algés, Portugal, ⁴Centro de Ciencias do Mar do Algarve, Universidade do Algarve, Campus Gambelas, 8005-139 Faro, Portugal, ⁵Universidade de Trás-os-Montes e Alto Douro, Qunta dos Prados, 5000-801 Vila Real, Portugal; jorgedias@sparos.pt

Due to the rising demand for nutritious, safe and sustainable seafood products (fish and shellfish), aquaculture is predicted to be a major contributor to the nutritional needs of future generations. A continued research effort led to significant progress on lowering the use of fishmeal and fish oil in aquafeeds. However, this trend is altering the nutritional value of edible fish, conditioning the expected beneficial effects for consumers. Some of the strategies available today to counteract this potential loss of nutritional value in fish comprise the use of novel sustainable feed ingredients and feed fortification with selected healthy nutrients. Several trials undertaken with rainbow trout (*Oncorhynchus mykiss*) and gilthead seabream (*Sparus aurata*) evaluated the use of several emergent raw materials (microalgae, macroalgae, yeasts) as tools to fortify fish fillets with health valuable nutrients. In trout, the dietary incorporation of an iodine-rich macroalgae (*Laminaria digitata*) and a selenised-yeast, at the maximum iodine and selenium permitted levels in feed, resulted in a 6-fold increase for iodine and a 2.9-fold increase for selenium contents in trout fillets, without altering sensorial traits. The fortified trout presented a nutritional contribution of 12.5% DRI for iodine, 78% DRI for selenium and 80% DRI for vitamin D3. One meal portion of seabream fed a diet with 10% *Laminaria digitata* covered 84% DRI of iodine and 60% DRI of vitamin D3. Market-size seabream fed a diet with 2.5% of *Phaeodactylum tricornutum*, a fucoxanthin-rich microalgae, showed a significantly higher lightness in ventral skin and a more vivid yellow pigmentation in the operculum and scored higher than the control, in terms of external appearance and brightness assessed by a consumer panel. Integrating consumers' dietary needs and expectations must be considered when designing aquafeeds.

Session 07

Poster 10

Evaluation of growth performance of pure *Clarias gariepinus* and its hybrid in monosex cultureF.O. Olukoya^{1,2}, O.T.F. Abanikannda^{2,3}, K.O. Kareem-Ibrahim³, M.S. Hedonukun² and S.O. Adebambo²¹University of Lagos, Department of Marine Sciences, Faculty of Science, Akoka, Lagos, Nigeria, ²Lagos State University, Department of Zoology and Environmental Biology, Faculty of Science, Badagry Expressway, Ojo, Lagos, Nigeria, ³Lagos State University, Department of Animal Science, School of Agriculture, Epe Campus, Lagos, Nigeria; ofabanikannda@hotmail.com

This study compared sexual differences in growth parameters of pure and hybrid African catfishes (*Clarias gariepinus* and *Clariabanchus*) raised in a monosex culture. The two species were obtained from an earlier study and grouped by sex separately as male and female in four separate plastic tanks, representing two replicates per sex. Ten each of the pure clarias and its hybrid were reared in each tank. In all, 40 male and 40 female fish comprising 20 each of the pure clarias and its hybrid for each sex were evaluated for the growth parameters. A total of 80 fish were included in the study and the study lasted nine (9) weeks. The mean weight of the fish at the commencement of the experiment was 419.9±21.5 and 429.4±23.9 g respectively for male and female, which was not statistically different ($P>0.05$). The fish were fed commercially compounded feed twice daily throughout the period of the experiment. Length-weight relationship and growth parameters such as mean growth rate (MGR), specific growth rate (SGR), absolute growth rate (AGR), relative growth rate (RGR), condition factor (CF) were computed and evaluated for sex effect. All statistical analyses involving descriptive, general linear model analysis of variance (ANOVA) and post hoc test were done using Minitab® 17 Statistical Software. Sex had significant ($P<0.05$) effects on all growth parameters albeit at different levels, except Absolute Growth Rate (AGR), but specie only had significant ($P<0.05$) effect on Mean Growth Rate (MGR), while the interaction of sex × specie exerted significant ($P<0.05$) effects on all growth parameters except Condition Factor (CF). This study revealed that growth performance is significantly ($P<0.05$) affected by sexual dimorphism and also by interaction of sex and specie.

The effect of feeding on dissolved oxygen and turbidity in trout cultivated in an aquaponics*I. Sirakov¹, K. Velichkova¹, A. Asenov² and R. Rusev³**¹Trakia University, Students campus, 6000 Stara Zagora, Bulgaria, ²University of Ruse Angel Kanchev, 8 Studentska str., 7000 Ruse, Bulgaria, ³Hach Bulgaria, Kr.Sarafov №45, 1000 Sofia, Bulgaria; ivailo_sir@abv.bg*

The control of hydrochemical parameters in recirculation systems in the cultivation of hydrobionts is of the paramount importance. One of the factors that significantly influence them is nutrition. The aim of the present study was to investigate the effect of feeding on two major hydrochemical parameters- dissolved oxygen and water turbidity, during rainbow trout cultivation in an aquaponic recirculating system. Rainbow trout in good health were stocked in an aquaponic system at 90 pc.m⁻³ stocking density. The fish had an initial mean mass of 43.5±2.2 g. Fish were fed with the trout feed of appropriate size and composition. Hach process probes and Sc 1000 controller were used to monitor the dynamics of the two hydrochemical parameters. During the experimental period over 37,500 data were received. On this basis, the dynamics of the two hydrochemical parameters during the day was determined. The relations of dissolved oxygen and turbidity with the nutrition of the cultured species were analysed.

Session 07

Poster 12

Factors affecting feeding of fish cultivated in recirculation aquaculture system*K. Velichkova and I. Sirakov**Trakia University, Students campus, 6000 Stara Zagora, Bulgaria; genova@abv.bg*

Recirculation systems are characterized by high intensity of production processes and are classified as super-intensive technologies. The normal operation of the recirculation systems is unthinkable without constant monitoring of the main parameters of the water and the technical condition of the various facilities. The main requirement when cultivating fish in a recirculation system is that the water meets certain quality indicators. Of these, the most important are temperature, amount of dissolved oxygen, pH, hardness, biogenic elements, etc. An important element is the quality of the feed to supply the necessary nutrients for the growth of the fish, the size of the granule should be matched to the size of the fish, it is easy to consume the feed and has a low consumption. Of particular importance are the correct amount and the right time to eat. Feeding frequency is affected by the amount of feed consumed in one day and it is very important to manage the feeding process in fish because it affects growth, survival, feed conversion, water quality as well as profit maximization. The role of nutrition is a powerful modulator of the endocrine system governing the feeding behaviour and growth of fish. Food availability and feed composition are two of the most influential external cues modulating hormones, regulating appetite, and modulating growth. The provision and setting of optimal conditions specific to the cultured species are of primary importance for its successful cultivation in aquaculture. It is through the application of scientific developments in this regard that fish farmers will be able to optimize management practices and will provide micro environment for better food intake and its utilization.

Effect of mycotoxin co-occurrence on zootechnical performance and health indices of *Sparus aurata*

C. Papadouli¹, S. Vardali¹, T. Karatzinos¹, M. Maniaki¹, P. Panagiotaki¹, D. Kogiannou², C. Nikoloudaki², I. Nengas², M. Henry², G. Rigos² and E. Golomazou¹

¹University of Thessaly, Department of Ichthyology and Aquatic Environment, University of Thessaly, Fytokou str., 38446, Volos, Greece, ²Institute of Marine Biology, Biotechnology, and Aquaculture, Hellenic Centre for Marine Research, 46.7 km Athens-Sounion, 19013, Attiki, Greece; egolom@uth.gr

This study aimed to investigate the effects of the emerging dietary mixture of mycotoxins deoxynivalenol (DON), fumonisin B1 (FB), and aflatoxin B1 (AFB1), at various contamination levels, on the growth and health performance of gilthead seabream (*Sparus aurata*). Fish held in triplicate aquariums received five experimental diets: A (DON:500, FB:1000, AFB1:5 ppb), B (DON:150, FB:650, AFB1:2 ppb), C (DON:3,000, FB:40, AFB1:2 ppb), D (DON:150, FB:40, AFB1:10 ppb), E (DON:150, FB:100, AFB1:2 ppb), and were compared against the control group (CTRL) that was fed a mycotoxin-free diet. The feeding trial lasted 12 weeks. To assess the effect of mycotoxin-contaminated feeds, fish were hand-fed *ad libitum* two meals per day, six days per week. Feed intake was recorded daily, and fish were observed for signs of abnormal behaviour, disease symptoms, and mortalities. Water physiochemical parameters were maintained within the standard levels. Endpoint assessment included the evaluation of haematological parameters, feed intake, growth parameters, and induced genotoxicity. One-way ANOVA was used to determine the variance among treatments, followed by Tukey's post hoc test at a significance level of $P < 0.05$. All treatments containing mycotoxins caused significantly lower food consumption compared to the control group. Group C, with the highest concentration in DON, posed the lowest feed intake ($P < 0.05$), followed by group D with the highest concentration in AFB1. Similarly, a stunted growth (lower mean weight, length, and total biomass increase) was also recorded in group C. A significantly lower haematocrit was measured in all groups compared to the CTRL group. No differences in induced genotoxicity were recorded between experimental groups, using the single-cell gel electrophoresis method for DNA damage evaluation.

Poster 14

Fasting influences on several blood chemistry changes: indicators of malnutrition in Nile tilapia

S. Boonanutanasarn, P. Pasomboon, S. Seedum and W. Auppakhun

Suranaree University of Technology, School of Animal Technology and Innovation, Institute of Agricultural Technology, 111 University Avenue, Tambon Suranaree, Muang, Nakhon Ratchasima, 30000, Thailand; surinton@sut.ac.th

This study investigated the effect of food deprivation on whole body composition and blood chemistry in Nile tilapia (*Oreochromis niloticus*). Fish were subjected to starve for 0 (fed fish), 1, 2, 3 or 4 weeks. Body chemical composition and chemical blood chemistry were determined. The results showed food deprivation affected to decrease lipid contents in whole body ($P < 0.05$). However, protein and ash contents in the whole body did not change. Food deprivation led to decrease blood triglyceride and phosphorous ($P < 0.05$). Food deprivation affected to increase SGOT, SGPT, chloride, iron, and phosphorous ($P < 0.05$). Blood glucose decrease during week 2 and 3 of food deprivation, but it increased at week 4. Food deprivation for 3 weeks led to decreased blood cholesterol; however, it induced to increase blood cholesterol at week 4. Food deprivation did not changed blood protein, albumin, blood urea nitrogen and calcium. Taken together, food deprivation influenced whole body contents. Additionally, food deprivation affected several blood chemistry parameters which could be interpret as indicators of malnutrition.

Technological developments and 3D imaging for the diagnosis of aquaculture fish diseasesM. Merhaz¹, M. Frétau², D. Rigau² and C. Langevin¹¹INRAE, IERP, Domaine de Vilvert, 78350 Jouy en Josas, France, ²INRAE, VIM, Domaine de Vilvert, 78350 Jouy en Josas, France; christelle.langevin@inrae.fr

The development of cutting-edge technologies such as high-resolution imaging has paved the way for fundamental discoveries in cell biology. The implementation of such techniques has the potential to revolutionise the field of host-microbe's interactions and is likely to generate unprecedented insights into human and animal health. Veterinary medicine does not have the means available in human medicine, despite recent lifting of technological barriers achieved by innovation in imaging instruments. Tissue clearing techniques aim to render fixed biological tissue transparent for 3D visualization of entire organs and organisms at cellular resolution. Various fields of biology have taken benefits from these techniques which have contributed to improve the analysis / visualization of complex biological tissue. The co-development of in toto immunohistochemistry and imaging methods applied to large cleared samples (>1 cm) has been an important milestone allowing the broad usage of tissue clearing from mammalian to other animal species. We recently described the adaptation of such clearing techniques to render transparent zebrafish but also trout and carps (4cm long). These developments, when combined to lightsheet deep fluorescence microscopy and data processing with visualization tools provide unprecedented 3D visualization of entire trout, carp and stickleback fish bodies at cellular resolutions. Therefore, in addition to functional imaging (CT-scan /MRI) and classical histology (on thin tissue sections), these 3D imaging techniques enabled multiscale analyses of fish organisms assessing the tissue architecture, the presence of tissue damages and the activation of immune responses. To go further in the development of novel diagnosis tools, we extend these methods to monitor the intestinal health of various fish species using a so-called '3D histology' method. Such techniques have already been reported for biomedical applications such as 3D histopathology of human tumour microenvironments. Our work demonstrates for the first time their potential for applications in developmental biology, comparative anatomy, toxicology but also diagnosis of aquaculture fish diseases.

Poster 16

Comparative analyses of growth parameters of pure and hybrid African Catfishes fed two feed typesO.T.F. Abanikannda^{1,2}, F.O. Olukoya^{1,3}, K.O. Kareem-Ibrahim², S.M. Adebambo¹ and M.S. Hedonukun¹¹Lagos State University, Department of Zoology and Environmental Biology, Faculty of Science, Badagry Expressway, Ojo, Lagos, Nigeria, ²Lagos State University, Department of Animal Science, School of Agriculture, Epe Campus, Lagos, Nigeria,³University of Lagos, Department of Marine Sciences, Faculty of Science, Akoka, Lagos, Nigeria; otfabanikannda@hotmail.com

Cost of feed has been the biggest challenge confronting aquaculture and efforts are geared towards reducing cost of production occasioned by feed. The standard feed used in aquaculture tanks are the extruded (floating) type which are more expensive than the non-extruded (sinking) feed types common in earthen ponds. This study aimed to evaluate the effect of feed types (extruded and non-extruded) on growth parameters in pure *Clarias gariepinus* and its hybrid. Two strains of 40 fishes each with an initial weight ranging from 134 to 820 g due to differences in breed, and an overall mean weight of 414.00 ± 26.4 g were randomly assigned to either of the two feed types, in two replicates each in a randomized complete block design, and reared for eight weeks. Growth parameters such as mean growth rate (MGR), specific growth rate (SGR), absolute growth rate (AGR), relative growth rate (RGR) and condition factor (CF) were computed for all subclasses. Statistical analyses included descriptive and general linear model analysis of variance (ANOVA) using Minitab® 17 Statistical Software. Feed type was significant ($P < 0.05$) on all growth parameters except Absolute Growth Rate (AGR), while specie and interaction of feed $\times$ specie was not significant ($P > 0.05$) on all growth parameters studied. Similarly, feed type was a significant ($P < 0.05$) source of variation on weekly gain at weeks 7 and 8 whereas specie was significant ($P < 0.05$) on gains at weeks 1, 4, 5 and 8, but the interaction of both was not significant ($P > 0.05$) throughout the period of study. This study revealed that growth performance as indicated by the growth parameters and weekly gain is influenced by feed type, with the extruded feed (floating) exerting superior influence over the non-extruded (sinking) feed.

Influence of feeding frequency on growth parameters of African Catfish

F.O. Olukoya^{1,2}, K.O. Kareem-Ibrahim³, A.A. Jimoh², K.O. Bakare², Z.F. Shopeyin², S.A. Shitta² and O.T.F. Abanikannda^{2,3}

¹University of Lagos, Department of Marine Sciences, Faculty of Science, Akoka, Lagos, Nigeria, ²Lagos State University, Department of Zoology and Environmental Biology, Faculty of Science, Badagry Expressway, Ojo, Lagos, Nigeria, ³Lagos State University, Department of Animal Science, School of Agriculture, Epe Campus, Lagos, Nigeria; otfabanikannda@hotmail.com

Fish growth is influenced by feed availability and intake, genetics, age and size, environment and nutrition, and feed intake is perhaps the most prominent factor affecting growth rate of fish. In a bid to surmount this, there is need to strike a balance between rapid fish growth and optimum use of supplied feed by recommending the optimal feeding frequency to reduce wastage and its attendant economic losses, by avoiding the twin traps of overfeeding and underfeeding, that are both detrimental to fish health and may cause marked deterioration in water quality, reduced weight, poor food utilization, and increased susceptibility to infections. A total of 270 African Catfish fingerlings were evaluated for the effects of feeding frequency on growth performance. The fish were hatched and reared to 12 weeks under similar conditions prior to the experiment which lasted for 40 days. Feeding frequency included equally shared feed based on recommended 5% of body weight, equally spaced feed allocation at 6, 8 and 12 hourly intervals. Each of the three treatment groups comprised of six replicates of 15 fish per plastic tank. Body weight, and two linear measurements (Total and Standard Length) were taken twice weekly on each of the fish in all the tanks and the respective length-weight relationship and condition factor (K) were computed. Weekly gain, final weight, average daily gain, absolute, relative, specific and mean growth rates for the three groups were evaluated and compared. Results showed that the 6-hourly treatment group consistently had higher values across all growth parameters and the difference was mostly statistically significant ($P < 0.05$) except for total length that was not significant ($P > 0.05$). However, there was no statistical ($P > 0.05$) difference between the values recorded in the 6-hourly and 8-hourly treatment groups implying that either method can be adopted.

The impact of a probiotic supplementation in aquaculture – a bioinformatic modelling

A. Brzoza¹, L. Napora-Rutkowski², M. Mielczarek^{1,3}, T. Kaminska-Gibas², T. Suchocki^{1,3} and J. Szyda^{1,3}

¹Wroclaw University of Environmental and Life Sciences, Department of Genetics, The Biostatistics Group, Kozuchowska 7, 51-631 Wroclaw, Poland, ²Polish Academy of Sciences, Institute of Ichthyobiology and Aquaculture in Golysz, Kalinowa 2, 43-520 Chybie, Poland, ³National Research Institute of Animal Production, Krakowska 1, 32-083 Balice, Poland; joanna.szyda@upwr.edu.pl

The goal of the research was to study the effect of different commercially available EM (effective microorganism) supplements on the microbial communities of the intestine of Common carp (*Cyprinus carpio*) and water, as well as on fish growth, by conducting the 94-day experiment. The microbiome composition was identified by sequencing two hypervariable regions (V3 and V4) of the gene encoding the 16S rRNA ribosomal subunit. The experimental setup comprised seven tanks including: a control tank without fish and without probiotic supplementation, two water tanks with fish and no probiotic supplementation, two tanks with fish and the commercially available water supplement W1 and feed supplement F1, two water tanks with fish and with the commercially available water supplement W2 and feed supplement F2. The modelling of abundance diversity was carried out on the family taxonomic level. The overall diversity within each sample quantified by the Shannon index was generally very low and no significant differences in diversities between experimental groups were observed. Neither among water, nor among intestinal samples. Considering changes in abundance of particular families, we observed that 22/13 families significantly increased/decreased their abundance in water during the course of experiment. The highest increase was registered for Acidobacteriaceae ($\log_2\text{FoldChange} = -15.5$, $P = 6 \cdot 10^{-15}$) while Devosiaceae was the family with highest decrease in abundance ($\log_2\text{FoldChange} = 8.3$, $P = 1 \cdot 10^{-12}$). However, no difference in the dynamics of abundance changes could be observed between the experimental and control tanks. All the significant comparisons for the intestinal microbiome after W1F1 and W2F2 supplementation involved cases when sequence reads representing a given family were either not detected in the supplemented individuals, but present in the intestines of some of the control individuals or the opposite.

Role of daily feeding rhythms in the genetics of feed efficiency in growing pigs*H. Gilbert¹, L. Agboola¹, A. Foury², M. Teissier¹, F. Gondret³ and M.P. Moisan²**¹INRAE, GenPhySE, Castanet-Tolosan, 31320, France, ²INRAE, NutriNeuro, Bordeaux, 33076, France, ³INRAE, Institut Agro, PEGASE, Saint-Gilles, 35100, France; helene.gilbert@inrae.fr*

Feed efficiency is a major driver for sustainable pig breeding, saving feed resources and lowering environmental impacts. In pigs, contrasted feed efficiency are associated to differences in feeding behaviour, with a reduced feeding time in more efficient pigs. Studies in human and rodents have shown that aligning feed intakes with day/night cycles is essential to optimize energy metabolism and body composition. In pigs, the role of daily feeding rhythms on feed efficiency remains to be explored. In our study, temporal feed intake data of about 4,000 pigs from two divergent lines selected for residual feed intake (RFI) were recorded by automatic feeders. Feeding rhythm was mainly distributed during the day, with two peaks, in the morning and in the afternoon. Significant differences were reported between lines for this pattern, with pigs from the more efficient line eating proportionally more during the peaks (+ 73 g/d and +89 g/d, $P < 0.001$, respectively) and less in the intervals between the peaks (-119 g/d, $P < 0.001$) than pigs from the less efficient line. These traits had significant heritability estimates ($> 0.30 \pm 0.04$), and showed significant genetic correlations with daily feed intake and RFI. The sequence variants detected in the founders of the two lines were then imputed to all breeding pigs of the lines previously genotyped for a 60K medium density SNP chip. The allele frequencies were computed for the genomic variants segregating in the ten core clock genes regulating circadian rhythm. Changes of allele frequencies with selection were tested separately in each line. Significant responses to selection were pointed out in the ARNTL and CLOCK genes in the less efficient line ($P < 0.05$ genome-wide level), suggesting a molecular basis for the differences of feeding rhythm detected between the lines. These results indicate that the genetic variability of feed efficiency in pigs could be related to alterations in circadian rhythms.

Session 08

Using sequence variants to detect SNP and pathways affecting pig gut microbiota and feed efficiency*H. Gilbert¹, M. Teissier¹, K. Fève¹, S. Legoueix¹, Y. Billon², V. Déru^{1,3}, A. Aliakbari¹, J. Bidane⁴, O. Zemb¹, Y. Labrunet¹ and J. Riquet¹**¹INRAE, GenPhySE, 31320 Castanet-Tolosan, France, ²INRAE, UE GenESI, 17700 Surgères, France, ³FG Porc, La Motte au Vicomte, 35650 Le Rheu, France, ⁴IFIP, La Motte au Vicomte, 35650 Le Rheu, France; helene.gilbert@inrae.fr*

Only few genomic variants are reported as associated to feed efficiency. To empower our analysis, we used imputation of sequence variants in two Large White pig designs (1,943 pigs and 1,942 pigs, respectively) with records for feed efficiency, and abundances of faecal microbiota genera from 16S rRNA gene sequencing (600 and 1,400 pigs, respectively). Imputation was carried out jointly on the two designs with FImpute, in two steps. First, the 650 K genotypes of 128 founders (Affymetrix Axiom Porcine Array) of the two designs were imputed to animals of the full designs, that had been genotyped with 60K SNP chips. Then, sequence variants, called on 45 founders of the two designs using the nf-core/sarek workflow, were imputed to full designs, leading to a total of 17,033,057 SNP imputed (correlation between true and imputed genotypes per animal = 0.94 ± 0.011). After quality control, association studies were carried out with GEMMA in each design separately, and meta-analyses were used to combine the corresponding outputs with the *metal* package in R. The simpleM approach was used (principal component analysis applied to the matrix of genotypes) to estimate the number of independent tests, leading to a genome-wide threshold of 7.22 for the $-\log_{10}(P\text{-values})$. In total, 26 QTL regions were significant, and 272 regions were considered as suggestive. An enrichment analysis applied to all annotated genes in these regions pointed out GO terms related to membrane compounds and functions. Focusing on the 10 QTL regions associated with the abundances of 9 microbiota genera, functional candidate genes were suggested, for instance previously reported in colorectal cancer in mice or human. Altogether, the approach combining sizable datasets, imputation of sequence variants and records of traits related to sub-functions of complex traits allowed to pinpoint new pathways and genes related to variation of feed efficiency in pigs.

Using digestive efficiency to improve feed efficiency in pig breeding schemes

Selection on feed efficiency (FE) is carried out for 50 years in French pig breeding schemes. Recent work has highlighted the interest of digestive efficiency (DE) measurements to improve FE. Indeed, DE is heritable ($h^2 > 0.26$) and genetically favourably correlated (> 0.23) with FE, with affordable costs. This study aimed at determining the best strategie(s) to integrate DE into pig breeding schemes to improve FE. For this purpose, simulations of pig breeding schemes for paternal lines were set up with the AlphaSimR package in R. A generic pig breeding scheme was first simulated over 8 generations and 6-months cycles. The initial cohort was composed of 5,000 young boars (40% with FE) and 5,000 gilts (no FE data). The top 1% of boars without FE data, 2% of boars with FE data and 13% of gilts were selected. Then, animals could remain active during 5 cycles, with selection from 42 to 7% of sires, and from 38 to 8% of dams from cycle 1 to 5. The genetic and phenotypic parameters were initialized from data collected on 2,287 Large White pigs, with FE, DE and carcass traits. Then, various scenarios were simulated, including the phenotyping of various proportions of candidates to selection for DE with different strategies: on-farm or on-station candidates, with different family relationships with pigs phenotyped for FE. For all scenarios, indicators including genetic gain and genetic variance for each trait, pig breeding values, inbreeding coefficient and phenotyping cost were computed. They were compared with those of the reference scenario to identify if DE measures can improve genetic gains at a given cost, or can reduce costs while maintaining the genetic gain. Thus, our results contribute to propose strategies to improve genetic progress on FE in French paternal pig populations.

Can automatic records of activity predict maternal ability and health in sows?

K. Nilsson¹, A. Bergh² and A. Wallenbeck³

¹Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, P.O. Box 7023, 75007, Sweden, ²Swedish University of Agricultural Sciences, Department of Clinical Sciences, P.O. Box 7054, 75007, Sweden, ³Swedish University of Agricultural Sciences, Department of Animal Environment and Health, P.O. Box 7068, 75007, Sweden; katja.nilsson@slu.se

Litter size is the major reproduction trait of economic importance in piglet production. However, larger litters generally have a larger proportion of smaller and weaker piglets, and a higher mortality rate. One of the most common causes for pre-weaning mortality are crushing by the sow, and previous research has shown that the risk of crushing is related to the frequency and manner of position changes and movements performed by the sow. Transition from standing or sitting to lying and rolling movements have been shown to be especially risky. Lameness and poor leg quality of the sow is, apart from being painful and causing discomfort to the sow, also associated with an increased risk of crushing of piglets. Our aim was to investigate if records of general activity can predict risk of crushing, and also if activity can serve as an indicator of lameness in sows. Records of activity were collected using accelerometers attached to a collar around the neck of the sow. Activity data have so far been collected from approximately 60 sows at Research centre Lövsta, Uppsala. The accelerometers recorded movements over a period of 2.5-7 days for each sow, around farrowing and during lactation. Sows were loose-housed individually in farrowing pens, with access to straw. Litter size at birth, number of dead piglets and cause of death was recorded by the staff in the stable. Sows varied in total amount of activity, especially around the day of farrowing. However, preliminary analyses showed no correlation between activity and piglet mortality, suggesting that sows that move more do so without putting their piglets at risk. We will continue to analyse the relationship between activity and lameness.

Cross-breeding strategies to optimize litter size – a way to improve piglet survival?K. Nilsson¹ and A. Wallenbeck²¹Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, P.O. Box 7023, 75007, Sweden, ²Swedish University of Agricultural Sciences, Department of Animal Environment and Health, P.O. Box 7068, 75007, Sweden; katja.nilsson@slu.se

Larger litters generally have a larger proportion of smaller and weaker piglets. The negative consequences of this are even more pronounced in organic production systems, where piglet mortality is generally higher compared with conventional systems. Organic pig production makes use of the same sow breeds and breed crosses as conventional production systems – breeds that are selected heavily for litter size. Many producers, and organic producers, in particular, would prefer more moderate litter sizes with heavier and more vital piglets. The aim of this project was to investigate the consequences of obtaining a more moderate litter size by crossing so-called sire breeds into breeding sows in piglet-producing herds. Sire breeds are not selected for litter size, but rather for growth rate and meat quality traits. The project was carried out at the research herd at Lövsta Research Center, Uppsala. 16 crossbred sows between Yorkshire and Landrace (YL) were compared with 12 sows crossbred between Yorkshire and Hampshire (YH) and 9 sows crossbred between Yorkshire and Duroc (YD). Sows were loose-housed in individual farrowing pens with access to straw. Litter size, individual piglet growth from birth to weaning, mortality, and cause of death was recorded by the stable staff. YL sows had significantly larger litters at birth, 15 piglets compared with approx. 12 for YH and YD. However, the survival rate was also better for YL sows, resulting in the same advantage of approx. three extra piglets at weaning. The growth rate from birth to weaning was similar for all breed crosses. YL sows lost significantly more weight during lactation, leading us to conclude that they invest more resources in milk production compared with the sire line crosses. Crossing sows with sire lines does result in a more moderate litter size but does not improve survival and pre-weaning growth due to poorer maternal ability in the sows.

Session 08

Theatre 6

Genetic parameters for genetic variance uniformity in Swiss pigs' birth weightC. Kasper¹, A. Lepori², J.P. Gutiérrez³, N. Formoso-Rafferty⁴, E. Sell-Kubiak⁵ and I. Cervantes³¹Agroscope, Animal GenoPhenomics, Tirolley 4, 1725, Switzerland, ²Suisag, Allmend 10, 6204 Sempach, Switzerland, ³UCM, Department of Animal Production, Veterinary Faculty, Avda. Puerta de Hierro s/n, 28040 Madrid, Spain, ⁴Universidad Politécnica de Madrid, Department of Agricultural Production, ETSIAAB, Sende del Rey 18, 28040 Madrid, Spain, ⁵Poznan University of Life Sciences, Department of Genetics and Animal Breeding, Wojska Polskiego 28, 60-637 Poznań, Poland; claudia.kasper@agroscope.admin.ch

Increasing litter sizes require cross-fostering to regulate litter size, but also to homogenize the weight of piglets growing up together. This practice increases labour costs and poses immunity concerns, but increases preweaning survival and thus farm productivity. Therefore, identifying factors resulting in birth weight (BW) variability is a priority. We estimated the genetic component of residual variance for BW using a data set with 23,313 BW records from 1,748 litters of 813 sows and 26,107 individuals in the pedigree. The heteroscedastic model included the sex (2 levels), farm-month-year (75 levels), litter size (21 levels), breed (4 levels), and age of the sow (300 to 1,956 days) as fixed effects. The litter effect (nested to the sow) was included as random effect in addition to the genetic effect. The data was assigned to the mother, and the same effects were fitted for mean BW and its variability. The model was fitted using a Markov chain Monte Carlo software (GSEVM). The genetic coefficient of variation was 0.189, and the genetic correlation between the mean BW and its variability was 0.398 (SE=0.116). Regarding fixed effects, female piglets were more consistent regarding BW variability despite having lower weight, and litters with more than 9 piglets were less variable than smaller ones. The age of the sow affected mean BW positively, and reduced BW variation. The results are in line with previous genetic parameters estimated for BW uniformity in pigs. Even though the mean birth weight might decrease, selection for uniformity is expected to be beneficial since selection for uniformity has been shown to increase the robustness of the animal. Finally, homogenizing BW might reduce the occurrence of intrauterine growth retardation, thereby improving piglet health and carcass value.

A multivariate gametic model for the analysis from reciprocal crosses for two Iberian varietiesH. Srihi¹, D. López-Carbonell¹, N. Ibáñez-Escriche², J. Casellas³, P. Hernández², S. Negro⁴ and L. Varona¹¹Universidad de Zaragoza, Instituto Agroalimentario de Aragón (IA2), C. Miguel Servet, 177, 50013, Zaragoza, Spain, ²Universitat Politècnica de València, Camino de Vera, s/n, 46071, València, Spain, ³Universitat Autònoma de Barcelona, Plaza Cívica, 08193 Barcelona, Spain, ⁴INGA FOOD S.A., Av. de a Rúa, 2, 06200 Almendralejo, Spain; houssemsrihi@unizar.es

Crossbreeding is used in pig breeding schemes to obtain heterosis for reproductive traits in the crossbred maternal lines. In some cases, the performance of reciprocal crosses may be different, and selection in purebred populations may be more effective for one reciprocal cross than for the opposite. This phenomenon can be explained by variability in the correlations between the gametic effects acting as sire or dam in pure and crossbred populations. Therefore, we propose a multivariate gametic model that defines up to four correlated gametic effects for each parental population (sire for purebred, sire for crossbred, dam for purebred, dam for crossbred). The model was applied to a data set of litter size (total number born) from a reciprocal cross between two Iberian pig populations (Entrepelado and Retinto). It consists of 6,933 records from 1,564 purebred Entrepelado (EE) sows, 4,995 from 1,015 Entrepelado × Retinto (ER), 2,977 from 756 Retinto × Entrepelado (RE) and 7,497 from 1,577 purebred Retinto (RR). The gametic effects were calculated by using a pedigree of 6,007 individual-sire-dam entries. The model of analysis also includes the order of parity (6 levels), breed of the sire of service (5 levels), herd-year-season (141 levels) and a random dominance effect for each pure or crossbred population. The analysis was implemented with a Bayesian approach using a Gibbs Sampler with a single long chain of 1,100,000 iterations after discarding the first 100,000. All the posterior estimates of the gametic correlations were positive, and they ranged between 0.05 (Sire for purebred with Dam for crossbred in Retinto) and 0.57 (Sire for purebred with Dam for Purebred in Entrepelado). Moreover, the posterior mean-variance estimates of the maternal gametic effects were larger than the paternal in the four populations.

Session 08

Theatre 8

Impact of vaccination against GnRF on growth performance and meat quality of gilts at market weightN. Quiniou¹, P. Chevillon¹ and F. Colin²¹IFIP-Institut du Porc, BP35, 35650 Le Rheu, France, ²ZOETIS, 10 rue Raymond David, 92240 Malakoff, France; nathalie.quiniou@ifip.asso.fr

Immunization against GnRF (gonadotropin-releasing-factor) is being investigated by the dry-cured ham industry as a solution to increase carcass fatness of entire male pigs in a context of physical castration ban. In gilts, the vaccine temporarily suppresses the ovarian function and the associated secondary effects have been characterized in a trial involving 144 crossbred Piétrain × (Large White × Landrace) group-housed (6/pen) gilts. At 70 d of age (26.3±3.6 kg), full- or half-sisters were randomly allocated to a control non-treated group (C, 12 pens) or to the vaccinated (Improvac®, Zoetis) group (V, 12 pens). Gilts V were vaccinated at 103 (V1) and 132 (V2) d of age. Pigs were harvested either 4 or 5 weeks after V2. A 2-phase *ad libitum* feeding strategy was used, with Phase-1 and -2 diets formulated for 9.75 MJ net energy/kg, and 9.0 and 7.8 g ileal standardized digestible lysine/kg, respectively. Growth before V2 was similar for both groups ($P>0.10$). Within the 1st week after V2, no difference in average daily feed intake (ADFI) was observed between groups, whereas significant differences were observed afterwards: between V2 and harvest, ADFI was 0.39 kg higher ($P<0.001$), growth rate was 89 g/d higher ($P=0.002$) and feed conversion ratio tended to be 0.15 kg/kg higher ($P=0.08$) in gilts V. They tended to be 2.6 kg heavier at harvest than gilts C (115.6 vs 113.0 kg, $P=0.06$). The significant ($P<0.05$) increase in ultimate pH in the Semimembranosus (+0.08 unit) and the Longissimus dorsi (+0.03 unit), and the reduced drip losses (-1.2%) in meat from gilts V suggest an improvement in meat quality for cooking and slicing yields. The increase in backfat thickness (+2 mm, $P<0.01$) would increase the proportion of carcasses that fit better the expectations of the dry-cured ham industry. In conclusion, vaccination of gilts against GnRF may help producers to improve production performance and meat quality, allowing for more carcasses meeting the industry requirements. The carcass payment grid should be adapted so that it compensates the carcass value for the cost of vaccination and the increase in feed intake when the pig farmer adapts the management of the pigs in response to the quality expectations of the meat industry.

Using different gas mixtures for pig stunning – influence on meat quality and gene expressionJ. Gelhausen¹, T. Krebs¹, T. Friehs¹, J. Knöll², I. Wilk², D. Mörlein¹ and J. Tetens¹¹Georg-August-University, Department of Animal Science, Burckhardtweg 2, 37077 Göttingen, Germany, ²Friedrich-Loeffler-Institute, Institute of Animal Welfare and Animal Husbandry, Dörnbergstr. 25/27, 29223 Celle, Germany; julia.gelhausen@uni-goettingen.com

Carbon dioxide (CO₂) stunning is the most commonly used method for pig slaughter. It causes a deep unconsciousness and allows group stunning. However, aversions such as hyperventilation or escape attempts can be observed. Inert gases such as Nitrogen (N₂) and Argon (Ar) seem to be promising alternatives to reduce these aversions. In the project for Testing Inert Gases in order to Establish Replacements for high concentration CO₂ stunning for pigs at the time of slaughter (TIGER), we are investigating the effect of ten different gas mixtures on animal welfare and meat quality in a commercial slaughterhouse using a Dip-lift system with a newly developed gas supply technology. From each group samples were taken from 30 [DE × DL] × PI animals. The pigs were either stunned with Ar (100%) or N₂ (70%N₂ /30%Ar) as well as mixtures of those with 10-30% CO₂ or two CO₂ control atmospheres (<1% or <2% O₂). Meat quality traits (pH, temperature, and electrical conductivity) were assessed in loin (*M. longissimus thoracis et lumborum*) and ham (*M. semimembranosus*) 40 min and 24 h *post mortem*, respectively. Corresponding RNA samples were taken from the loin and sequenced. The hams were further examined for petechial haemorrhages and the loin for drip loss, cooking loss, shear force, and colour. Statistically significant differences ($P < 0.05$) were found for both, pH_{45min} and pH_{24h} in ham and loin, with no evidence of PSE or DFD meat formation. RNA sequencing showed few differentially expressed genes between gases, which is in line with the results for meat quality. However, notably the conductivity in the ham was increased in the mixtures containing nitrogen, as was the incidence of haemorrhages in the ham with these gases. Concluding from these pilot trials, the alternative gas mixtures investigated here are not inferior to conventional CO₂ stunning concerning loin meat quality. On the other hand, the increased incidence of haemorrhages in the ham requires further investigations.

Session 08

Theatre 10

Lean tissue grows slower in the belly and loin regions of Australian domestic pork carcasses

L.T. King, F. Anderson, M. Corlett, A. Williams and G.E. Gardner

Murdoch University, Centre for Animal Production and Health, 60 South Street, Murdoch 6150, Western Australia, Australia; l.king@murdoch.edu.au

Pork supply chains in Australia select for pigs displaying rapid lean growth. Cuts from different carcass regions vary in value; therefore, selection focused on growth in high valued regions and finishing practices that allow their maturation may maximise economic returns. Therefore, we quantified the relative rates of lean growth across carcass regions to benchmark domestic Australian pork. 360 pork carcasses from 3 separate processing plants were CT-scanned and simple thresholds were used to differentiate lean/rind from fat, and bone. Huxley's allometric equation ($y = ax^b$) was used to determine the relative rate of growth of carcass lean relative to carcass weight and either the fore, loin, belly, or hind section lean relative to carcass lean weight. Data was converted to natural logarithms ($\ln$) to linearise the data and allow subsequent analysis using least squared regression. B values >1 represent slower rates of lean maturation within the carcass, while values <1 represent early rates of lean maturation within the carcass. For $\ln$ whole carcass lean weight vs $\ln$ carcass total weight, the b value was 1.02 ($R^2=0.87$), indicating that carcass lean matured at a similar rate to total carcass weight. For $\ln$ section weight vs $\ln$ total lean weight, b values for $\ln$ loin lean ($b=1.15$; $R^2=0.84$) and $\ln$ belly lean ($b=1.64$; $R^2=0.83$) were greater than 1, indicating that the lean in these regions matured slower than total carcass lean. Alternatively, b values for $\ln$ fore lean ($b=0.84$; $R^2=0.91$) and $\ln$ hind lean ($b=0.78$; $R^2=0.92$) were less than 1, indicating more rapid rates of lean maturation than total carcass lean. These results indicate that whole carcass lean grows at a similar rate to carcass weight, and yet varies substantially across different regions of the pork carcass. This implies that production systems focused on optimising the weight of belly and loin cuts will reap benefits from finishing to heavier weights, allowing this lean to grow proportionately more than in other carcass regions.

Carcass characteristics and boar taint in entire male pigs from commercial French organic farmsS. Lombard¹, A. Roinsard² and A. Prunier³¹ITAB, 9 rue André Brouard, 49105 Angers, France, ²FOREBIO, 117 rue de Charenton, 75012 Paris, France, ³PEGASE, Institut Agro, INRAe, 35590 Saint-Gilles, France; sarah.lombard@itab.asso.fr

Surgical castration of male pigs is now forbidden without anaesthesia and analgesia in France. Rearing entire male pigs is a way to stop castration and to improve feed conversion and Lean Meat Percentage (LMP) which have important economic values in organic pig production. However, there is a risk of tainted meat which is mainly due to androstenone (A) and skatole (S) stored in fat tissues. This project focuses on the performance and boar taint of entire male pigs in organic farming. Entire male pigs from six organic farms located in the western part of France were followed along one year. Data collection included age at slaughter, carcass weight, LMP (n=849), human nose evaluation (n=622), S and A concentrations in backfat (n=577). For human nose evaluation, carcasses were scored 0 (no boar taint), 1 (suspicious odour), or 2 (boar taint). Most of the boars (84%) were slaughtered before 210 days of age with great variation between farms from 178±1 to 209±2 days (mean ± SE, $P<0.001$). The average carcass weight varied also between farms (90.1±0.7 to 99.2±1.6 kg, $P<0.001$) as well as the average LMP (59.2±0.3 to 60.7±0.3 $P<0.001$). For human nose evaluation, most carcasses (94.5%) were scored 0, 4.0% were scored 1, and 1.4% scored 2. Median S (0.02 to 0.06 µg/g pure fat) and A (0.54 to 1.78 µg/g) concentrations in backfat varied a lot between farms ($P<0.001$). A positive correlation was depicted between A and S ($P<0.0001$), and between carcass weight and A ($P<0.03$). Within farms, analyses revealed a significant variation between trimesters in one farm for A and in a second farm for S and a positive correlation between age at slaughter and A in two farms ($P<0.03$). Rearing entire male pigs can be a good alternative to castration in organic farming provided the risk of boar taint is under control choosing a genotype with low risk for A, avoiding old and heavy pigs at slaughter, and maintaining a clean and well-ventilated housing.

Session 08

Theatre 12

Boot swabs to assess efficiency of cleaning and disinfection of slatted floors in pig barnsR.H. Mateus-Vargas^{1,2}, N. Kemper², K. Butenholz², N. Volkmann², C. Sürle³ and J. Schulz²¹Department of Animal Sciences, University of Göttingen, Burckhardtweg 2, 37077 Göttingen, Germany, ²Institute for Animal Hygiene, Animal Welfare and Farm Animal Behavior (ITTN), University of Veterinary Medicine Hannover, Foundation, Bischofsholer Damm 15, 30173 Hannover, Germany, ³Lehr- und Forschungsgut Ruthe, University of Veterinary Medicine Hannover, Foundation, Schäferberg 1, 31157 Sarstedt, Germany; rafael.mateus-vargas@uni-goettingen.de

Cleaning and disinfection (C&D) of animal houses within and between production cycles are important hygienic measures to control the transmission of pathogens between batches. To adequately assess the level of success of C&D procedures in barns, the use of boot swab sampling may represent an adequate alternative. The aim of this study was to utilize a boot swab sample method to assess the success of C&D in pig barns (farrowing, rearing, and fattening) with slatted floors on two farms located in Northern Germany. Animal houses were cleaned and disinfected by a specialized contractor according to standard protocols. The success of C&D procedures was assessed using a boot swab method before water cleaning (BC), after water cleaning (AC), and after disinfection (AD). Microbiological examinations of swabs included the quantitative determination of indicator bacteria. With one exception, water cleaning alone resulted in statistically significantly reduced hygiene indicators (around 2 log₁₀ cfu per boot swab pair). Additionally, an average decrease of bacterial loads of about 1 log₁₀ cfu per boot swab pair was observed at AD in comparison to AC. Thus, the use of the boot swab sampling method allowed to assess the efficiency of C&D procedures at different time points in pig barns, including the detection of unexpected outcomes, which may indicate incorrectly performed C&D protocols. Such results are valuable for evaluations of C&D practices by animal owner or specialist contractors. However, the boot swab sampling method may only record the microbial contamination on the upper surface, while bacterial loads between and beneath the slots in the floor might not be considered adequately. Combinations with other methods should be further evaluated. This work was supported by the QS-Wissenschaftsfonds.

The impact of temperature on transmission of African swine fever in contaminated livestock vehiclesY. Gao¹, A. Boklund², L. Nielsen³, L. Alban^{2,3} and M. De Jong¹¹Quantitative Veterinary Epidemiology, Wageningen University and Research, Radix, 6700 AH, Wageningen, the Netherlands, ²Faculty of Health and Medical Sciences, University of Copenhagen, Blegdamsvej 3B, 2200, Copenhagen, Denmark, ³Danish Agriculture & Food Council, Axelburg, 1609, Copenhagen, Denmark; yuqi.gao@wur.nl

African Swine Fever Virus (ASFV) is the cause of an infectious disease in pigs. The disease is lethal and can bring huge economic losses to an area once introduced. There is neither a vaccine nor a treatment available. Long viability of the virus has been shown for several contaminated materials, especially under low temperature. Therefore, when exposed to a contaminated environment, new infections could occur without the presence of infectious individuals. For example, a contaminated, poorly washed, empty livestock vehicle poses a risk to the next load of pigs. Here we calculated the duration of infectivity of fomites, depending on the temperature in the empty period of a pen/vehicle after contamination. A quantitative stochastic environmental transmission model was applied to both a direct transmission experiment and an environmental transmission experiment to estimate the epidemiological parameters. For a latent period of 5 days, the estimated parameters were as follows: the transmission rate parameter was 1.5 (0.9-2.4) day⁻¹, the decay rate parameter was 1.0 (0.7-1.5) day⁻¹ (at 20 °C), and the excretion rate parameter was 2.7 (2.5-3.1) day⁻¹. However, the experiments we referred to were conducted at 20 °C, and data describing such experiments at low temperatures are absent. Thus, we extrapolated from earlier half-life research on urine, faeces, and organ tissues. Based upon this, the hazard level of the environment and the probabilities of infection at 20, 10, 0, and -10 °C were calculated. The results show that the probability of the contaminated environment causing at least one of four recipient pigs (based on the initial study set-up) to become infected was 100% before the start of the empty period and declined to 6.2% after 5 days at 20 °C, compared to 42.9, 94.4, and 100%, at 10, 0, and -10 °C, respectively, all after 5 days. Thus, although in the original experiment the probability of recipients becoming infected was low, the probabilities at commonly occurring lower temperatures are non-negligible.

Session 08

Theatre 14

Porcine ear necrosis is associated with social behavior and blood biomarkers in weaned pigsT. Nicolazo¹, C. Clouard², C. Teixeira Costa¹, G. Boulbria¹, A. Lebre¹, V. Normand¹ and E. Merlot²¹Rezoolution, ZA De Gohelève, 56920 Noyal-Pontivy, France, ²INRAE, PEGASE, Le Clos, 35590 Saint-Gilles, France; t.nicolazo@rezoolution.fr

Porcine ear necrosis (PEN) is a worldwide health issue and its aetiology is still unclear. The aim of this study was to describe the prevalence and the severity of PEN in a commercial farm, associated with behavioural changes and health biomarkers measures. On two consecutive batches, PEN prevalence was determined at the pen level. PEN scores, blood haptoglobin concentration and oxidative status biomarkers were measured on two pigs per pen (n=48 pens), 9, 30 and 50 days (D) after arrival to the post-weaning unit. For two to three other pigs per pen, social nosing, oral manipulation, aggression of pen mates and exploration of enrichments were observed twice a week from D9 to D50. At the pen level, the higher the time spent nosing pen mates, the lower the proportion of pigs affected by PEN during both the D9-D30 and the D31-D50 periods ($P<0.002$). On the opposite, the higher the time spent manipulating orally pen mates during the D31-D50 period, the higher the percentage of affected pigs within a pen ($P=0.03$). Mean PEN scores on D50 were higher in pens in which focal piglets spent more time nosing pen mates during the D31-D50 period ($P=0.02$), and to a lesser extent, during the D9-D30 period ($P=0.08$). At the pig level, the higher the increases in hydroperoxides and haptoglobin during the D9-D30 period, the higher the PEN scores on D30 ($P<0.001$). Our study evidenced that an increase in inflammatory and oxidative stress biomarkers might be associated with PEN severity. In addition, this study is the first to suggest that social nosing and oral manipulations have opposite associations with PEN syndrome.

Pelleting and botanical source influence starch utilization in growing pigsA. Agouros^{1,2}, M. Le Gall¹, K. Quéméneur¹, Y. Lechevestrier¹, L. Montagne², N. Quiniou³ and E. Labussière²¹Cargill, Ferchaud, 35320 CREVIN, France, ²INRAE, Institut AGRO, 16 Le Clos Domaine de, La Prise, 35590 St-Gilles, France, ³Institut du Porc, La Motte au Vicomte, 35650 Le Rheu, France; etienne.labussiere@inrae.fr

Feed pelleting improves digestibility and metabolic use of energy. As starch provides almost 70% of the dietary energy, the study aimed to test the effects of starch origin and pelleting on metabolism of pig. Six diets were obtained in a 3×2 factorial design differing by starch source (wheat, W; maize, M or barley, B) and presentation (flour, F or pelleted, P). The diets were named as the combination of botanical source and presentation form. Diets were distributed four times a day, providing 2.4 MJ ME/kg BW^{0.60} per day to 72 male pigs (mean body weight (BW): 52.2±4.7 kg) housed in pairs during one week in an open-circuit respiration chamber to measure the dynamics of gas exchanges and energy balance. Pigs were fitted with a catheter in the portal vein to study the dynamics of blood metabolites after a meal. At the end of the experimental period, pigs received two meals with indigestible markers 6 and 1 h before slaughter for quantifying marker recovery in each digestive tract segment. Marker passage in stomach 6-h after intake was higher with WP, MF and MP than with WF, BF and BP (87 vs 73%; $P<0.05$). Passage rate in stomach of marker given 1-h before slaughter were similar with WP, MF, MP and BF but higher than with WF and BP (34 vs 14 and 18%, respectively; $P<0.05$). Dry matter faecal digestibility was greater with WP and BP (+1.9 and +1.0%; $P<0.05$) compared to WF and BF. Preprandial portal insulinemia was higher with MP than MF (54 vs 9 µU/ml; $P<0.05$). From 150 to 180 min after the meal, insulinemia was greater with WP and BP than WF and BF (41, 29, 12.5 and 16.4 µU/ml; $P<0.05$). Mean portal glycaemia was greater with BP than BF from 30 to 150 min after the meal (1.30 vs 1.47 g/l) and tended to be higher with WP compared to WF (1.44 vs 1.66 g/l). Pelleting improved digestive utilization and modified nutrient metabolic dynamics with W- and B- but not M-based diets. Varying responses to digestive and metabolic use between botanical sources have to be taken into account for feed formulation.

Effects of a blend of phytogenic feed additives on performance in fattening pigs fed liquid feed

A. Samson, W. De Gaiffier, E. Janvier and S. Constantin

ADM, Z. A. La Pièce 3, 1180 Rolle, Switzerland; werner.degaiffier@adm.com

Plant extracts may optimize feed efficiency in pigs by increasing the activity of endogenous enzymes involved in digestion and absorption. This study aimed to assess the effect of a blend of phytogenic feed additives on growth performance of fattening pigs fed restricted-feed liquid diets. In total, 270, 68-days-old pigs housed in pens of 6 were fed on a growing diet for the first 35 days, followed by a finishing diet until slaughter. Pigs were divided into 3 experimental groups: a Negative Control (NC) fed diets with low nutritional value (Growing: 9.6 MJ NE/kg, 0.84% SID Lys; Finishing: 9.7 MJ NE/kg, 0.78% SID Lys), a Positive Control (PC) consisting of the same diets as the NC but with a higher NE and SID Lys content (+0.2 MJ NE/kg and +0.02% SID Lys), and a Phytogenic group (PHYT) fed the same diets as the NC but supplemented with 80ppm of phytogenic feed additive containing cinnamaldehyde (3%), capsicum oleoresin (2%) and carvacrol (5%). As pigs were on restricted-feed regimes, the ADFI did not differ significantly between the groups over the study (2.26 kg/d on average, $P=NS$). As expected, PC pigs significantly improved their performance over the fattening period compared to the NC group (+ 6.3% ADG and -6.6% F/G, $P<0.0001$). The PHYT group also had a significantly improved performance compared to the NC (+ 6.1% ADG and -6.6% F/G, $P<0.0001$) and it was comparable to the PC performance throughout the study. Lean meat percentage was significantly lower for the PC group compared to the NC pigs (-1.5%, $P=0.01$) and intermediate for the PHYT group. This data confirms that this blend of phytogenic feed additives can improve feed efficiency in fattening pigs on restricted-feed liquid diets and can compensate for the reduced nutritional value of the diet administered in the study.

Genetic parameters of digestive coefficients in three pig breeds

C. Carillier-Jacquin¹, P. Ganier², J. Bidanel³, C. Hassenfratz⁴, B. Blanchet⁵, V. Deru^{1,6}, E. Labussiere² and H. Gilbert¹

Digestive efficiency predicted via near infrared spectrometry (NIRS) is a new indicator of interest for pig selection schemes, making it possible to target a component of feed efficiency particularly interesting in a context where feed contains more dietary fibres. The aim of this study is to estimate genetic parameters of digestive ability for three French pig breeds: Large White, Landrace and Piétrain. Faecal samples at 21 weeks of age were taken from 629 Large White, 188 Landrace and 213 Piétrain male pigs. All Large White animals were genotyped, and digestibility coefficients (DC) for organic matter, energy and nitrogen were predicted from faecal samples by NIRS. Genetic parameters (genetic variance, residual variance and heritability) of DC and genetic correlations with classical production traits (growth rate, feed efficiency and carcass composition) were estimated using REML algorithms considering genotyped data when it was available. Heritabilities of DC estimated were moderate (between 0.10 for DC of nitrogen and 0.35 for DC of energy in Landrace), which is close to estimations reported in the literature for Large White pigs. Heritability for DC in the three breeds were similar, with slightly lower estimates for DC of organic matter in Landrace and Piétrain breeds compared to Large White. Trends of the genetic correlations with production traits were similar in the three breeds: negative for growth rate, feed intake and null for carcass leanness. These first estimates of genetic parameters for DC in Landrace and Piétrain suggest that the NIRS predictions can be used in most selected pig breeds to further improve feed efficiency.

Breeding for uniformity in piglet birth weight to improve survival

C. Kasper¹, A. Lepori², J.P. Gutiérrez³, N. Formoso-Rafferty⁴, E. Sell-Kubiak⁵ and I. Cervantes³

¹Agroscope, Animal GenoPhenomics, Tiöleyre 4, 1725, Switzerland, ²Suisag, Allmend 10, 6204 Sempach, Switzerland, ³UCM, Department of Animal Production, Veterinary Faculty, Avda. Selection for uniformity in birth weight (BW) could lead to a more ethical and efficient livestock production because it results in more robust animals, which are easier to manage, more feed-efficient and are more likely to survive to weaning. This study aimed to estimate the genetic component of residual variance for BW and its relationship with piglet survival in a Swiss experimental farm. The data set comprised 43,135 records of BW from 3,163 litters of 986 sows, and pedigree data for 45,737 individuals. A heteroscedastic model was used, including fixed effects such as sex, month-year, litter size, and parity, and the litter effect was added as a random effect in addition to the genetic effect. The data was assigned to the mother, and the same effects were fitted for mean BW and its variability. A threshold homoscedastic model was performed for the probability of stillbirth (SB). A multivariate analysis was performed for BW and SB including the additive genetic effect and the maternal genetic effect using a Markov Chain Monte Carlo software (GSEVM) for the heteroscedastic model and TM software for the homoscedastic one. The genetic coefficient of variation was 0.29, and the genetic correlation between the mean BW and its variability was 0.24 (SE=0.09). The individual and maternal h^2 were 0.04 (0.01) and 0.23 (0.03) and 0.00 (0.00) and 0.05 (0.01), for BW and SB, respectively. The direct genetic correlation between BW and SB was 0.14 (0.31) and the maternal one 0.01 (0.11). In conclusion, our results show that there is potential for selection for the reduction of environmental BW variability, and the correlation between maternal breeding values indicates that it will not negatively affect the survival of piglets.

Genetic lines influence carcass traits and quality of porkX. Li¹, M. Ha¹, R. Warner¹, R. Hewitt², D. D'Souza² and F. Dunshea^{1,3}¹School of Agriculture and Food, Faculty of Science, University of Melbourne, 3010, Parkville, VIC, Australia, ²SunPork Group, SunPork Group, 4009, Eagle Farm, QLD, Australia, ³Faculty of Biological Sciences, University of Leeds, Leeds, LS2 9JT, United Kingdom; xyiingl@student.unimelb.edu.au

While the Australian swine industry has made efforts in selecting for lean growth, especially in the terminal lines, this may have adverse effects on pork quality. This study aimed to investigate how genetic lines affect carcass traits and pork quality and how chemical composition affects pork texture. Female pigs from 6 lines were used: Pure maternal, Landrace-type (PM-LR, n=18); Pure maternal, Large White-type (PM-LW, n=18); Pure maternal, Duroc-type (PM-D, n=18); Synthetic terminal, large white and Landrace-type (SynT-LWLR, n=12); Pure terminal, Duroc-type (PT-D, n=18); and Pure terminal, Large White-type (PT-LW, n=18). Live weight, dressing percentage, P2 fat depth and ultimate pH were recorded. From each line, 12 carcasses were used to measure the cooking loss, Warner-Bratzler shear force (WBSF), texture profile analysis (hardness, cohesiveness, adhesiveness, chewiness, and springiness), collagen content and solubility and intramuscular fat (IMF) content of Longissimus thoracis et lumborum and Semimembranosus. Results showed that the terminal lines had lower P2 fat depth than the maternal lines (9.26 vs 11.8 mm, $P<0.001$) and their pork showed higher cooking loss (17.2 vs 16.1%, $P=0.002$), hardness (35.7 vs 34.0 N, $P=0.027$) and chewiness (12.4 vs 11.7 N, $P=0.037$) than maternal lines. Considering individual lines, SynT-LWLR showed the highest hardness ($P=0.039$) and cohesiveness ($P=0.023$). The IMF content of SynT-LWLR was lower than the other five lines (1.08 vs 1.69% to 1.73%, $P=0.004$). When all lines were analysed, muscle collagen content was correlated ($P<0.05$) with hardness ($r=0.20$), chewiness ($r=0.27$), adhesiveness ($r=0.29$) and springiness ($r=0.30$), while collagen solubility was correlated ($P<0.05$) with chewiness ($r=-0.18$) and springiness ($r=-0.22$). IMF was correlated ($P<0.05$) with WBSF ($r=-0.29$), adhesiveness ($r=0.25$) and springiness ($r=0.34$). In individual line, no significant correlations were found in PM-D or PT-LW. Genetic selection may adversely influence pork quality and genetic lines affect the contribution of collagen and IMF to pork texture.

Boar taint: pedigree-based BLUP and genomic BLUP, and associations with green-ham quality traits

S. Faggion, P. Carnier and V. Bonfatti

University of Padova, Department of Comparative Biomedicine and Food Science, viale dell'Università, 16, 35020, Legnaro, Italy; sara.faggion@unipd.it

Boar taint (BT) occurs in entire male pigs after puberty due to the accumulation in the adipose tissue of three main compounds: androstenone (AND), skatole (SKA), and indole (IND). Slaughtering entire male pigs before sexual maturity is not feasible for pigs intended for protected designation of origin (PDO) dry-cured ham production and, with a perspective future ban on surgical castration in Europe, selecting pigs with reduced ability to accumulate BT compounds in their tissues seems a promising strategy. BT compound concentrations were measured in 1,115 purebred pigs; animals were genotyped using a high-density SNP chip (29,844 SNPs after quality control). Breeding values for BT compounds were computed with pedigree-based BLUP (PBLUP) and genomic BLUP (GBLUP) using the genomic relationship matrix. Model performance was estimated in a 5-fold random cross-validation. The accuracy of PBLUP and GBLUP (defined as the Pearson correlation between predicted EBV and adjusted phenotypes divided by the square root of heritability) was 0.38 and 0.61, respectively, for AND, 0.54 and 0.51 for IND, 0.50 and 0.54 for SKA. Since most slaughter pigs are crossbred, it is important to consider potential effects on commercial traits in crossbreds before selecting against BT in purebreds. Genetic correlations between BT compound concentrations and carcass and ham quality traits from 26,577 crossbred Italian heavy pigs were then estimated. Estimates were obtained in a set of bivariate Bayesian analyses including one BT trait and one production/ham quality trait at a time. Heritability estimates for AND, SKA and IND were 0.41, 0.49 and 0.37, respectively. Genetic correlations between BT compounds were positive (0.40 to 0.85). Negative correlations between SKA and carcass yield (-0.40) and between BT compounds and backfat (between -0.26 and -0.55) were observed. Conversely, positive correlations (from 0.11 to 0.54) between SKA and ham fat thickness traits were detected. Correlations between BT compounds and iodine number ranged from -0.07 (AND) to -0.64 (SKA), whereas those with PUFA ranged from -0.13 (IND) to -0.33 (SKA).

Diversity of pig breeds reared in the Czech RepublicE. Krupa¹, Z. Krupová¹, E. Žáková¹, N. Moravčíková² and I. Vrtková³¹Institute of Animal Science, Prátelství 815, 10400 Prague, Czech Republic, ²Slovak University of Agriculture, Tr. A. Hlinku 2, 94901 Nitra, Slovak Republic, ³Mendel University, Zemědělská 1, 613 00 Brno, Czech Republic; krupova.zuzana@vuzv.cz

The aim of the study was to compare the diversity parameters of the dam pig breeds: Czech Large White (CLW) and Czech Landrace (CL) based on pedigree and SNP data. Total number of animals in pedigree were 16,438 and 7,266 for CLW and CL, respectively. A slight increase in the inbreeding and the proportion of inbred animals used in the breeding was observed. The average inbreeding rates in 2010, 2015, 2020 and 2022 for the CLW were 0.7, 1.5, 1.7 and 2.0%, respectively. The proportion of inbred animals included in the breeding program in these years was 39.5, 83.1, 97.8 and 97.4%, respectively. The CL breed had slightly higher values in those years. The effective population size ranged from 99 (CLW) to 181 (CL) animals. Selected DNA isolates (603 and 201 animals of CLW and CL, respectively) were applied to a GGP Porcine 50k chip using the Illumina HD Infinium technology protocol. A total of 50,697 SNPs were identified in the selected DNA isolates. The average 'call rate' was 0.99, 0.97 and 0.96 for bristle, insemination batch and ear graft samples used as source, respectively. Thus, data from 590 CLW and 196 CL animals containing 45,065 and 46,257 SNPs, respectively, were used for further evaluation. The genomic inbreeding coefficient was calculated for each ROH class (FROH). The effective population size based on genomic data was calculated using GONE software. The inbreeding coefficient obtained from SNP data was lower than that obtained from pedigree data. It was 0.40% for the CLW breed and 2.23% for the CL breed. The differences were probably due to smaller number of genotyped animals. The effective population size over the last 9 generations exceeded 300 individuals for both breeds, although a decrease in effective population size was observed, especially in the last three years. The results of the SNP analyses are generally consistent with the results from the pedigree analysis in both breeds – a slight increase in inbreeding and a decrease in effective population size. The study was supported by Czech Republic project QK1910217 and MZE-RO0723 – V02.

Session 08

Poster 22

Wild boar and domestic pig identification based on GBS studyA. Koseniuk¹, G. Smolucha¹, A. Gurgul², T. Szmatoła², M. Oczkowicz¹ and A. Radko¹¹National Institute of Animal Production, Department of Animal Molecular Biology, Krakowska 1, Street, 32-083, Poland,²University of Agriculture in Krakow, Center for Experimental and Innovative Medicine, Rędzina 1c, 30-248 Kraków, Poland; anna.koseniuk@iz.edu.pl

According to scientific reports, efforts have also been made to provide an efficient diagnostic tool for distinguishing wild boar (*Sus scrofa scrofa*), domestic pig (*Sus scrofa domestica*), and their hybrids. The issue is getting more complex since both subspecies interbred sporadically over the last few decades and after the last glaciation. Genotyping-by-sequencing (GBS) is a method of identifying genetic variants that do not require knowledge of the genome. Recently, the method has become more attractive due to its relatively short analysis time and low cost. The research aims to identify the DNA regions that underwent strong selection during pig domestication and give an insight into Polish wild boar and domestic pigs' genetic diversity by implementing the genotyping-by-sequencing (GBS) technique. We have DNA extracted from ear fragments of wild boars (n=20) from southern Poland and hair bulbs pigs (n=10). The pig samples belonged to the breeds: PBZ (Polish Landrace, n=2), WBP (Polish Large White, n=4), DUR (Duroc, n=1), PUL (n=3), P (Pietrain, n=2). PstI endonuclease was used for DNA digestion. After the digestion stage, the ligation of DNA fragments with adapters was carried out, and the libraries prepared in this way were subjected to PCR. Fragment sequencing was performed using the HiScanSQ system (Illumina, USA). The genetic distance was calculated in the MEGAX program and the phylogenetic tree was created using the Maximum Likelihood (ML) method. The structure of the population and the degree of hybridization were assessed using the Structure program. Results and conclusions. The conducted analyses showed that both groups of animals are phylogenetically separated from each other. The study of the genetic structure of both populations showed that the most probable number K=2, wild boar samples are genetically uniform, while several subpopulations were identified in the group of domestic pigs. Based on the obtained results, the presence of hybrids in both tested groups of animals cannot be unequivocally stated.

Structural analysis of the HK2 gene in the aspect of pigs performance and meat quality parametersK. Woźniak¹, A. Terman¹, D. Polasik¹, G. Żak², M. Tyra² and K. Ropka-Molik²¹West Pomeranian University of Technology in Szczecin, al. Piastów 17, 70-310 Szczecin, Poland, ²National Research Institute of Animal Production, ul. Sarego 2, 31-047, Poland; grzegorz.zak@iz.edu.pl

Scientific research in the area of pork quality may in the future enable the selection of animals with a preferred genetic variant, whose meat will be characterized by more favourable meat quality parameters. In this context, the analysis of polymorphic variants of the HK2 gene in terms of pig performance characteristics and pork quality parameters can be considered justified due to the biological role in the regulation of the glycolysis process, as well as due to the molecular nature of the mechanism indicating the variability of the encoded proteins. The aim of this study was to detect polymorphisms in the gene encoding hexokinase (HK2) in domestic pig (*Sus scrofa domestica*) and to determine the potential relationships between the genotypes of the analysed gene fragments and the performance characteristics of pigs (fattening and slaughter) and selected parameters of meat quality. The research covered 722 pigs of 3 breeds: Polish Landrace, Polish Large White and native breed Puławska. The animals were kept at Pig Tests Stations. Feeding and housing conditions were consistent for all animals. Genomic DNA was isolated from longissimus dorsi muscle with the use of A&A Biotechnology (Poland). In the first phase of the research, exons in the gene HK2 had to go through PCR-HRM method. Fragments of PCR amplification selected by this technique, and the obtained products were sequenced using the Sanger method. 15 mutations were found in the analysed HK2 gene fragments. For two identified polymorphisms, SNP type located in the splicing region of exon 7 and in exon 12 an appropriate molecular method was developed (PCR-RFLP and PCR-ACRS, respectively) allowing to determine the frequency of selected mutations on a larger group of animals. The obtained frequencies of the polymorphic variants of the analysed gene show that there is variability within the HK2 gene. The identified polymorphisms show a significant association with selected fattening and slaughter characteristics as well as meat quality in pigs of various breeds.

Session 08

Poster 24

Methods to maximize accuracy of selection in maternal genetic model for genetic evaluation of pigs

M. Satoh

Tohoku University, Graduate School of Agricultural Science, Aramaki-Aza-Aoba 468-1, Sendai, Miyagi, 980-8572, Japan; masahiro.satoh.d5@tohoku.ac.jp

A mixed model allows us to estimate genetic parameters and easily obtain estimates of direct genetic effects (g_d) and maternal genetic effects (g_m). However, it is difficult to assign appropriate economic weights for g_d and g_m . In this study, we devised a method to obtain an appropriate weighting vector (v) for g_d and g_m . First, for the i th animal, let $g_i = [g_{di} \ g_{mi}]'$ and its BLUP vector be $g_i^\wedge$. When v is known, we confirmed that the weighting vector w that minimizes the prediction error variance, $\text{var}(v'g_i - w'g_i^\wedge)$, of $H_i (= v'g_i)$ is $w = v$ when $H_i^\wedge = v'g_i^\wedge$. Next, when v is unknown, we determined that the v that maximizes the coefficient of determination ($r_{H_i^\wedge H_i}^2$) between H_i and $H_i^\wedge$ is approximately the solution of the eigen equation $[G_0^{-1}C^T - kI]v = 0$, where $G_0 = \text{var}(g_i)$ and C^T is a 2×2 matrix derived from the inverse matrix of the left-hand side of the mixed-model equations. Since the eigenvalue $k = v'C^T v / v'G_0 v$, $(1 - k)^{1/2}$ represents the accuracy of selection. Let $k_1 < k_2$ be the two eigenvalues, then k_1 maximizes $r_{H_i^\wedge H_i}$ and k_2 minimizes $r_{H_i^\wedge H_i}$. Moreover, the elements of the eigenvector are the weights for g_d and g_m . This method was verified using a Monte Carlo simulation. The genetic parameters used were 0.3 for direct heritability, 0.1 for maternal heritability, and -0.5, 0, and 0.5 for the correlations between them. A closed breeding herd of 20 sires and 100 dams over four generations was simulated. Each litter produced two males and two females. All animals were randomly selected and five females were randomly mated to one male. Let G_0 be the base population and animals in G_4 are candidates for selection. Data were generated based on an infinitesimal additive genetic model. $r_{H_i^\wedge H_i}$ in G_4 was 0.614, 0.671, and 0.722 for correlations between direct and maternal heritability conditions of -0.5, 0, and 0.5, respectively. In addition, when the element of eigenvectors v_1 (for g_d) = 1, v_2 (for g_m) was 0.513, 0.546, and 0.549, for the three correlation conditions, respectively.

Parentage control of pigs based on SNP dataE. Žáková¹, Z. Krupová¹, E. Krupa¹, J. Stibál² and I. Vrtková³¹*Institute of Animal Science, Prátelsví 815, 10400 Prague, Czech Republic,* ²*Czech Pig Breeders Association, Bavorská 14, 155 41 Prague, Czech Republic,* ³*Mendel University, Zemědělská 1, 613 00 Brno, Czech Republic; krupova.zuzana@vuzv.cz*

Genotyping of animals included in the national breeding programme CzePig has been applied for genomic evaluation and pedigree assessment. To determine accurate animal evaluation and selection the parentage test is necessary. Therefore, the present study is aimed to exploit the pig genomic data to define an SNP panel that could be used for routine parentage control. Samples were taken from the animals that were parents of the next generation of breeding animals or that had sufficient performance data records in the studbook database. From the 1,489 animal sampled, 68% belongs to maternal and 17% to sire breeds and 15% were of the endangered Prestice black-pied breed. In 869 and 221 animals one and both parents were genotyped, respectively. The ratio of the evaluated samples by sex was 55:45 for sows and boars. Three SNP chips were used for genotyping (Illumina, Inc. Porcine SNP60v2 and PorcineSNP60 BeadChip and GeneSeek® Genomic Profiler™ GGP Porcine 50K). From all of the SNP 32,898 were shared between these chips. The GenCall score ($GC \geq 70$ and ≥ 80), minor allele frequency ($30\% \leq pM \leq 50\%$) and known position of each SNP locus on all autosomes were considered. The evaluation was done separately for each breed. Panels consisting of 435 ($GC \geq 70$) and 240 ($GC \geq 80$) SNP loci were selected for routine parentage control. The SNPs have to be known for more than 95% of animals. Subsequently, the genotype of an individual was compared with one or with both of parents. Only 3.6% of samples were assessed as incorrect (unreliable sample or pedigree error). These may be refined in the future as data increases. Simultaneously, the panels will be continuously reassessed due to upcoming samples (especially of sire breeds). The study was supported by Czech Republic project QK1910217 and MZE-RO0723 – V02.

Prediction of piglet survival based only on birth weight or within-litter birth weight variabilityJ.M. Mbuthia¹, C. Kasper², M. Zenk¹, G. Bee², C.C. Metges¹ and G. Das¹¹*Research Institute for Farm Animal Biology (FBN), Institute of Nutritional Physiology, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany,* ²*Agroscope, 'Animal GenoPhenomics' and 'Swine Research Unit', Rte de la Tioleyre 4, Posieux, 1725, Switzerland; gdas@fhn-dummerstorf.de*

High piglet mortality is of both economical and ethical relevance. Piglet birth weight (BW) and the birth weight variability within litter (BWvar) highly affect the pre-weaning survival. Further, the identification of low birth weight (LBW) piglets often relies on arbitrary statistical classifications. We established optimal cut-off values for BW and BWvar to predict pre-weaning piglet survival. BW, BWvar and survival data were obtained from FBN and Agroscope experimental pig facilities. The FBN data (2012 to 2021) for the German Landrace breed consisted of records from 28,242 total number of piglets born (TNB) i.e. born dead or alive from 752 sows. The Agroscope data (2004 to 2022) for the Swiss Large White consisted of 43,159 piglet records from 980 sows. The cut-off values for BW and BWvar to predict piglet survival from birth to weaning were estimated by the Receiver Operating Characteristic (ROC) curves analysis using the cutpoint package of R (v 4.0.3). Postnatal piglet mortality was highest within the first 3 days. From the piglets born alive, about 85.2 and 83.7% survived day 3 at FBN and Agroscope, respectively. Respective survival rates at weaning were 81.1 and 78.6%. Overall, the piglets below a BW cut-off value of 1.18 kg (i.e. FBN=1.17 kg and Agroscope=1.19 kg) had a lower survival probability at birth than those piglets >1.18 kg, and can be considered as LBW piglets. With a cut-off value of 0.278 g (AUC=0.55) the BWvar had a lower prediction accuracy than BW (AUC=0.66). Moreover, a BW cut-off value of 1.22 g (AUC=0.74) would increase the probability of piglets to survive until weaning. Although facilities were different in terms of genotypes and environments, highly similar cut-off values were estimated for identification of LBW with smaller survival probability for both facilities. The results also suggest that prediction of piglet survival with only BW is more informative than only with BWvar. The identified LWB piglets may benefit from extra support measures such as e.g. supplemental milk.

Effect of fenugreek cotyledons on farrowing sow performances

M. Le Bot, J. Laurain, E. Belz and A. Benarbia

Nor-Feed SAS, 3 rue Amédéo Avogadro, 49070 Beaucauzé, France; amine.benarbia@norfeed.net

Nutritional management of sow from the gestation to the end of lactation is critical for achieving and maintaining optimal sow productivity, longevity and litter growth. Fenugreek (*Trigonella foenum-graecum*) is an annual plant that belongs to the family of the *Fabaceae*. Due to the secondary metabolites, as steroidal saponins providing therapeutic properties and appetite stimulation, fenugreek seeds are commonly used in human and animal diets to stimulate appetite and weight gain. Feeding gestating and lactating sows with fenugreek cotyledons, the saponin-rich part of the seed, could improve optimal sow productivity and consequently litter growth during these periods. In this study, we assessed the effect of a commercial product based on fenugreek cotyledons (Norponin® Cotyl) on sow productivity and the impact on litter. Briefly, 100 sows (experimental farm, France) were randomly divided into two groups from 2 consecutive batches: a control group (CTL) fed with a standard diet (gestation and lactation) and a group (COTYL) supplemented with 1,500 ppm of fenugreek cotyledons. The trial started at the arrival of sows in farrowing unit (9 days before farrowing) and during all lactation (21 days) for a total of 30 days. Results showed that the average daily gain was higher in the COTYL group compared to the CTL group with 6.17 and 5.86 kg/day/sow respectively. This difference of +5.3% ($P < 0.05$) could lead to an increase in the milk production of the sows and would explain in part the improvement of the average daily gain of the piglets observed during this trial. Indeed, results corresponded to 3.03 for the CTL group and 3.13 kg/day/litter (+3.3%) for the COTYL group. The results obtained from this trial show that the supplementation with fenugreek cotyledons contributes to significantly increase feed intake and thus to improve piglet's growth during lactation. Further studies are however necessary to confirm these results.

Poster 28

Effects of different dietary fibres on constipation in sows during late pregnancyD. Lu^{1,2}, Y. Pi², H. Ye¹, D. Han², B. Kemp¹, N. Soede¹ and J. Wang²¹Wageningen University&Research, Department of Animal Sciences, Adaptation Physiology Group, Zodiac, De Elst 1, 6700 AH Wageningen, the Netherlands, ²China Agricultural University, College of Animal Science and Technology, State Key Laboratory of Animal Nutrition, Yuanmingyuan Road, Haidian District, 100193, Beijing, China, P.R.; dongdong.lu@wur.nl

Constipation in sows during late pregnancy increases farrowing duration and thereby increases the number of stillborn piglets. Dietary fibre supplementation can change intestinal microbiota composition, thereby increasing intestinal motility and reducing constipation in many animal models. However, the effects and mechanisms of fibres with different physicochemical properties on constipation have not been fully explored. In this study, 80 sows were randomly allocated to Control (CON, basic corn-soybean meal) and one of three dietary fibre treatments with the same total dietary fibre content (TDF) from day 85 of gestation to delivery: LIG (replace 1.5% of wheat bran with lignocellulose), PRS (replace 2.0% of wheat bran with resistant starch), and KON (replace 2.0% of wheat bran with konjaku flour). Results showed that the defecation frequency and faecal consistency were highest in PRS (2.93/day and 3.03). PRS and KON significantly increased serum levels of gut motility regulatory factors, 5-hydroxytryptamine (5-HT), motilin (MTL), endothelin-1 (ET-1), acetylcholinesterase (AChE) and reduced serum inflammation factors IL-6 and TNF- α . Furthermore, PRS and KON significantly reduced the number of stillborn piglets compared to CON. Microbial sequencing analysis showed that PRS and KON increased short-chain fatty acids (SCFAs) producing genera *Bacteroides*, *Parabacteroides*, and decreased the relative abundance of endotoxin-producing bacteria *Desulfovibrio* and *Oscillibacter*. Besides, the relative abundance of *Turicibacter* was highest in PRS. In conclusion, PRS and KON reduced sow constipation, which was associated with higher levels of gut motility regulatory factors under the genus *Turicibacter* and SCFAs stimulation, thereby increasing gut motility and reducing the number of stillborn piglets.

Effect of transportation condition of pigs during transport for slaughter under different season

D.C. Song, S.Y. Chang, J.W. An, S.H. Park, K.H. Jeon and J.H. Cho

Chungbuk National University, Department of Animal Science, 1, Chungdae-ro, Seowon-gu, Cheongju-si, Chungcheongbuk-do, Republic of Korea, 28644, Korea, South; paul741@daum.net

Animal welfare during transport became an largely issue because of increasing demand for improved animal welfare standards. The welfare of pigs during transportation is impacted by vibration brought on the driver's driving style. In vehicles, animals are exposed to vibration and environmental variations, which can lead to physiological and behavioural disturbances. Also, bedding may affect transport losses as a significant microenvironment component. Thus, the objective of study was to collect and quantify three axis acceleration and determine the effect of rubber type of bedding for transporting pigs from farm to slaughterhouse. A total of 2,553 crossbred pigs of mixed sex with same genetics ([Yorkshire × Landrace] × Duroc) were transported from same commercial farms to same commercial slaughterhouse. A 2×2 completely randomized factorial design was used to investigate the effects of bedding (bedding or non-bedding) and with two levels of driving style (wild or normal). Pigs transported bedding with normal driving style groups had higher ($P<0.05$) than pigs transported bedding with wild driving style groups. Transported with bedding groups showed higher pH, L value and sensory colour than transported with non-bedding groups in winter. Also, transported with bedding groups showed higher ($P<0.05$) standing behaviour but lower ($P<0.05$) lying behaviour than transported with non-bedding groups in winter. Also, transported with bedding groups showed higher ($P<0.05$) standing behaviour but lower ($P<0.05$) lying behaviour than transported with non-bedding groups in winter. Transported with bedding groups showed less ($P<0.05$) aggression behaviour than transported with non-bedding groups in spring, fall and winter. In spring, autumn and winter season, normal driving style groups or bedding groups showed low ($P<0.05$) cortisol level compared to wild driving style or non-bedding groups. In conclusion, driving style and bedding are important part of animal transportation to protect animal welfare and economic losses.

Session 08

Poster 30

Salmonella excretion level by pigs and impact of disinfection on antibiotic resistance of *E. coli*C. Soumet¹, A. Kerouanton², A. Bridier¹, B. Anger¹, V. Dorenlor³, V. Rose², F. Eono³, C. Houdayer², E. Houard², E. Eveno³, F. Souchaud², B. Houry², C. Valentin¹, P. Houée¹, I. Attig⁴, N. Haddache⁴, M. Denis² and C. Fablet³¹Anses, CS 40608, 35306 Fougères, France, ²Anses, BP 53, 22440 Ploufragan, France, ³Anses, BP 53, 22440 Ploufragan, France, ⁴Anses, 14 rue Pierre et Marie Curie, 94700 Maisons Alfort, France; christelle.fablet@anses.fr

The control of contamination of food by *Salmonella* and the reduction of antibiotic resistance are two major public health issues. The study aimed at acquiring data on the level of *Salmonella* excretion by pigs and assessing the impact of disinfectants on the evolution of antibiotic resistance in *Escherichia coli* strains. Four French pig farms deemed to be *Salmonella* positive were sampled 3 times. At each visit, individual faeces from 10 lactating sows and 20 finishers were collected. The detection and enumeration of *Salmonella* was carried out from faeces by standardized methods. On 3 farms, the pen partitions and floor surfaces of 3 farrowing rooms were swabbed before and after cleaning and disinfection (CD) procedures with quaternary ammonium compounds based disinfectants. Total *E. coli* and *E. coli* resistant to antibiotic were enumerated from swabs on Petrifilm™ Select *E. coli* without and with a concentration of antibiotics respectively. Total bacteria were enumerated on non-selective media. No sow and 21.6% of finishers tested positive for *Salmonella*. A low *Salmonella* excretion level was estimated on most of the positive samples. The excretion level was variable between farms and pigs within a farm. Ten of 36 samples after CD were positive for *E. coli*. CD procedures reduced counts of *E. coli* and total bacteria (by 3 to 4 Log10) and antibiotics resistant *E. coli*. This exploratory study allows collecting for the first time in France quantitative data on the level of *Salmonella* excretion in pigs naturally infected. These data are required to build accurate risk assessment models and ultimately allow better control of the risk associated with *Salmonella* contamination of food. Disinfection of pig premises was effective to reduce total bacteria and *E. coli* counts. Reduction of *E. coli* resistant to tested antibiotics suggested that disinfectant exposure would not have selected antibiotic resistance in *E. coli* strains on these herds at the time of the study.

Climate change adaptation in mixed pigs-beef cattle systems in grasslands areas: key role of organicS. Mugnier¹, L. Valero¹, C. Husson¹, F. Von Kerssenbrock², B. Dounies³, H. Rapey² and C. Philippeau¹¹L'Institut Agro Dijon, BP 87999, 21079 Dijon, France, ²Université Clermont Auvergne, AgroParisTech, INRAE, VetAgro Sup, UMR 1273 Territoires, 9 Av. Blaise Pascal, 63170 Aubière, France, ³Association Porc Montagne, 9 allée Pierre de Fermat, 63170 Aubière, France; sylvie.mugnier@agrosupdijon.fr

Global climate change may increase the frequency and severity of drought periods which may potentially strongly reduce grass yields due to reduced water and nutrient availability in soils. In this context, the grassland management is essential to ensure the fodder autonomy in cattle farms. Several studies showed that multi-species livestock farming (in particularly, sheep and cattle) increases the resource-use efficiency. However, the potential benefits of systems combining pigs and cattle are less studied. We can suppose that the careful management of the different types of manures may limit variation in plant productivity and, more particularly, grass yield due to climate changes. Our objective was to develop a comprehensive analysis of mixed pigs-cattle farming systems in the French Massif Central area in order to outline and discuss potential benefits and limitations of using different manures to fertilise grasslands and crops. Two studies were performed. Firstly, on-farm 40 surveys were carried out in order to characterize how pigs and cattle effluents were used as organic fertilisers. Most farmers assigned specific fertiliser properties according to each type of effluent. For example, for most farmers, the livestock slurry promotes a rapid growth of grass whereas the application of solid manure enhance organic matter enrichment in soil. Slurry is applied to grass pastures in the spring and solid manure preferentially before the sowing date of cereals. A second survey was carried out on 20 mixed pigs-beef cattle farms which were located in a same pedoclimatic area (North of the French Massif Central) to analyse the variations in fertilisation management of grassland between the last 3 years. This study provided more precise knowledges about the pig manure application as organic fertiliser. Also, farmers seemed aware of the interest of pig slurry in the grassland management in extensive livestock production systems in order to limit variations in grass yields due to climate changes.

Financial implications associated with ante- and post-mortem inspection findings in finishing pigsD.L. Teixeira¹, L.C. Salazar² and L.A. Boyle³¹Hartpury University, Department of Animal and Agriculture, Gloucester, GL19 3BE, United Kingdom, ²Pontificia Universidad Católica de Chile, Departamento de Ciencias Animales, Santiago, Region Metropolitana, Chile, ³TEAGASC Moorepark, Pig Development Department, Fermoy, Co. Cork, Ireland; laura.boyle@teagasc.ie

This study aimed to investigate the associations between severe ear, tail and skin lesions, hernias, bursitis and rectal prolapses and meat inspection finding in slaughter pigs, including carcass weight and financial implications associated with carcass condemnations at batch level. Data were collected from 13,296 pigs from 116 batches from a single abattoir. Spearman's correlation coefficients were calculated to analyse the degree of association between the prevalence of welfare issues and condemnation findings. The association between batch-level results of carcass weight, batch size and the prevalence of welfare issues was analysed using generalized linear mixed models. The prevalence of tail lesions was significantly associated with both entire ($r=0.224$; $P=0.0432$) and partial ($r=0.276$; $P=0.0120$) carcass condemnation. Batches with pigs affected by more than one welfare issue were 9.9 kg lighter than those without welfare issues ($P<0.05$), which was equivalent to a potential loss of €11.28 per pig. Our findings indicate that *ante-mortem* inspection could be useful to predict *post-mortem* findings at batch level and that welfare issues in pigs represent a financial loss to producers, as they are paid on a per kg basis and have tight margins.

Training during rearing: effect on body reserves' flexibility & long-term reproduction in rabbit doe

J.J. Pascual, E. Martínez-Paredes, L. Ródenas, E. Blas and M. Cambra-López

Universitat Politècnica de Valencia, Institute for Animal Science and Technology, Camino de Vera s/n., 46022, Spain; jupascu@dca.upv.es

Animals' flexibility to mobilize and recover body reserves increases with age or parities. As most breeds are selected for early productive criteria, training the body reserves flexibility of young breeds could improve their future reproduction and survival. This work evaluated the effect of a rearing training strategy for young rabbit does, based on 0 to 3 feed restriction schemes, on their body reserves flexibility and long-term reproduction. Each restriction was addressed to simulate the mobilization of reserves around parturition, 6 days of progressive reduction from *ad libitum* to zero and 3 days of progressive recovery until *ad libitum* feeding. At 63 days of age, 120 rabbit females were divided into 4 groups (30 each): A, fed *ad libitum*; 1R, fed *ad libitum* with one restriction scheme from 92 to 101 days of age; 2R, fed *ad libitum* with two restriction schemes from 70 to 79 and 114 to 123 days of age; 3R, fed *ad libitum* with three restriction schemes from 70 to 79, 92 to 101 and 114 to 123 days of age. Females were artificially inseminated (AI) at 137 days of age and at 11 days postpartum thereafter. Live weight (LW), perirenal fat thickness (PFT) and feed intake of females were controlled until the 2nd parturition. Alive and total litter size at birth was controlled until the 9th reproductive cycle. A few days before the first AI, does were challenged with isoproterenol to determine their lipolytic potential. Young rabbit does from the R groups showed clear losses of LW and PFT during the application of restriction schemes but recovered the A group values some weeks after refeeding. At first AI, R females had lower basal blood concentration of non-esterified fatty acids with respect to A females (on av. -13.9 ± 4.5 uEq NEFA/l; $P=0.002$), but no differences were observed between groups in the increase of NEFA after challenge. There was a linear increase of total born and born alive during 9 reproductive cycles with the number of restrictions applied during rearing ($+0.47 \pm 0.20$ and $+0.42 \pm 0.19$ per restriction, respectively; $P<0.05$). The restrictions applied during rearing did not affect body reserves' flexibility but improved the prolificacy of the females.

Theatre 1

Replacement of poultry by-product meal by black soldier fly larvae meal in diets for dogsB. Agy Loureiro¹, R.K. Nobrega Cardoso², R. Silva Carvalho², W.A. Zamora Restan³, M. Dalim¹, N. Martin Tome¹ and A. Paul¹¹Protix B.V., Industriestraat 3, 5107 NC Dongen, the Netherlands, ²Universidade Federal da Bahia, Adhemar de Barros, 40170-110, Salvador, Brazil, ³Universidade Federal da Paraíba, PB 079 km 12, 58.397-000, Areia, Brazil; bruna.loureiro@protix.eu

The study evaluated the use of black soldier fly larvae (BSFL) meal in diets for dogs on digestibility, intestinal fermentation end-products and faecal microbiota. Two kibble iso-nutrient diets were developed using either poultry by-product (PBP) meal or BSFL meal as main protein. Eight beagle dogs were assigned in a cross-over design, with 2 treatments (diets) and 2 periods of 50 days each (with 7 days of wash-out between periods). In the first period, 4 dogs received either the PBP diet or the BSFL diet, while in the second period the diets were inverted. At day 15 of each period, dry matter, organic matter, crude protein and fat digestibility; and metabolizable energy (ME) were determined by total faeces collection method for 5 days. Volatile fatty acids and ammonia were analysed in fresh faecal samples collected on days 21 to 24 of each period. After each period (50 d) fresh faeces were collected for metagenomic analysis using bacterial 16s rRNA marker gene sequence. Nutrients digestibility was similar between the food treatments, except for fat digestibility and diet ME, which was higher when dogs were fed BSFL food ($P=0.01$). Faecal ammonia was lower (151 vs 94 mmol/g faeces) when dogs were fed BSFL in comparison to PBP ($P=0.004$). BSFL diet promoted changes in faecal microbiota, with a significant difference in beta diversity, with taxa dissimilarity by Unifrac ($P=0.036$). BSFL diet promoted a higher relative abundance of *Bacteroides* ($P=0.040$), responsible to contributes to intestinal permeability; and *Phocaeciola* ($P=0.028$), considered a biomarker of human health. On the other hand, BSFL reduced the abundance of *Lachnospira* ($P=0.003$), positively correlated with intestinal butyrate production, despite no diet differences found for volatile fatty acid in faeces. In conclusion, the use of BSFL meal in dog diet didn't affect the use of nutrients, but increased diet fat digestibility and ME; reduced faecal ammonia, and positively modified the faecal microbiome of dogs, favouring some beneficial bacteria genera.

***Hermetia illucens* meal in Rainbow trout diet – preliminary data of a commercial scenario**S. Bellezza Oddon¹, I. Biasato¹, C. Caimi¹, P. Badino¹, F. Gai², M. Renna¹ and L. Gasco¹¹University of Turin, Largo Paolo Braccini, 2, 10095, Grugliasco, Italy, ²Institute of Sciences of Food Production, Largo Paolo Braccini, 2, 10095, Grugliasco, Italy; sara.bellezzaoddon@unito.it

Hermetia illucens (HI) meal has already been tested as feed ingredient in rainbow trout under experimental conditions, but few studies have been carried out under commercial farm conditions. The present study aimed to evaluate the inclusion of 0, 2.5, 5 and 10% (named C, HI2.5, HI5 and HI10) of partially defatted HI meal as substitute of fish meal in iso-nutrient diets. 1,560 rainbow trout (117.1±6.4 g) were allotted to 12 tanks (130 fish/tank, 3 replicates/treatment) and fed on a fish tank biomass basis (from 1.4 to 1.1%) with the daily quantity of feed updated every 14 days. Every 38 days (T1, T2 and T3, respectively), blood samples were collected from 6 fish/tank to evaluate the oxidative stress biomarkers in serum (dROM and OXY-Test). At the trial end, all fish were lightly anesthetised and weighed. The following performance parameters were calculated: mortality, individual weight gain, specific growth rate, feed conversion ratio (FCR) and protein efficiency ratio. After slaughter, the following indexes were calculated on 30 fish/treatment: carcass yield, Fulton's condition factor, coefficient of fatness, hepatosomatic and viscerosomatic indexes, and 5 fish/tank were filleted for the evaluation of the fillet physical quality (pH, colour, drip, thawing and cooking losses). Data were analysed by one-way ANOVA (post-hoc: Tukey). The dROM and OXY-Test were influenced by the dietary treatment at T2 and T3. The HI10 group showed lower concentration of dROM than C ($P<0.05$), while OXY-Test values were statistically lower in all insect-based diets than C (HI2.5, $P<0.01$ and HI5-10, $P<0.001$). Among growth performance parameters, only FCR was affected by the diet – with HI10 value being reduced compared to other HI treatments ($P<0.05$). No differences were observed in term of somatic indexes and fillet physical quality ($P>0.05$). These preliminary results confirm that the use of HI meal in rainbow trout diets does not negatively influence production parameters and fillet physical quality, with a positive effect being even observed on oxidative stress.

Theatre 3

Mealworm protein hydrolysate as a novel functional ingredient for aquaculture applications

L. Sanchez

Ynsect, R&D Department, 1 rue Pierre Fontaine, 91000 Evry, France; lorena.sanchez@ynsect.com

Animal protein hydrolysates are used in animal nutrition for diverse purposes. They are a source of highly digestible protein and provide bioactive peptides and amino acids, which confer nutritional and physiological functions in animals. In aquaculture, hydrolysates can function as functional feeds that are able to provide superior performance by promoting growth and health when incorporated to conventional feeds. In the alternative protein space, mealworms are rising as a high quality and sustainable source of dietary proteins in animal nutrition. In this work, the role of an enzymatically hydrolysed mealworm protein ingredient in the diet was investigated using two salmonoid species as a model in recirculating aquaculture system (RAS). A 84-day zootechnical test was performed with juvenile rainbow trout to assess the impact of the mealworm hydrolysate on the growth parameters of fish using a low incorporation dosage (1% in dry matter). Compared to a control diet based on fishmeal, the experimental diet supplemented with the protein hydrolysate from *T. molitor* gave higher values for final body weight and final total length ($P<0.05$). In a three-week zootechnical test with juvenile Atlantic Salmon (17 g), the experimental diets supplemented with the *T. molitor* protein hydrolysate (1% in dry matter) improved the proportion of solid faeces from 40% in the fishmeal control diet to 70% in the diets with the functional ingredient. Growth and welfare parameters remained unchanged between the fish under the control and experimental diet. Lower incidence of semi solid stools, makes this ingredient interesting for application in RAS, which need high water quality to avoid negative effects on the biofilters. This novel functional aquafeed, based on a mealworm protein hydrolysate, have the potential to play an important role on the pathway to more sustainable practices with higher fish yields and improved water quality, thereby decreasing environmental footprint.

Effect of black soldier fly larvae oil on performance and health of lactating sows and pigletsC. Omphalius¹, M. Walraven², S. Juliani¹ and H. Bergoug²¹Lab To Field, 26 bd Dr Petitjean, 21000 Dijon, France, ²Innovafeed, 85 rue de Maubeuge, 75010 Paris, France; hakim.bergoug@innovafeed.com

Insect oil (IO) is an alternative to imported soybean oil (SO) because of its lower environmental cost. The specific fatty acid (FA) profile of IO could modulate performance and health in pigs. Thus, 36 sows Large White × Youli and their offspring were included in a longitudinal trial to evaluate whether *H. illucens* larvae oil boosts zootechnical efficiency and health of sows and piglets. Two homogeneous groups of sows and then their offspring received feeds adapted to each stage containing either IO or SO as the sole source of oil (1.5% inclusion during lactation, 2% otherwise). The weight and back fat thickness of sows were recorded 7 days before farrowing (birth=d0) and at weaning (d28). At d7, milk was sampled, and the FA profile was determined. Performances (numbers of piglets born alive and stillbirths, deaths until weaning) were recorded. Piglets were weighed at d1, d27, and d63, and scored at d7, d14 and d21 for diarrhoea. The effect of oil source on performances was tested using a MIXED procedure, and a Chi² test was performed to compare the prevalence of diarrhoea between groups (SAS). Feed intake and zootechnical performances were similar between groups: no significant difference among treatments was recorded on sows' weight, maternal performances, and daily weight gain and weight of piglets all along the trial. Sows in IO tended to lose less fat (-1.2 mm) during lactation than SO (-2.1 mm), suggesting that they mobilized less stored fat ($P=0.083$). This could be beneficial to sustain reproductive performances during the next cycle. Milk FA profile highly differed between groups, especially lauric and myristic acids which represented a higher proportion of FA in group IO ($P\leq 0.001$). As these FA carry antibacterial properties, this could benefit piglets' health. Due to the low incidence of diarrhoea in this trial, although the prevalence was lower in IO (0.8% at d7; 95% CI: 0-2.0%) during the first week of life, it did not differ significantly ($P=0.263$) with SO (2.0% at d7; 95% CI: 0.3-3.8%). Further works on the effect of IO over several parities or on gastrointestinal ecosystem will be valuable to characterize the impacts on health and performance in pigs.

Session 09

Theatre 5

Effects of dietary *Tenebrio molitor* meal and chitosan on health and meat quality of weaned pigletsC. Zacharis¹, E. Bonos¹, A. Tzora¹, I. Skoufos¹, G. Magklaras¹, I. Giavasis², I. Giannenas³, E. Antonopoulou⁴, C. Athanasiou⁵ and A. Tsinas¹¹University of Ioannina, Department of Agriculture, Arta, 47100, Greece, ²University of Thessaly, Department of Food Science and Nutrition, Karditsa, 43100, Greece, ³Aristotle University of Thessaloniki, School of Veterinary Medicine, Thessaloniki, 54124, Greece, ⁴Aristotle University of Thessaloniki, Department of Biology, Thessaloniki, 54124, Greece, ⁵University of Thessaly, Department of Agriculture, Plant Production and Rural Development, Volos, 38446, Greece; ebonos@uoi.gr

The purpose of this trial was to examine the effects of the dietary use of *Tenebrio molitor* meal and chitosan in weaned piglet diets. 48 weaned piglets (34-day-old) were allocated to 4 groups: (1) control; (2) insect meal 100 g/kg; (3) chitosan 0.5 g/kg; (4) insect meal 100 g/kg and chitosan 0.5 g/kg. At the last day of the trial (42nd), fresh stools were sampled from each piglet to determine gut microbial populations. Then, six piglets per group were sacrificed, and meat samples were procured for chemical, microbiological, and oxidative stability analyses. Two-way analysis of variance (ANOVA, insect meal × chitosan supplementation; SPSS) was performed. Insect meal supplementation increased ($P\leq 0.05$) body weight and growth rate on the 21st day of the trial, decreased ($P\leq 0.05$) pancetta sample ash content, decreased ($P\leq 0.05$) *E. coli* and *C. jejuni* populations on shoulder samples and increased ($P\leq 0.05$) total phenols on the same samples. Chitosan supplementation decreased ($P\leq 0.05$) total aerobic gut populations, increased ($P\leq 0.05$) total anaerobic gut populations and decreased ($P\leq 0.05$) TBARS counts on shoulder sample. The combined use of insect meal and chitosan increased the final body weight ($P\leq 0.05$) and the growth rate ($P\leq 0.05$) compared to the single chitosan use, decreased ($P\leq 0.05$) total aerobic gut populations compared to the other groups, decreased ($P\leq 0.05$) *E. coli* and *Staphylococcus* spp. populations on shoulder samples, and tended to increase ($0.05 < P \leq 0.01$) total phenols on pancetta meat samples. Acknowledgements: The research has been funded by National Greek Funds. Project code: T2EAK-02356. Acronym 'InsectFeedAroma'.

Defatted insect meals: impact on *in vitro* ruminal fermentation and lipid biohydrogenationM. Renna¹, M. Coppa², C. Lussiana³, A. Le Morvan⁴, L. Gasco³, L. Rastello¹ and G. Maxin⁴¹University of Turin, Dept. Veterinary Sciences, L.go Paolo Braccini 2, 10095, Italy, ²Independent Researcher, INRAE – UMR 1213 Herbivores, Rte de Theix, 63122 Saint-Genès-Champanelle, France, ³University of Turin, Dept. Agricultural, Forest and Food Sciences, L.go Paolo Braccini 2, 10095, Italy, ⁴INRAE, UMR 1213 Herbivores, Rte de Theix, 63122 Saint-Genès-Champanelle, France; manuela.renna@unito.it

Ruminant diets are characterized by low amounts of lipids (<6%), hence defatted insect meals could be an interesting sustainable solution to provide both protein and energy to the rations. The residual ether extract (EE) content of defatted insect meals can vary widely depending on the applied defatting technology. In this study, we evaluated the effects of residual EE of defatted *Hermetia illucens* (HI) and *Tenebrio molitor* (TM) meals on *in vitro* ruminal digestibility and lipid biohydrogenation. Six EE levels for HI (26.9, 19.7, 12.8, 9.2, 7.0 and 4.7 g EE/100 g dry matter – DM) and three EE levels for TM (39.2, 8.1 and 5.7 g EE/100 g DM) were tested. Rumen fluid for the *in vitro* fermentations was obtained from four cannulated sheep. Fermentation parameters and fatty acids (FA) of rumen digesta after 24 h *in vitro* ruminal incubation of the insect meals were measured. A GLM ANOVA was performed to test the effects of the residual EE (regressive factor) and of its interaction with the insect species (fixed factor). We observed a decrease by 0.78 and 0.36% of DM digestibility per 1% increase of EE content for the HI and TM meals, respectively. Irrespective of insect species, a decrease by 12.90% in CH₄ and 15.70% in CO₂ production was also observed. On the contrary, for both HI and TM, the residual EE content had little effect on the FA profile of rumen digesta (e.g. C18:2 c9t11: +0.01 and +0.02% for HI and TM meals, respectively). One of the major effects in FA was observed for C18:1 c9, which decreased by 0.14% for HI and increased by 0.32% for TM. Thus, the use of defatting processes can simplify the inclusion of insect meals in ruminant diets by limiting the negative effects on nutrient digestibility related to a high EE content, with minor effects on lipid biohydrogenation.

Can the mixture of *Hermetia illucens* and *Tenebrio molitor* meals improve performance in broilers?I. Biasato, M. Gariglio, E. Fiorilla, V. Bongiorno, E.E. Cappone, S. Bellezza Oddon, L. Gasco and A. Schiavone
University of Torino, Largo Paolo Braccini 2, 10095 Grugliasco (TO), Italy; ilaria.biasato@unito.it

Hermetia illucens (HI) and *Tenebrio molitor* (TM) meals have widely been used in broiler chickens, but their mixture has never been tested. This study investigated the effects of HI and TM meals – alone and as mixture (1:1) – on growth and slaughtering performance of broiler chickens under commercial conditions. A total of 420 1-day-old male broiler chicks were allotted to 7 diets (6 pens/diet, 10 birds/pen, 3 feeding phases): C (control), HI5 (5% HI meal), HI10 (10% HI meal), TM5 (5% TM meal), TM10 (10% TM meal), MIX5 (5% HI-TM mixture), and MIX10 (10% HI-TM mixture). Growth performance were calculated, and, at 38 days of age, 12 birds/diet were slaughtered to record carcass traits. Data were analysed by SPSS software ($P \leq 0.05$). Growth performance were similar in starter phase ($P > 0.05$). In grower phase, TM5 birds displayed the highest live weight (LW), average daily gain (ADG) and daily feed intake (DFI), while the lowest ones were observed in HI10, TM10 and MIX10 groups ($P < 0.01$). The best and worst feed conversion ratio (FCR) were observed in TM5 and MIX5 birds, and C, HI10 and TM10 groups, respectively ($P < 0.05$). In finisher phase, TM5 birds showed the highest LW, whereas the worst performance were highlighted in HI10 (LW, ADG, DFI and FCR) and MIX10 (DFI and FCR) groups ($P < 0.001$). Overall, the best performance were recorded in TM5 (ADG, DFI and FCR), and TM10 and MIX5 (FCR) birds, while the worst ones in HI10 group ($P < 0.001$). The TM5 and MIX5 birds showed the highest slaughtering weight (SW), ready-to-cook carcass weight, and chilled carcass weight (CCW), while the lowest values were observed in HI10 and MIX10 groups ($P < 0.001$). The MIX5 and TM5 birds also displayed the highest CC (%SW) and breast (%CCW) yields, respectively, whereas the lowest ones were highlighted in HI10 and MIX10 groups ($P < 0.001$). MIX10 and TM5 birds also showed the highest and the lowest thighs yield (%CCW), respectively ($P < 0.05$). In conclusion, the use of TM and MIX meals at lower inclusion levels may improve both the growth and the slaughtering performance in broiler chickens.

Including different products from black soldier fly larvae in the diet of slow-growing broilers

A. Rezaei Far, T. Veldkamp, J. Van Harn, S. Naser El Deen, P. Van Wikselaar and I. Fodor
Wageningen Livestock Research, De Elst 1, 6700 AH Wageningen, the Netherlands; arya.rezaeifar@wur.nl

Despite the crucial role of chicken meat in human food security, there are environmental and social concerns about intensive farming and the use of soybean (SB) meal as a protein source in broiler diets. In response, several innovations have emerged in broiler production, e.g. the use of more sustainable ingredients and the emergence of production systems with slow-growing broilers (SG). In 2021, Dutch supermarkets shifted completely their supply of fresh chicken meat to meat from SG. Of the alternative ingredients, black soldier fly larvae (BSFL) products are valuable sources of protein and energy and their bioactive components, e.g. chitin and lauric acid may provide health benefits for broilers. Although the inclusion of insect products in diets of fast-growing broilers has been studied, little is known about insect products in the diets of SG. This study aims to evaluate the effect of different dietary inclusion levels (1%, 5%) of BSFL meal (BSFLM) or BSFLM with extra chitin (BSFLMc) in exchange for SB meal, and two inclusion levels of BSFL oil (1%, 2.5%) in exchange to SB oil on production performance and carcass characteristics of SG broilers. This study consists of 8 treatments and 8 replicates per treatment. Day-old male Hubbard JA757 were assigned to 64 floor pens (22 bird/pen). From day one, birds were fed either a control diet program or one of the 7 experimental diet programs that were isocaloric and with the same digestible content of essential amino acids in each feeding phase. In general and compared to the control diet program, including insect products did not affect performance parameters, mortality, or relative weight of carcass and carcass parts. Over 0-56 d, including 1% BSFLMc resulted in the highest body weight gain but did not significantly differ from the control diet program and the diet programs with insect oil. Increasing the inclusion level of BSFLMc to 5% reduced body weight (3.8%) and feed intake (4.6%). The results suggest that replacing SB meal and SB oil with insect meal and insect oil is possible in SG broilers without negative effects on performance and carcass characteristics.

Effect of feeding black soldier fly larvae products to slow-growing broilers on welfare and health

A. Doerper¹, G. Gort², I.C. De Jong³, T. Veldkamp³ and M. Dicke¹

¹Wageningen University & Research, Laboratory of Entomology, P.O. Box 16, 6700 AA Wageningen, the Netherlands,

²Wageningen University & Research, Biometris, P.O. Box 16, 6700 AA Wageningen, the Netherlands, ³Wageningen University & Research, Wageningen Livestock Research, De Elst 1, 6700 AH Wageningen, the Netherlands; anna.dorper@wur.nl

Insects as feed ingredients for poultry is a topic of increasing interest. Research often focusses on replacing unsustainable feed ingredients. Insects such as black soldier fly larvae (BSFL) might influence also poultry health and welfare. Bioactive compounds have the potential to shape the health of chickens, while the visual attractiveness of live larvae can stimulate natural behaviour. Broilers could benefit from this, since a major issue in broiler production is their increasing inactivity during growth, leading to leg issues. While promoting natural behaviour is likely to be an exclusive function of live BSFL, bioactive compounds might still be present and functioning in processed BSFL such as meal and oil. Bioactive compounds could support broilers, making them more robust against infections. When considering BSFL products in broiler diets there is no consensus on product inclusion levels to achieve health and welfare benefits. In the current experiment, 1,728 one-day-old slow-growing broilers (Hubbard JA757) were housed for seven weeks. In total nine different treatments (T1 to T9) were tested and each treatment had eight replicates (24 broilers/pen of 2.15 m²). As control (T1), a commercial broiler diet was used. In T2, 5% of the dry matter feed intake (DMFI) was replaced by live BSFL. In T3, 5% DMFI was replaced by 2/3 BSFL meal and 1/3 BSFL oil. The diets of T4 and T5 were based on T3, with diet T4 containing the same amount of BSF meal as only replacement and diet T5 the same amount of BSF oil. The same pattern of diets was applied in T6 to T9 with a replacement of 10% DMFI by live BSFL as a baseline. All diets were isocaloric and balanced for digestible amino acids. During the experiment, each pen was recorded biweekly during the morning, noon and afternoon to evaluate broiler behaviour. Blood was sampled at the end of the trial to evaluate broiler health. The results show that BSFL influence broiler behaviour and that effects on broiler health were limited.

The immune response of slow-growing broiler chickens fed black soldier fly larvae mealA. Rezaei Far¹, C.A. Jansen², J. Van Harn¹, P. Van Wikselaar¹, S.K. Kar¹ and T. Veldkamp¹¹Wageningen Livestock Research, Animal Nutrition, De Elst1, 6708 WD, the Netherlands, ²Wageningen University, Cell Biology & Immunology, De Elst1, 6708 WD, the Netherlands; soumya.kar@wur.nl

There is no evidence on the effects of feeding black soldier fly larvae meal (BSF) to slow-growing broiler chickens (SGBC) on immunity. In this study, we investigated the effects of feeding a BSF based diet on the systemic immune cells of SGBC. A soybean meal (SBM) based diet served as a reference. Experimental diets were formulated by substituting the corresponding amounts of BSF for SBM in the reference diet, i.e. 1% BSF, 5% BSF, 1% BSF with extra chitin, 5% BSF with extra chitin; or by substituting the appropriate amounts of BSF oil for soybean oil, i.e. 1% BSF oil and 2.5% BSF oil. At 42 days of age, blood samples were collected from 2 birds per pen to measure the effects of feeding BSF and its derived ingredients on the systemic immune response. Using flow cytometry, we measured subsets of T lymphocytes (CD4+, CD8+, CD4+ CD8+), B cells, leukocytes (CD45+), and natural killer cells (NKC) in whole blood samples. In addition, we measured antibody titers to New-Castle Disease Virus (NCDV). Researchers are interested in the low levels of inclusion to examine how this affects SGBC, thus we focused on the results of diets based on 1% BSF. The addition of 1% BSF diet had no significant ($P < 0.05$) effect on zootechnical and performance parameters compared with the reference feed. For systemic immune cells, only the number of B cells was significantly ($P < 0.05$) higher in the 1% BSF treatment compared to 5% BSF with additional chitin. Higher (statistically not significant, $P > 0.05$) antibody titer against NCDV was observed in the 1% BSF group compared to the reference and other treatment groups. These results are interesting as with low inclusion level of BSF in SGBC diet resulted in a higher humoral immunity, especially due to the increased frequency of the B-cell population in the peripheral blood. The results of our study suggest that lower inclusion level of BSF results in better adaptive immunity in SGBC.

Session 09

Theatre 11

Does BSF meal have an impact in broilers with a subclinical necrotic enteritis challenge?T. Veldkamp¹, J.J. Mes², A. Rezaei Far¹, S. Naser El Deen¹, P. Van Wikselaar¹, I. Fodor¹, R. Van Emous³ and L. Van Eck³¹Wageningen University & Research, Wageningen Livestock Research, De Elst 1, 6700 AH Wageningen, the Netherlands,²Wageningen University & Research, Wageningen Food & Biobased Research, Bornse Weiland 9, 6708 WG Wageningen, the Netherlands, ³Cargill Animal Nutrition & Health, Global Innovation Center Velddriel, Veilingweg 23, 5334 LD Velddriel, the Netherlands; teun.veldkamp@wur.nl

Black soldier fly larvae (BSFL; *Hermetia illucens*) and its bioactive components such as chitin, antimicrobial peptides, and lauric acid may result in additional health benefits compared to traditional protein sources in animal feed. Based on the observed *in vitro* inhibitory effects of BSF products on *Clostridium perfringens*, BSFL protein meal and chitin-rich BSFL protein meal were selected for an *in vivo* broiler experiment to study the effect at different dietary inclusion levels (5 and 10%) during mild necrotic enteritis (NE) on growth performance. A standardized model for *C. perfringens*-associated NE was used in combination with an *Eimeria maxima* infection. NE-challenged broilers were inoculated at day 8 with *E. maxima* and at day 14 with *C. perfringens*. The experiment was conducted with 468 NE-challenged and 468 non-challenged Ross 308 male broilers between 0 to 35 d of age. The broiler diets with the two BSFL protein meals at different inclusion levels were formulated isocaloric and isonitrogenous. Soybean meal in the diet was substituted by BSFL protein meals. After *E. maxima* inoculation, between 8 to 14 d of age, challenged broilers in comparison to non-challenged broilers had lower daily feed intake (12.8%), daily weight gain (ADG) (28.7%), and gain:feed (G:F) ratio (18.3%) (all $P < 0.05$). The *C. perfringens* inoculation at 14 d of age exacerbated the impaired performance in challenged treatments. The effect of the NE-challenge on performance alleviated between 28 to 35 days of age and challenged treatments had a higher ADG (5.2%) and G:F ratio (6.0%) (both $P < 0.05$) compared with the unchallenged treatments indicating a compensatory growth. During the presentation, the effects of including BSFL protein sources on performance of NE-challenged and non-challenged broilers will be shown.

Black soldier fly larval diet eliminate chicken coronavirus at an early infection stageY. Zhang^{1,2}, C.Y. Yang¹, C.J. Li^{1,3}, Z.H. Xu¹, P. Peng¹, C.Y. Xue¹, J.K. Tomberlin⁴, W.F. Hu⁵ and Y.C. Cao¹

Avian infectious bronchitis virus (IBV), belonging to Gammacoronavirus, is an economically important respiratory virus affecting poultry industry worldwide. The virus can infect chickens at all ages, whereas young chickens (less than 15 day old) are more susceptible to it. The present study was conducted to investigate effects of dietary supplementation of black soldier fly (*Hermetia illucens* L.) larvae (BSFL) on immune responses in IBV infected 10-day-old chickens. BSFL were ground to powder and mixed with commercial fodder (1, 5 and 10% [mass] BSFL powder) to feed 1-day-old yellow broilers for ten days and then challenged with IBV. Our results indicated that commercial fodder supplemented with 10% BSFL [mass] reduced mortalities (20%) and morbidities (80%), as well as IBV viral loads in tracheas (65.8%) and kidneys (20.4%) from 3-day post challenge (dpc), comparing to that of IBV-infected chickens fed with non-additive commercial fodder. Furthermore, at 3-day post challenge (dpc), 10% BSFL [mass] supplemented chickens presented more CD8⁺ T lymphocytes in peripheral blood and a rise in interferon- γ (IFN- γ) at both mRNA and protein levels in spleens, comparing with chickens fed with commercial fodder. Furthermore, the mRNA abundance of MHC-I, *Fas*, *LITAF*, and *IL-2* in the spleens of 10% BSFL [mass] supplemented chickens increased at different time points after challenge. The present results suggest that supplemental BSFL could improve CD8⁺ T lymphocytes proliferation, thus benefit young chickens to defend against IBV infection.

Session 09

Theatre 13

Black soldier fly larvae meal alter chicken gut microbiota to restricts coronavirus infectionC.Y. Yang¹, Y. Zhao¹, O. Peng¹, C. Li¹, Y. Cao¹ and Y. Zhang²

¹Sun Yat-sen University, State Key Laboratory of Biocontrol, School of Life Science, No. 135 Xingang Xi Road, 510275 Guangzhou, China, 510275 Guangzhou, China, P.R., ²Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Brain Cognition and Brain Disease Institute (BCBDI), No. 1068 Xueyuan Road, University Town of Shenzhen, 518055 Shenzhen, China, 518055 Shenzhen, China, P.R.; chujun.li2013@gmail.com

Insects, containing high quality and quantity of proteins, are novel, alternative feed ingredients for animal nutrition. Among various insect species, black soldier fly larvae (BSFL) meal is the most widely used in poultry feeding. In the current research, we evaluated the effect of diet black soldier fly larvae supplementation on resistance of coronavirus in young SPF chickens. Day-old SPF chickens were randomly assigned to six groups assessing to bean-based diet as control or BSFL diet with 10% [mass] black soldier fly larvae (BSFL) powder. After challenged with chicken coronavirus, chickens fed with BSFL fodder presented less viral loads in different organs including tracheas, kidneys, and ileums. Transcriptional expression of type I interferon (IFN) signalling was also enhanced in the BSFL group. We further found an alternative structure of gut microbiota of the chickens fed with BSFL meal with main differences in Clostridia, Gammaproteobacteria, and Bacilli, comparing with that of the control group. Furthermore, when gut microbiota transplantation was performed in chickens fed with bean-based control fodder using cecum microbes of the BSFL-fed chickens, decreased viral loads and enhanced type I IFN expression were also observed in these transplanted-chickens after coronavirus infection. Our present results indicate that supplemental BSFL could enhance host immunity through affecting gut microbiota, thus benefit young chicken with resistance to coronavirus infection.

Black soldier fly larvae meal as the main protein source improves feed efficiency in laying hens

A. Rezaei Far, I. Fodor, P. Van Wikselaar, S. Naser El Deen and T. Veldkamp

Wageningen Livestock Research, De Elst 1, 6700 AH Wageningen, the Netherlands; arya.rezaeifar@wur.nl

Chicken egg is an inexpensive but highly nutritious animal product, and its global consumption is expected to grow to 102 Mt by 2050. Consequently, the egg production sector requires about 214 Mt of feed by that time. Feed has a major contribution to the environmental impact of egg production, especially as soybean meal (SBM) has been the most common protein source in laying hens diets. Finding more sustainable alternative protein sources for poultry is an important goal. The European Commission recently authorised using insect proteins such as black soldier fly larvae meal (BSFM) in poultry diets. So far, a few studies investigated the effects of including BSFM in laying hen diets, however, there is no consensus about the effects of BSFM inclusion level on production performance yet. This study aims to evaluate the effects of replacing SBM with two inclusion levels of BSFM (5 and 10%) on production performance and egg quality in laying hens in the aviary system. This study consisted of 3 treatments with 9 replicates each. Brown Nick pullets (n=378) at 19 weeks of age and prior to the onset of lay were transported from a commercial farm and were assigned to 27 floor pens (14 birds/pen). For the first 3 weeks, birds were fed the control diet representing the commercial laying hen diet in the Netherlands. For the rest of the experimental period (8 weeks) birds were fed either the control diet (13% SBM w/w) or diets including 5% (SBM 7% w/w) or 10% (0% SBM w/w) BSFM. Diets were isocaloric and with the same digestible content of essential amino acids. Over the experimental period, including BSFM reduced the feed intake ($P<0.05$), while egg weight, laying rate, and body weight of the laying hens were not affected ($P>0.05$). Hence, the feed conversion ratio improved by 0.097 units using 10% BSFL meal compared to the control diet ($P<0.05$). In comparison to the control, including 10% BSFM increased the relative weight and colour of yolk, and shell thickness ($P<0.05$). In conclusion, we demonstrated that replacing SBM with 10% BSFM in the diet of laying hens improves feed efficiency while increasing the thickness of the eggshell.

Session 09

Theatre 15

Antibacterial and anticoccidial activities of black soldier fly extractL. Sedano¹, E. Chambellon¹, F.I. Bussiere¹, E. Helloin¹, M. Vian², C. Guidou³, C. Trespuech³ and A. Silvestre¹¹INRAE, Animal Health, Université de Tours, UMR 1282, 37380, France, ²INRAE, Université Avignon, UMR SQPOV, Avignon, France, ³MUTATEC, Châteaurenard, France; anne.silvestre@inrae.fr

To improve the protein autonomy and enrichment for animal welfare, the production of insects for animal feed is growing. Black soldier fly (*Hermetia illucens*) larvae (BSFL) are easily raised and can valorise co-products and food wastes. Besides a high nutrient content, BSFL contain compounds (chitin, lauric acid, antimicrobial peptides) of interest for gut microbiota and animal health. A wide variety of bacteria can cause diseases in poultry and foodborne illness in human. Avian coccidiosis is another highly prevalent disease, caused by *Eimeria* protozoan. Disease severity extends from morbidity to mortality. Its economic impact was recently reassessed to 13 billion \$/year worldwide. The occurrence of antibacterial and coccidiostat drugs residues in animal-food products may promote: (1) risk of allergic reactions by hypersensitive individuals; (2) bad impact on the dynamics of gastrointestinal flora; and (3) the antibiotic resistance in gut bacteria. The steady increase of occurrence of bacteria resistant to multiple antibiotics has become a global public health threat that is driving the prudent use of antimicrobial in animals and the development of new alternatives. The aim of this study was to evaluate antimicrobial activities of BSFL extracts, comparing protein extracts solubilized in water and lipid extracts solubilized in methanol. We screened a library of bacterial strains that threaten livestock production (poultry, cattle, pigs) and against *Eimeria tenella*, responsible for avian caecal coccidiosis. Although protein extracts had no antibacterial activity, an inhibition of *Eimeria* development was observed at [0.001-0.01 g/l] of dry matter. The lipid extracts were efficient (0.7-5.66 g/l dry matter) against some strains of *Pasteurella multocida*, *Corynebacterium bovis*, *Streptococcus suis*, *Riemerella anatipestifer* and *Trueperella pyogenes*. They also inhibited *Eimeria* development at 0.6 mg/l dry matter. More research is needed to confirm those results *in vivo*: the antimicrobial effects of BSFL could improve the health and immune response of birds, when facing sanitary or environmental challenges.

The metabolizable energy value of black soldier fly larvae fat used in broiler chicken diets

B. Kierończyk¹, M. Rawski², K. Stuper-Szablewska³, K. Dudek⁴ and D. Józefiak¹

¹Poznań University of Life Sciences, Department of Animal Nutrition, Wołyńska 33, 60-637 Poznań, Poland, ²Poznań University of Life Sciences, Department of Zoology, Laboratory of Inland Fisheries and Aquaculture, Wojska Polskiego 71C, 60-637 Poznań, Poland, ³Poznań University of Life Sciences, Department of Chemistry, Wojska Polskiego 38/42, 60-637 Poznań, Poland, ⁴HiProMine S.A., Poznańska, 12F, 62-023 Robakowo, Poland; krzysztof.dudek@hipromine.com

The present study aimed to investigate the apparent metabolizable energy (AME) and apparent metabolizable energy corrected to zero nitrogen balance (AMEn) levels of *H. illucens* (BSF) larvae fat for broiler chickens of various ages. A total of 400 1-day-old male Ross 308 birds were randomly assigned to four dietary groups (10 replicate pens per treatment; 10 birds per pen). The following treatments were applied: HI0 – basal diet without dietary fat inclusion, HI03 – basal diet enriched with 30 g/kg BSF larvae fat, HI06 – basal diet enriched with 60 g/kg BSF larvae fat, and HI09 – basal diet enriched with 90 g/kg BSF larvae fat. Broilers had *ad libitum* access to mash form feed and water. Excreta samples were collected on d 14, d 28, and d 35. To establish the AME and AMEn values of BSF larvae fat, the simple linear regression method was used. The results show that the AME and AMEn values of BSF larvae fat for broiler chickens are 9,049 kcal/kg, and 9,019 kcal/kg, respectively. Furthermore, because of the fact that the birds' age significantly affected the AME and AMEn levels, the implementation of BSF larvae fat to broiler diets should be considered in each nutritional period using the recommended regression model $AME = 2,559.758 + 62.989 \times \text{fat inclusion (\%)} + 7.405 \times \text{day of age}$ and $AMEn = 2,543.2663 + 62.8649 \times \text{fat inclusion (\%)} + 7.3777 \times \text{day of age}$. The present data highlighted that the BSF larvae fat metabolizable energy level is similar to that of soybean oil. However, the authors do not recommend using the above-mentioned regression equations to calculate the energy level of BSF larvae fat for young birds, i.e. before 14 d of age. This work was supported by an OPUS-20 grant titled 'The role of *Hermetia illucens* larvae fat in poultry nutrition – from the nutritive value to the health status of broiler chickens' no. 2020/39/B/ NZ9/00237.

***Hermetia illucens* larva fat affects broiler chicken breast meat quality**

B. Kierończyk¹, M. Rawski², Z. Mikołajczak¹, P. Szymkowiak¹, K. Stuper-Szablewska³, M. Dudek⁴ and D. Józefiak¹

¹Poznań University of Life Sciences, Department of Animal Nutrition, Wołyńska 33, 60-637 Poznań, Poland, ²Poznań University of Life Sciences, Department of Zoology, Laboratory of Inland Fisheries and Aquaculture, Wojska Polskiego 71C, 60-637 Poznań, Poland, ³Poznań University of Life Sciences, Department of Chemistry, Wojska Polskiego 38/42, 60-637 Poznań, Poland, ⁴HiProMine S.A., ul. Poznańska, 12F, 62-023 Robakowo, Poland; monika.dudek@hipromine.com

This study aimed to evaluate the dose-dependent effect of black soldier fly (BFL) larvae fat inclusion in broiler chicken diets on breast meat quality. Four hundred 1-day-old birds were assigned to the following 4 treatments (10 replicates, 10 birds each): HI0, a basal diet without dietary fat inclusion, and HI03, HI06, and HI09, basal diets enriched with 30 g/kg, 60 g/kg, and 90 g/kg of BSF larvae fat, respectively. Principal component analysis showed noticeable differentiation between the selected plant, animal, and insect-origin dietary fats. The BSF fat exhibits a strong relationship with saturated fatty acids (SFAs) resulting in a high concentration of C12:0 and C14:0. The fatty acid (FA) profile in breast muscle obtained from broilers fed diets with increasing insect fat inclusion showed a significant linear effect in terms of C12:0, C15:0, C18:2, C18:3n6, and total FAs. The proportion of dietary insect fat had a quadratic effect on meat colour. The water-holding capacity indices have stayed consistent with the meat colour changes. Throughout the experiment, favourable growth performance results were noticed in HI06. The present study confirmed that BSF larvae fat negatively affects the n3 level in meat. However, the physico-chemical indices related to consumer acceptance were not altered to negatively limit their final decision, even when a relatively high inclusion of insect fat was used. This work was supported by an OPUS-20 grant titled 'The role of *Hermetia illucens* larvae fat in poultry nutrition – from the nutritive value to the health status of broiler chickens' (no. 2020/39/B/ NZ9/00237), which was financed by the National Science Center (Poland).

Evaluation of two black soldier fly products on hens' performance, hatchability, and health traitsP. Hristakieva¹, N. Mincheva¹, I. Ivanova¹, K. Velikov¹ and A. Petrova²¹Agricultural Institute, Agricultural Academy, Stara Zagora, 6000, Bulgaria, ²NASEKOMO, bul. Dragan Tzankov 8, Sofia, 1164, Bulgaria; adelina.petrova@nasekomo.life

Insect products have a great potential in addressing sustainability in poultry. To understand their impact on hens' homeostasis and performance, differential analyses of the inclusion of two Black soldier fly products in hens' diets were investigated. A total of 180 Rhode Island White hens (Line N; 45 week old) were individually weighed to make uniform groups (60 hens/group; 20 hens/pen) and assigned to three dietary treatments: Control (soybean meal), 7% Black soldier fly defatted (BSFd) and 7% Black soldier fly whole larvae (BSFw). All production parameters were measured real time, and at week 6 of the experiment significant differences were noted. The egg production of BSFw-fed hens was significantly higher (85.47%; $P < 0.01$) compared to the BSFd (72.26%) and Control (78.79%) groups. Similar trend was observed for the feed conversion ratio (FCR), where the BSFw group had a better performance (2.39; $P < 0.05$) compared to the BSFd (3.14) and the Control (2.74) group. Hens from the experimental groups produced smaller eggs, however, statistical significance was recorded for the BSFd (56.32 g; $P < 0.05$) compared to the Control (59.12 g). Yolk colour is an important parameter for consumers and its higher intensity is often regarded as healthier eggs. All diets were free of artificial colorants and assessment of this parameter showed higher Roche colour score in egg yolks of BSFw-fed group (4.7; $P < 0.001$) compared to the Control (3.83) and BSFd (3.47) groups. The shell thickness increased in both experimental groups, but a significant difference was observed only for BSFd (0.359 mm; $P < 0.05$) compared to the Control (0.321 mm) and BSFw (0.339 mm) groups. No differences were observed among egg incubation parameters except the lower weight of hatched chicks in the experimental groups (BSFd-36.70 g and BSFw-36.39 g; $P < 0.01$) compared to the Control (38.55 g). Several blood serum parameters were analysed indicating no negative impact on hens' health status. The two BSF products had a different impact on hens' performance with BSFw having superior results. Overall, the study underlines the need for more detailed analyses of insect products.

Insect meals digestibility for rainbow trout aquafeeds: *in vivo* and *in vitro* preliminary resultsC. Caimi¹, F. Moyano Lopez², S. Bellezza Oddon¹, M.J. Aznar², V. Zambotto³, F. Gai³ and L. Gasco¹¹University of Turin, Largo Paolo Braccini 2, 10095, Italy, ²University of Almeria, Ctra. Sacramento s/n, 04120 La Cañada de San Urbano, Spain, ³National Research Center, Largo Paolo Braccini 2, 10095, Italy; laura.gasco@unito.it

The apparent digestibility coefficients (ADCs) of the dry matter (DM), crude protein (CP) and ether extract (EE) of 0, 2.5, 5 and 10% (named C, HI2.5, HI5 and HI10) of partially defatted *Hermetia illucens* (HI) meal, as substitute of fish meal, in iso-nutrient diets for rainbow trout (*Oncorhynchus mykiss*) have been assessed by an *in vivo* digestibility trial. Moreover an *in vitro* digestibility assay, simulating stomach and intestine digestion in rainbow trout, was carried out in order to assess protein hydrolysis of the experimental diets. For the *in vivo* trial, rainbow trout (115±6.4 g) were allotted to 12 tanks (16 fish/tank, 3 replicates/treatment) and fed by hand to visual satiety twice a day, seven days a week. The fish faeces were collected from each tank twice a day during the collection periods for four consecutive weeks, using a continuous automatic device. The faeces were frozen and then freeze-dried prior to the subsequent chemical analyses. *In vitro* digestibility assays were performed using bioreactors where acid and alkaline stages of the hydrolysis were carried out at pH 3.5 and 8.5, respectively. Total Amino Acids (AA) released, expressed as % initial protein, were recorded after 1, 2, 3, 4.5 and 6 hours of incubation and assays were run in triplicate for each diet. Data were analysed by one-way ANOVA (post-hoc: Tukey). *In vivo* trial showed significant results for ADCs of DM and CP. As far as ADC_{CP}, C diet showed the highest value (89.8%) followed by HI2.5 (87.5%) and HI5 and HI10 diets (84.3 and 86.3, respectively). On the other hand, results of total AA released after 6 h of hydrolysis showed that C diet performed better (67.4%) than HI2.5 (65.2%) diet with HI5 and HI10 having similar values (61.9 and 61.7, respectively). In conclusion, experimental data about dietary protein digestibility obtained with both approaches demonstrate a good correlation between the *in vivo* and *in vitro* results.

Suitability of full-fat and defatted black soldier fly meal as ingredient for chicken dietsD. Murawska¹, D. Witkowska², M. Gesek³, T. Bakula⁴ and J. Błażej-Gabowska⁵¹University of Warmia and Mazury in Olsztyn, Oczapowski St.2, 10-719, Poland, ²University of Warmia and Mazury in Olsztyn, Oczapowski St.2, 10-719, Poland, ³University of Warmia and Mazury in Olsztyn, Oczapowski St.2, 10-719, Poland,⁴University of Warmia and Mazury in Olsztyn, Oczapowski St.2, 10-719, Poland, ⁵University of Warmia and Mazury in Olsztyn, Oczapowski St.2, 10-719, Poland; daria.murawska@uwm.edu.pl

Nowadays black soldier fly (*Hermetia illucens* L.) has been widely used as an ingredient of animal diets, but the results of studies on the protein of diet on poultry growth performance, are inconsistent. The aim of this study was to compare selected growth performance effects in broiler chickens fed diets with different full fat (HIF) or defatted (HID) black soldier fly (HI) larvae meal – processed animal proteins (PAP) content. The experiment was run on a total of 420 1-day-old female Ross 308 broilers. Chickens were randomly assigned to 7 dietary treatments (6 replications per treatment, 10 birds per pen). The diets were formulated by including, on as-fed basis, increasing levels of HIF or HID larvae meal (5, 10 and 15%). The birds were raised to 35 d of age and fed *ad libitum*. At 35 d of age, two birds per pen were selected in each feeding group and slaughtered. The results are presented as means and the SEM. The significance of differences in mean values between age groups was determined by Duncan's test. Significance was set at $P \leq 0.05$. The final body weight (BW) of chickens fed diets containing 15% HI-PAP was smaller to BW in the control ($P \leq 0.05$, respectively: 1,780 g HI0, 1,830 g HIF5, 1,806 g HIF10, 1,585 g HIF15, 1,754 g HID5, 1,645 g HID10, 1,411 g HID15). A positive effect of the HIF10 diet on the proportion of pectoral muscles in the body weight of birds was found, and a negative one for the HIF15 and HID15 diets ($P \leq 0.05$). In conclusion, the replacement of soybean protein (5-10%) to full-fat or defatted HI-PAP in the chicken's diet did not deteriorate the final BW and the basic characteristics of the slaughter value. Acknowledgements: this work was supported by the National Science Centre, Grant: 'Development of a strategy for the use of alternative protein sources in animal nutrition enabling the development of its production on the territory of the Republic of Poland', No Gospostrateg1/ 385141/16/NCBR/2018.

Protein and amino acids digestibility of two black soldier fly larvae meal forms in broilersA. Cerisuelo¹, E.A. Gómez¹, A. Martínez-Talaván¹, L. Piquer¹, D. Belloumi¹, C. Cano¹, M. Martínez¹, C. Fernández² and S. Rojo³¹IVIA, CITA, Pol. Ind. La Esperanza, 100, 12400 Segorbe, Castellón, Spain, ²Bioflytech, S.L., Ctra. Cementerio, km2,2, 30320 Fuente Álamo, Murcia, Spain, ³UA, Dep. C. Ambientales y R. Naturales, Ap. 99, 03080 Alicante, Spain; dhekrbelloumi1@gmail.com

A trial was conducted to evaluate the protein (CP) and amino acids (AA) digestibility of two types dehydrated black soldier fly (i.e. *Hermetia illucens*) larvae meal: a defatted meal (DF) and a full fat meal (FF) in broilers. These insects were all fed with agri-food by-products. A total of 140 male broilers of 21 days of age were used. Five experimental feeds were formulated to calculate standardized ileal digestibility (SID) of CP and AA using the regression method. After 7 days of receiving the experimental diets, animals were slaughtered and the terminal ileum content was collected to determine CP and the individual AA digestibility. The FF meal showed a higher amount of crude fat, gross energy and calcium and a lower amount of CP (52.8 vs 43.2% in dry matter basis) compared with DF insect meal. The AA profile was similar between the two insect meals, and the most abundant essential AA were valine, isoleucine, and lysine in both ingredients. The digestibility of CP and essential AA was high (>70%) in both ingredients. The SID of CP was similar in DF and FF (76.6 vs 73.0%, respectively). In general, AA digestibility was lower in FF compared with DF, but the differences were not significant. Among the essential AA, those with a higher SID were methionine, phenylalanine and arginine in both insect meals (95.5 vs 91.8, 88.7 vs 80.5 and 88.9 vs 79.4 in DF and FF, respectively). Regarding the non-essential AA, glutamic acid and tyrosine were the most digestible in both ingredients. In conclusion, in terms of CP and AA, both DF and FF black soldier fly larvae meals can be suitable protein and AA sources for broiler chickens' diets, especially methionine. Thus, insects fed agricultural by-products represent a novel and promising feed ingredient for poultry diets and could potentially be used as substitution ingredients of soybean in broiler diets, especially DF sources. This work was supported by the project Wayst'up, funded by the European union's horizon 2020 research and innovation programme under grant agreement no. 818308.

CIPROMED: a PRIMA project on the use of alternative proteins in the Mediterranean value chains

To cover the needs for livestock feeds and aquafeeds, as well as for human food, current EU agri-food production systems largely depend on protein imports. However, this dependency renders them unprotected from unforeseen events that disrupt the global supply chains. Therefore, there is an urgent need for efficient, viable and locally produced alternative protein sources. CIPROMED aims to apply, validate and scale up an integrated array of processes, to recover a significant amount of by-products and related sources that can be used as protein for food and feed. These sources are based on insects, microalgae and legumes, as well as agri-industrial side-streams that will subsequently be integrated with animal production and aquaculture, but also directly for human consumption. The integration of insects, microalgae and legumes in food and feed will be based on circular economy attributes, along a wide range of LCA- and CEA-proofed economically and environmentally sustainable extraction, modification and stabilization techniques. The resulting high-value ingredients will be extensively tested on different 'real-world' systems, through feeding trials and clinical studies. This research is supported by the EU-PRIMA program project CIPROMED (Prima 2022 – Section 1).

Replacing fishmeal by *Hermetia illucens* larvae on growth performance and meat quality in broiler

K.H. Jeon, D.C. Song, S.Y. Chang, J.W. Ahn, H.A. Cho, S.H. Park, H. Kim and J.H. Cho

Chungbuk National University, Animal Science, 344, S21-5, 1, Chungdae-ro, Seowon-gu, Cheongju-si, Chungcheongbuk-do, Korea, 28644, Korea, South; jeonkh1222@gmail.com

This study was conducted to investigate the effects of replacing fish meal with black soldier fly larvae (*Hermetia illucens* larvae; HL) as defatted powder form and hydrolysates form in broiler diets on growth performance, blood profiles, nutrient digestibility, faecal bacterial count, meat quality characteristics, and foot-pad dermatitis. The 60 Arbor Acres (AA) broilers with an initial body weight (BW) of 39.52±0.11 g were randomly assigned to a completely randomized three dietary treatments (5 broilers per cage and 4 replicates cage per treatments). For 4 weeks, three experimental diets were provided: (1) CON, basal diet; (2) T1, basal diet without a fish meal and substitute with defatted HL powder; (3) T2, basal diet without a fish meal and substitute with HL hydrolysates. The T2 group had significantly higher ($P<0.05$) BW than the other groups at 4 weeks. Also, the T2 group had significantly higher ($P<0.05$) BW gain and feed intake than the other groups during the overall periods. The T2 groups showed higher ($P<0.05$) Valine, and Leucine digestibility at 2 weeks and Lysine, Methionine, and Tryptophan digestibility at 4 weeks than the other groups. Besides, the T2 groups significantly improved ($P<0.05$) Glycine digestibility at both 2 weeks and 4 weeks. The CP digestibility at 2 weeks showed higher ($P<0.05$) in T2 group than in other groups. In meat quality characteristics, the T1 group showed higher ($P<0.05$) water-holding capacity than the other groups. Regarding pH in meat quality characteristics, substitute HL in the diet showed higher ($P<0.05$) than the basal diet. However, blood profile, faecal bacterial count, and foot-pad dermatitis had no significant effect among the treatment groups. In summary, substitute defatted HL powder induced positive effects on growth performance and nutrient digestibility. Substitute HL hydrolysates exerted beneficial effects on meat quality characteristics. These findings revealed that HL was a potential replacement for fishmeal.

Investigation of the suitability of two *Tenebrio molitor* meals in diets of weaned piglets

In the present work, two insect meals from *Tenebrio molitor* which were created previously by our team were examined in weaned piglet diets. The insects for the first meal were reared using a conventional substrate, while the insect for the second meal were reared in a substrate enriched with functional ingredients of aromatic and medicinal plants. In total, 36 weaned piglets, 34-days-old were allocated in 3 groups: (A) Control; (B) conventional insect meal; (C) enriched insect meal. The whole experiment lasted 42 days. On the last day of the experiment fresh stool from each pig was sampled to examine gut microbiota. Then six piglets from each group were sacrificed and meat samples from shoulder, ham, pancetta, and boneless steak were procured for chemical analysis, microbiological analysis and oxidative stability analysis. The results of the statistical analysis (ANOVA, using SPSS software) showed that the bodyweight on day 21 increased ($P \leq 0.05$) in Group B compared to the Group A. Concerning gut microbiota, total aerobes were reduced ($P \leq 0.05$) in Group C, while the others examined microbial populations did not differ ($P > 0.10$). On shoulder and pancetta meat samples the microbiological analysis showed a reduction ($P \leq 0.05$) of *E. coli*, *C. jejuni* and sulphite reducing *Clostridium* in Groups B and C. Total phenols were increased ($P \leq 0.05$) on shoulder, pancetta and boneless meat cuts in Groups B and C, while a reduction ($P \leq 0.05$) of TBARs in Group B was observed on shoulder meat samples. Based on the results of our experiment, insect meal can be added in weaned piglet diets without negative effects on growth performance, gut microbiota, and produced meat quality. Black soldier fly (BSF) larvae have an outstanding capacity of biodegrading organic wastes. The resulting frass can be considered a high-quality organic fertiliser, although it usually has varying composition that is dependent of the nature of the organic waste being converted. This study aimed to evaluate the effect of frass (deriving from food industry coproducts-TFE; and from sludge from wastewater treatment-TFN) on plant yield and quality. A greenhouse study was designed in pots, in which the commercial mixture AVEX® (oats, ryegrass, vetch and annual clovers) was cultivated in three treatments: TFE, TFN and TM (mineral fertilizer), with 5 replicates each. To each of the frass treatments, 10% nitrate N was added. The treatment TFN rendered the highest yield per pot 77 ± 7 g, in comparison to 63 ± 7 g in TM. Similarly, TFN plants had higher Na concentration than TM 3.7 ± 0.4 vs 2.5 ± 0.5 g/kg, respectively. N concentration was higher in TM, followed by TFE and TFN, with respective values of 4.4 ± 1.2 , 3.5 ± 0.3 and 3.1 ± 0.2 %. Plants from TFN had the lowest content of K 56 ± 3 g/kg while those from TFE showed the highest content of P 8.3 ± 0.5 g/kg. The plants fertilised with frass displayed lower Mn levels comparatively to TM 68 ± 11 mg/kg. There were no significant differences among the three treatments for NDF, ADF, Ca, Mg, Fe and Zn. The frass types evaluated in this study, resulting from the bioremediation by BSF larvae of organic wastes (food coproducts and wastewater sludge) are adequate to be used as fertilizers in crop production.

The place of epigenetics in the livestock of tomorrow*E.M. Ibeagha-Awemu and M. Wang**Agriculture & Agri-Food Canada, Sherbrooke Research & Development Centre, 2000 Rue College, Sherbrooke, QC, J1M 0C8, Canada; eveline.ibeagha-awemu@agr.gc.ca*

Epigenome alterations resulting from the intricate interactions of the genome and the exposome have been implicated in the growth, development, health, reproduction and environmental adaptation of livestock through links to improved immune response, feed efficiency, growth performance and livestock products. Thus, epigenetic factors are widely acknowledged as vital players in individual growth, development, health and production ability. Consequently, epigenetics has gained considerable interest due to its potential to provide new insights into the mechanisms underlying complex livestock traits, disease and environmental adaptation. Such new insights have the potential to contribute to the improvement of current breeding programs or the development of new breeding strategies in livestock. As seen with most new technologies, the inclusion of epigenetics information in current livestock breeding programs could lead to further improvements in the rate of genetic gain by increasing the accuracy of genomic selection and selection intensity amongst others. Moreover, knowledge of epigenome alterations is a prerequisite to the application of an emerging technology like epigenome editing which could lead to further improvements in livestock productivity and sustainability. However, significant challenges remain before the wide adoption of epigenetics data in the livestock industry, such as (1) elaborate investigations to identify the causal relationships between epigenetic modifications and complex traits, (2) development of robust tools to support the identification of epigenetic alterations and their associations with livestock traits on a large scale and (3) significant investments in research and development to support realization of the potential of epigenetics in the livestock of tomorrow. In conclusion, epigenetics holds enormous potential to revolutionize the livestock industry by providing additional levels of information for the further enhancement of livestock production efficiency, animal health and welfare, and development of breeding and management practices to support improved and sustainable livestock production to meet the growing demand for high-quality animal products while minimizing the environmental impact of animal agriculture.

DNA methylation is a potential source of phenotypic variation that may help refining genomic prediction in livestock, provided that affordable tools that can be used in routine analyses become available. Several methods have been developed for whole genome DNA methylation analysis, allowing important advances in the field of epigenetics. However, their cost is yet a limitation for their implementation in large populations. A cost-effective alternative is to target a panel of informative CpGs that show methylation variations across individuals. We assessed the potential of a capture-based approach to measure methylation at selected CpGs in the cattle genome. These CpGs were highlighted by reduced representation bisulphite sequencing (RRBS) conducted on 236 bull semen samples and 82 cow blood samples. Their methylation status in semen varied according to fertility, age, breed or early life nutrition; whereas it varied according to age, nutrition, physiological status and inflammatory status in blood samples. Furthermore, Oxford Nanopore Technology (ONT) was applied to 6 semen samples and 12 blood samples; and CpGs with differential methylation status according to fertility, somatic cell scores and heat stress were identified. The RRBS and ONT results were merged into a list of 128,059 unique, non polymorphic CpGs. A custom design was conducted on the ARS-UCD1.2 genome assembly by Twist Bioscience, and 64,237 probes targeting 97,412 CpGs were synthesized. The technology was assessed on 71 semen, 91 blood and 30 mixed samples, for which RRBS and/or ONT data are available. Enzymatic conversion of DNA, capture, library construction and sequencing at a 100× depth on a Novaseq6000 were carried out by Integrigen. Results about the repeatability and sensitivity of the method will be showed, as well as the consistency with RRBS and ONT data (H2020 grant 101000226, RUMIGEN).

DNA-methylome analysis of milk somatic cells upon subclinical mastitis in Holstein cattle

S. Pegolo¹, D. Giannuzzi¹, A. Vanzin¹, V. Bisutti¹, A. Toscano¹, E. Capra², P. Ajmone Marsan³ and A. Cecchinato¹
¹DAFNAE, University of Padua, Viale dell'università 16, 35020, Legnaro PD, Italy, ²IBBA, CNR, via Einstein, 26900, Lodi, Italy, ³DIANA, Catholic University of the Sacred Heart, Via Emilia Parmense 84, 29122, Piacenza, Italy; sara.pegolo@unipd.it

DNA methylation, as a key epigenetic mechanism for the regulation of gene function, is involved in bovine mastitis. We analysed genome-wide DNA methylation profiles of bovine milk somatic cells in Holstein cows naturally infected by subclinical mastitis to identify differences in DNA methylation pattern linked with disease susceptibility. Three experimental groups were defined based on the bacteriological analyses conducted on 188 animals belonging to one farm: healthy animals (H, n=15), animals infected by *Streptococcus agalactiae* (Sa+, n=10) and animals infected by *Prototheca* spp. (P+, n=9). Sequencing was done a HiSeqX platform using a 150 bp PE approach. Bowtie2 was used for aligning sequencing reads to the reference genome (ARS-UCD1.2.108) and MACS2 was used for peaks calling. Peaks annotated by HOMER within genes promoter regions were 3,787 for H, 5,197 for Sa+, and 4,793 for P+. Around 40% of these genes were shared among groups and 20% were shared between Sa+ and P+. The group-specific genes were 472 for H, 812 for Sa+ and 478 for P+. Functional analyses showed that P+ group includes genes mainly involved in immune pathways, especially related to the cytokine production and regulation (e.g. TLR4, IL13) while the Sa+ group includes genes involved in fat metabolism (e.g. FASN) and innate immune pathways such as the complement activation (e.g. C4A). A further step will explore the identification of differentially methylated regions, using the DiffBind R package. The results will enhance the knowledge on the role of DNA methylation in mastitis infection and help providing new target genes and epigenetic markers for mastitis resistance in dairy cattle. Acknowledgements. The research was part of the LATSAN project funded by MIPAAF (Italy). This study was also carried out within the Agritech National Research Center and received funding from the European Union Next-Generation EU (Piano Nazionale di Ripresa e Resilienza (PNRR) – Missione 4 Componente 2, Investimento 1.4 – D.D. 1032 17/06/2022, CN00000022).

Feed efficiency correlates with the transcriptomic response to feed intake in the pig duodenum

G. Devailly¹, K. Fève¹, S. Saci¹, J. Sarry¹, S. Valière², J. Lluch², O. Bouchez², L. Ravon³, Y. Billon³, H. Gilbert¹, M. Beaumont¹ and J. Demars¹

¹GenPhySE, Université de Toulouse, INRAE, ENVT, 31326, Castanet Tolosan, France, ²INRAE, US 1426, GeT-PlaGe, Genotoul, 31326, Castanet Tolosan, France, ³Pig phenotyping and Innovative breeding facility, GenESI, UE1372, INRAE, 17700 Surgères, France; guillaume.devailly@inrae.fr

Feed efficiency is a trait of interest in pigs as it contributes to lowering the ecological and economical costs of pig production. A divergent genetic selection experiment from a Large White pig population was performed for 10 generations, leading to pig lines with relative low- (LRFI, more efficient) and high- (HRFI, less efficient) residual feed intake (RFI). The meals of pigs from the LRFI line are shorter and less frequent as compared to the HRFI line. We hypothesised that these differences in feeding behaviour could be related to differential sensing and absorption of nutrients in the intestine. We investigated the duodenum transcriptomic response and DNA methylation profile to short term feed intake in LRFI and HRFI lines (n=24). We identified 1,106 differentially expressed genes between the two lines, notably affecting pathways of the transmembrane transport activity and related to mitosis or chromosome separation. The LRFI line showed a greater transcriptomic response to feed intake, with 2,222 differentially expressed genes before and after a meal, as compared to 61 differentially expressed genes in the HRFI line. Feed intake affected genes from both anabolic and catabolic pathways in the pig duodenum, such as autophagy and rRNA production. We noted that several nutrient transporter genes were differentially expressed between lines and/or by short term feed intake. Duodenal DNA methylation profiles were not altered by feed intake. However differences in DNA methylation profiles could be identified between LRFI and HRFI. Altogether, our findings highlighted that the genetic selection for feed efficiency in pigs changed the transcriptome profiles of the duodenum, and notably its response to feed intake.

Epigenetic biomarkers for environmental enrichment and parity in pregnant sows

M.M. Lopes¹, A. Chaulot-Talmon², A. Frambourg², H. Kiefer², C. Gerard³, J. Demars⁴, E. Merlot¹ and H. Jammes²
¹INRAE, PEGASE, 16 Le Clos, 35590 Saint-Gilles, France, ²INRAE, BREED, All. de Vilvert, 78352 Jouy-en-Josas, France, ³Chambre Régionale d'Agriculture de Bretagne, Maurice le Lannou, 35042 Rennes, France, ⁴INRAE, GenPhySE, Chemin de Borde-Rouge, 31326 Castanet Tolosan, France; mariana.mescouto-lobes@inrae.fr

Changes in the blood cells' epigenome, such as variations in DNA methylation, have been proposed as markers of the long-term effects of various factors in humans and in livestock. Therefore, this study aimed to identify pan-genomic DNA methylation variations in association with the well-being of animals submitted to contrasted welfare states. Pregnant sows of mixed parities (low parity (LP) – 2nd and 3rd gestation and high parity (HP) – 4th gestation or higher) were housed in two contrasting conditions throughout gestation (0 to 105 days): in a conventional system on a slatted floor (C: LP, n=9 and HP, n=6) or in an enriched system on accumulated straw with additional space per sow (E: LP, n=6 and HP, n=7). At gestation day 98, pan-genomic DNA methylation from the sows' blood mononuclear cells was analysed by reduced representation bisulphite sequencing (RRBS), following the lab's protocol. Only CpGs sites covered by at least 10 uniquely mapped reads (CpG₁₀) were retained and filtered out using a list of 105,171 known Single Nucleotide Polymorphisms (SNPs). Methylation percentages at each CpG₁₀ were calculated and cluster analyses were conducted. Differentially methylated cytosines (DMCs) were identified using methylKit v1.0. ($\Delta_{\text{meth}} \geq 25\%$ and adjusted P -value $< 1\%$) considering the following comparisons: [LPvsHP]_C and [LPvsHP]_E (parity effect); [CvsE]_{LP} and [CvsE]_{HP} (system effect). Cluster analyses revealed a clear separation corresponding to parity groups. [LPvsHP] displayed more DMC in C (5,391) than in E (3,886) with a similar loss of methylation (53 and 55% in C and E, respectively). Regarding the housing effect, the contrast [CvsE] displayed more DMCs in HP (2,769) than in LP sows (2,183), with an equal number of hypo and hyper DMCs. DMC-targeted genes were mostly associated with cell migration and adhesion, and other immune processes. Taken together, these results suggest that parity has a stronger effect on the immune cells' methylome than the housing system.

Prenatal factors may influence the future performance of dairy cows. We therefore investigated the impact of a suboptimal prenatal environment of a cow on the performance of the resulting daughter in the Holstein breed. The factors investigated in this analysis were associated either with the use of assisted reproductive technologies (sexed semen, embryo transfer (ET) or ET combined with *in vitro* fertilization (IVF-ET)) or with different stress factors during dam's gestation (parity, milk fat-to-protein ratio as a proxy for the metabolic status of the dam). The effects on daughter's performance of these factors, occurring before or during different periods of the dam's gestation, were tested in a model including non-genetic effects commonly used in genetic evaluations and the own direct genomic value for the trait considered, as a covariate. Depending on the factor considered, from 10,000 to 200,000 genotyped cows were used. IVF-ET calves were found to have more difficult birth conditions, suggesting a heavier weight, although neither IVF-ET, nor ET had any effect on the stature in first parity and on the milk performance of the resulting cows. Cows born from heifers and derived from sexed semen produced slightly less milk (-0.3%) than their counterparts derived from conventional AI. Low and high fat/protein ratios of the dam's milk, which are indicators of metabolic disorders, were associated with slightly reduced offspring milk production (-1%) and fertility. The parity of the dam was positively associated with the milk performance of the offspring. For all the factors tested in our study the adverse effect was moderate (e.g. less than 1% for milk yield), suggesting that the negative impact of foetal programming appears to be limited. Further work will be carried out to investigate the effects of other situations, on a wider range of traits and breeds. CF is recipient of a CIFRE PhD grant from ANRT and APIS-GENE. This work was part of the POLYPHEME project funded by ANR and APIS-GENE.

Non-coding exonic microsatellite in bovine Nrf2 gene influences sperm oxidative stress capacity

K. Anwar, G. Thaller and M. Saeed-Zidane

Institute of Animal Breeding and Husbandry, Christian-Albrechts-University Kiel, Olshausenstraße 40, 24098 Kiel, Germany; kanwar@tierzucht.uni-kiel.de

Nrf2 signalling plays a crucial role in cellular defence against oxidative stress that could impair bull fertility. In this regard, the current study was conducted to investigate the potential genetic and epigenetic regulations of Nrf2 gene associated with higher oxidative stress capacity and semen quality in bovine. For that, 12 qualified (older bulls, relatively long duration at service, $n=6$), and non-qualified (young bulls, relatively short duration at service, $n=6$) Holstein bulls were subjected to semen collection in 4 seasons. The Nrf2 gene was genotyped in all animals for the GCC microsatellite (9 repeats, NCBI Reference Sequence Database) located within the untranslated region of the first exon. Spermatozoa-borne-relative mRNA expression levels of Nrf2 signalling-related genes were analysed for all semen samples. Interestingly, one bull showed 15 GCC repeats in each group, and one bull had 8 GCC repeats. However, 4 bulls in each group had 9 GCC repeats. Furthermore, mRNA expression analysis revealed that the PRDX1 gene was the most abundant sperm-borne-mRNA among all analysed genes, and was significantly higher expressed in qualified bulls. Across the year's four seasons, higher mRNA expression level was found for Nrf2-202 in winter, Keap1, Nrf2-201, NF- κ B, GPX1 in spring, Keap1, Nrf2-201, Nrf2-202, Prdx1, NF- κ B, GPX1 in summer, and Keap1, Nrf2-202, and NF- κ B in autumn semen of qualified bulls. Meanwhile, higher mRNA expression level was found for Keap1, Nrf2-201, NF- κ B, and GPX1 in winter, Nrf2-202 in spring, and Nrf2-201, GPX1 in autumn semen of non-qualified bulls. On the other hand, except for spring the mRNA level of the DNA methyltransferase 3A gene (DNMT3A) was higher in non-qualified bulls. Overall results showed that predominantly higher expression of Nrf2 transcripts and the downstream antioxidants (Prdx1 and GPX1) in qualified bulls in stress seasons alleviated the harmful effects of oxidative stress, which is associated with spermatozoa gDNA fragmentation in non-qualified counterparts. Further ongoing work is to investigate the methylation pattern of Nrf2 in bovine sperm cells.

Session 10

Maternal methionine restriction affects liver metabolism and foie gras production in duck offspringC.M.D. Bonnefont¹, A. Sécula¹, H. Chapuis¹, L. Bodin¹, L.E. Bluy¹, A. Bonnet¹, A. Cornuez², M.-D. Bernadet², J. Barrieu², E. Cobo¹, X. Martin², H. Manse¹, L. Gressl¹, M. Lessire³, F. Mercerand⁴, M.-C. Le Bourhis⁴, A. Collin³ and M. Morisson¹¹GenPhySE, Université de Toulouse, INRAE, ENVT, 31326, Castanet Tolosan, France, ²UEPFG INRAE Bordeaux-Aquitaine, Domaine d'Artigüères, 40280 Benquet, France, ³INRAE, Université de Tours, BOA, 37380 Nouzilly, France, ⁴INRAE, PEAT, 37380 Nouzilly, France; cecile.bonnefont@inrae.fr

Maternal nutrition effects on offspring phenotypes and production performance have been documented in livestock including farmed birds. We thus studied the effects of a reduced dietary methionine level applied to common female ducks on the hepatic metabolism and zootechnical performance of their offspring in relation to 'foie gras' production. Sixty female ducks were divided into 2 groups receiving either 0.25% or 0.40% of methionine during the growing and laying periods. The restriction reduced egg weight ($P<0.001$), albumen weight ($P<0.001$) and duckling body weight at hatching ($P<0.001$). It also affected the ducklings' energy metabolism, as their plasma glucose ($P=0.03$) and triglyceride ($P=0.01$) levels were increased, while their plasma free fatty acid level was decreased ($P=0.01$), as was the alanine aminotransferase activity ($P=0.002$). The study of the hepatic expression level of 170 target genes identified 38 differentially expressed genes between the 2 groups of ducklings, some being related to energy metabolism and others to one-carbon metabolism and epigenetic mechanisms. This suggested a modulation in the establishment of metabolic pathways in the very early liver development with long-term effects on energy metabolism. Indeed, ducks issued of the restricted dams were leaner, with lower liver lipid ($P=0.005$) and abdominal fat ($P<0.04$) at 12 weeks of age. Later, at 14 weeks of age and after force-feeding, 'foie gras' production was reduced by over 10% ($P=0.003$). Expression analysis of the 170 target genes at 12 et 14 weeks of age is under progress. Thus, maternal methionine restriction resulted in nutritional programming of the hepatic metabolism of their progeny with effects persisting beyond their period of force-feeding and altering their 'foie gras' production.

Garcinol promotes hepatic gluconeogenesis by inhibiting PCAF acetyltransferases in late-pregnant Sow

W.L. Yao, Q.Y. Fu and J.X. Ning

huazhong Agricultural University, Shizishan Street, Hongshan District, Wuhan City, Hubei Province, 430070, China, P.R.; 85755350@qq.com

Disorder of hepatic glucose metabolism is the characteristic of late pregnant sows. The purport of our study was to look into the mechanism of garcinol on the improvement of hepatic gluconeogenic enzyme in late pregnant sows. Thirty second- and third-parity sows (Duroc × Yorkshire × Landrace, n=10/diet) were fed a basal diet (control) or that supplemented with 100 mg/kg (Low Gar) or 500 mg/kg (High Gar) garcinol from day 90 of gestation to the end of farrowing. The livers were processed to measure enzymatic activity. Hepatocytes from pregnant sows were transfected with P300/CBP associating factor (PCAF) siRNAs or treated with garcinol. Dietary garcinol had no effect on average daily feed intake (ADFI), body weight (BW), backfat and BW gain of late pregnant sows. Garcinol promoted plasma glucose levels in pregnant sows and newborn piglets. Garcinol upregulated hepatic gluconeogenic enzymes expression and decreased PCAF activity. Garcinol had no effect on the expression of peroxisome proliferator activated receptor-γ co-activator 1 (PGC-1α) and forkhead box O1 (FOXO1), but significantly increased their activity and decreased their acetylation in late pregnant sows. Transfection of PCAF siRNAs to hepatocytes of pregnant sows increased PGC-1α and FOXO1 activities. Furthermore, in hepatocytes of pregnant sows, garcinol treatment also upregulated the activities of PGC-1α and FOXO1 and inhibited the acetylation of PGC-1α and FOXO1. Garcinol improves hepatic gluconeogenic enzyme expression in late pregnant sows, and this may be due to the mechanism of downregulating the acetylation of PGC-1α and FOXO1 induced by PCAF in isolated hepatocytes.

Session 10

Theatre 10

Early high nutrition affects epigenetics related to lipogenesis in grass-fed WagyuD. Nishino¹, S. Khounsaknalath¹, K. Saito², A. Saito³, T. Abe², E. Kobayashi², S. Yasuo¹ and T. Gotoh⁴¹Kyushu University, Fukuoka, 819-0395, Japan, ²National Livestock Breeding Center, Fukushima, 961-8511, Japan, ³Zenrakuren, Tokyo, 151-0053, Japan, ⁴Hokkaido University, Hokkaido, 060-0811, Japan; 0214daichi@gmail.com

The early high plane of nutrition improved meat quality and meat production in Wagyu (Japanese black cattle) fattened on roughage (Khounsaknalath et al, 2021) and altered DNA methylation level significantly. We hypothesized that this was an epigenetic effect of early nutrition on skeletal muscles. In this study, we comprehensively analysed transcriptomics by microarray and DNA methylation level by whole genome bisulphite sequence (WGBS) analysis in the longissimus muscle (LM) of this grass-fed Wagyu model. Wagyu calves were randomly allocated into two groups. EHN (n=12) received intensified nursing (maximum intake of 1.8 kg/day) until 3 months of age (mo) and then fed a high-concentrate diet from 4 to 10 mo. Another ELN (n=11) received normal nursing (maximum intake of 0.6 kg/day) until 3 mo and then fed only roughage *ad libitum* until 10 mo. After 11 mo, both groups were fed roughage *ad libitum* until 31 mo (Khounsaknalath et al, 2021). We analysed the transcriptomics in LM at 3, 10, 14, 20, and 31 mo and DNA methylation levels in LM at 31 mo. Additionally, we integrally analysed gene expression and DNA methylation level of differentially expressed genes from 10 mo, which is immediately after the metabolomic imprinting event, to 31 mo consistently. In EHN, 1 gene was hypo-methylated and highly expressed, and 6 genes were hyper-methylated and consistently under-expressed. We focused on forkhead box O1 (FOXO1) which is involved in fat synthesis by GO analysis because the intramuscular fat content in LM of EHN was significantly high (Khounsaknalath et al, 2021). FOXO1 which inhibits the transcription of peroxisome proliferator-activated receptor γ (PPARG), a master regulator of adipogenesis, was highly methylated and consistently under-expressed after 10 mo in EHN. Additionally, PPARG was highly expressed at 10, 14, and 31 mo in EHN. These results suggested that FOXO1 was affected epigenetically by the early metabolic imprinting event, and it possibly contributes to fat cell differentiation and lipid accumulation by not inhibiting the transcription of PPARG.

Construction of a single-cell transcriptome map of sheep horn development

X.H. He, Y.Y. Luan, S.J. Wu, Y.H. Ma and L. Jiang

Institute of Animal Sciences, Chinese Academy of Agricultural Sciences (CAAS), No. 2, Yuanmingyuan West Road, Haidian District, Beijing, China, 100193, Beijing, China, P.R.; hexiaohong@caas.cn

Horns are headgear, which are unique structures of ruminants. As a globally distributed ruminant, the study of horn formation is critical not only for the understanding of natural and sexual selection but also for the breeding of polled sheep breeds to facilitate modern sheep farming. Nevertheless, the underlying genetic mechanisms in sheep horn remain largely unknown. In the present study, we performed scRNA-seq of horn buds and forehead skin during Mongolian sheep the embryonic period. Single cell transcriptome sequencing and analysis was performed on the forehead skin of a 90-day-old sheep fetus and three developmental stages of horn buds (90-day-old, 120-day-old, and 150-day-old). To construct single-cell pseudotime differentiation trajectory, we used Monocle (v 2.10.0) to order single cells along pseudotime according to the official tutorial. Metascape was used to perform gene ontology (GO) analysis to investigate gene functions in each gene cluster. Histological appearances indicate that the horn buds were significantly different from the forehead skin, with a thicker epidermis and more layers of epithelial cell. Interestingly, we found that the hair follicles degenerated in the horn region. Single-cell suspensions from the horn buds and forehead skin tissues were prepared for unbiased scRNA-seq. Based on UAMP dimension reduction analysis, we identified 6 distinct cell populations from 41,405 single-cell transcriptomes. Increased proportions were observed for endothelial cells and pericyte cells in horn buds, suggesting that it was related to the development of horn buds. Furthermore, we identified 9 cell populations in the epithelial cell subset and found two cell subsets associated with horn development. GO and KEGG analysis showed that the two cell subsets were related to epidermis development, ECM-receptor interaction, Focal adhesion and PI3K-AKT signalling pathway. By using pseudotime ordering analysis, we constructed the epithelial cell subsets trajectory and revealed the different cell fates. Meanwhile, we found that the proportions for dermal papilla cells were reduced in the dermal cell subset.

The effect of short and long term cryopreservation on chicken primordial germ cellsM. Ibrahim¹, K. Stadnicka², E. Grochowska¹, B. Lazar³, E. Varkonyi³ and M. Bednarczyk¹*¹Bydgoszcz University of Science and Technology, Department of Animal Biotechnology and Genetics, Mazowiecka 28, 85-039 Bydgoszcz, Poland, ²Collegium Medicum, Nicolaus Copernicus University in Torun, Bydgoszcz, Faculty of Health Sciences, Łukasiewicza 1, 85-821 Bydgoszcz, Poland, ³Institute for Farm Animal Gene Conservation, National Centre for Biodiversity and Gene Conservation, 200 Isaszegi, 2100 Gödöllő, Hungary; miriam.ibrahim@pbs.edu.pl*

Chicken primordial germ cells (PGCs) are the precursors of functional gametes, and the only cell type capable of transmitting genetic and epigenetic information from generation to generation. These cells offer valuable starting material for cell-based genetic engineering and genetic preservation. Chicken PGCs can be cultured and cryopreserved without losing their biological features; however, the handling of PGCs is challenging and requires further development. Herein, we sought to compare the effects of different conditions (freezing-thawing and *in vitro* cultivation) on the expression of PGC-specific gene markers. The chicken used in this study was a purebred Green-legged Partridge like (ZS-11). Embryonic blood containing circulating PGCs was isolated after 2.5 days of egg incubation (13-17 HH embryonic development stage). The blood was pooled separately for males and females following sex determination. The conditions applied to the blood containing PGCs were as follows: (1) fresh isolation; (2) cryopreservation for a short duration (2 days); and (3) *in vitro* culture (30 days) with long term cryopreservation of purified PGCs (~2 years). RNA was isolated in order to further characterize PGCs by reverse transcription-polymerase chain reaction (RT-PCR) for the specific germ cell markers (*SSEA1*, *CVH*, *DAZL*), pluripotency markers (*OCT4*, *NANOG*), and the chemokine/receptor axis (*CXCR4*, *SDF1-α*). A validation study using whole genome sequencing was performed on the *in vitro* purified PGCs vs freshly isolated blood containing PGCs to distinguish the specified PGC markers panel from embryonic whole blood. This study may support avian germplasm conservation strategies via culture and cryopreservation of chicken PGCs. Research was funded by National Science Centre, Poland (UMO-2017/27/B/NZ9/01510, and 2020/37/B/NZ9/00497) and The Excellence Initiative-Research University IDUB programme, UMK Poland.

The effect of garcinol on muscle *post mortem* glycolysis and meat quality in pigs

T.X. Wang, L. Huang and X.M. Liu

Huazhong Agricultural University, 1 Shizishan Street, Hongshan District, Wuhan City, Hubei Province, 430070, China, P.R.; 535996673@qq.com

The objective of this study was to evaluate the effects of dietary garcinol (0, 200, 400 and 600 mg/kg) on the growth performance, meat quality, *post mortem* glycolysis and antioxidative capacity of finishing pigs. Dietary garcinol increased pigs' average daily gain, pH 24 h, a* and myoglobin content of longissimus dorsi (LM) ($P<0.05$), and decreased feed/gain ratio, the L* 24 h, glycolytic potential, drip loss, shear force, and backfat depth ($P<0.05$). The glutathione peroxidase (GPx), catalase (CAT) and total antioxidative capacity (T-AOC) were significantly increased by garcinol ($P<0.05$), while the activity of lactate dehydrogenase (LDH) and malonaldehyde (MDA) content were decreased ($P<0.05$). Moreover, garcinol decreased the p300/CBP-associated factor (PCAF) activity, the acetylation level and activities of glycolysis enzymes phosphoglycerate kinase 1 (PGK1), glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and 6-phosphofructo-2-kinase/fructose-2, 6-bisphosphatase-3 (PFKFB3) ($P<0.05$). The results of this study showed that garcinol decreased *post mortem* glycolysis, and this may be due to the mechanism of decreasing glycolytic enzyme acetylation induced by PCAF. The present study indicates that garcinol can facilitate the growth performance of pigs and improve pork quality by changing *post mortem* glycolysis and antioxidative capacity.

Session 10

Poster 14

The effect of methionine supplementation on DNA methylation during the suckling period of ewe lambsA. Martín¹, O. Madsen², F.J. Giráldez¹, J. De Vos² and S. Andrés¹¹Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas s/n, 24346, Grulleros (León), Spain, ²Wageningen University and Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands; alba.martin@csic.es

Nutritional programming events during early life of ewe lambs might program feed efficiency during the whole life time due to stable changes of epigenetic marks caused by methylation of DNA. Nutritional strategies supplying methyl donors, such as methionine, during the early post-natal period might therefore be used to improve animal performance along the whole life. In this study, 26 newborn ewe lambs from the same flock were stratified and distributed into two groups with equal distribution of body weight. The control group (CTRL, n=13) was fed *ad libitum* with a milk replacer, whereas the second group (n=13) received the same milk replacer supplemented with 1 g of methionine/kg of milk replacer on a dry matter basis. After weaning, all animals were raised in exactly the same way, being fed *ad libitum* with a complete pelleted diet during the replacement phase. Blood was sampled from the jugular vein for DNA isolation at 45 days of age, and blood was also sampled at 45 days and 9 months of age using TEMPUS Blood RNA tubes for RNA extraction. DNA methylation was assessed by reduced representation bisulphite sequencing (RRBS) in ten animals [5 ewe lambs (MET) vs 5 ewe lambs (CTRL), corresponding to 5 twin births, from which a lamb was assigned to each group]. The first preliminary results indicate that there were no global differences in the level of methylation between the two groups. Differentially methylation analysis (CTRL vs MET lambs) at 45 days of age resulted in 61 genes differentially methylated in either promoter and/or gene bodies. A selection of these genes was validated by RT-qPCR on samples at 45 days and 9 months of age and most notable was the increased expression of KIF4 and RFLN genes, thus corroborating the hypo-methylation observed by RRBS. These genes are involved in mitotic spindle elongation (KIF4) and regulation of chondrocyte development (RFLN). Furthermore, the methionine supplementation of ewe lambs during the suckling period was not sufficient to result in a clear difference in live body weight when animals were 9 months old.

Effect of supplementary diet at cow-calf phase on DNA methylation in muscle of Angus-Nellore calvesR. Curi¹, L. Rodrigues¹, R. Cooke², W. Baldassini¹, L.A. Chardulo¹ and O. Machado Neto¹¹São Paulo State University, Campus de Botucatu, SP, 13618-681, Brazil, ²Texas A&M University, College Station, TX 77845, USA; rogerio.curi@unesp.br

Different strategies are used to increase the intramuscular fat in beef produced in Brazil. The use of Nellore (*Bos indicus*) × *Bos taurus* and creep-feeding, a supplementation system of calves at cow-calf phase with a diet rich in energy and protein, are examples. Nutritional stimuli can modify DNA methylation, gene expression and phenotypes. However, there are no studies evaluating the effect of creep-feeding on the epigenetic state of adipogenic and lipogenic genes in the muscle of beef cattle. The objective was to analyse methylation levels in the genome of the *Longissimus thoracis* (LT) muscle at weaning of crossbred cattle submitted to different nutritional strategies during the lactation phase. Forty-eight F1 Angus-Nellore steers, not castrated, half-sibs, kept from 30 days of age until weaning under two treatments (n=24/treatment): group 1 (G1) – no creep-feeding; group 2 (G2) – creep-feeding, were used. The animals were weaned at 210 days and then finished in a feedlot for 180 days. The groups showed differences ($P<0.05$) for weaning weight and marbling content in the LT, without differing in weights at the beginning of the experiment and slaughter. At weaning, biopsies of LT were collected and differences in methylation patterns of regulatory gene regions were prospected between five individuals per group by RRBS technique. A total of 272 differentially methylated regions were identified (>25%: q-value<0.01), of which 30 were found overlapping the promoter regions of 20 genes. Among these, *HDAC5* hyper-methylated in G2, was highlighted for their potential relationship with the difference in the intramuscular fat content, due to adipogenesis and lipogenesis, observed between animals from G1 and G2. Enrichment analysis showed *HDAC5* related to (FDR<0.05): apelin signalling pathway; regulation of lipid metabolism by PPAR α ; HDACs deacetylase histones; cell differentiation; and adipogenesis. In the model studied, the effects of observed methylation patterns for *HDAC5* gene can lead to excessive fat accumulation in the muscle tissue and, consequently, an increase in meat quality.

Session 11

Theatre 1

Improving pig welfare in commercial pig farms

K. O'Driscoll

Teagasc, Pig Development Department, Moorepark, Fermoy, Co. Cork, Ireland; keelin.odriscoll@teagasc.ie

The welfare of pigs on commercial farms is of concern to the public, and as such is an area that is increasingly becoming a policy question for governments, non-profit, and commercial enterprises. The most significant indicator that the welfare needs of pigs are not typically met is the widespread occurrence of damaging and inappropriate behaviours that they perform. These can be an indicator of poor welfare, and in the case of tail biting, can also cause poor welfare. In the face of stressors, animals adjust their behaviour as a component of an initial attempt to cope. When the duration or intensity of stressors experienced by pigs surpasses their ability to cope, tail biting often ensues. To prevent this behaviour, docking of pigs' tails is a widespread practice in commercial pig farming. This is the case world-wide, even though in the EU in particular there is legislation in place that prohibits its routine use. In recent years, there has been a spotlight on this legislation, and the lack of enforcement. This has included an increased amount of national and EU level funding being allocated towards research projects aiming to find methods to reduce the stress levels that pigs' experience, and thus reduce the need to dock. In Ireland, pig farms typically consist of systems with fully slatted floors, which makes provision of functional enrichment challenging – a barren environment is considered a key risk for tail biting. Pig farms are large, and the cost of production is high. This means that there is a perceived high level of cost and risk for producers when it comes to changing to management strategies and infrastructure that may better meet the pigs' needs. During the past 10 years we have undertaken a research programme in Teagasc Moorepark which has aimed to elucidate strategies that can be employed to reduce the need to tail dock in a typical Irish pig farm. Our findings have confirmed that it is possible to significantly reduce these risks, even in fully slatted systems.

Effects of different nutritional strategies on the prevalence of tail biting in weaned pigletsE. Janvier¹, W. De Gaiffier², J. Piqué³, S. Lebas¹ and A. Samson¹¹ADM, Animal Nutrition, Talhouët, 56250 Saint-Nolff, France, ²ADM, Animal Nutrition, A One Business Center, La Pièce 3, 1180 Rolle, Switzerland, ³SETNA, Rambla d'Egara, 235, 5^o AB, 08224 Terrassa (Barcelona), Spain; werner.degaiffier@adm.com

Discussions are ongoing in the EU to assess the feasibility of banning tail docking in pigs, this however, may increase the frequency and severity of tail biting. This study aimed to investigate the potential of nutritional solutions to lower the risk of tail biting. A total of 106 mixed-sex piglets were assigned to three experimental groups during the post-weaning phase (d21-d70). Pigs were housed in pens of 35 or 36 piglets in a single pen per room, each receiving a different dietary treatment. Rooms were otherwise managed similarly. In phase 1 (d21-d42), dietary treatments were as follows: CON: P1 basal diet; ADD: P1 basal diet + feed additives implicated in stress resilience (magnesium, valerian and Passiflora extracts and lavender flavour); ADD+NUT: diet with optimized nutrients implicated in tail biting (energy fraction, protein, tryptophan, crude fibre, sodium) + stress resilience feed additives. In phase 2 (d42-d70), CON and ADD received the P2 basal diet only, and the ADD+NUT group was fed a diet with optimal nutrient levels as in Phase 1, but without the stress resilience feed additives. Piglets were weighed individually, and feed intake recorded at the pen level. Tail lesions were scored daily using the IFIP's score grid (from 0 = no visible lesions to 3 = severe lesions). For the groups ADD and ADD+NUT, a lick block was added as additional enrichment when 10% of the piglets had slight injuries (score 1). The proportion of severe lesions (scores 2+3) was 8.4, 5.4 and 0.8% in the CON, ADD and ADD+NUT treatments, respectively (d21-70, $P < 0.001$). There was no effect of sex on the proportion of severe lesions ($P > 0.10$). The tail lesions were mainly observed early in Phase 2 when the feed was changed without transition. Piglets' body weights were significantly improved in the ADD and ADD+NUT groups for the overall period ($P < 0.01$). This trial suggests the potential of nutritional solutions to reduce tail biting in piglets when all other husbandry practices are well managed.

Session 11

Theatre 3

Validation of an Irish tail biting risk assessment toolR.M. D'Alessio^{1,2}, C.G. Mc Aloon¹, C. Correia-Gomes³, A. Hanlon¹ and K. O'Driscoll²¹UCD Veterinary Sciences Centre, University College Dublin, University College Dublin, Belfield, Dublin 4, Ireland, D04W6F6, Ireland, ²Teagasc Moorepark, Pig Development Department, Teagasc Moorepark, Fermoy, Co Cork, Ireland, P61C996, Ireland, ³Animal Health Ireland, 2-5 The Archways, Carrick on Shannon, Co. Leitrim, Ireland, N41WN27, Ireland; robertamaria.dalessio@teagasc.ie

Tail biting is a complex multifactorial, and farm-specific problem often observed in commercial pig farms. The risk factors contributing to developing this damaging behaviour can be difficult to recognise. Therefore, using a farm-specific husbandry assessment tool, to identify the causes, can help to determine the risk of tail biting on the farm and guide the development of a tail-biting prevention and management plan. This study sought to validate a novel tail-biting risk assessment protocol, by investigating whether the level of risk determined by the tool would be reflected in tail lesion scores recorded at slaughter. A total of 27 farms (six pens/farm) were assessed using the tool by trained assessors, all private veterinary practitioners. The assessment included reporting on animal-based measures such as lesions and behaviour observations. Based on these, the assessors decided whether they considered the pigs in the pen had a risk of tail biting. Following the assessment a batch of pigs per farm was followed to the abattoir, where the severity of tail skin damage (0 [undamaged] - 4 [partial/full loss of tail]) and presence/absence of bruises was scored. Data were analysed using SAS v9.4. Visible injuries, dirty flanks and tucked tails was not associated with the risk of tail biting in pen as reported by the assessors ($P > 0.05$). Similarly, the risk of tail biting per pen was not associated with aggressive, damaging and exploratory behaviours ($P > 0.05$). At slaughter, 70% of pigs' tails *post-mortem* did not present tail skin damage, and only 4% presented moderate and severe tail skin damage. Additionally, there was no association between the scores reported at slaughter with the risk of tail biting reported by the assessors. These data suggest that this risk assessment tool may not help to correctly evaluate the risk of tail biting on pig farms.

Improving finishing pig welfare by providing rooting and bedding materials*M. Ocepek, R.C. Newberry and I.L. Andersen**Norwegian University of Life Sciences, Faculty of Biosciences, Department of Animal and Aquacultural Sciences, P.O. Box 5003, 1432 Ås, Norway; marko.ocepek@nmbu.no*

Norwegian pig producers are required to provide rooting and bedding materials in commercial production. Information about how rooting and bedding material types and management routines around their provision (amount, frequency) influence the pigs has not been well documented. The aim of this field study ($n=87$ pig farms; $n=648$ pens; $n=5,769$ pigs; about 8 pens per farm) was to investigate associations between these factors. We predicted that all of these factors would be associated with bite marks on pigs (≥ 1 red stripe, including healed wounds). Proportions of pigs with bite marks on the body, tail, and ears were analysed using a generalised linear mixed model with binomial distribution. Rooting material types (1 vs >1 of: chopped or long straw, silage, hay, newspaper), rooting material distribution frequency (≤ 1 daily vs >1 daily), and amount of bedding (sparse, low, or moderate amount of wood shavings, or high amount of straw bedding), as well as the interactions between them, were included as fixed effects in the model. Provision of newspaper resulted in a lower proportion of pigs with bite marks on the body ($P=0.050$), and provision of hay reduced the proportion of pigs with bite marks on the tail ($P=0.015$) and ears ($P=0.002$), compared to the other rooting material types. With increasing amount of bedding, the proportion of pigs with body ($P<0.001$), tail ($P=0.048$) and ear ($P=0.031$) bite marks was lower. A lower proportion of pigs had body bite marks when given more than one rooting material at a frequency of more than once daily compared with providing only one rooting material type at a frequency of up to once daily ($P=0.020$). Similarly, the proportion of pigs with body bite marks was lower when providing a combination of more than one rooting material type and a greater amount of bedding ($P<0.001$). Furthermore, the proportion of pigs with body bite marks was lower when pigs were given more bedding along with more frequent provision of rooting materials ($P<0.001$). Our results suggest that the pigs receiving more than one type of rooting material, distributed more than once daily, in addition to ample bedding material over the solid-floored resting area, had better welfare.

Session 11

Theatre 5

Impact of enrichment material and space allowance on damaging behaviour in pigs*M. Cupido^{1,2}, S.M. Mullan¹, K.M. O'Driscoll² and L.A. Boyle²**¹University College Dublin, School of Veterinary Medicine, Belfield, Dublin 4, D04 W6F6, Ireland, ²Teagasc Moorepark, Pig Development Department, Fermoy, Co. Cork, P61 P302, Ireland; lissacupido@gmail.com*

The majority of commercial pigs in Ireland are reared in intensive systems with little meaningful enrichment provided, limiting them from expressing instinctive investigative behaviours. Legally permissible stocking densities in countries that do not permit tail docking are all lower than that currently allowed in Ireland, and across the EU. This study compared the effectiveness of four manipulable enrichment materials (Straw, Haylage, Hay and Grass) applied to pigs in similar pens containing either 8 (LOW), 10 (MID) or 12 (HIGH) pigs (weaner: 0.78, 0.62, 0.52 m²/pig; finisher: 1.2, 0.6, 0.8 m²/pig, respectively) in reducing damaging behaviour for 10 weeks post weaning. Thirty-two litters containing healthy piglets with undocked tails were assigned at weaning to enrichment and space allowance treatments using a 4×3 experimental design. Every 2 weeks, pens were directly observed continuously for 5 min, 4 times/day and all occurrences of pigs interacting with the enrichment, and performing aggressive (head-knock, bite, fight) and damaging (tail or ear biting, and belly nosing) behaviours were recorded. Pigs were individually scored every week for ear and tail lesions. Data were analysed using SAS v9.4. There was an effect of material on interaction with enrichment ($P<0.05$), with Grass pigs tending to interact more with it than Hay ($P=0.07$) and Haylage pigs ($P=0.07$), but there was no impact on damaging or aggressive behaviour. Pigs in LOW (0.41 ± 0.04 instances/pig/5 min) and MID (0.37 ± 0.05 instances/pig/5 min) performed less aggressive behaviour than HIGH (0.68 ± 0.04 instances/pig/5 min; $P<0.001$ for both) and LOW also performed less damaging behaviour (0.29 ± 0.03 instances/pig/5 min; $P<0.05$) than HIGH (0.38 ± 0.03 instances/pig/5 min). More Hay pigs (35.00%) had some tail length reduction (via biting) than Straw (26.25%), Haylage (27.50%), or Grass (12.50%) pigs. Although space allowance had a greater impact on damaging behaviour than enrichment material, Grass pigs has most enrichment interactions, and least damage to their tails. Thus both space allowance and enrichment material could have a part to play in reducing tail biting risk.

An investigation of early life indicators in relation to ear necrosis in pigsL. Markland^{1,2}, K. O'Driscoll², F. Leonard¹ and L. Boyle²¹University College of Dublin, School of Veterinary Medicine, Belfield, Dublin, D04 V1W8, Ireland, ²Teagasc, Animal & Grassland Research & Innovation Centre, Moorepark, Fermoy, P61 C996 Cork, Ireland; lucy.markland@teagasc.ie

Ear necrosis is a poorly understood pig welfare concern. We investigated associations between early life characteristics of piglets and subsequent ear lesion (EL) development. Piglets born to 94 sows in 6 batches from March 2022 to January 2023 were followed from birth until 11 weeks of age. All piglets were handled a min. of 3 times for weighing at birth and at weaning and for teeth clipping and tail docking. Piglets were inspected weekly for EL post-weaning which were scored according to severity from 0 to 5 and collapsed into 1] presence or absence of EL; 2] presence or absence of severe EL (scores 4+5). Batches were involved in 4 experiments investigating pre-weaning (batches 3-6) or post-weaning (batch 1+2) factors. Piglets in three of the batches (3-5) were weighed throughout the suckling period such that they were HANDLED (n=689 piglets) 8 times compared to piglets in batches 1, 2 and 6 that were handled 3 times (NOHAND=589 piglets). Data were analysed using SASv9.4 to investigate the role of parity (young=0 [n=166 gilts]; mid=1-3 [n=687]; old≥4 [n=425]), birthweight, and whether or not piglets received antibiotics or were HANDLED during the suckling period on the likelihood of developing EL. There were no treatment effects on EL within experiment ($P>0.05$) and birthweight had no effect on the likelihood of developing EL ($P>0.05$). Offspring of gilts were more likely to develop EL (52% of piglets) compared to mid (27%) and old (28%) sows ($P<0.001$). More HANDLED piglets developed EL (46 vs 12.7%, $P<0.001$) and severe EL (12.8 vs 2.2%, $P<0.001$). Whether or not piglets received antibiotics had no effect on the likelihood of developing EL ($P>0.05$). However, a higher proportion of HANDLED pigs were treated with antibiotics than NOHAND piglets ($P<0.01$). This study supports the generalised poorer immunity in piglets from gilts. Further, while ear necrosis is a multifactorial issue, it is clearly exacerbated by frequent handling during the suckling period. The mechanism appears to be partially one of stress induced immunosuppression given the associated finding of higher antibiotic use in frequently handled piglets.

Improving the welfare of sows and piglets: an exploration of teeth resection under the 3S framework

L. Boyle

Teagasc, Pig Development Department, Moorepark, P61 P302, Ireland; laura.boyle@teagasc.ie

In commercial production, piglets' canine teeth are resected (clipped or grinded) to prevent them from injuring one another (piglet facial lesions-FL) when fighting to establish the teat order. Teeth resection is stressful and pain can result from the procedure itself and/or the resultant injuries which can become infected. Hence, the procedure is legally restricted but leaving the teeth intact means piglets may injure the sows (teat lesions-TL) so the practice is widespread and presents a substantial pig welfare issue. In the same way that Russell and Burch's 3R's (reduce, refine and replace) help to improve the treatment and reduce the suffering, of laboratory animals, the 3S's (suppress, substitute and soothe) offers a framework to address painful procedures in animal production. A recent survey indicated several means of suppressing the need for teeth resection including better focus on sow mothering traits and nutrition, improving piglet water intake and nutrition, conducting frequent checks in the farrowing house and using nurse sows. Also respondents using alternative farrowing systems more frequently reported that FL and TL were manageable. Additionally, the recent EFSA report on pig welfare indicated the importance of reduced litter size in suppressing the need for teeth resection. There is some evidence that substituting clipping for grinding can mitigate resection pain and associated injury. However grinding is still painful and because it takes longer to perform, is associated with handling stress. Given emerging findings on the detrimental effects on piglet health and welfare of handling pre-weaning, even in the absence of painful procedures, substituting clipping for grinding is not ideal. The issue of analgesia to soothe pain in piglets following teeth resection is not well studied but there is recent evidence that pain persists for up to 6 weeks. Hence, piglets should be provided with pain relief when subjected to either procedure. General anaesthetic is excessive for teeth resection and local anaesthesia likely impractical so veterinarian intervention is unnecessary but pig producers should administer NSAIDS to piglets undergoing teeth resection to soothe related pain.

Mitigating the impacts of hot conditions on lactating sows through meal delivery or feedN. Quiniou¹, J. Dupuis¹ and D. Renaudeau²¹IFIP-Institut du Porc, BP35, 35650 Le Rheu, France, ²Pegase, INRAE, Institut Agro, 35590 Saint-Gilles, France; nathalie.quiniou@ifip.asso.fr

Six batches of 24 sows were used to study the impacts of the feeding schedule (alternative frequency and time, group M) or the diet (alternative net energy content (NE) and NE to metabolizable energy (ME) ratio, group D) on performance, either under natural summer heat wave situation (trial 1, 2 batches) or chronic heat stress induced with a fan setpoint kept at 25 °C (trial 2, 4 batches). Control sows (group C) and group D were fed 4 times a day between 7:30 am and 8:00 pm and group M 6 times between 6:30 pm and 12:00 am. The diet delivered to groups C and M was formulated at 9.5 MJ NE/kg with a NE/ME ratio of 73.6%. Corresponding values were 10.3 MJ/kg and 76.3% for group D. At farrowing and weaning, Sows and piglets were weighed, and backfat (BT) and muscle (MT) thicknesses were measured by ultrasound. Sows suckled 14.7 and 14.6 piglets on average in trials 1 ($P=0.78$) and 2 ($P=0.77$), respectively. Litter growth rate was not influenced by treatments in trial 1 (3.08 kg/d, $P=0.42$) and 2 (2.99 kg/d, $P=0.35$). In trial 1, a small number of heat waves of limited intensity occurred either during the first or the second half of the lactation depending on the batch, but the cumulated spontaneous NE intake was significantly higher in groups D and M than in group C (1,616, 1,512 and 1,325 MJ NE/sow, respectively, $P=0.04$). However, the difference in BW, BT and MT losses was not statistically significant (-39, -38 and -40 kg, $P=0.88$; -4.5, -5.2 and -4.6 mm, $P=0.67$; -4.6, -4.9 and -7.1 mm, $P=0.56$). In trial 2, the NE intake was higher in group D than in groups M and C (1,708, 1,398 and 1,428 MJ NE/sow, $P<0.001$) and associated to a lower MT loss (-4.1, -9.9 and -8.6 mm, respectively, $P=0.007$) but no difference in BW loss (-38, -40 and -43 kg, $P=0.41$) and BT loss (-4.1, -4.8 and -4.7 mm, $P=0.34$). In conclusion, these results demonstrate that a low thermogenic diet can help to increase NE intake when sows are exposed to heat waves and chronic heat stress, while changing the meal delivery increases feed intake only under heat waves. More data are expected under heat waves to characterize more precisely the interest of alternative feeding strategies on maternal body reserves and piglets.

Theatre 9

Effect of comfort and enrichment for pregnant sows on the health and resilience of their offspringM. Lagoda^{1,2}, K. O'Driscoll², M. Galli³, J. Cerón⁴, A. Ortín-Bustillo⁴, J. Marchewka¹ and L. Boyle²¹Institute of Genetics and Animal Biotechnology, Dept of Animal Behaviour, Jastrzębiec, 05-552, Poland, ²Teagasc, Pig Development Dept, Fermoy, P61 P302, Ireland, ³University of Padova, Legnaro, 35020, Italy, ⁴Interdisciplinary Laboratory of Clinical Analysis, University of Murcia, Murcia, 30100, Spain; laura.boyle@teagasc.ie

Poor welfare experienced by pregnant sows has negative effects on piglet health mediated by prenatal stress. We compared sow welfare in 2 gestation housing systems (improved, IMP; conventional, CON) and investigated whether improvements to housing would benefit piglet health. Sows were mixed into 12 stable groups (6 groups/treatment, 20 sows/group) 29 d post-service in pens with 20 free-access, full-length stalls. CON pens had fully-slatted concrete floors, with 2 blocks of wood and 2 chains in the group area. IMP pens were the same but with rubber mats and 1 m of rope in each stall, and straw in 3 racks in the group area. Saliva was collected from each sow on d80 of pregnancy and analysed for haptoglobin (Hp). Tear stains (TS) on sows' right and left eyes were scored in mid-lactation and at weaning. Reproductive performance measures included number of piglets born alive, dead or mummified, and total number of piglets born. Piglets were weighed, scored for vitality and intrauterine growth retardation (IUGR) at birth. Presence of scour in farrowing crates was scored every 2nd day during lactation, and scores were summed to give a total score per litter/sow during lactation. Sows in IMP pens had lower Hp (CON 672 ± 54.0 , IMP 463 ± 54.1 ; $P=0.007$) and TS scores during lactation ($P<0.05$), and had fewer mummified piglets than CON sows (CON 0.4 ± 0.06 , IMP 0.2 ± 0.04 ; $P=0.013$). Piglets of IMP sows had lower IUGR scores ($P=0.006$) and scoured less (CON 5.4 ± 0.2 , IMP 3.7 ± 0.2 ; $P<0.001$) during the suckling period. Improved housing during pregnancy led to less stressed sows with less inflammation. In turn their offspring were better developed at birth and healthier during the suckling period. Improvements in reproductive performance (fewer mummified piglets) were significant but small, and though arguably not relevant biologically, should be confirmed using larger numbers. Such benefits offer incentives to producers to improve sow welfare during pregnancy.

Use of organic nest-building material in free-farrowing pens with short term fixationJ. Wahnhoff¹, N. Kemper², A. Van Asten³ and I. Traulsen¹¹Georg-August-University, Department of Animal Sciences, Albrecht-Thaer-Weg 3, 37075 Goettingen, Germany, ²University of Veterinary Medicine Hannover, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany, ³Chamber of Agriculture of North Rhine-Westphalia, Centre for Agriculture Haus Düsse, Ostinghausen, 59505 Bad Sassendorf, Germany; johann.wahnhoff@uni-goettingen.de

The aim of this study was to investigate the use of organic nest-building material on a commercial sow farm in relation to piglet crushing and animal behaviour. The study was carried out on a farm in Northern Germany where farrowing systems with a short-term fixation (2 days a.p. until approx. day 7 p.p.) and a pen area of 7.0 m² were installed. In up to now 3 out of 12 planned batches, the sows were provided with hay (n=29) or straw (n=29) as nest-building material within a permanently accessible rack from gestation day 112 until birth. Jute bags were offered in the control pens (n=24). Sows got up to 240 g of material per day (120 g in the morning and 120 g in the afternoon if needed). To determine daily intake, the residues in the racks were reweighed each morning. In addition, crushed piglets were documented daily until day 3 p.p. and at the end of each batch. Focal animals were videotaped. Results showed that on day 3 a.p., the intake of straw (112.7±71.7 g) tended to be higher than the intake of hay (93.4±98.4 g), but no significant difference was detected ($P=0.201$). On day 1 a.p., the intake of hay (144.1±94.54 g) and straw (143.3±86.5) was very similar ($P=0.65$). Based on the high standard deviations, a clear animal-specific effect was identified. Independently of the material, the intake of nest-building material tended to increase towards time of birth ($P=0.065$), based on nest-building behaviour. First results on the number of crushed piglets showed no significant difference between the various materials (jute bags: 5.65%, hay: 7.14%, straw: 7.05%). This work is funded by the German Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE; grant number 28N305602).

Session 11

Theatre 11

Welfare of group-housed sows in the mating areaS. Geisler¹, A. Van Asten², N. Kemper³ and I. Traulsen¹¹Georg-August-University, Department of Animal Sciences, Albrecht-Thaer-Weg 3, 37075 Goettingen, Germany, ²Chamber of Agriculture of North Rhine-Westphalia, Centre for Agriculture Haus Düsse, Ostinghausen, 59505 Bad Sassendorf, Germany, ³University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour, Bischofsholer Damm 15, 30173 Hannover, Germany; swantje.geisler@uni-goettingen.de

Legislative adjustments by the German government are leading to changes in housing conditions for sows in oestrus, requiring a group housing system with short-term fixation and a space allowance of 5 m²/animal. To assess how sows cope with the modified housing conditions a skin lesion assessment was conducted on two German commercial sow farms that already comply with the new legislative standards. The applied skin lesion assessment, used as an indicator of welfare, was based on the Welfare Quality® assessment for pigs. Skin lesions were recorded three times (day 0, day 2 and day 6/7 after weaning) for each sow (farm A n=205, farm B n=127) in three body areas (front, middle, back) on a scale from a (no/low extent of lesions) to d (very high extent of lesions). A total skin score (TS) was calculated from the individual body area scores on a scale from 0 (low extent) to 2 (high extent). Performance and fertility data were also collected (farm A n=152, farm B n=38). Binary logistic regression was used to investigate the association between skin lesions and insemination success (0-1). On both farms, a significant effect of the recording day on TS was determined ($P<0.001$). On farm A, a significant increase in the frequency of higher TS was observed between day 0 and day 2 and between day 2 and day 7 ($P<0.001$), whereas on farm B only a significant increase between day 0 and day 2 was detected ($P<0.001$). No effect of the skin lesions on the insemination success could be detected. In conclusion, these first results suggest that group housing may affect the magnitude and severity of skin lesions. To improve welfare in group-housing systems, focusing on the management of the social cohabitation could be a control element.

Current knowledge and ways forward to improve welfare of cull sows during transport and in lairage

C. Kobek-Kjeldager¹, L.D. Jensen¹, L. Foldager^{1,2}, L.M. Gould¹, K. Thodberg¹, D.L. Schrøder-Petersen³ and M.S. Herskin¹

¹Aarhus University, Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, ²Aarhus University, Bioinformatics Research Centre, Universitetsbyen 81, 8000 Aarhus, Denmark, ³DMRI, Danish Technological Institute, Gregersensvej 9, 2630 Taastrup, Denmark; cecilie.kobek-kjeldager@anivet.au.dk

Across Europe, annual culling rates per sow herd of ~50% means that millions of sows are sent to slaughter each year, while there is a knowledge gap on the welfare of this distinct category of swine according to a recent EFSA Scientific Opinion. In two studies, we investigated effects of journey duration and temperature inside vehicles transporting sows to slaughter on the behaviour during transport and in lairage. In the first experimental study, behaviour was observed during transport of 28 loads of sows in a 3×2 factorial design of journey duration (4 h, 6 h, 8 h), and with or without a pre-planned stop halfway (±Stop). In the second observational study, sows from 23 commercial loads with varying journey duration were observed 1 h in lairage. During transport, sows were upright 89-92% (median) of observations/hour; more in the first hour after departure and less when temperature was higher ($P<0.05$). With a longer latency until the stop, less sows were upright during the stop ($P<0.05$). The median events of aggression were 2-3/sow for each duration (0-155). No differences were detected during stop and immediately before or after. Time since departure and temperature in the vehicle had no influence on aggression. In lairage, most sows were active at first, decreasing to 30-46% after ~30 min. Drinking was observed in 36% of the sows. Aggression was initiated by 36% and received by 72%. After short journeys, the level of aggression was higher with increasing temperature, while after long journeys more lying and less aggression and drinking was observed when temperature was higher ($P<0.05$). Reduced aggression can be interpreted as positive for welfare but also as a sign of fatigue when newly mixed sows do not fight. Overall, the results indicate that the welfare of sows during transport and lairage may be challenged by mixing and resting problems. Physiological and motivational indicators are needed to clarify this. Recommendations on ways forward will be presented.

Theatre 13

Exposure times and stunning effectiveness for argon and nitrogen-argon mixture for pigs at slaughter

J. Knöll¹, J. Gelhausen², T. Friehs², T. Krebs², D. Mörlein², J. Tetens² and I. Wilk¹

¹Friedrich-Loeffler-Institute, Institute of Animal Welfare and Animal Husbandry, Dörnbergstr. 25/27, 29223 Celle, Germany,

²Georg-August-Universität Göttingen, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany; jonas.knoell@fli.de

Despite concerns over its aversiveness, stunning of pigs at the time of slaughter using a high concentration of CO₂ is the most common method in Europe. Inert gases and mixtures of inert gases with low concentration of CO₂ have been proposed as an alternative, but have so far not been considered market-ready due to concerns of gas stability, meat quality, costs and stunning effectiveness. As part of the project for Testing Inert Gases in order to Establish Replacements for high concentration CO₂ stunning for pigs at the time of slaughter (TIGER), experiments were conducted in a commercial Dip-Lift system using a new gassing system, which allowed for residual oxygen concentrations <1%. Pigs were stunned and slaughtered using argon, a nitrogen-argon mixture or high concentrations of CO₂ (control). Stunning effectiveness was closely monitored by checking reflexes, stimulus-response tests and signs of breathing activity (e.g. gasping) for at least three minutes after ejection from the stunning system. Exposure time was dynamically adjusted for each gas mixture using an adaptive staircase procedure in 10 s steps. Initially, exposure time was reduced for every two successfully stunned animals. With each insufficiently stunned animal, exposure time was increased and the number of successfully stunned animals needed for the next reduction was doubled up to a maximum of 200. Using a probit model, exposure times to reach a likelihood of insufficient stuns of <0.5% were estimated. Exposure times in the adaptive method reached more than 4 minutes for both inert gas atmospheres. Stun failures were typically well predicted by the onset of gasping or other obvious signs like a righting reflex. Sufficiently stunned animals typically did not show any breathing activity. We conclude that, while longer exposure times were needed for inert gas atmospheres compared to CO₂ in high concentrations, safe levels for stunning can be reached, with a potentially easy assessment of insufficient stuns based on onset of gasping or righting reflex.

Stability of performance in sows switching between crate and pen from one parity to the nextL. Canario¹, J. Bailly², S. Reignier², M. Poupin², Y. Billon² and W. Hébrard²¹INRAE, Animal Genetics, GenPhySE, 31326 Castanet-Tolosan, France, ²INRAE, UE GenESI, 17700 Surgères, France; laurianne.canario@inrae.fr

Maintaining sows on farm longer contributes to the sustainability of pig production. As guidelines for limiting the use of heavy restraint systems are being developed, another difficulty is to produce piglets at an economically viable level in different housing systems. We set a protocol to characterise a population of Large White sows in a conventional farm equipped with 2 types of farrowing units, with either farrowing crates or individual pens. The aim was to analyse the stability of individual performance in the face of repeated changes of environment. Sows switched from 100% blocked (B) to 100% free (F) – or the opposite – from one parity to the next. Performance of their purebred litters was recorded over the 4 or 5 first parities, with 44 sows alternating as per B1F2B3F4 (number is parity) and 23 sows alternating as per B1B2F3B4F5. The ideal sow is one that maintain a high and stable production level in successive litters regardless of the restraint system. Piglet survival and growth, and maternal ability traits were recorded. Crossfostering was implemented 24 h after farrowing according to the number of functional teats. Models for analysis included the fixed effect of parity, and the random effects of sow identity and farrowing batch. On average, in the B1F2B3F4 sows, number of piglets born alive was similar in B1 and F2 (14.4 and 14.8), increased in B3 (16.6; $P < 0.05$) and was 15.6 in F4. The piglet survival rate until weaning was lower in F4 than previous parities (71 vs 80%). The B1B2F3B4F5 sows had similar litter size across parities (14.8) and lower piglet survival rate in F5 than previous parities (62 vs 81%). More piglet crushing occurred in the latest parity. Variation in other traits is under study. Next, groups of sows with highest and lowest variations were identified according to CV values. Finally, the effect of physical enrichment was evaluated in the entire population, considering the mean change of performance from B to F of each sow. Some sows less sensitive than others to change of environment were identified.

Session 12

Theatre 1

Preliminary results on the use of weather data to predict production output in a Merino flockP.G. Theron¹, T.S. Brand^{1,2}, S.W.P. Cloete¹ and K. Dzama¹¹University of Stellenbosch, Animal Sciences, Private Bag X1, Matieland, 7600, Stellenbosch, South Africa, ²Western Cape Department of Agriculture, Directorate: Animal Sciences, 80 Muldersvlei Road, 7600, Stellenbosch, South Africa; pieter.theron@westerncape.gov.za

Extensive small ruminant production systems globally are under threat from climate change and associated changes in weather patterns but little information on the precise relationship between production traits and weather conditions is available. This study aimed to explore the use of weather data as input factors in predictive models for flock production. Weather and (re)production data recorded between 1993 and 2021 on Elsenburg Research Farm were used. Multiple linear regressions were used to relate production traits in two Merino lines divergently selected for number of lambs weaned (NLW) to climate data. Climate data included maximum and minimum temperatures, rainfall, maximum and minimum relative humidity as well as temperature-humidity indices for both day- and night-time. Weather data from the preceding year (y-1) was related to production data from year y to allow for the effect of a full years' weather patterns on production to be studied. Approximately a third of the variation in ewe reproductive performance (conception, lambing and multiple birth rate) in both lines was accounted for by the fitting of multivariate models. Thus producers could experience year-to-year fluctuations in production of more than 30% even when the same management program is applied. Weaning performance was also modelled successfully in the line selected for NLW. Average weaning weight was mainly determined by rainfall. Overall it seemed that weather played a greater role in influencing production in the line selected against NLW, potentially due to the lower genetic reproductive capacity. The study provides empirical evidence of the effect of weather on production output. The models could potentially be used to estimate climate change impacts on production output in extensive sheep farming systems. More work needs to be done to refine the models and elucidate relationships between the various weather parameters and production traits in different environments.

GIS-based data integration system as a design tool for rangeland management in productive landscapes

M. Odintsov Vaintrub, M. Bianchini, L. Lizzi, F. Paciocco, M. Francioni and P. D'Ottavio

Universita Politecnica delle Marche, Agriculture, Piazza Roma, 22, Ancona, 60121, Italy; m.odintsov.vaintrub@gmail.com

'Productive landscape' is a management system used in protected areas (e.g. national parks, and nature reserves) to integrate complex local dynamics. The 'Monte Genzana' Special Areas of Conservation (SAC, IT7110100) is one such area that includes 3 main municipalities (58 km² total) each with its own grazing areas for privately own livestock (horses, cattle and sheep). The current work aims to provide a GIS-based expert system to design conservation management strategies for the rangeland productive landscapes of Monte Genzana. Land existing databases (i.e. topographic, geological, soil) were collected and integrated with rangeland biodiversity and livestock management data in a multi-layer geographic information system (QGIS). The dataset was analysed by creating a 10×10 m grid to obtain a map of pastoral value (PV: 0-100) and potential carrying capacity (PCC, expressed in LU/ha/grazing period). Traditional methods of planning (i.e. planimetric area corrected by the average slope) were also implemented. The resulting PCC was compared with the recorded actual stocking rate (LU/ha). Additionally, on-site botanical surveys were performed in 12 sites to assess the impact of the vegetation dynamics on: (1) plant biodiversity conservation; (2) PV and PCC; and (3) land use change. A generalized understocking condition was recorded in most areas, with the PCC of both systems resulted to be similar (1-2% deviations). However, the 10×10 m grid assessment was significantly more reliable in detecting changes in land morphology and local under/over grazing. This was supported by vegetation dynamics observed by Satellite imagery (i.e. encroachment by shrubs and herbaceous species) and on-site botanical surveys which detected large grazing areas with standing dead biomass. In conclusion, the use of an integrated data approach, by using a multi-layer GIS combined with available real-time analysis can significantly reduce the margins for errors in pasture allocation. It can facilitate the monitoring of designated site-specific management strategies in complex environments of rangeland productive landscapes.

Session 12

Remotely monitored animal behaviour using sensor ear tags on cattle in Switzerland

K. Ueda¹, U. Heikkilä¹, N. Gobbo Oliveira Erünlü², J. Bérard², O. Wellnitz² and S. Rieder¹

¹Identitas AG, R&D, Stauffacherstrasse 130A, 3014 Bern, Switzerland, ²Agroscope, Animal Production Systems and Animal Health, Route de la Tioleyre 4, 1725 Posieux, Switzerland; kosuke.ueda@identitas.ch

Sensor ear tags (SET) serve for the identification, and localization, of individual animals and herds, but are also capable of delivering individual welfare and behavioural metrics. For remote summering pastures, a sound delineation of normal behaviour variations can be key to better identify potential responses to the presence of large predators. The present contribution is based on a comprehensive evaluation of a SET as identification and remote monitoring tool under Swiss conditions, regarding tolerance and technical feasibility, which has been reported elsewhere. Behaviour-related data were collected for two cattle groups under different settings, one a summer long stay on Alpine pastures, and one a mixed barn-pasture husbandry setting that is typical for low-land enterprises. The datasets contain metrics of individual activity and derived alerts for all settings. These were transmitted in an autonomous fashion over a satellite network. In addition, high-resolution raw data were downloaded over Bluetooth in and around the barn in the mixed husbandry setting. For the latter setting, data were both acquired with the SET fixed on the ear and on a collar, separately. Activities exhibit strong diurnal variation that likely reflects the circadian rhythm, for both settings. The pattern matches the distribution of alerts for very high activity. Behavioural metrics computed on the device correspond well to each other when comparing ear and collar fixation, except for the highest activity class, where frequent twitching of the ear in response to insects is suspected to contribute strong accelerations. Geographical location patterns also bear relevance to understanding and establishing herd behaviour baselines. Analyses on herd level behaviour potentially leverage the use of tags on larger herds and are reported separately. Here, a terrain-based time-space distribution survey is reported, in conjunction with weather and SET communication patterns. Analyses of sensor raw data deliver indications on nightly repositioning of individual cattle and establish a footprint of their sleep behaviour.

Differentiating feeding behaviour in grazing cattle based on IMU data and machine learning algorithmsN. Tilkens^{1,2}, A.L.H. Andriamandroso² and J. Bindelle^{1,3}¹University of Liège, AgricultureIsLife, TERRA, Passage des Déportés 2, 5030 Gembloux, Belgium, ²University of Lille, Junia, UMRT 1158 BioEcoAgro, 2 rue Norbert Ségard, 59800 Lille, France, ³University of Liège, Precision Livestock and Nutrition Unit, AgroBioChem, Passage des Déportés 2, 5030 Gembloux, Belgium; nicolas.tilkens@junia.com

A better understanding of the ecological mechanisms is key to empower agroecological approaches increasing the sustainability of grassland-based livestock systems. To do so, the first steps require to monitor how herbivores spend their time on pastures and identify the grazing movement from other types of unitary behaviours. A fine-level description of the time budget use by grazing animals could be enabled using precision livestock farming approaches combining wearable sensors to machine-learning algorithms. We equipped 9 dry red-pied Holstein cattle and 2 Blonde d'Aquitaine × Belgian White and Blue cross-bred with collar-mounted inertial measurement units (IMU) recording 3D accelerometer and gyroscope data at a 100 Hz frequency and set them to graze on ryegrass (*Lolium perenne*) pastures. We also shot 106 videos clips (average 28'07", standard deviation 4'38") to record the cows' behaviour focusing on the identification of grazing moments against other types of behaviours. Quadratic support vector machine (QSVM) and bagged tree (BT) algorithms were explored as Machine Learning classifiers to automatically detect the grazing moment in the time series. Four different time-windows were tested (3 and 5 seconds without overlap, and 10 and 30 seconds with 90% overlap) as well as two different splits of the datasets: split 1 was set to have different breed in the training and testing data, and split 2 was set for an equal representation of 'grazing' and 'other' behaviours in both training and testing data. Results show that for both splits BT algorithms gave the best results, with an accuracy of 91,8% using 5 seconds windows without overlap for split 1 and 94,0% using 30 seconds windows with 90% overlap for split 2. Finally, this paper will explore how the detection of grazing behaviour could be used in future works as a first step to quantify the amount and frequency of bites during each meal and at the scale of a grazing day.

Theatre 5

Monitoring animal movements by virtual fencing collars – a comparison of different GPS intervalsD. Hamidi¹, M. Komainda¹, N.A. Grinnell¹, F. Riesch^{1,2}, J. Horn¹, M. Hamidi¹, I. Traulsen³ and J. Isselstein^{1,2}¹University of Goettingen, Crop Sciences, Von-Siebold-Str. 8, 37075 Göttingen, Germany, ²University of Goettingen, Centre for Biodiversity and Sustainable Land Use, Büsgenweg 1, 37077 Göttingen, Germany, ³University of Goettingen, Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany; dina.hamidi@uni-goettingen.de

The grazing of farm animals, in particular access to pasture for cattle is an essential issue for the design of sustainable future livestock systems. Barriers to the implementation of grazing are the laborious tasks of ground-based-fencing on the one hand and, the difficulties associated with monitoring animals on pasture on the other hand. Using virtual fencing (VF) collars to enclose animals without physical fences can greatly simplify grazing, especially for more complex systems such as rotational grazing. Additionally, VF collars provide GPS data on animal locations, which can be used for calculating walking distances as an indicator to assess livestock vitality. High frequency GPS data from collared animals on pasture can provide continuous data for an improved animal monitoring. However, a lower frequency of GPS relocations reduces the energy demand and prolongs the working life of the precision livestock equipment. An open question regarding the performance of GPS tracking to monitor livestock behaviour is the setup of an appropriate frequency of recorded GPS positions as this likely affects the walking distances. To quantify the information loss using lower frequency data, we calculated the daily walking distances using 5, 10 and 15-min recording intervals, and compared them to the walking distances derived from one-minute data. The GPS recording was performed in a replicated rotational grazing trial with Fleckvieh heifers during 2021 using VF collars (Nofence®, Norway). An average reduction of 55% of the daily walking distances under a 15-min interval compared to a one-minute interval indicated a significant information loss. Moreover, walking distances calculated by using different time intervals differed significantly ($P < 0.0001$) (1 min: $2,984 \pm 54.8$; 5 min: $2,181 \pm 54.8$; 10 min: $1,658 \pm 54.8$; 15 min: $1,345 \pm 54.8$ (mean $\pm$ SE)). This is an obvious trade-off between battery life and the accuracy of monitoring cattle behaviour.

The impact of virtual fence use on blood markers linked to stress and acute phase response in cattle

J. Ranches¹, M. Ferreira¹, G.M.P. Hernandez¹, A.R. Santos¹, R.C. O'Connor², D. Johnson¹, D.W. Bohnert¹ and C. Boyd²

¹Oregon State University, Eastern Oregon Agricultural Research Center (EOARC), 67826-A Hwy 205, 97720, USA,

²USDA-ARS, Eastern Oregon Agricultural Research Center (EOARC), 67826-A Hwy 205, 97720, USA; juliana.ranches@oregonstate.edu

This study evaluated the effects of an automated virtual fence (VF) on blood markers associated with stress and inflammatory response in beef cattle. The automated VF employs auditory and electric stimuli to control cattle movement within a predefined virtual boundary, thus possibly raising concerns about cattle welfare. Forty mature Angus × Hereford cows were enrolled in this study. Cows enrolled in the study had never worn VF collars and therefore were considered naïve to the technology. All cows were equipped with VF collars on day 0 (d0). Body weight, body condition score, chute score, chute exit velocity, and blood samples were collected from all cows on d0. Upon collaring and collections, cows were moved to a drylot with predefined VF boundaries that were unknown to the cows. Cows remained in the pasture with VF boundaries for 4 consecutive days. Cows were brought to the working facility on d5 for a second round of collections as performed on d0. Cows were considered the experimental unit for this study, and all data were analysed using day as a repeated measure with the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC, USA). No effects ($P \geq 0.89$) were observed on body weight (595 and 594 kg, respectively for d0 and d5). Chute exit velocity changed ($P = 0.001$) from d0 to d5, with cows being slower on d5 (1.20 and 0.94 m/s, respectively). Blood samples were analysed for cortisol (COR), haptoglobin (HP), and ceruloplasmin (CP). No differences ($P \geq 0.11$) in blood COR (2.70 and 2.50 µg/dl, respectively for d0 and d5) or CP (28.3 and 29.3 mg/ml, respectively for d0 and d5) concentrations were observed from d0 to d5. However, HP concentration increased ($P < 0.0001$) from d0 to d5 (0.40 and 0.45 mg/ml, respectively). These findings suggest that brief exposure to VF boundaries and the associated stimuli does not have adverse effects on production traits. Moreover, COR concentration appears to remain unaffected by VF use. However, changes in HP concentration may indicate a mild inflammatory response, possibly attributable to local stimuli.

Theatre 7

Drones to facilitate the monitoring of grazing animal: which application and opportunities?

A. Lebreton¹, A. Demarbaix², F. Demarquet³, J. Douhay¹, P.-G. Grisot¹, L. Depuille¹ and E. Nicolas¹

¹Institut de l'Élevage, 149 Rue de Bercy, 75595 Paris, France, ²Ferm'Inov, La Prairie, 71250 Jalogny, France, ³EPLEFPA Carmejeane, Route d'Espinouse, 04510 Le Chaffaut-Saint-Jurson, France; adrien.lebreton@idele.fr

Drone technologies are becoming more and more accessible including for farmers. Many authors have seen the potential of drones to automate animal detection and counting. Others have focused on automating drone flights on rangelands. However, there is not much scientific or grey literature on the use and the impact of using 'off-the-shelf' drones on the current legal framework even if many challenges exist: choice of the technology, the understanding of the regulations and the risks, the safety for people and animals. We studied the use of drones as 'eyes in the sky' piloted by farmers themselves on different rangelands (meadows, woody rangelands, summer mountain rangelands). We first analysed the possible applications by crossing an analysis of European drone regulations, technologies performances and farmer's needs on sheep and beef cattle systems. Farmer's needs were recorded through an online survey (19 European farmers), interviews (4 farmers) and a survey during an on-farm demonstration (22 farmers and livestock industry stakeholders). It appears that livestock stakeholders appreciate drone technology, many would recommend it to others, and many could easily implement it on their farms. However, only a few are already equipped due to significant barriers to adoption: (1) most believe it is an unaffordable technology although some would take the risk of investing in it; (2) drones are considered not that easy to use. On-farm demonstrations seem to be an important lever for farmers to have a better understanding of the technologies and can be complemented by other training materials. Defining an applicable framework for the use of drones in grazing-based livestock farming was the first step of the ICAERUS project and will soon be communicated through guidelines and recommendations. Further works will assess risk and interest of using drones on the technical, economic, environmental, and social aspects with an important focus on the impact on the 'work dimensions' described by Hostiou and Fagon.

Modular communication gateways, a new opportunity for precision management of agroecological farms*M. Odintsov Vaintrub and P. Di Giuseppe**Regrowth s.r.l.s, Contrada specola (snc), 64100, Italy; m.odintsov.vaintrub@gmail.com*

Agroecology is a farming practice that works in conjunction with natural processes by emulating ecological nutrient dynamics. Agroecological producers usually cater to a niche market of high-value direct sales and clients that appreciate their ecosystem services and values. This makes the farmers particularly interested in technologies useful in showcasing their unique value proposition. However, the farming method presents particular challenges for technology adoption as it usually includes smaller numbers of animals, distributed in different plots frequently located in areas with minimal network coverage. In the current work, we evaluated the feasibility of using a unified data management and communication 'gateway' as a modular solution to address some of the challenges. A custom ESP32 board was used for the initial screening and analysis of data collected with a LoRa receiver from various on-field nodes. The data was then stored both physically on a local removable SD support and on a cloud server via GSM/Satellite communication. This field unit also included its own energy supply (5-12V solar panels and battery modules) and energy efficiency methods were implemented to increase overall resilience. The total costs of the gateway amounted to roughly 100€, with a monthly cost of another 20€/farm. During 2020-2023, three independent trials were conducted in diversified farm settings. In all trials, the gateway was installed where network coverage was unavailable, and managed 3-12 Walk-over-Weight stations at a time. For periods of 30-60 days, the gateway was able to provide a consistent connection with only occasional failure of the external casing. Integration of additional data sources such as VR alarms was also supported by the gateway, with direct streaming activation on demand with a lag time of 5-10 sec. In conclusion, the installation of an affordable and reliable communication system is feasible with the currently available components. It facilitates the installation of IoT systems needed for PLF data collection, significantly reducing the challenges each of them would have faced independently. This modular approach is particularly adapted for the small number, and high diversity typical to agroecological livestock production.

Session 12

Theatre 9

Deploying a LoRa network in mountainous areas to connect animals and shepherds*T. Kriszt¹, O. Benoit², G. Besche², J.D. Guyonneau², E. González-García¹ and J.B. Menassol¹**¹SELMET, L'Institut Agro Montpellier, CIRAD, INRAE, Univ Montpellier, 34000, Montpellier, France, ²SELMET, INRAE, CIRAD, L'Institut Agro Montpellier, Univ Montpellier, 13300, Salon-de-Provence, France; theo.kriszt@supagro.fr*

In remote and mountainous areas, the heterogenous and often low quality of the mobile network limits the potential for the introduction of digital technologies requiring connected services for the shepherds or digital tools to monitor livestock movements and activities. Consequently, few digital solutions exist despite numerous possible applications associated for instance with real-time monitoring of the animals (recovery of animals, predator alerts, etc.). As an alternative, we tested the deployment of a LoRa network in the French Alps during the summer period when animals are grazing in altitude. The test area consisted in the summer pasture (from June to September) for one flock (Institut Agro Domaine du Merle) of roughly 1000 sheep guarded by one shepherd and covering 5.77 km² (2,109 and 1,505 m of highest and lowest altitudes, respectively). Two LoRa gateways were deployed on pre-determined sites at an altitude of 2,049 and 2,006 meters for GATE-1 and GATE-2 respectively, using the Longley Rice Irregular Terrain Model (ITM) to predict radio coverage given the existing mobile network quality. Each gateway was fitted on a mast of up to 16 metres in height and was powered by a battery and a solar panel to meet the energy requirements for the whole monitoring period. LoRa connectivity was tested based on a virtual grid of 400 m squares. At each vertex (n=57), GNSS modules designed to be embarked on animals were used to transmit their current position through LoRa. Data on network connectivity showed that both GATE-1 and GATE-2 provided a coverage in accordance with the ITM simulation. In our conditions, LoRa network proved to be resilient to highly uneven terrain and showed overall great performances. The coverage simulation allowed to accurately plan the deployment of the gateways and prevented unnecessary on-site efforts. In order to ensure connectivity for animal and human applications at reduced costs, since one gateway can relay on the internet the communications from a large number of low-cost devices, the LoRa network proves to be a good alternative.

Effect of successive drone herding on behaviour and spatial distribution of grazing cattle*H. Anzai and M. Kumaishi**University of Miyazaki, Faculty of Agriculture, 1-1 Gakuen Kibanadai Nishi, Miyazaki, 889-2192, Japan; anzai.hiroki@gmail.com*

Robotic herding is attracting attention as a new technology for managing grazing animals. We investigated the behavioural responses of cows to drone herding over consecutive days and its performance in manipulating grazing distribution in a pasture. A herd of approximately 30 cows was stocked in a 1.1-ha pasture for 5 consecutive days each month from May to October 2022. The cows were herded by a drone for 10 days during the grazing period in August and September. The pasture was divided into nine plots, with two plots assigned as the herding area in August and three plots in September. When the cows grazed in the herding area, the operator manoeuvred the drone to move them out of the area. The drone was first approached at an altitude of 10 m, and if the cows did not move away, the altitude was gradually lowered to 3 m. The behavioural responses to the drone, the success or failure of the herding (whether cows exited the area or not), and the altitude of the drone were classified based on videos recorded during herding. The behaviour and location of the cows were observed during the time in the pasture. Utilization rates (percentage of grazing time) of the plots were calculated to evaluate the effect of herding. On the first and second days of the herding, the cows responded in 59 and 46% of the cases. On the first day, cows were startled in 23% of responses. From the first to the third day, the herding was successful in 51-75% of cases. However, these percentages declined thereafter. Both when the cows responded to the drone and exited the area, the drone altitude was most frequently 3-4 m, the lowest altitude. On the first day, the utilization rate of the herding area was about half of that on the days without herding. It increased from the second day, and the effect of herding almost disappeared from the third day onward. These findings suggest that cows were not afraid of an approaching drone after one day, but that subsequent habituation also reduced the desired behavioural responses in manipulating grazing distribution. Further studies are warranted to determine the stimuli that persistently elicit the desired responses.

Session 12

Poster 11

Evaluation of the RumiWatchSystem to measure activity and grazing behaviour of sheep*E. Dunne, N. McHugh and F.M. McGovern**Teagasc, Animal & Grassland, Teagasc, H65R718, Ireland; eoin.dunne@teagasc.ie*

Animal health and performance are highly influenced by feeding behaviour. The RumiWatchSystem provides an opportunity to quantify grazing practices in livestock farming. Data collected gives potential to optimize grazing practices and make informed management decisions; thus improving animal welfare and increasing the sustainability and efficiency of grazing operations. The objective of this experiment was to evaluate the RumiWatchSystem in comparison to visual observations on animal activity and grazing behaviour. A total of 12 animals were monitored for a total of 6 hours each on two separate occasions. Minute by minute observations were carried out whereby grazing, rumination, eating and other behaviours of the sheep were recorded at pasture by both the RumiWatchSystem sensors and the two observers. The final dataset contained 121 unique 1-minute measurement time points per animal per measurement, providing a dataset of 8,704 unique time point measurements. Analysis were undertaken to compare the RumiWatch System observations to the visual observations. Results showed that the percentage of agreement between the RumiWatchSystem and the visual observations was 87.33%. Strong correlations were also observed between the RumiWatchSystem sensor and visual observations, with a Spearman's rank and concordance correlation coefficient of 0.90 and 0.87, respectively ($P < 0.001$). Almost perfect agreement was calculated between the visual observations and the RumiWatchSystem based on the Cohens kappa value of 0.81; with a bias value of 0.08 between both methods. These results indicate a strong relationship between the visual observations and the RumiWatchSystem sensor technology in activity and grazing behaviours of sheep in a pasture based system, enabling further research using this technology to optimise sheep grazing performance, animal health and welfare.

Remote monitoring of cattle using sensor ear tags

K. Ueda¹, T. Kuntzer¹, U. Heikkilä¹, N. Gobbo Oliveira Erünlü², J. Bérard², C. Beglinger¹, O. Wellnitz² and S. Rieder¹
¹Identitas AG, R&D, Stauffacherstrasse 130A, 3014 Bern, Switzerland, ²Agroscope, Animal Production Systems and Animal Health, Rte de la Tioleyre 4, 1725 Posieux, Switzerland; kosuke.ueda@identitas.ch

The remote monitoring of animals by means of digital instruments is gaining in importance. This is due, i.e., to evolving production systems, due to structural developments in agriculture, such as ever larger farms and rising costs for personnel, or simply the lack of qualified personnel. On the other hand, digital 'shepherds' collect data on a 24/7 basis. Remote monitoring of individual animals and herds can lead to early insights that would otherwise remain hidden to livestock keepers. In the present study, a sensor ear tag (SET) was used and evaluated for remote monitoring of cattle under Swiss livestock management conditions. The tolerance of the SET regarding animal welfare as well as the suitability of the technology, data acquisition and processing were the focus of the investigation. A SET seems to be particularly attractive for remote monitoring because it is presumably able to combine the mandatory animal identification of cloven-hoofed animals with information obtained directly from the animal. The findings show that the SET in its present form, fixation and placement is not yet suitable for animal identification in Switzerland. Alternatively, the SET was fixed to a neck collar to continue data acquisition via three independent data channels (SATCOM, Bluetooth, RFID). Information was derived, i.e. on animal locations and movements, animal behaviour (daily rhythmicity), and land use. Combining SET data and satellite images, the effect of grazing and draught during summer 2022 was traced. During the winter half-year, or while animals are housed, the energy level of the SET battery, powered by solar panels, showed a rather low level. Hardly any data packages via SATCOM were received when animals were kept indoors. However, the data stream via Bluetooth was maintained throughout. RFID turned out to be a secure, albeit static, data source depending heavily on the placement of antennas. During summering, data flow was exclusively upheld via SATCOM, without additional infrastructure needed. The latter makes the SET particularly attractive for remote monitoring of livestock in pasture-based production systems.

Session 13

Theatre 1

Update on sensor technologies for performance recording, management and welfare in small ruminants

G. Caja¹, A. Elhadi¹, E. González², J.B. Menassol², G. Tessnière³, V. Giovanetti⁴, M. Decandia⁴, M. Acciaro⁴, E.M. Sossidou⁵, S.I. Patsios⁵, L.T. Csiszter⁶, L. Grova⁷, G.H.M. Jorgensen⁷, I. Halachmi⁸, A.B. Shamai⁸, T.W.J. Keady⁹, C.M. Dwyer¹⁰, T. Waterhouse¹⁰, A. McLaren¹⁰ and C. Morgan-Davis¹⁰

¹UAB, G2R, 08193 Bellaterra, Spain, ²INRAE, SELMET, 34060 Montpellier, France, ³IDELE, CS 52637, 31321 Castanet-Tolosan, France, ⁴Agris, Sardegna, 07100 Sassari, Italy, ⁵ELGO, Dimitra, 57001 Thessaloniki, Greece, ⁶BUAS, BFAR, 300645 Timisoara, Romania, ⁷NIBIO, Wildlife and Rangelands, 6630 Tingvoll, Norway, ⁸ARO, PLF lab, 7505101 Rishon Lezion, Israel, ⁹Teagasc, Athenry, Galway H65 R718, Ireland, ¹⁰SRUC, Kirkton, Crianlarich FK20 8RU, United Kingdom; gerardo.caja@uab.cat

Small ruminants (SR) are numerous livestock species with a low uptake of modern technologies. In the EU, most SR are electronically identified with transponders, which is a key opportunity for the implementation of sensors for PLF. Compared to transponders, which send fixed outputs, sensors send variable signals according to the type and intensity of the input. In practice, sensors are classified as non-wearable and wearable. Among them, their use for: behaviour, animal tracking, virtual fencing, automated weighing, performance recording and health problems detection (lameness, mortality, etc.), with special attention to early warning systems, will be analysed in SR. The study of sensors for SR welfare monitoring is the main aim of the Project TechCare (<https://techcare-project.eu/>), currently in progress. Advanced results showed that prioritization (by experts and stakeholders) of welfare problems throughout the value chain of SR, varies according to countries, productive purposes and production systems (meat and dairy sheep, dairy goats, suckling and fattening lambs/kids). The tools of interest for the detection of welfare problems were also prioritized and are currently under evaluation to be implemented in large scale trials in commercial farms. Stakeholders showed positive interest on PLF uses in SR and wearable sensors seem to be the ideal solution for animal-based indicators, although non-wearable sensors may be an option of interest in large farms due to their cost-benefit. Further research is needed to support the current opportunities of using sensors in SR. Funded by the EU H2020 program (Contract #862050).

P@stor-all: a spatialized information system for decision-making in extensive grazing systems

U. Kalenga Tshingomba^{1,2}, L. Sautot², M. Teisseire² and M. Jouven¹

¹Univ Montpellier, Institut Agro, CIRAD, INRAE, SELMET, 2 place Pierre Viala, 34060, France, ²Univ Montpellier, AgroParisTech, CIRAD, CNRS, INRAE, TETIS, 500 rue Jean-François Breton, 34090, France; lucile.sautot@agroparistech.fr

Agro-silvo-pastoralism is common in Mediterranean regions and provides multiple services. The sustainability of such systems depends on efficient utilization of rangelands. The latter requires good knowledge of the spatial behaviour of the flock, which can be documented with digital tools. The diversity of agro-silvo-pastoral systems complicates both data acquisition and processing, and has slowed down the uptake of precision farming. However, a variety of data is available to document the functioning of the pastoral ecosystem: free satellite data, GPS collars, meteorological data but also technical references in digital format and feedback from farmers. The objective of the P@stor-all project was to group such heterogeneous data in one single tool and combine it in order to provide knowledge and indicators for the improvement of grazing management. Designing such an information system (IS) required to find solutions to integrate structured and unstructured data and produce meaningful indicators for the farmers. A participatory approach was chosen: 7 farmers and 2 research farms representing a variety of systems were partners in the project and were associated in the discussions and decisions about the functionalities of the IS, the conceptual model of the pastoral ecosystem, the spatio-temporal resolution of data, the choice of indicators, the user interface and the terms of use of the IS. GPS collars were deployed in the farms and their data was cross-analysed with free satellite data in order to produce indicators of the spatial utilization of rangelands by the flocks. The proposed indicators were different for the commercial farms (1 commercial GPS collar to localize the flock in real time and record spatial behaviour), and for the research farms (up to 30 GPS collars to test the correlations between spatial behaviour, animal characteristics and environmental conditions). A first prototype of the P@stor-all IS will be tested and refined in spring and summer 2023; by the end of the year, the platform will be freely available to all French farmers.

Session 13

Theatre 3

Day and night sexual activity of rams as recorded by an automatic heat detector

M. Alhamada^{1,2}, E. González-García², N. Debus², A. Lurette², J.-B. Menassol³ and F. Bocquier³

¹Istom, 4 Rue Joseph Lakanal, Angers, 49000, France, ²SELMET, INRAE, CIRAD, L'Institut Agro Montpellier SupAgro, Univ Montpellier, 34000 Montpellier, Fr, 2 Place Viala, Montpellier, 3400, France, ³SELMET, L'Institut Agro Montpellier SupAgro, CIRAD, INRAE, Univ Montpellier, 34000 Montpellier, Fr, 2 Place Viala, Montpellier, 34000, France; moutaz.alhamada@hotmail.com

The objective was to analyse the day and night-time sexual behaviour of Mérinos d'Arles rams reared under extensive farming conditions. Eight rams were evaluated in their interaction with the ewes (ratio 1♂:40♀) during two consecutive years at the timing of the reproductive period from late April to early May. An automatic heat detection device, already validated in such conditions, was used to monitor the timing and number of mounts for each ram. Data were analysed within two distinct periods i.e. daytime 14 h (from 6 a.m. to 8 p.m.) and nighttime 10 h (from 8 p.m. to 6 a.m.). Means were compared using Tukey's HSD test. Results show that all rams kept a nocturnal sexual activity. The circadian rhythm of ram activity differed from one animal to another ($P < 0.05$). One ram displayed 11 ± 6 and 36 ± 25 mounts/h during the night and day, respectively (corresponding to 23 and 77% of its daily activity averaging 25 ± 18 mounts/h). Conversely, another ram displayed 65% of its activity during the night (13 ± 9 mounts/h). No correlation was observed between total daily and diurnal sexual activity ($P > 0.05$). Within a same year, the total mounting activity between rams was significantly different ($P < 0.001$) and ranged from 1.9 to 89.8 mounts/h. Between years, the total number of mounts for each ram was significantly different ($P < 0.01$) but this did not affect the ranking among rams based on this criteria (repeatability 83%; $P < 0.05$). Our results suggest that sheep, often classified as diurnal animals in their sexual behaviour, may display a significant nocturnal activity which must be taken into account. We can conclude that studying the animal only during the daytime may lead to a lack of information and/or efficiency in the management of reproduction. In this context, the automatic heat detector developed by our team may be an effective and easy-to-use alternative tool for studying ram reproduction behaviour.

Walking distance and maintenance energy requirements of sheep during mountain pasturing

T. Zanon, M. Gruber and M. Gauly

Free University of Bolzano, Piazza Università 5, 39100, Italy; thomas.zanon@unibz.it

Sheep pasturing has become an important means for landscape management and conservation in marginal areas of mountain regions by reducing succession with dwarf shrubs and bushes, thus creating space for valuable forage grasses. Furthermore, mountain sheep pasturing for meat production also contributes to local food security. However, little is known about the energetic expenditures of sheep during mountain pasturing, which is important information for optimizing the productivity and economic efficiency, environmental aspects (e.g. biodiversity) as well as animal welfare. Therefore, the aim of the following study was to estimate the maintenance energy requirements of ewes over the whole mountain pasturing period (transhumance) considering movement patterns assessed by using satellite-based Global Positioning System (GPS) tracking devices. Energy requirements for walking increased rapidly at the beginning of transhumance (May-June) (4.14-4.17 MJ/d), which could be explained by the longer walked distance and by overcoming variable altitude during that phase. Walking speed (2-8 m/min) was slower compared to previous findings due to the difficult terrain of mountain pastures on which sheep moved. Energy demand for walking was correlated with walking distance (0.45, $P<0.001$) and walking speed (0.26, $P<0.001$). Results out of this study contribute in promoting the efficiency and consequently the rentability of alpine sheep pasturing systems. The latter ensures the production of local food and further preserves the ecosystem services linked to this low-input production system.

Percutaneous liver biopsy obtention by ultrasonographic guidance in small ruminantsS. González-Luna^{1,2}, X. Moll³, S. Serhan², B. Chaalia², A.A.K. Salama², X. Such² and G. Caja²

¹Facultad de Estudios Superiores Cuautitlán, Universidad Nacional Autónoma de México, Departamento de Ciencias Pecuarias, Ctra. Cuautitlán-Teoloyucan km 2.5, 54714 Cuautitlán Izcalli, Mexico, ²Universitat Autònoma de Barcelona, Group of Research in Ruminants (G2R), Department of Animal and Food Sciences, Campus Universitari de la UAB, 08193 Bellaterra, Spain, ³Universitat Autònoma de Barcelona, Department of Animals, Medicine and Surgery, Campus Universitari de la UAB, 08193 Bellaterra, Spain; san_dy_sam@hotmail.com

Liver biopsies can provide relevant information about metabolism. However, there is no reference describing a biopsy technique for dairy small ruminants. The objective was to develop a liver biopsy procedure by ultrasonographic guidance for ewes and goats. A total of 20 Murciano-Granadina goats (42.4±1.3 kg BW) in mid lactation (141±4 DIM) and 10 Manchega ewes (68.6±1.2 kg BW) in late lactation (199±8 DIM) were used. Liver biopsies were obtained twice from each animal (6-wk interval) under aseptic conditions. Animals were sedated and placed in left lateral recumbency with previous right flank shaving (7th to 12th intercostal spaces) for local anaesthesia at the biopsy site. Semiautomatic VI Trucut type SuperCore 14G × 9 cm biopsy needles (Argon Medical Devices, Athens, TX) were used. Liver visualization and needle insertion was accomplished by real time B-mode ultrasonography with a convex C60/5-2 MHz transducer (SonoSite Ultrasound System, Vet180 Plus, Bothell, WA). Liver biopsies were snap frozen in liquid N, and stored at -80 °C. Time from antisepsis to stapling averaged 13±2 min in goats and ewes. Milk yield before biopsy averaged 1.78±0.08 in goats and 0.59±0.05 kg/d in ewes. Milk yield declined by 52% (-0.92±0.10 kg/d) the day after biopsy, but recovered after 4 d (1.75±0.09 kg/d) in goats, whereas milk decline was 57% (-0.34±0.05 kg/d) and they recovered after 7 d (0.56±0.09 kg/d) in ewes. The RNA concentration of biopsies averaged 1,313±102 and 246±52 ng/μl in goats and ewes, respectively. In conclusion, percutaneous liver biopsy obtention by ultrasonographic guidance is a recommendable technique that allowed a full recovery of milk production and to be suitable for RNA extraction and RNA-seq analyses in dairy small ruminants.

Modelling milk yields of New Zealand dairy goats undergoing normal and extended lactations*N. Lopez-Villalobos¹ and S.A. Turner²*¹Massey University, School of Agriculture and Environment, 4410 Palmerston North, New Zealand, ²Dairy Goat Co-operative, 18 Gallagher Drive, 3240 Hamilton, New Zealand; n.lopez-villalobos@massey.ac.nz

Daily milk yields from dairy goats, in a New Zealand herd, undergoing normal and extended lactations, were predicted using a random regression (RR) with 3rd and 5th order Legendre polynomials, respectively. Normal lactations were defined as those lactations with less than or equal to 305 days in milk. Extended lactations were defined as those lactations with more than 305 days, but less than 670 days in milk. Persistency of extended lactation was defined as $(B/A) \times 100$ where A was the accumulated yield from day 1 to 305 days and B was the accumulated yield from day 306 to the last day in milk (but only up to 670 days). The relative prediction errors between the actual and the predicted yields using RR were close to 10% and the concordance correlation coefficients were >0.92 indicating that the RR models with Legendre polynomials are an adequate technique to model the normal and extended lactation curves of daily milk yields for dairy goats. Average total milk production in normal and extended lactations were 1,183 kg and 2,473 kg respectively. Average persistency of extended lactation was 117%. Effects of parity were significant ($P < 0.01$) on both, 305-day and 670-day totals yields of milk. The average total milk yield of first-parity goats with a normal lactation was 946 kg while the average total milk yield of second-parity goats with a normal lactation was 1,284 kg, a total of 2,230 kg from the two normal lactations. The average total milk yield of first-parity goats with an extended lactation was 2,140 kg. Thus, on average, a goat with two normal lactations following the first- and second-parity produced 90 kg more milk than a first-parity goat did from an extended lactation. However, a second-parity goat produced 43 kg more milk from an extended lactation than the total milk produced by a goat with normal lactations following the second- and third-parity (2,639 kg vs 1,284 kg + 1,312 kg). These results indicate that the persistency of extended lactations is high and that goats subjected in a 670-day extended lactation will produce similar amounts of milk compared with goats subjected to two 305-day normal lactations.

Operational use of GPS collars for decision making by agro-silvo-pastoral farmers in Mediterranean areas*L. Sautot¹, I. Candela² and M. Joven²*¹AgroParisTech, UMR TETIS, 500 rue JF Breton, 34090 Montpellier, France, ²Institut Agro Montpellier, UMR SELMET, 2 Place Pierre Viala, 34060 Montpellier, France; luile.sautot@agroparistech.fr

In the last decade, GPS collars have increasingly been used in Mediterranean agro-silvo-pastoral farms, especially when animals graze unsupervised in large surface areas of rangeland, with or without fences. Farmers' interest is mainly to reduce the time spent finding and gathering the animals and eventually to identify off-limit behaviours or predation. However, GPS tracks can be analysed further and provide additional useful information. In the P@stor-all project, we explored ways to exploit the tracks recorded with GPS collars to provide operational indicators for decision making in pastoral contexts. Our main objective was to describe the spatial behaviour of the flock in terms of both occupation of the rangeland and grazing effort for the animals. The indicators should interest the farmers and be suited to 'real life' conditions. Seven farmers participated in the P@stor-all project, representing a variety of agro-silvo-pastoral systems and were trusted with a GPS collar, to be deployed in their flock. The frequency of data acquisition was set at 5 min, in order to strike a balance between the accuracy of data acquisition and the feasibility of recharging the batteries. The GPS tracks were recorded in various seasons, grazing conditions and locations. Based on the characteristics of the collected data and the associated free satellite data, but also on repeated interviews with the farmers, we proposed and calibrated a set of 7 indicators: area explored by the flock, occupation density, daily distance covered by the flock, instant speed along the grazing route and daily total ascent. In the P@stor-all platform, each farmer may visualize these various indicators, together with basic information about calculation methods, sensitivity to the quality of GPS data, and suggestions of interpretation. A variety of indicators is needed to account for the diversity of grazing contexts: depending on the farm and season, different indicators might be meaningful to adjust grazing management. The absolute values and relative changes in each indicator also depend on local conditions, thus each farmer will need to build his own local references and make his own decisions.

AGRICYGEN: innovative phenotyping and high-throughput genotyping studies of Cyprus sheep and goats

G. Hadjipavlou, S. Andreou, T. Christofi, A.C. Dimitriou, A.N. Georgiou, L. Koniali, G. Maimaris, P. Markou and S. Panayidou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516 Lefkosia, Cyprus; ghadjipavlou@ari.moa.gov.cy

The Project AGRICYGEN (CYprus AGRicultural Genomics CENTre) has been fully supported by national funds since 2021 and is coordinated and run by the Agricultural Research Institute (ARI) in Cyprus. The project employs a unified approach, through genomics, to improve the productivity and sustainability of the whole system (animals, plants and microbes), and produce novel products, services and recommendations for improving livestock output, crops used for feed and soils cultivated for feed production. In addition, an Aid Scheme through the Cyprus Resilience and Reform Plan was approved for supporting new phenotyping technology implementation and genomic analyses of local Cyprus Chios sheep and Damascus goats in private farms, and has been initiated in 2022 (with funding from the EC-NextGenerationEU), under ARI coordination. The Scheme is connected with the AGRICYGEN research project and aims to upgrade the sheep and goat farming sector in Cyprus by granting targeted subsidies to sheep and/or goat breeders to achieve advanced recording practices on farm as well as ARI-led genetic and genomic evaluation services, improved reproductive and overall livestock and breeding unit management. The long-term goal for the implementation of both initiatives is to implement research outcomes to achieve advanced genetic improvement of an extensive number of sheep and goat animals by 2026 and concurrently a significant increase in farm productivity, mainly in terms of milk production. Research findings from the initial stages of project implementation, are promising and signify the importance of combining various technological approaches to promote the advancement of the Cyprus sheep and goat sector in semi-extensive Mediterranean systems, such as the one predominantly present in Cyprus.

Genetic improvement of milk production traits in the Cyprus Damascus goat population

S. Andreou, A.N. Georgiou, G. Maimaris, A. Dimitriou, L. Koniali and G. Hadjipavlou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516, Lefkosia, Cyprus; sandreou@ari.moa.gov.cy

Small ruminant breeding is of great financial and environmental importance around the world. The Damascus goat is of Syrian origin and was imported in Cyprus in early 20th century in order to increase milk and meat yield, and has since then been genetically improved and become a local breed. The Agricultural Research Institute (ARI) is the core research centre in Cyprus for ruminant genetic improvement. Currently, selection of high producing animals in Cyprus is achieved by combining pedigree information with selection indices and with the evaluation of phenotypes on growth rate in young animals and milk production capacity of their ancestors. Research efforts at the ARI Animal Production unit focus on advancing the genetic evaluation of the Cyprus sheep and goat populations under the AGRICYGEN project and Recovery and Resilience Plan (RRP) (NextGenerationEU). Therefore, within the present study, high-throughput genomic mapping techniques were used to pursue for the first time the implementation of genomic evaluations of milk production in Cyprus Damascus goats, combined with a primary investigation of possible genomic regions associated with high levels of milk yield. Records on 2,872 goats born between 2000 and 2022 have been collected and analysed, with the earliest milk quantity and quality information recorded in 2008. In addition, a pool of 891 goat DNA samples were genotyped with the GoatSNP65 BeadChip. Quality control analysis resulted in 55,772 informative SNPs. This is the first case study focusing on Cyprus goat population, exploring genome-wide associations (GWAS) with milk yield volume and quality traits of economic interest such as protein and fat content. In addition, implementation of genomic BLUP models enabled the calculation of individual genomic breeding value and hence more precise genetic improvement for milk quality and quantity in subsequent generations. This study will be further expanded to pursue genomic evaluations and GWAS of genomic and phenotypic data collected from private Cyprus Damascus goat flocks, as part of an Aid Scheme under the Cyprus Resilience and Recovery Plan, funded by the European Commission.

Genetic trends for test day milk yield in White Maritza and Patch-faced Maritza sheep breeds

P. Zhelyazkova and D. Dimov

Agricultural university, Animal sciences, 12, Mendelev blvd., 4000 Plovdiv, Bulgaria; angela_pp@abv.bg

Data from milk recording were used to analyse genetic trends of test day milk yields for White Maritza and Patch-faced Maritza sheep breeds in Bulgaria. Both breeds are native to the country and are subject to conservation and improvement through approved breeding programs. A total of 9,556 (White Maritza) and 22,029 (Patch-faced Maritza) test-day records gathered by the Breeding association of native Maritza sheep breeds for the period 1990-2020 were entered in the analyses. The respective pedigree data comprised 4,687 (White Maritza) and 3,961 (Patch-faced) records. Repeatability test day model was used to calculate the heritability and breeding value estimations for test day milk yield (TDMY) and also to estimate the fixed and random effects assumed to affect the TDMY, separately for each breed. The genetic trends of the two breeds were estimated by the weighted regression of the average breeding value estimations of the animals on the year of birth. The average values for the TDMYs in the total database of the White Maritza was 790.27 ml and in the Patch-faced Maritza population was 744.67 ml. The heritability estimates of TDMY were 0.29 ± 0.024 and 0.19 ± 0.045 respectively for the two breeds. In the population of White Maritza breed, the straight line of the genetic trend over the 30-year period was slightly positive, but in the population of Patch-faced Maritza breed was negative. Over the years the graphs show positive and negative fluctuations between generations. Distinctive cyclical patterns which reflected long-time variation in genetic trends of the two breeds were found. Explanations for the different tendencies of genetic trends are given and discussed.

Session 13

Theatre 11

Genetic and environmental effects on the survival and growth rates of Cyprus Chios lambs

T. Christofi, S. Panayidou, L. Koniali and G. Hadjipavlou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516, Lefkosia, Cyprus; tchristofi@ari.moa.gov.cy

The Chios sheep has been imported in Cyprus more than 60 years ago and, through genetic improvement, has been adapted to the environmental conditions of the island. It is the main commercial breed in Cyprus, both raised as pure-bred and in crossbreeding, as it is resilient and has high performance for both milk and meat production. Recent research efforts at the Agricultural Research Institute focus on employing genomic breeding methodologies to enhance productivity as well as to include additional traits in the selection objective, such as survival, reproductive success, longevity and others. Within this study, we utilized 16,864 individual lamb records of the Chios breed collected between 1989 and 2022 from the ARI Athalassa breeding nucleus, located in Nicosia district, Cyprus. Pedigree information was available for all animals with records and reproduction data were available for each dam. Lamb survival at various stages of lamb growth was recorded, in addition to pre and post weaning weights (birth, weaning, 90 days). Heritability estimates and coefficient of variation for maternal (litter size born/reared, litter size live, gestation length) and lamb (survival, rearing method, longitudinal weights) traits were estimated. In addition, for ewes with repeated parturitions, estimated breeding values predicted per animal regarding survival and growth were compared to observed breeding values. In addition, for lamb survival from birth to 3 months of age, analyses were conducted using regression/threshold animal models to estimate genetic and environmental effects. Moreover, various non-linear models were used to fit longitudinal weight data for the Chios breed. Besides phenotypic and pedigree data analyses, genomic analysis (GWAS) will also be pursued to dissect genetic associations with growth and survival traits.

Genetic and non-genetic factors affecting survival and growth of Cyprus Damascus goat kids

L. Koniali, S. Andreou, T. Christofi and G. Hadjipavlou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516, Lefkosia, Cyprus; lkoniali@ari.moa.gov.cy

Mortality among pre-weaned goat kids represents an important economic loss for farmers. A number of environmental and animal related parameters have been reported to contribute to neonatal mortality in different breeds and locations, with preliminary studies on Cyprus Damascus goats indicating the birth season, the length of gestation and the birth weight to significantly effect kid mortality both at birth and at weaning. Furthermore, maternal age was found to significantly affect neonatal mortality. In an effort to improve productivity of local goats and reduce reproductive losses, the present study aimed to examine both genetic and non-genetic factors affecting the survival and early growth of Cyprus Damascus goats from birth to weaning with a view to developing more effective genetic selection programs. Records on 5,692 Cyprus Damascus goats (2,756 female and 2,936 male) born between 2005 and 2021 were obtained from the Agricultural Research Institute's experimental farm, situated in the Nicosia district. Information of goat kids' gender, birth type (singleton vs twin vs triplet vs quadruplet), kidding season, live weights at birth (BW) and at weaning (WW), the rearing system used (natural suckling vs artificial feeding), lactation number of the dam (1-10) and weight (DW) and goat kids' survival at birth (day 0), at weaning (day 50) and post-weaning period (day 110) were extracted from the ARI database. Pedigree information was also available for all animals with records. The potential effect of early growth-related traits was analysed with the use of linear mixed models, whereas logistic and binomial analysis were performed for survival traits. In parallel, genome-wide association studies using medium-throughput SNP bead chip genotyping data of a second cohort of ARI kids are in progress to further assess genomic factors contributing to neonatal survival and growth potential of kids.

Session 13

Theatre 13

Feed restriction in dairy ewes decreases milk lipolysis and remodels the milk proteome and lipidomeM. Delosière¹, L. Bernard¹, C. Hurtaud², H. Larroque³, S. Emery¹, A. Delavaud¹, M. Taillandier¹, P. Le Faouder⁴, M. Bonnet¹ and C. Cebo⁵

¹Univ Clermont Auvergne, INRAE, VetAgro Sup, UMRHerbivores, St-Genès-Champanelle, 63122, France, ²INRAE, Institut Agro, PEGASE, Saint Gilles, 35590, France, ³Univ de Toulouse, INRAE, ENVT, GenPhySE, Castanet Tolosan, 31326, France, ⁴MetaboHUB-MetaToul-Lipidomique, MetaboHUB-ANR-11-INBS-0010, Inserm U1297/Univ Paul Sabatier Toulouse III, Toulouse, 31432, France, ⁵Univ Paris-Saclay, INRAE, AgroParisTech, GABI, Jouy-en-Josas, 78350, France; mylene.delosiere@inrae.fr

Milk lipolysis is defined as the hydrolysis of triglycerides, the main components of milk fat, resulting in the release of free fatty acids and partial glycerides that alter the taste and functional properties of the milk such as foaming and creaming abilities, respectively. Milk lipolysis is therefore an important criterion of milk quality. Feed restriction was used as a model to study milk spontaneous lipolysis (SL) and its mechanisms in three ruminant species (dairy cows, goats and ewes). The objective of this experiment in dairy ewes was to characterize the effects of dietary restriction on milk SL in relation with the milk proteome and lipidome. For this purpose, a subset of 2 groups of 10 ewes with contrasted milk lipolysis levels were selected from a larger experiment with 2 groups of 24 ewes (102±2.0 DIM) receiving for 5 days either a control diet (100% of DMI *ad libitum*: unrestricted) or the experimental diet (65% of DMI *ad libitum*: restricted) in a 2×2 cross-over design. The feeding restriction caused a large decrease in morning milk SL (-0.43 Meq/100 g of fat) measured by the BDI method, a decrease in milk yield (-0.43 l/d), an increase of milk fat and protein contents (+3.0 and +0.9 g/l) and no variation in milk fat globules diameter. This significant decrease in SL was accompanied by changes in the milk proteome and lipidome that are being studied in depth. In ewe's skim milk with low lipolysis, we displayed a protein inhibitor of the lipoprotein lipase gene expression and a list of proteins that signal an immune process. In conclusion, in contrast to cows, a large decrease of milk spontaneous lipolysis in dairy ewes was observed in response to feed restriction which was associated with substantial variations in milk protein and lipid abundances.

Garlic essential oil supplementation in sheep: effect on fermentation parameters

C. Saro^{1,2}, I. Mateos^{1,2}, F.J. Giráldez¹ and M.J. Ranilla^{1,2}

¹Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, s/n, 24346 Grulleros, Spain,

²Universidad de León, Campus Vegazana, s/n, 24071 León, Spain; cristina.saro@unileon.es

Garlic essential oil is an additive used to modulate ruminal fermentation. Most of the studies using this additive have been conducted *in vitro* but its effects on ruminal fermentation *in vivo* remain unelucidated. The aim of this trial was to evaluate the effects of garlic essential oil on volatile fatty acid (VFA) concentration and profile and ammonia concentration in the rumen of sheep. Eight non-lactating sheep were randomly divided into two groups and received a 50:50 forage:concentrate diet. One of the groups (GO) received daily through the rumen cannula 200 mg of garlic essential oil in two equal doses administered in the morning and in the evening. The other group received no additive (CON). Rumen fluid was collected before starting the administration of the additive and at 1, 2 and 3 days of treatment. At each sampling day rumen was collected before morning feeding and treatment (0 h) and 6 hours after administration of the diet (6 h). Samples were analysed to determine concentration of VFA and molar proportions of acetate, propionate, butyrate, isobutyrate, valerate, isovalerate and caproate by gas chromatography and ammonia concentration by a colorimetric technique. The results were analysed separately for 0 and 6 h. When comparing GO and CON sheep at 0 hours no effects of the additive were observed for total VFA concentration or ammonia concentration in rumen fluid. Concentration of valerate tended to be higher in GO sheep but the rest of the VFA profile was similar for both groups. However, when samples were taken 6 h after the administration of diet, no differences was observed in total VFA concentration, but concentrations of isobutyrate and isovalerate were lower and that of valerate tended to be lower in GO sheep. Ammonia concentration was also lower in GO sheep when rumen parameters were assessed 6 hours after feeding. Under the conditions of the present study, garlic essential oil affected ruminal fermentation, slightly modifying VFA profile and ammonia concentration.

Effect of garlic essential oil supplementation on rumen microbial community of sheep

I. Mateos^{1,2}, E. Mata-Nicolás^{1,2}, C. Saro^{1,2}, R. Li³, R. Baldwin³, F.J. Giráldez¹ and M.J. Ranilla^{1,2}

¹Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, s/n, 24346 Grulleros, Spain,

²Universidad de León, Campus Vegazana, s/n, 24071 León, Spain, ³USDAARS, Beltsville, MD, USA; mjrang@unileon.es

Garlic essential oil is an additive used to reduce methane emissions from ruminants presumably due to its broad antimicrobial activity. However, most of the studies have been conducted *in vitro*. The aim of this *in vivo* research was to evaluate the effects of garlic essential oil on microbial communities present in the rumen of sheep. Eight non-lactating sheep were randomly divided into two groups and received a 50:50 forage:concentrate diet. One of the groups (GO) received daily through the rumen cannula 200 mg of garlic essential oil and the other group received no additive (CON). Rumen fluid was collected before starting the treatment and at 1, 2 and 3 weeks of trial. DNA was extracted and bacterial and archaeal community were assessed by high throughput sequencing. The reads generated were processed using FROGS pipeline and the results were analysed using Phyloseq package in R. Shannon diversity index was unaffected by treatment when comparing GO and CON sheep, but it decreased in GO sheep after starting the treatment. When assessing beta-diversity, the principal component analysis showed that samples tended to group according to treatment, but a strongest effect of individual animal was observed. Similarly to alpha-diversity, the abundance of bacterial and archaeal phyla was similar between groups but it varied along the experimental period in treated sheep. Under the conditions of this study, garlic essential oil slightly modified the structure of the rumen bacterial and archaeal community of sheep.

High-precision scanning system for complete 3D goat udder and teat imaging and analysisG. Coquereau¹, P.G. Marnet², L. Delattre³, J.M. Delouard³ and P. Martin⁴¹Institut de l'Élevage, 2133 Rte de Chauvigny, 86550 Mignaloux-Beauvoir, France, ²Institut Agro Rennes-Angers, 65 Rue de Saint-Brieuc, 35042 Rennes, France, ³3D Ouest, 5 rue Louis de Broglie, 22300 Lannion, France, ⁴CapGènes, 2135 Rte de Chauvigny, 86550 Mignaloux-Beauvoir, France; gaelle.coquereau@idele.fr

Nowadays, udder scoring for goat udder phenotyping is made by specialized technician. They are trained to score 5 traits for the udder and 4 for teats. Only one trait, the teat length, is being measured. This work is done only once in the life of the goat and some farms have flocks exceeding 400 goats, so it can easily become a hard work. Recent works underlined a clear degradation of udder/teat shape with parity and an increasing proportion of morphological and functional unbalance of half udders. Thus, for a better genetic selection, we must increase the number and quality of quantitative udder traits measured throughout the productive lifespan of dairy goats. To achieve this goal, we aimed to design a 3D Scanner device to scan the entire udder and to produce high-definition numeric images. The device consists of a portable corridor cage in which the goat can enter freely. The size makes it easy to carry in a van. The goat is blocked for a few minutes while the images are taken and then released. We use 3 Intel Realsense depth D 455 cameras mounted on a mobile trolley situated 60 cm under and on the two sides of the cage and sliding from the front to the back of the animal in approximately 10 s. The D455 extends the distance between the depth sensors to 95 mm which improves the depth error to less than 2% at 4 m and an internal software allow an autocalibration that ensure better evaluation of distances. The image resolution is 1,280×800 pixels and real time scene capture could be done at up to 90 frames per second. The reconstruction of the 3D Image is done by a specific software from these 3 sources. The first prototype was tested and produced very accurate images. It is very promising for a close future usage for the Goat selection scheme.

Session 13

Poster 17

Asymmetric udder – a possible indicator of subclinical mastitis in ewesK. Tvarožková¹, V. Tančin^{1,2}, M. Oravcová², M. Uhrinčat², L. Mačuhová², B. Gancárová¹ and M. Ptáček³¹Slovak University of Agriculture in Nitra, Institute of Animal Husbandry, Tr. A. Hlinku 2, 94976, Nitra, Slovak Republic, ²NPPC – Research Institute for Animal Production Nitra, Hlohovecka 2, 951 41 Lužianky, Slovak Republic, ³Faculty of Agrobiolgy, Food & Natural Resources Czech Univ Life Sci Prague, Kamýčká 129, 165 00 Prague-Suchdol, Czech Republic; xtvarozkova@uniag.sk

Mastitis is one of the serious health and economic problem in dairy ewes farming and may adversely affect milk yield, its quality and increase the somatic cell count (SCC). The reduction of milk yield caused by mastitis could affect also half udder size. The aim of our study was to determine how asymmetric udder is related to the occurrence of subclinical mastitis. The study was performed at four dairy farms. Totally 162 milk samples at half udder level were collected from 81 ewes. Only ewes with asymmetric udder (larger and smaller half) and free of clinical mastitis were included in the study. For bacteriological analysis, 82 milk samples were cultivated. Milk samples were cultured on blood agar (M&B Test a.s., Rosina, SR). MALDI-TOF MS (Bruker Daltonics, Germany) was used to identify pathogens. SCC was determined using the Fossomatic 90 (Foss Electric, Hillerød, Denmark). Somatic cell score (SCS) was used for statistical evaluation: $SCS = \log_2 (SCC/100,000) + 3$. The significant lower SCS (3.45 ± 0.27) in larger half udder compared to smaller half udder (5.61 ± 0.27) ($P < 0.001$) were found out. On the other side, 16.46% udders had opposite cells count where higher SCC in larger half was found out but smaller ones still had SCC over 500×10^3 cells/ml with pathogen presence. Additionally, there were detected 66.67% samples with the mastitis pathogens in smaller half udder. The most common pathogens were coagulase-negative staphylococci (CNS) – 87.88% from bacteriological positive samples. *Staphylococcus caprae* was the most frequent CNS (44.83%). *Staphylococcus aureus* was identified in 9.09% of bacteriological positive samples. In conclusion, asymmetric udder could help farmers to identify animals with subclinical mastitis. Supported by the APVV-21-0134, VEGA 1/0597/22 and GA FAPZ 06/2023.

Effects of the nature of milk replacer on growth performances and carcass and meat quality of kidsJ. Normand¹, C. Boyer¹, S. Meurisse¹, A. Pommaret² and M. Drouet¹¹Institut de l'Élevage, Carcass and Meat Quality, 69007 Lyon, France, ²EPLEFPA Olivier de Serres, Ferme du Pradel, 07170 Mirabel, France; jerome.normand@idele.fr

In France, goat kid meat production is regarded as a co-product of goat milk. It represents about 3.000 tons of equivalent carcass for nearly 635.000 kids (GEB, 2021). It is poorly valued as it is very seasonal and not well adapted to French consumer demand. The goat sector therefore wanted to revitalize on-farm kids fattening to improve the image, quality and profitability of kid meat production. The 'ValCabri' project was built to investigate different ways aimed at boosting on-farm kids fattening, and especially the optimization of technical fattening itineraries. During this project, a trial was set up in the experimental farm of 'Le Pradel' to evaluate the impact of the nature of milk replacer on zootechnical performances of kids, characteristics of their carcasses and meat qualities. After the colostral period, 60 male Alpine kids, weighing 4.7 kg on average at birth, were divided into 3 groups and fed either goat milk (GM group) or a milk replacer containing 0% or 65% of SMP (Skimmed Milk Powder – groups 0SMP and 65SMP). The kids were slaughtered at 24 d, with 10 kg live weight and 5.6 kg carcass weight, and no significant difference between groups. The average daily gain from birth to slaughter was similar for the 3 groups: 210 g/d. The kids of the 0SMP group consumed more milk replacer than those of the 65SMP one (respectively 7.8 vs 6.2 kg/kid) but the feeding cost remained slightly lower (14.5 vs 17 €/kid, January 2020 prices). The GM kids consumed a total of 37.7 l of milk per kid, or 1.5 l/d on average. The feeding cost of kids fed with maternal milk varies according to the proportion of post-colostral milk used. It can be null if it is only post-colostral milk and can represent from 27 €/kid if it is milk delivered to the cooperative, to 75 €/kid if it is milk transformed on the farm into Picodon PDO. Regarding the quality of the carcasses, no difference in measurements was observed between the 3 lots. However, the carcasses of the GM group were significantly lighter than those of the 2 others. The sensory qualities of the leg (*semimembranosus*) evaluated in the laboratory by a panel of 12 experts were not different between the 3 groups.

Effect of somatic cell count and stage of lactation on milk productionL. Mačuhová¹, V. Tančin^{1,2}, J. Mačuhová³, M. Uhrinčat¹ and M. Oravcová¹¹NPPC, Research Institute for Animal Production Nitra, Hlohovecká 2, 951 41 Lužianky, Slovak Republic, ²Slovak University of Agriculture in Nitra, Institute of Animal Husbandry, Faculty of Agrobiological and Food Resources, Tr. A. Hlinku 2, 94901 Nitra, Slovak Republic, ³Institute for Agricultural Engineering and Animal Husbandry, Vöttinger Str. 36, 85354 Freising, Germany; lucia.macuhova@nppc.sk

Somatic cell count is not regularly evaluated in milk of dairy ewes for mastitis diagnostics. Mastitis negatively influences milk yield and its composition. The aim of this study was to evaluate the effect of somatic cell count (SCC) and stage of lactation on milk production in Tsigai (75%) × Lacaune (25%) dairy sheep (n=124). Therefore, in one flock, individual milk production was recorded and individual milk samples were collected once a month from February to July (i.e. from the start of lambing and thus during milking period to the end of lactation). SCC was measured using Fossomatic devices. Ewes were assigned according to current SCC to very low (VLSCC), low (LSCC), middle (MSCC), high (HSCC), and very high (VHSCC) SCC groups with SCC of ≤200,000 cells/ml, between 200,001 and 400,000 cells/ml, between 400,001 and 600,000 cells/ml, between 600,001 and 1,000,000 cells/ml, and >1,000,000 cells/ml, respectively. No significant differences ($P=0.7564$) were observed between different SCC groups in milk yield. The occurrence frequency of SCC in evaluated SCC groups was 86, 6.5, 1.5, 1.5, and 4.5% in VLSCC, LSCC, MSCC, HSCC, and VHSCC, respectively. The month of measurement had a significant influence ($P<0.0001$) on milk production. Significant differences were observed between all evaluated months except between February and April. The highest milk production was recorded in March (915.35 ± 24.06 ml) and the lowest in July (389.44 ± 22.71 ml). In conclusion, the assessed flock had a very good udder health, and no effect of SCC on milk production is observed within healthy flock. Milk production was affected only by the advancing stage of lactation. This publication was written during carrying out of the projects APVV-21-0134 and SMART 313011W112.

Fit of mathematical models to the lactation curves of dairy sheepL. Guevara¹, L.S. Gloria¹, J.C. Angeles-Hernandez², A.M. Fernandes¹ and M.L.C. Abreu³¹Universidade Estadual do Norte Fluminense, Pós-graduação em ciência animal, Av. Alberto Lamego, 2000, 28013-602, Campos dos Goytacazes, RJ, Brazil, ²Universidad Autónoma del Estado de Hidalgo, Instituto de Ciencias Agropecuarias, Rancho Universitario, Av. Universidad km. 1, 43600, Tulancingo, Hgo, Mexico, ³Universidade Federal de Mato Grosso, Pós-graduação em ciência animal, Av. Fernando Corrêa da Costa, no. 2367, 78060-900, Cuiaba, MT, Brazil; lilian.mvz@gmail.com

Sheep milk production is an incipient activity in Latin America. Due to this, there is a need to establish work plans in the productive activity and to know the biological behaviour of the production to establish strategies within the system that allow the activity to be economical, profitable and sustainable. The use of mathematical models to describe lactation of sheep has been limited, but the best adjustment of these allows predicting and making decisions on production. The objective of this work is to fit different mathematical models that describe the lactation curve of sheep in an experimental farm in Mexico. A total of 477 weekly test day records from 32 dairy crossbred sheep were analysed. The parameters of models were estimated using the 'nlme' package in the R software. A total of 42 models were tested and the goodness of fit was evaluated by means of AICc. Finally, 6 models were selected (Michaelis-Menten, Brody, exponential parabolic form Sikka, Morant and Gnanasakthy and Pollot multiplicative reduced form two parameters and Guo and Swalve modified) and compared by AICc and evidence ratio criteria. The characteristics for lactation peak yield, time of peak yield, total milk yield and persistence were calculated. The Morant & Gnanasakthy model was the best fit to represent dairy sheep lactation in ewes from México. This study represents an advancement in the knowledge of the lactation curve of sheep in Latin America.

Session 13**Poster 21****Udder health in dairy ewes in Slovakia: current situation**V. Tančin^{1,2}, K. Tvarožková², B. Gancárová², L. Mačuhová¹, M. Uhrinčat¹, M. Vršková¹ and M. Oravcová¹¹NPPC – Research Institute for Animal Production Nitra, Hlohovecka 2, 951 41 Lužianky, Slovak Republic, ²Slovak University of Agriculture in Nitra, Institute of Animal Husbandry, Tr. A. Hlinku 2, 949 76 Nitra, Slovak Republic; xgancarova@uniag.sk

Somatic cell count (SCC) is used for diagnostic of udder health problems – mastitis in dairy cows. However, it is still in high scientific discussion about physiological level of SCC for diagnostic of mastitis in ewes. Therefore, the aim of the study was to review the current situation of udder health in dairy farms and possible importance to use SCC for diagnostic of mastitis through the relationship of SCC with pathogen presence. We have analysed the data obtained during the three years. First data set: in total 9,211 samples in 2019, 11,826 in 2020 and 11,915 in 2021 were available from 26 farms. The samples on the basis of SCC were divided into 5 SCC classes – C1 ($\leq 2.10^5$ cells/ml), C2 (2.10^5 – 4.10^5 cells/ml), C3 (4.10^5 – 6.10^5 cells/ml), C4 (6.10^5 – 10.10^5 cells/ml), C5 ($\geq 10.10^5$ cells/ml). Second data set: in selected farms 1,499 milk samples at half udder level were collected for SCC analysis. Milk samples were cultured on blood agar (MKB Test a.s., Rosina, SR). MALDI-TOF MS (Bruker Daltonics, Germany) was used to identify pathogens. From the first data set there were 52.67, 15.01, 6.55, 7.34 and 18.40% samples in SCC classes, respectively. There were increasing % in C1 (42.16, 51.45 and 62.01%, respectively), and reduction % in C5 from the year to year (22.80, 17.38, 16.00%, respectively). From second data, there were 5.77% samples with mastitis pathogens in both C1 and C2 SCC groups, but in C5 there were 77.23% of samples with pathogens. The most frequent pathogens were coagulase negative staphylococci and among them *S. chromogenes* was with highest frequency, followed by *S. epidermidis* and *S. xylosus*. In conclusion, we could consider SCC below 4.10^5 cells/ml as the proposal level for diagnostic purposes and that on the basis of pathogens detected the improving of housing and milking environment in dairy practice could significantly contribute to better udder health. Supported by project: APVV-21-0134, VEGA 1/0597/22 and SMART 313011W112.

Evaluation of udder health of dairy goats using electrical conductivity under practical conditionsM. Uhrinčat¹, V. Tančin^{1,2}, K. Tvarožková², B. Gancárová², L. Mačuhová¹ and M. Oravcová¹¹NPPC-Research Institute for Animal Production Nitra, Hlohovecká 2, 951 41 Lužianky, Slovak Republic, ²Slovak University of Agriculture, Tr. A. Hlinku 2, 949 76 Nitra, Slovak Republic; michal.uhrincat@nppc.sk

In practice, the portable conductivity meter is used as a rapid method applied to detect bovine mastitis. The aim of the study was to evaluate this method for dairy goats. In the experiment, the milk samples from 484 udder halves of goats at the same farm were evaluated. After forestripping (2 streams of milk), 10 ml were milked into a Milk Checker N-4L and the electrical conductivity (EC; mS/cm) was measured. Afterwards 1 ml of milk was aseptically gathered into a sterile test tube for cytobacteriological analysis and an additional sample of 30 ml was taken for somatic cell count (SCC) analysis. SCC was log transformed to somatic cell score (SCS). Based on the SCC, the samples were divided into classes: (1) $SCC < 2 \times 10^5$ (n=29); (2) $2 \times 10^5 \leq SCC < 4 \times 10^5$ (n=53); (3) $4 \times 10^5 \leq SCC < 6 \times 10^5$ (n=76); (4) $6 \times 10^5 \leq SCC < 1 \times 10^6$ (n=95); and (5) $SCC \geq 1 \times 10^6$ cells/ml (n=211). EC in the classes 1:2:3:4:5 (mean $\pm$ SD) 6.34 ± 0.62 : 6.38 ± 0.50 : 6.46 ± 0.43 : 6.63 ± 0.48 : 6.82 ± 0.75 had an upward trend, without significant differences. We found only a moderate correlation ($r=0.35$) between EC and SCS. A difference in EC greater than 0.5 between halves within the same udder indicates a health problem. At difference EC=0 there were 48 goats with SCC difference less than 2×10^5 , 23 goats with a difference from 2×10^5 to 4×10^5 and 41 with a difference of more than 4×10^5 cells/ml. At difference EC=0.2-0.4 there were 39 goats with SCC difference less than 2×10^5 , 10 goats with a difference from 2×10^5 to 4×10^5 and 45 with a difference of more than 4×10^5 . There were only 23 goats with an EC difference of more than 0.5. Eight different pathogens were detected in 59 bacterially positive samples. The most frequent pathogen was *Staphylococcus caprae* (n=28; EC= 6.82 ± 0.75), but *Staphylococcus aureus* caused the highest EC in positive samples (n=4; EC= 7.40 ± 0.51). We concluded that the detection of mastitis by measuring the milk EC of dairy goats proved to be a less reliable method in this case. This study was supported by APVV -21-0134 and SMART 313011W112.

Session 13

Poster 23

Milk recording protocols and goodness of fit of models applied to dairy sheep lactationsL. Guevara¹, L.S. Gloria¹, J.C. Angeles-Hernandez², I. Nacarati Da Silva¹, A.M. Fernandes¹ and A. Peláez Acero²¹Universidade Estadual do Norte Fluminense, Pós-graduação em ciência animal, Av. Alberto Lamego, 2000, 28013-602, Campos dos Goytacazes, RJ, Brazil, ²Universidad Autónoma del Estado de Hidalgo, Instituto de Ciencias Agropecuarias, Rancho Universitario, Av. Universidad km. 1, 43600, Tulancingo, Hgo, Mexico; lilian.mvz@gmail.com

The lactation curve can be described by mathematical models, which can never completely represent a biological process, but provide useful information for decision-making at herd level. The ability of mathematical models to represent the lactation curve can be influenced by factors such as the interval between test day records (TDR). The aim of this study was to evaluate the effect of different TDR intervals on the goodness of fit of the empirical (Wood and Wilmink) and mechanistic models (Pollott and Dijkstra) applied to dairy sheep lactation. A total of 4,494 weekly TDRs from 156 lactation of dairy crossbred sheep were analysed. Three new databases were generated from the original weekly TDR data (7D), comprising intervals of 14(14D), 21(21D), and 28(28D) days. Also, the shape of the lactation curve (typical and atypical) was defined. The goodness of fit was evaluated using the mean square of prediction error (MSPE), Root of MSPE (RMSPE), Akaike's Information Criterion (AIC), Bayesian's Information Criterion (BIC), and the coefficient of correlation (r) between the actual and estimated total milk yield (TMY). Most models exhibited the greatest values of r^2 (0.56 to 0.99) to 7D interval. We found higher values of r^2 for typical curves in comparison with atypical curves (0.91 vs 0.74, respectively). The TDRs interval affected the capability of Wood and Dijkstra models to estimate the peak and time to peak lactation, with better estimations for the 28D interval for the Dijkstra model. However, the TMY can be adequately estimated by the four models in all TDR intervals evaluated. Therefore, the selection of lactation model and TDR interval must consider the estimation objectives and structure of the database.

Heritability of milk lipolysis in French Alpine goats

H. Larroque¹, C. Robert-Granié¹, S. Meurisse², P. Trossat³, L. Bernard⁴, C. Hurtaud⁵, C. Huau¹, T. Fassier⁶, R. Rupp¹ and C. Cebo⁷

¹GenPhySE, université de Toulouse, INRAE, ENVT, 31326 Castanet-Tolosan, France, ²Institut de l'Elevage, 149 rue de Bercy, 75595 Paris, France, ³Actalia-Cécalait, Rue de Versailles, 39800 Poligny, France, ⁴INRAE, Université Clermont Auvergne, Vétagro Sup, UMRH, 63112 Saint-Genes-Champagnelle, France, ⁵PEGASE, INRAE, Institut Agro, 35590 Saint Gilles, France, ⁶INRAE, P3R, Domaine de la sapinière, 18390 Osmoy, France, ⁷Université Paris-Saclay, INRAE, AgroParisTech, GABI, 78350 Jouy-en-Josas, France; helene.larroque@inrae.fr

Milk lipolysis, i.e. the hydrolysis of milk triglycerides, is not routinely measured and its occurrence and genetic determinism can therefore be hardly studied. In order to overcome this limitation, in France the LIPOMECA project (ANR-19-CE21-0010) has developed an equation for the prediction of goat milk lipolysis from mid-infrared (MIR) milk spectra. This prediction lipolysis equation was applied to non-standardized MIR spectra of milk samples of Alpine goats with a high diversity of α s1 casein genotypes. Finally, 22,745 log-normalized predictions of 1,035 goats were retained. First, environmental factors affecting milk lipolysis were identified. Then, variance components were estimated using a single trait animal model with repeatability and including the same environmental effects. The part of variance explained by the category of α s1 casein genotypes (for their known effect on protein content) was evaluated by including or excluding it in the model. Among the environmental factors identified, longer intervals between milking and milk analysis increased lipolysis in milk, as well as the evening milking compared with the morning milking. Lipolysis decreased with lactation stage, and its level was higher in the second lactation than in subsequent lactations. The lipolysis level was related to the category of α s1 casein genotypes, and reached a maximum for OO genotypes. Heritability of lipolysis was estimated to 0.21 ± 0.03 and decreased to 0.18 ± 0.03 when including α s1 casein genotypes in the model. The α s1 casein genotype would explain 3% of the total phenotypic variance of lipolysis. These first results will need to be verified using data from commercial farms in order to overcome the small size and the particular genetic structure of the population studied.

Castration method affects the fatty acid profile of subcutaneous and intramuscular fat in sheep

H.A. O'Neill, N. Skele, O.B. Einkamerer, A. Hugo and F.W. Naser

University of the Free State, Animal Science, 205 Nelson Mandela Drive Park West Bloemfontein, 9301, South Africa; naserfw@ufs.ac.za

This study investigated the effect of lamb castration method on the fatty acid profile of subcutaneous and intramuscular fat of South African Mutton Merino lambs ($n=30$). This project was approved by the Animal Ethics Committee (UFS-AED2019/0136/2410). Ten ($n=10$; EC) lambs were castrated at one week of age using rubber rings; ten ($n=10$; LC) were castrated at 8 weeks of age using a burdizzo and ten ($n=10$; NC) were kept intact. These methods mimic commercial procedures that are also ethically acceptable. After castration, sheep were kept individually in a metabolic building and fed a finishing diet for 67 days. The animals were slaughtered at a commercial abattoir when they reached an average of ± 45 kg live weight on an empty stomach. Muscle and fat samples were collected from the left m. longissimus at the 9th through 11th rib and frozen at -20°C until analysis by gas chromatography. The method by Folch *et al.* was used to extract the lipid fraction from previously frozen muscle and subcutaneous fat samples. Fatty acid methyl esters were quantified using a Varian 430 flame ionization Gas Chromatography, with a fused silica capillary column, chrompack CPSIL 88 (100 m length, 0.25 mm ID, 0.2 μm film thicknesses). Fatty acids were indicated as the proportion of each fatty acid to the total of all fatty acids present in the sample. Atherogenicity index was calculated as: $\text{AI} = (\text{C12:0} + 4 \times \text{C14:0} + \text{C16:0}) / (\text{MUFA} + \text{PUFA})$. For intramuscular fat, NC lambs had higher ($P<0.05$) PUFA, α -linolenic acid, n-6, linoleic acid, PUFA: SFA ratio, and PUFA: MUFA compared to both EC and LC lambs. Eicosapentaenoic acid (EPA) and total n-3 were higher ($P<0.05$) for NC lambs than LC lambs. Palmitic acid and CLA were higher ($P<0.05$) for EC lambs compared to NC and LC lambs. For subcutaneous fat, NC lambs had higher ($P<0.05$) heptadecenoic acid and linoleic acid than LC lambs. The atherogenicity index (AI) of subcutaneous fat was higher ($P<0.05$) for LC lambs compared to NC lambs. In conclusion, meat and fat from NC lambs are healthier options to consume compared to meat and fat from castrates. It is recommended to keep lambs intact or castrate at a later stage.

Somatic cell count and prevalence of udder pathogens isolated in raw goat milkB. Gancárová¹, K. Tvarožková¹, M. Uhrinčat², L. Mačuhová² and V. Tančin^{1,2}¹Slovak University of Agriculture in Nitra, Institute of Animal Husbandry, Tr. A. Hlinku 2, Nitra, 949 76, Slovak Republic, ²NPPC-Research Institute for Animal Production Nitra, Hlohovecká 2, Lužianky, 95141, Slovak Republic; vladimir.tancin@uniag.sk

The physiological value of somatic cell count (SCC) representing a healthy udder for goats is still not clearly defined in many countries. Our objective was to assess the health status of the udder at the mid and late lactation stages based on the identification of bacterial pathogens in the raw milk of White Short-haired goats and their relationship to SCC. The goats had kidded from mid February to mid-March. A total of 405 milk samples of half udders were aseptically collected from the dairy goat farm which is located in the northern part of the Orava region (Slovakia). The samples were divided on the basis of SCC: $SCC1 < 500 \times 10^3$; $SCC2 \geq 500 < 1000 \times 10^3$; $SCC3 \geq 1000 < 2,000 \times 10^3$; $SCC4 \geq 2,000 \times 10^3$ cells/ml. The bacteriologically positive samples represented 14.07% of all samples. The main pathogens were coagulase-negative staphylococci (CNS) (80.7%). Interestingly, in the group SCC4 there were only 50.9% samples with identified pathogens. The most prevalent CNS were *Staphylococcus caprae* (40.4%) and *S. epidermidis* (32%). Other CNS like *S. simulans*, *S. warneri* and *S. equorum* were less represented. A contagious pathogen *S. aureus* was identified only in mid-lactation in two milk samples. Additionally, *Enterobacter kobei* (14.0%), *Enterobacter cloacae* (3.5%) and *Citrobacter braakii* (1.8%) were identified. The prevalence of the pathogens was similar in mid-lactation (29/57) compared with late lactation (28/57). It can be concluded that with increasing SCC, the occurrence of mastitis pathogens also increases, especially in samples with over one million cells. However a high SCC doesn't necessarily indicate the presence of pathogens in goat milk. Thus the threshold level of SCC for mastitis detection is still undefined for dairy goats. Supported by the VEGA 1/0597/22, APVV-21-0134, and by the GA FAPZ 06/2023.

Lowering crude protein and supplementing rumen protected methionine and lysine in dairy ewesK. Droumtsekas¹, A. Plomaritou¹, I.C.C. Christou¹, A. Tsigkas¹, M.A. Belaid², D. Martinez Del Olmo², J. Mateos² and A. Foskolos¹¹University of Thessaly, Department of Animal Science, Campus Gaiopolis, Larissa, 41222, Greece, ²KEMIN Animal Nutrition and Health, Toekomstlaan 42, 2200 Herentals, Belgium; afoskolos@uth.gr

In several dairy sheep systems, crude protein (CP) overfeeding has been documented leading to lower nitrogen (N) use efficiency (NUE) and increased N excretion into the environment. This study investigated the effect of lowering the dietary CP level by supplementing rumen protected methionine (RPM; KESSENT®) and rumen protected lysine (RPL; LysiGEM®) at a constant ratio on milk yield and composition. A total of fifty-four (54) Lacaune ewes were involved in a randomized block design with five treatments: a basal diet with CP at 19.3%DM (CTR), a diet with lower CP at 15.1% DM (NEG), and three treatments with decreasing CP compared with CTR, supplemented with RPM and RPL at a fixed ration, namely AA1, AA2 and AA3. The AA1 treatment consisted on the NEG, supplemented with 3 g/d RPM and 5 g/d RPL, AA2 had a CP level at 16.2%DM supplemented with 3 g/d RPM and 4 g/d RPL, and AA3 had a CP level at 16.9%DM supplemented with 3 g/d RPM and 3 g/d RPL. The study lasted for 12 weeks. Each week, for two consecutive days, milk yield, composition and dry matter intake were measured. Dry matter intake was on average 3.26 kg. Lowering CP levels without adding rumen protected amino acids, reduced milk yield by 12.2% (2.36 vs 2.07 kg/d for CTR and NEG respectively; $P < 0.001$), but when NEG was supplemented with RPM and RPL milk yield differences were not significant compared with CTR. The AA3 had the highest milk yield but was not different than CTR (2.51 kg/d). However, milk fat composition was significantly higher (6.69 vs 6.25 for AA3 vs CTR, respectively) without affecting milk protein composition. When protein and fat composition were considered calculating fat and protein corrected milk yield (FPCMY), differences between AA3 and CTR became clear leading to improved FPCMY for AA3. In conclusion, lowering CP levels and supplementing rumen protected amino acids is a valid strategy to improve NUE and increase ewes' productivity.

FASTOChe project: meat sheep grazing on plant species rich in bioactive secondary compoundsM. Bernard^{1,2}, H. Hoste^{3,4}, L. Sagot^{1,2} and D. Gautier^{1,2}¹CIIRPO, Le Mourier, 87800 Saint Priest Ligoure, France, ²Institut de l'élevage, 149 rue de Bercy, 75595 Paris, France, ³ENVIT, UMR IHAP, 31076 Toulouse, France, ⁴INRAE, 147 rue de l'Université, 75007 Paris, France; mickael.bernard@idele.fr

For several decades, the control of gastrointestinal strongyles has been based exclusively on the use of chemical molecules with broad-spectrum anthelmintic activities. For a long time, these synthetic molecules were applied in an unreasonable way. These practices have led to the increasing development of resistance to these molecules and to a direct impact on lamb performance. In this context, the search for alternatives is a priority to avoid finding ourselves without effective solutions in the coming years. Several *in vitro* and *in vivo* studies have shown that the intake of feeds and forages rich in bioactive secondary metabolites (BSM) by small ruminants disrupts the biology of gastrointestinal strongyles and the dynamics of infestations. The FASTOChe project is studying the anthelmintic and zootechnical interest of three plants rich in BSM, sainfoin, chicory and lanceolate plantain, grazed by meat sheep. Eight trials on experimental farms and agricultural high schools were conducted between 2019 and 2021. Fields were sown in pure plots and grazed either continuously or in 2-3 weeks courses by growing lambs or renewal ewe lambs. Various measurements were carried out on the grasslands (quantity available, quality, etc.) and on the animals, in terms of health (excretion and parasite infestation, evaluation of anaemia, etc.), performance (weighing, body condition score) and animal welfare. In our experimental conditions, chicory and plantain did not reduce the parasite load. Only sainfoin reduced parasite excretion but to a limited level (1000 vs 771 eggs per gram), which did not allow a reduction in the number of treatments. In terms of zootechnical performance, these three plants had moderate positive effects on growth, but here again sainfoin stood out with higher results (30g vs 142g per day) compared to grazing grass. In conclusion, these three plants do not replace anthelmintic treatments but their feed value allowed the animals to grow correctly.

Multiple mitigation strategies may lead to reduction in emissions for mixed Kenyan dairy systemsM.W. Graham¹, C. Arndt¹, D. Korir¹, S. Leitner¹, L. Merbold², P. Ndung'u¹, F. Teillard³ and A. Mottet³¹International Livestock Research Institute, Mazingira, Box 30709, Nairobi, 00100, Kenya, ²Agroscope, Agroecology and Environment, Agroscope Reckenholzstrasse 191, Zurich 8046, Switzerland, ³U.N. Food and Agriculture Organization, Viale delle terme di Caracalla, Rome, 00153, Italy; lutz.merbold@agroscope.admin.ch

Livestock systems are an important source of livelihoods in Africa, but are also a large source of anthropogenic greenhouse gas (GHG) emissions (i.e. CH₄ from enteric fermentation; CH₄ and N₂O from manure) in most African countries. Many African countries, such as Kenya, have prioritized livestock emissions in their Nationally Determined Contributions under the Paris Agreement. However, there are limited data available on GHG emissions from livestock systems in Africa. Scaled livestock emissions in Africa have been estimated using modelling approaches and were not necessarily based on locally appropriate data. To bridge this gap between limited local data and modelling, we used datasets collected from representative smallholder mixed dairy cattle systems in Kenya to up-scale GHG emissions using the Global Livestock Environmental Assessment Model – interactive (GLEAM-i). We evaluated effects of the following previously evaluated mitigation interventions on milk emission intensities (EI) to compare against baseline data: reduced age at first calving; increased fertility rate; sweet potato vine silage (SPVS) supplementation; dairy concentrate feeding; increased feeding level; all interventions combined. EIs for milk were lower than the baseline for all individual intervention scenarios (-3.6 to -11.0%), and the combined scenario reduced EIs additively by 36%. Individual interventions with the highest overall impact on milk EIs were supplementation with SPVS (-11.0%), increased fertility rate (-10.3%), and increasing feeding level (-10.1%). These results indicate the 'many little hammers' approach to interventions can lead to additive reductions in EIs when combined. Further, we demonstrate that in-situ data based mitigation interventions can be captured by the GLEAM-i model. Future work should focus on filling existing data gaps for emissions from livestock in East Africa to allow further upscaling, particularly for pastoralist systems, small ruminants, and manure.

Assessing multifunctionality of livestock breeds and species at global levelG. Leroy¹, F. Joly², C. Looft³, P. Boettcher¹ and R. Baumung¹¹FAO, Viale delle Terme di Caracalla, Roma, Italy, ²University of Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Route de Theix, Saint-Genès-Champagnelle, France, ³Neubrandenburg University of Applied Sciences, Brodaer Str. 2, Neubrandenburg, Germany; roswitha.baumung@fao.org

The choice of appropriate livestock species and populations is one of the key levers of the multiple trade-offs that must be considered for the sustainability of food systems worldwide. Although often considered less productive than their exotic counterparts, native and locally adapted breeds are also known to provide a wide range of ecosystem services. Based on information reported by 41 countries on 3,361 national breed populations of 27 species in FAO's Domestic Animal Diversity Information System (DAD-IS), we investigate the factors influencing the recognition of their links to a set of 52 uses and ecosystem services. On average, 4.46 uses and ecosystem services were reported per national breed population. A larger number of cultural services were reported for horses (2.47 vs 0.75 on average), while ruminants were found to be linked to a greater number of provisioning, as well as regulating and maintaining ecosystem services (2.99 and 1.86 vs 2.39 and 1.32 on average, respectively). Compared to European breeds, livestock in Africa were reported to contribute to a larger number of provision services (3.95 vs 1.88). Native and locally adapted breeds were linked to a greater number of services than exotic breeds, either for cultural (0.83 vs 0.69), provision (2.85 vs 1.68) or regulation and maintenance services (1.75 vs 0.54). This highlights the fact that the former tend to be raised in less specialized production systems than the latter, and are recognized to play multiple roles for the livelihoods of rural communities and the environmental sustainability of food systems. This multifunctionality needs to be carefully assessed and taken into account in the development of livestock policies.

Session 14

Theatre 3

Predicting sustainable futures: does disease in early life result in trade-offs in ewe productivity?J. Duncan¹, H. McDougall¹, G. Mitchell¹, R. Evans¹, M. Reeves², L. Andrews¹, E. Geddes¹, L. Melville¹, D. Ewing³ and F. Kenyon¹¹Moredun Research Institute, Pentlands Science Park, Bush Loan, EH26 0PZ Penicuik, United Kingdom, ²SRUC, Roslin Institute Building, Easter Bush Campus, EH25 9RG Midlothian, United Kingdom, ³Biomathematics and Statistics Scotland (BioSS), JCMB, The King's Buildings, Peter Guthrie, Tait Road, EH9 3FD Edinburgh, United Kingdom; jade.duncan@moredun.ac.uk

Livestock encounter numerous challenges in early life; however, we do not yet understand how these affect the long-term productivity of the animal. Here, our aim is to determine the impact of disease in early life on later performance in ewes. We hypothesise that ewe-lambs exposed to high levels of disease in their first 12 months will have reduced productivity when they mature. Female lambs (n=100) born between 28th March-23rd April 2022 at the Moredun Research Institute, Scotland were closely monitored throughout their first grazing season, for a range of natural gastrointestinal parasite (GIN) infections. Records included birthing ease, maternal bond, litter size, weight gain, faecal egg count (FEC) and faecal oocyst count (FOC), presence of other opportunistic diseases, welfare measures, medicines administered, and number of anthelmintic treatments required. A treatment criterion was used to determine if an animal should receive anthelmintic treatment. At weaning ewes were removed and lambs maintained. The ewe-lambs will be monitored throughout their first year until they give birth at 2 years old. We will then monitor their offspring's health and welfare to account for early life experiences. The 100 female twin lambs' average birth weight was 5.2 kg (range 2.5-7.25). Mean strongyle FEC was 186 epg (range 0-2,421), mean *Nematodirus* FEC was 44 epg (range 0-468) and mean coccidia FOC was 7,605 EPG (range 210-411,399). Notable welfare measures were dag score and presence of injury. Initial modelling suggests that there may be relationships between parasite burden, welfare measures and performance. Furthermore, there may be a negative relationship between the weight gain and the strongyle and *Nematodirus* FEC's ($r=-0.24$, $P<0.01$), which are themselves correlated with one another. This study shows that there is variation present in the disease challenge in a group of co-grazing ewe-lambs.

The welfare of housed and grazing beef cattle assessed by hormones levels and physical check scoresM.J. Rivero¹ and A.S. Cooke²¹Rothamsted Research, Net Zero and Resilient Farming, North Wyke, Okehampton, EX20 2SB, United Kingdom, ²University of Lincoln, School of Life Sciences, Brayford Pool Campus, Lincoln, LN6 7TS, United Kingdom; jordana.rivero-viera@rothamsted.ac.uk

Housing/grazing time is a key decision with potential impacts on health and welfare. Understanding welfare implications of husbandry strategies is essential for future farming. The objective of this study was to compare the health and welfare of housed and grazing beef cattle using hormone levels and physical health scores. Two herds of beef cattle (30 heads each) were directly compared from housing at weaning in October 2020 to July 2021 across welfare indicators (i.e. physical health, hormones and behaviour). Here we are only presenting the physical and hormonal results. One herd ('HH') was housed this entire time and fed silage and concentrate to finish animals at 14-months, and the other ('HG') was housed until April, fed mainly silage, before being turned out onto pasture and aimed at finishing animals at 18-20 months. Twice during winter and twice during summer, physical inspections of animals were conducted to assess body condition, cleanliness, diarrhoea, hairlessness, nasal discharge, and ocular discharge. At the same time, hair and nasal mucus samples were taken for quantification of cortisol and serotonin. Physical health indicators were broadly comparable between herds except for body condition scores, which were higher in the HH herd (attributed to diet) ($P=0.002$) and nasal discharge which was more prevalent in the HH herd ($P<0.001$). Across all indicators there was an impact of time, with scores improving in summer compared to winter. Similarly, hormone data varied mostly across timepoints. However, a difference was found in hair cortisol levels, with the greatest concentrations observed in the HG herd ($P=0.011$), however such a pattern was not seen for nasal mucus cortisol, or for serotonin levels. In conclusion, animal welfare indicators in this case study varied more with time than with the production system. Animal behaviour will need to be included in the assessment to better understand the impact of housing and grazing on animal welfare. Acknowledgments: Soil to Nutrition (BBS/E/C/00010320) and the North Wyke Farm Platform (NWFP, BBS/E/C/000J0100), funded by BBSRC.

Smith^{3,6}¹Wageningen Research, Wageningen Economic Research, Bronlan 103, Wageningen 6708 WH, the Netherlands, ²Aarhus University, Department of Agroecology, Blichers Allé 20, 8830 Tjele, Denmark, ³University of Reading, School of Agriculture, Policy and Development, Reading, RG66BZ, United Kingdom, ⁴Acta – les instituts techniques agricoles, 149 Rue de Bercy, 75012, Paris, France, ⁵SEGES Innovation, P/S, Agro Food Park 15, 8200 Aarhus, Denmark, ⁶Swedish University of Agricultural Sciences, Department of Biosystems and Technology, Box 190, 2, Sweden, ⁷Research Institute of Organic Agriculture (FiBL), Department of Socio-Economics, Frick, Switzerland, Ackerstrasse 113 / Postfach 219, 5070, Switzerland, ⁸Institute of Soil Science and Plant Cultivation, Czartoryskich Str. 8, 24-100 Pulawy, Poland, ⁹Estación Experimental del Zaidín (CSIC), Profesor Albareda 1, 18008 Granada, Spain; l.g.smith@reading.ac.uk

The intensification of animal production has been identified as a major contributor to environmental impacts however livestock products remain crucial for the human diet, and for key ecosystem services. To address the sustainability of livestock systems, Life Cycle Assessment (LCA) has become a vital tool. However, the accuracy and robustness of LCA methods must be improved. To achieve this goal, a participatory harmonization approach was employed, which involved 21 LCA experts in 29 workshops and two surveys. Five research topics were identified to enhance the accuracy of LCA methods for livestock: food, feed, fuel, and biomaterial competition; crop-livestock interaction; the circular economy; biodiversity; animal welfare; nutrition, and GHG emissions. Furthermore, general evaluation criteria were established based on the characteristics of livestock systems: transparency, reproducibility, completeness, fairness, acceptance, robustness, and accuracy. Overall, this participatory method was successful in narrowing down the evaluation criteria for livestock focused LCA methods, providing a holistic framework to assess the impacts of livestock systems on various key topics.

Defining operational sustainability and the need for systems approach in assessing livestock farmingA.H. Herlin¹, S. Hellstrand² and H.U. Sverdrup³¹Swedish University of Agricultural Sciences, Biosystems and technology, Box 190, 234 22 Lomma, Sweden, ²Nolby Ekostrategi, Tolita 8, 665 92 Kil, Sweden, ³Inland Norway University of Applied Sciences, Postboks 400 Vestad, 2418 Elverum, Norway; anders.herlin@slu.se

Livestock production has in recent times been accused of harming the environment, and climate and being unsafe to human health. The EAT-Lancet Commission has received a lot of attention for the proposal of a 'planetary diet', which claims to protect the health of people and the planet. The core of the suggestions is that red meat should be reduced by 82-100% globally. The planetary diet is part of a discourse arguing for the need for a food systems transformation that is enforced by a set of soft and firm policy measures. The planetary diet has a substantial influence on policy processes including e.g. land use and climate change by IPCC and the process for sustainable nutrition recommendations developed in the Nordic countries. Organizations at various levels of society have to some extent, adopted policies accordingly. The analysis of the environmental impact of agriculture producing 'the planetary diet' diet is based on LCA (life-cycle assessment) studies. Since LCA according to ISO14 040 and ISO 14 044 cannot capture the complexity of systems, where biology matters, 'the planetary diet' is decoupled from links to known limits of carrying capacity of agri-food systems, given their biophysical and socio-economic context. The internal logic of LCA studies and the lack of links to known characteristics of agricultural systems can lead to starvation. There is an urgent need to generate an operational definition of sustainability in agricultural systems that reflects the knowledge frontier in the disciplines that have the competence of excellence of the systems and issues in focus. The assessment methods to be chosen should be aligned with the sustainability objectives. This means systems analysis where the components are interconnected and capable to measure the sustainability performance of agricultural-food systems. We have developed a suggestion for a definition of operational sustainability in agriculture, and a supporting tool-kit for its evaluation, including a dynamic systems perspective.

Session 14

Theatre 7

The global roundtable for sustainable beef; multi-stakeholder engagement driving progress worldwide

R. Petre and J. Eisele

Global Roundtable for Sustainable Beef, 13570 Meadowgrass Drive, Colorado Springs, 80921, USA; ruaraidh.petre@grsbeef.org

Livestock Sustainability encompasses Environmental, Social and Economic realms and many factors impacting, people, animals and landscapes. Solutions to transform the livestock sector so that it can remain a positive contributor to a thriving food system need to take account of the geography, climate, legislative environment, production system and culture of those involved. Such solutions are therefore rarely simple or directly transferable from one location to another. In order for solutions to deliver sustainability benefits while contributing to a thriving food system, it is essential that all those involved in the livestock sector participate in their design and implementation. The Global Roundtable for Sustainable Beef, and its member National Roundtables are an example of multistakeholder collaboration at scale. These roundtables have brought together cattle producers, processors, retailers, allied industries and input suppliers, civil society and academia along with government and international organisation observers to define beef sustainability firstly at a global level, and then to add national context in 24 countries covered by 12 national / regional groups. Together GRSB members defined Principles and Criteria for Sustainable Beef covering Natural Resources, People & the Community, Animal Health & Welfare, Food, and Efficiency & Innovation. In 2021 GRSB released ambitious 2030 goals for Climate, Nature Positive Production and Animal Health and Welfare, and in the course of 2023 will set an additional Social goal. GRSB develops materials to assist in consistent measurement and reporting of progress. In 2022 GRSB released its Beef Carbon Footprint Guideline that allows sector wide alignment in the calculation of carbon footprint for the beef cattle lifecycle. GRSB is currently working with stakeholders to develop the reporting framework required to present progress against global goals on climate, nature positive production and animal welfare. The global, supply chain wide approach combined with national level, context specific implementation provides GRSB and its members with the most consistent, joined up and effective means available to meet sustainability challenges in the beef industry.

Developing a decision support system for integral sustainability improvement of Dutch dairy farm*M. De Vries¹, J.W. Reijls², G.J. Doornewaard², A.P. Bos¹ and C.A. Schep¹**¹Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, the Netherlands, ²Wageningen Economic Research, Prinses Beatrixlaan 582-528, 2595 BM Den Haag, the Netherlands; marion.devries@wur.nl*

Dairy production systems are causing severe pressure on diverse sustainability aspects, such as global warming, eutrophication, acidification, biodiversity loss, animal welfare, and food-feed competition. Choosing effective measures to improve integral sustainability performance, however, is difficult for farmers, given the complexity and wide range of potential effects on environmental, economic and social sustainability aspects. Moreover, whether measures can be implemented on farms depends on its specific biophysical and socio-economic context, and farmers' preferences. The aim of this study was to design a decision support system that: (1) assists Dutch dairy farmers in choosing measures suitable for their specific farming system and personal preferences; and (2) gives them insight in potential effects of these measures on environmental, economic and social sustainability. First, a database was developed containing 130 measures potentially contributing to reducing greenhouse gas emissions or improving biodiversity. The measures were assessed by 17 scientific experts and 2 dairy advisors for: (1) suitability for implementation given certain farm characteristics and farmer preferences; and (2) effects on 56 indicators of economic, ecological and social sustainability. Effects on sustainability indicators were scored on a 1-5 Likert scale ranging from very unfavourable to very favourable. An explanation of the effect was added, and, in case of a variable effect, reasons why the effect could vary. Second, a prototype tool was designed allowing farmers and advisors to access information about measures in the database, including functionalities of (automated) user input and weighting of sustainability themes; shortlisting and sorting user-specific measures; and information about sustainability effects. It was concluded that the decision support system designed in this study is a promising method to support farmers and advisors in orienting on measures for integral sustainability improvement of dairy farms. Further usability testing is needed for development and successful implementation of the tool.

Animal welfare index in sustainability assessments*L. Rydhmer¹ and E. Rööfs²**¹Swedish University of Agricultural Sciences, Department of Animal Breeding and Genetics, Box 7023, 75007 Uppsala, Sweden, ²Swedish University of Agricultural Sciences, Department of Energy and Technology, Box 7032, 75007 Uppsala, Sweden; lotta.rydhmer@slu.se*

Tools for evaluation of sustainability of food consumption are needed in several research projects and development programs. Since animal-sourced food is included in most people's diets, animal welfare aspects should be part of sustainability assessments. Preferably such assessments are based on observations from farm visits in different production systems. If the aim is to evaluate total consumption of all consumers in a country or region, farm visits are often not feasible for practical reasons. Instead, a rough assessment can be performed based on data available in national data bases, reports of various agricultural organisations and authorities and scientific studies. We propose an animal welfare index based on: (1) number of animals needed to produce a given amount of food (e.g. 1 kg meat, milk or egg); (2) animal welfare judgement of the most common production systems; (3) animals' ability to perceive how they are managed. The number of animals takes all involved animals into account, including e.g. male chickens in egg production. One kg food from small animals, such as crickets, involves many more animal lives than one kg meat from e.g. slaughter pigs. The animal welfare judgement of systems is based on key figures of mortality, disease frequency, barren or enriched environment and duration of slaughter process. Pasture is for example regarded as an enriched environment. Wild animals, such as the moose and the shrimp, also live in an 'enriched' environment. We have used a questionnaire answered by researchers in animal science and veterinary medicine to set values for different animal species' relative ability to perceive how they are managed (including the ability to perceive what kind of environment they are kept in). Mammals have higher ability than e.g. blue mussels. Today's typical diets and alternative diets can be compared with the animal welfare index. By including the animal welfare index in broad sustainability assessments, goal conflict between animal welfare and other sustainability aspects can be revealed.

Sustainability analysis of large-scale dairy farming in China from water-energy-labour nexus insight*X. Du, Q. Wang and Z. Shi**China Agricultural University, College of Water Resources and Civil Engineering, No.17, Tsinghua East Road, Haidian District, 100083 Beijing, China, P.R.; xinyidu@cau.edu.cn*

With the scale development of dairy farming in China, the cost of water, energy, and labour increased significantly, which are closely related to management and technique. Meanwhile, due to regional characteristics and policy bias, the economic and ecological efficiency varies greatly among provinces. To promote the sustainability of the sector, this study estimates the direct energy and water consumption, and labour use through on-farm production. Based on slack-based measurement data envelopment analysis, the dynamic efficiency of 11 inputs and 6 outputs was calculated from 2012 to 2020. In 2020, the cattle stock bred in large-scale farms (500 heads and above) reached 5.91 million heads, which is 2.41 times the stock in 2011. On the national level, the cost per cow of water, energy, and labour increased by 30, 59 and 106%, respectively. Correspondingly, the energy footprint increased by 22%, the related carbon emission increased by 57%, whereas the water footprint decreased by 12%. As great differences exist among provinces, the development of management practices is unbalanced and inadequate, which is incompatible with the rapid amplification of farm scale. Overall, the comprehensive efficiency of large-scale farms reached its lowest point in 2015 due to poor management, and the circumstance has been significantly improved. In 2020, Jiangsu is the only one that did not reach the production frontier while other provinces are able to allocate resources reasonably, and the number is 8 in 2015. Excessive consumption of coal and diesel is the most serious problem for Jiangsu to deal with, and the utilization of water and electricity is also expected to improve. As environmental requirements become increasingly strict, more efforts should be made to develop a high level of management adapted to regional characteristics, which is expected to present the due advantage of resource utilization in large-scale farms, as well as promote the economic and ecological performance of dairy farming.

Session 14

Theatre 11

Characterizing the socio-economic and environmental performance of Irish beef and sheep farms*M.C. Ayala^{1,2}, J.C.J. Groot³, K. Kilcline⁴, I.J.M. De Boer², C. Grace¹, J. Kennedy¹, B. Moran⁴ and R. Ripoll-Bosch²**¹Devenish Nutrition, Dowth hall, A92T2T7, Co. Meath, Ireland, ²Wageningen University, Animal Production Systems group, DeElst 1, 6708 WD, the Netherlands, ³Wageningen University, Farming Systems Ecology group, Droevendaalsesteeg 1, 6708 PB, the Netherlands, ⁴Teagasc, Rural Economy & Development Center, 3 Cross Street, H65WV00, Co. Galway, Ireland; cecilia.ayala@wur.nl*

Although the beef and sheep sectors are important contributors to the Irish economy, at farm level, socioeconomic viability is threatened by low profitability and low rates of generational renewal. In addition, these sectors incur negative environmental externalities (i.e. greenhouse gas – GHG- emissions, air and water pollution, nature loss) that must be addressed for Ireland to reach its environmental targets. However, identifying interventions to manage these socioeconomic and environmental issues is challenging due to the high heterogeneity of farming systems and contexts present in these sectors. We developed a typology of the Irish beef and sheep sectors to unravel their heterogeneity, better understand the socioeconomic and environmental performance of specific farm types and help identify which interventions would be suitable for them. Our preliminary results showed 6 distinct farm types, ranging from extensive cattle-rearing or sheep farms with low profitability and overall low negative environmental impact, to more intensive cattle-finishing farms with better socioeconomic profiles but higher negative environmental impact. For instance, farms in these last groups account for 60% of the total GHG emissions in the sample, which means that any intervention aiming at reducing GHG emissions will have a much larger impact if tailored to these specific farm types. Meanwhile, if the aim is to increase the economic viability of the sector, interventions should be tailored to the first groups of farms which account for 60% of the non-viable farms in the sample. Ultimately, by identifying the varying farm types and their weight in the sector and their impact as a whole, we hope to be able to help further the debate around proper targeted interventions, which could improve the beef and sheep sectors' viability while supporting Ireland in achieving its environmental targets.

Benchmarking the sustainability performance of pastoral dairy-beef production systems*M. Kearney^{1,2}, J. Breen¹, E. O` Riordan² and P. Crosson²**¹University College Dublin, School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, D04V1W8, Ireland, ²Teagasc, Animal & Grassland Research and Innovation Centre, Teagasc, Grange, Dunsany, Co. Meath, Ireland, c15pw93, Ireland; mark.kearney@teagasc.ie*

Sustainable beef production involves environmental stewardship and farm-level economic viability. It has emerged as an important global policy issue as demand for animal-sourced food increases due to population growth and growing affluence in developing countries. The abolition of the EU milk quota system and subsequent expansion of the dairy herd has increased the proportion of beef derived from dairy dams. Consequently, there is increasing interest in the performance of dairy-beef production systems particularly with respect to farm profitability and greenhouse gas (GHG) emissions. Therefore, the objective of this paper was to identify key economic and GHG performance indicators for dairy-beef systems. The Grange Dairy Beef Systems Model (GDBSM) was used to model three categories of dairy-beef farms representing Irish 'national average' farms (AVE), farms participating in a farm improvement program (IMP), and a research farm system (RES) in order to identify and quantify key performance metrics underpinning differences in farm performance levels. Key sustainability performance indicators identified in this study include live weight and carcass output per ha, age of slaughter, animal live weight performance, inorganic N application rates and proportion of grazed pasture in the animals' feed budget. It is evident from the current study that dairy-beef systems are multifaceted and that there is no one stand-alone key performance indicator that exists to achieve sustainability.

Session 14

Theatre 13

Measuring, reporting and verifying farm sustainability (Food Futures)*R. McGuire¹, A. Aubry², S. Morrison², J. Birnie¹ and N. Scollan¹**¹Queen's University Belfast, Institute for Global Food Security, 19 Chlorine Gardens, BT9 5DL, Belfast, United Kingdom, BT9 5DL, United Kingdom, ²Agri-Food and Biosciences Institute, Livestock Production Sciences, Large Park, Hillsborough, United Kingdom, BT366DR, United Kingdom; r.mcguire@qub.ac.uk*

Grassland agriculture requires a data-driven tool measuring, reporting and verifying whole-farm sustainability. This 'nature positive' tool must be scientifically informed, adapt to and satisfy emerging policy and enable / stimulate industry 'buy-in'. Co-created with industry, Food Futures (FF) has developed a holistic metric profile (i.e. carbon footprint, profit, well-being, etc.) which is substantiated by sustainability algorithms – functioning as a tool (dashboard) that measures sustainability and supports on-farm decision making. FF integrates digital technology (i.e. geographical positioning systems, light detection and ranging and life cycle analysis) to stream data from multiple sources to improve soil health, water quality, carbon sequestration, precision nutrient application and on-farm habitat management. FF has successfully completed a commercial pilot study with the Livestock Meat Commission Northern Ireland (06/06/22 – 19/08/22). These farms included 21 dairy, 78 beef, 23 sheep and 40 mixed farm enterprise. Additionally, 28 were designated as disadvantaged, 48 Less Favoured Area (LFA), 65 lowland and 20 severely disadvantaged. Initial results indicate that (1) 40% of farmers use low-emission slurry spreading equipment (LESSE), (2) 48% of farms had completed full-farm soil sampling analysis within the last 5 years and (3) only 96% store slurry and manures in a secure and environmentally friendly methods. In addition, the sustainability performance of these farms has been measured, with each farm receiving a targeted two-way knowledge-exchange output (dashboard) including tailored recommendations for improvement. This digital and targeted approach allows farmers to (1) measure their performance and operate within the parameters of sustainability, (2) delivers continuous environmental and climate 'smart' feedback to drive behavioural change, (3) collates evidence of production footprint for national and global markets and (4) contributes to net zero by 2050.

Closing of the 3rd ATF-EAAP LFS symposium

F. O'Mara¹ and M. Lee²

Closing of the symposium by the co-chairs.

Session 14

Poster 15

Environmental performance by type of Iberian farm in the Dehesa ecosystem

J. García-Gudiño¹, J. Perea², E. Angón² and I. Blanco-Penedo³

¹CICYTEX, Animal Production, Finca La Orden, 06187 Guadajira, Spain, ²University of Córdoba, Animal Production, Campus Universitario de Rabanales, 14071 Córdoba, Spain, ³University of Lleida, Department of Animal Science, Av. de l'Alcalde Rovira Roure, 191, 25198 Lleida, Spain; isabel.blanco.penedo@slu.se

Traditional Iberian pig production is developed in the Dehesa ecosystem, where the Iberian pigs are linked to the sustainable use of natural resources. Currently, Iberian pig production is diversified in the Dehesa ecosystem. As a result, the ecosystem of the Dehesa is threatened by overexploitation, and it is necessary to adopt measures to make traditional Iberian pig production more sustainable, in line with European policies focusing on sustainable food production. The aim of this paper was to identify different typologies of traditional Iberian farms, based on their economic and environmental performance, with the aim of increasing the sustainability of these farms. Sixty-eight Iberian pig farms were evaluated using multivariate statistical tools in order to establish Iberian farm typologies. Factor analysis revealed three factor components related to management, productivity and area yield that characterise Iberian pig farms. Two groups of Iberian farms were identified: Multiple orientation and Montanera orientation. From the analyses carried out, the relationship between the characteristics of the Iberian farm typologies and the economic and environmental performance was determined. The environmental performance of traditional Iberian pig production was analysed for both Iberian farm types as a result of cluster analysis. Overall, montanera farms obtained better environmental values and economic benefits per environmental unit produced than multi-orientation farms. Consequently, the analysis of the different farm types in Iberian traditional pig production can be used to generate best practice guidelines for a more sustainable Iberian pig production from an economic and environmental point of view.

Ration protein content affects intake, production, efficiency and methane emission of dairy cows

F. Schori, C. Kasper and A. Munger

Agroscope, Ruminant Nutrition and Emissions, Animal GenoPhenomics, Tioleyre 4, 1725 Posieux, Switzerland; fredy.schori@agroscope.admin.ch

The main N imports in a milk production system are from feedstuffs, fertilizer and atmospheric deposition. Improvements in management and adaptation of the diet composition have a great potential to improve N use efficiency of lactating cows. The goal of the study was to investigate the effects of protein reduced diets on feed intake, milk production, efficiency and methane emission of dairy cows. The trial lasted three weeks, two weeks for adaptation and one measurement week. A total of 30 Holstein cows were allocated based on their lactation number, milk yield before the trial, lactation stage and body weight. Cows in the control group (CONTROL) were offered a total mixed ration (TMR) that was balanced in terms of absorbable protein in the intestine (based on fermentable energy and rumen available nitrogen) and of net energy for lactation (NEL). The TMR of the N reduced group (REDN) was formulated to cover the requirements for crude protein (CP) and NEL. The two TMR, consisting of maize silage, hay, grass silage, two concentrates (energy and protein-rich in different proportions) and minerals, were iso-energetic with 6.1 MJ NEL/kg dry matter (DM). Only the CP content of the TMR was different, CONTROL 152 g/kg DM and REDN 136 g/kg DM. CONTROL cows ate more (23.4 vs 21.8 kg DM, $P<0.001$) and produced more energy corrected milk (35.1 vs 32.3 kg, $P=0.01$). Feed conversion rate (0.67 vs 0.68, $P=0.67$) and residual feed intake (-0.72 vs -0.89 kg, $P=0.82$) did not differ between the treatments. In contrast, milk urea content (19.7 vs 13.7 mg/dl, $P<0.001$), residual nitrogen intake (74.9 vs 13.3 g N, $P<0.001$) and daily nitrogen excretion via urine (170 vs 119 g, $P<0.001$) were increased in CONTROL cows, indicating more N losses compared to the REDN cows. At the same time, no differences were seen in the daily methane production between the treatments (481 vs 474 g/d, $P=0.71$), but the CONTROL cows emitted less methane per energy corrected milk (13.7 vs 14.8 g/kg, $P=0.02$) and per total DM intake (20.5 vs 21.8 g/kg, $P=0.03$) compared to the REDN cows. The impacts of measures to reduce N losses in milk production systems should be assessed in the broadest sense.

Session 14

Poster 17

Is protein autonomy synonymous with economic efficiency?

E. Bertrand, C. Corre and R. Bore

Institut de l'Elevage, Production laitire, 149, rue de Bercy, 75012 Paris, France; eric.bertrand@idele.fr

The economic performance of Cap Proteines dairy pilot farms was assessed through the calculation of production costs. The COUPROD tool provides a synthetic indicator through the feed cost (corresponding to the cost of purchased feed plus the cost of supplying the land used by the herd) to assess the link between protein autonomy and economy. Analysis of economic data from pilot and reference farms logically shows a relationship between the level of protein autonomy and the cost of feeding. The cost of feed decreases with the increase in protein autonomy and the reduction of feed purchases. In dairy cattle, for example, the feed cost decreases by 48% when the protein autonomy changes from 50 to 90%, going from 158  to 76 /1000 l of milk. There is statistically no change in the cost of soil inputs in relation to the level of protein autonomy of the livestock. Regarding the direct expenses, the savings from lower feed purchases exceed the increase in inputs related to GFS or self-consumed crops. Gaining protein autonomy therefore helps to reduce the feed cost of the herd. This relationship is not maintained at the level of the cost of the feeding system of the dairy workshop, whose calculation integrates the indirect loads and structures related to the areas used to feed the herd (mechanization and land). On the other hand, its composition differs with the improvement of protein autonomy: there is a deferral of purchase costs in mechanization costs (harvest and fodder crops, cereals and protein crops own consumption), and working land. In the end, the cost of the feeding system is neither reduced nor increased with the search for autonomy. This is true in all ruminant sectors. The linear correlation between protein autonomy and the economic efficiency indicator (EBE/PB) is low ($R^2=0.198$) but positive and significant. It is not related to the level of technical productivity or the size of the dairy workshop. Gaining protein autonomy improves the economic efficiency of the production system through mainly load saving.

Development of multicriteria analysis' methodology in an experimental farms network*C. Corre¹ and C. Brasseur²**¹Institut de l'Elevage, 8 route de Monvoisin, 35650 Le Rheu, France, ²Institut de l'Elevage, Boulevard des Arcades, 87000 Limoges, France; clemence.corre@idele.fr*

Today, environmental, economic, and societal context is complex. To pilot resilient livestock systems, technical indicators are no longer sufficient. Other indicators need to be calculated and analysed periodically to take all matters into account. The aim of this study was to develop a multicriteria analysis in an experimental farms' network, in all ruminants' productions (dairy cows, dairy sheep, dairy goats, suckler cows and suckler sheep). Twelve experimental farms were involved. These farms combine production of milk and meat, experimentation for research in real conditions and sometimes instruction for professionals or future ones. About 150 indicators were selected to describe each farm and assess their annual multiperformance, that means their economic, environmental, and social/societal performances. These indicators were calculated by existing tools and related to technical and economical results, feed self-sufficiency, environmental impacts and benefits, competition between feed and food, and animal welfare. This multicriteria analysis focused on the production system of farms. Some economic products and charges linked to experimentation or instruction were not considered. After validation, this analysis was rolled out in the twelve farms. For the first year, analysis was focus on 2020 or 2021. On these years, protein self-sufficiency varied from 68 to 95% in dairy cows' farms and from 76 to 100% in suckler cows' farms. In dairy and suckler sheep farms and dairy goats' farm protein self-sufficiency was respectively 77, 90 and 22%. Carbon footprint, calculated with CAP2ER®, was also various: from 4,050 to 7,410 kg eq. CO₂/ha UAA, depending on farms. This analysis will be repeat every year to analyse indicators' evolution on farms and to pilot choices.

Session 14

Poster 19

Multicriteria analysis on French experimental farm which develops its feed self-sufficiency*C. Corre¹ and R. Boré²**¹Institut de l'Elevage, 8 route de Monvoisin, 35650 Le Rheu, France, ²Institut de l'Elevage, 42 rue Georges Morel, 49070 Beaucouzé, France; clemence.corre@idele.fr*

Experimental dairy cows farm of Poisy is located in the lowlands of the Alps mountains in eastern France. A multicriteria analysis was made on this farm to assess its technic, economic, environmental, and societal performances, including feed self-sufficiency. More than 150 indicators were calculated with existing tools and some of them were compared to a group of similar farms. In 2021, global feed self-sufficiency was 83% and protein self-sufficiency was 74%, while group's average was respectively 79 and 68%. Many strategies are implemented to improve feed self-sufficiency in a context of climate change: diversification of grasslands composition, growing plant species better adapted to heat and drought like fodder beet and alfalfa, production and use of raw soybean for animal feeding. The carbon footprint calculated with CAP2ER® method was quite high: 0.92 kg eq. CO₂/l of milk produced, because of heifers' breeding for other farmers that increases methane emissions. The farm can feed 19 persons / ha UAA and 93% of proteins fed to cattle are non-digestible by human ! Indeed, 80% of the dry matter fed annually to animals is composed of grass and rapeseed cake is used instead of soybean cake. This analysis enables to have a global vision on the farm system regarding economic, environmental, and societal issues. Strengths and weaknesses were identified and some measures could be implemented to improve some points.

Partial indicators monitoring in dairy farm: effect of feed efficiency improvement on gross margin

G.S.S. Gian Simone Sechi and A.A.S. Alberto Stanislao Atzori

University of Sassari, Department of Agricultural Science, Viale Italia, 39, Sassari, 07100, Italy; giansimone.sechi@iusspavia.it

The use of partial indicators helps to improve technical and economic efficiency of dairy farms. The aim of this work was to propose a practical approach to monitor farm costs and incomes and related indicators of profitability. A methodological framework to calculate farm gross margin was developed and applied to a dairy cattle farm with 227 milking cows from Arborea (Or, Italy). Farm data were gathered at daily scale and elaborated twice per month. Replacement and dry cattle, health and reproduction cost, energy and other cost that included: fuel, electricity and other materials, were monitored separately gathered through the management software Ecostalla®. Monitored variables included: diet formulas, dry matter (DM) and costs of the produced and purchased feeds, milk delivered and price, meat and cattle sold (culled cows, live animals). The farmer was asked daily to input in an excel spreadsheet feed and milk delivered, milking cows, feed orts for lactation groups and then consistency, feed delivered and weekly the unifeed DM. Partial indicators were calculated for feed efficiency as mik/feed (FE), cost in €/kg of DM, IOFC, gross margin (revenues – considered costs). All the calculations were referred to the year 2022, the average milk price and feed cost of lactating cows were 0.465 €/l and 0.39 €/kg of DM, respectively. The average milk production and DMI per cow was 33 l/d and 25.5 kg/d respectively, with a FE of 1.29. Pooling daily data over the whole year a variation of ± 0.1 in FE corresponded to ± 1.01 €/head daily change in IOFC. At the end of the year the feeding cost were equal to 817,798 € for lactating cows, 229,354 € for heifers, dry cows and calves, health and reproduction cost were 60,852 € and energy and other cost were 212,132 €. The final gross margin was 18,461 €, ranging from a max of 14,282 € in March and a min of – 15,501 € in September. Improving FE from 1.29 to 1.43, thus reaching 26.5 kg/d of DMI and 38 l/d of milk, supposing increased dietary costs of 0.02 €/kg of DM and keeping constant other costs the gross margin would have been 128,707 €. This approach can be useful to stimulate the farm team of technicians and operators to focus on farm data and their economic implications.

Comparison of methodologies for estimating animal emissions from smallholder cattle systemsE. Balcha¹ and C. Arndt²¹Mekelle University, Mekelle, Ethiopia, ²ILRI, Naivasha Rd, Nairobi, Kenya; claudia.arndt@cgiar.org

The objective of this study was to compare gross energy intake (GEI; MJ/animal/day) and enteric methane (CH₄) emission factors (EF; CH₄ kg/animal/year) of different cattle categories from smallholder systems in Ethiopia based on Intergovernmental Panel on Climate Change (IPCC) Tier 1, IPCC Tier 2, and International Livestock Research Institute (ILRI) Tier 2 methodology. The ILRI Tier 2 methodology uses calculations that are based on or modified from equations published in 'Nutrient Requirements of Domesticated Ruminants' (CSIRO 2007). In comparison to IPCC, the ILRI methodology is based on metabolizable and not net energy requirements of the animal. Data from Ethiopian smallholder systems were collected four times corresponding to the beginning and end of the three seasons (spring, summer and winter) to account for the effect of seasonality on animal liveweight, diet and performance. There was a high correlation of GEI between IPCC and ILRI Tier 2 methodology ($R^2=0.87$). However, the IPCC Tier 2 methodology estimated a higher GEI than the ILRI methodology ($P<0.05$; based on one-sample t-test). The mean difference in GEI was 28 MJ/animal/day (s.d. 18.2), which was 27 and 38% of the average GEI estimated by IPCC and ILRI methodology, respectively. Compared to ILRI methodology, IPCC methodology used a greater methane conversion factor (Y_m ; 7.0 vs 6.3% of GE in feed converted to CH₄). Because of the greater GEI and Y_m , the IPCC methodology estimated on average 49% greater EFs than the ILRI methodology (48.4 vs 32.4 CH₄/animal/day, $P<0.05$). The EFs calculated across all cattle categories (adult females, intact and castrated males, heifers, young makes, and calves) for IPCC Tier 1 (2019) default EFs were found to be 23-38 and 38-59% lower for the IPCC and ILRI Tier 2 methodology, respectively. Similarly, when compared to Tier 1 methodology, IPCC and ILRI Tier 2 methodology estimated 27 and 51% lower total animal emission from smallholder cattle systems, respectively. The observed difference between the methodologies was based on the differences in predicted feed intakes and Y_m . Hence, the predictions by Tier 1 and 2 methodologies need to be compared to *in vivo* intake and CH₄ measurements to determine which methodology predicts GEI and Y_m more accurately.

Developing a common framework to measure sustainability in food systems with limited arable landP. Bhérier-Breton¹, A. Woodhouse², E. Svanes², H.F. Olsen¹ and B. Aspehølen Åby¹¹Norwegian University of Life Sciences (NMBU), Elizabeth Stephansens v. 15, 1430 Ås, Norway, ²Norwegian Institute for Sustainable Research (NORSUS), Stadion 4, 1671 Kråkør, Norway; paule.bherer-breton@nmbu.no

Food and food systems are important when finding solutions for the future sustainability challenges and to make progress for the sustainable development goals. To enable sustainable food transformations, frameworks that measure food system sustainability are a crucial tool. The Farm to Fork initiative from 2020 describes proposals for front-of-package labelling for both nutrition and sustainability to empower consumers to make knowledge-based decisions. Labelling systems for nutrition is already implemented in several countries, for instance the Nutri-Score. Whereas for sustainability, there is no common labelling framework yet covering several dimensions of sustainability, and themes and sub-themes within these. Creating a common framework for food labelling could represent a threat to local food security and national food sovereignty, if its' conceptualization is not transparent or do not consider the features of all countries within a region (e.g. Europe), and as such prevent sustainable resource utilization. The aim of this work is to identify the gaps between existing frameworks on environmental and social sustainability, and what is needed to foster sustainable food systems. Relevance and feasibility of those frameworks are discussed the case of Norway, a country where the specificities of local ecosystem are unique due to the country's topography, several climatic zones and limited arable land. This study is part of the project NewTools (Research Council of Norway) where the aim is to contribute to food system change through developing frameworks for food labelling focusing public health and environmental and social sustainability.

Together with other major international dairy organizations, Dairy Farmers of Canada has pledged to reach net-zero greenhouse gas emissions from farm-level dairy production by 2050. Consequently, Canada has been building capacity to measure and/or predict enteric methane (CH₄) emissions for both herd monitoring and genetic tools. First, milk mid-infrared (MIR) records have been saved and stored since 2017 for 90% of milk recorded cows in Canada. Then, data collection of CH₄ emissions started in 2016 in two research herds using the GreenFeed System. This data was then used to predict CH₄ production for first parity Holstein cows using MIR spectra data between 120 and 185 DIM. This prediction serves as input for a new genomic evaluation system that has been launched in April 2023 by Lactanet Canada. Research based out of the University of Guelph using a machine learning algorithm has shown great accuracy of predicting individual animal methane emissions for milk-recorded cows using milk MIR spectral data through two research projects, the Efficient Dairy Genome Project and the Resilient Dairy Genome Project, and milk spectral data collected via our milk recording services. Predicted methane had a genetic correlation with collected methane of 0.85 and a heritability of 0.23 (0.01). Lactanet's genomic evaluation for Methane Efficiency was developed using a 4-trait single-step genomic evaluation for predicted methane for the Holstein breed, including milk, fat and protein yields as energy sinks, and defined as genetic Residual Methane Production independent of milk, Fat and Protein via a linear regression approach. Methane Efficiency is an important selection tool, allowing dairy producers to reduce methane emissions without negatively affecting production.

Methane phenotyping for genetic selection – can we measure bulls, not cows?

L.R. McNaughton¹, P. Beatson², G. Worth¹, D.J. Garrick³, D. Garrick³, R. Handcock³ and R.J. Spelman¹

¹Livestock Improvement Corporation, 605 Ruakura Road, Hamilton, 3286, New Zealand, ²CRV, 2 Melody Lane, Hamilton 3216, New Zealand, ³The Helical Company Limited, 17 Appleby Rise, Whakatane 3120, New Zealand; lorna.mcnaughton@lic.co.nz

Most economically important traits relevant to dairy systems can only be measured on lactating females. Methane production and dry matter intake (DMI) are traits that can be measured on dairy bulls before semen collection begins. These traits were recorded on two farms in New Zealand. The purpose of the trial was to assess the adequacy of the data for the estimation of genetic parameters. Some 486 Jersey (J), Holstein-Friesian (HF) or Jersey × Holstein-Friesian (Crossbred) bulls, aged 6-15 months, were housed for 35-day periods. Bulls were fed lucerne hay cubes, with up to 10% of the diet as pelleted concentrate bait feed via Greenfeed (GF) devices. Hokofarm Ric2Discover feed intake bins were used for DMI while methane production was measured using GF systems. Bulls were allowed up to 6 visits per day to the GF device. Liveweights were recorded thrice per week. Genetic analysis was performed from a Bayesian bivariate repeatability model fitted by Monte Carlo Markov chain sampling using Julia for Whole-genome Analysis Software (JWAS v1.1.1). A further 300 bulls are being tested in 2023. There were 13,109 daily methane emission phenotypes and 12,687 daily DMI phenotypes from the initial 486 bulls. The methane emission phenotypes consisted of a daily methane yield-equivalent for each visit the bull made to the GF device. To obtain one daily value per bull, visits within a day were pooled to represent the total daily methane and total time in seconds a bull was measured for methane. Heritability estimates and 95% credibility intervals were obtained for methane of 0.1 (0.06, 0.15) and DMI 0.09 (0.05, 0.15). Breeding values (BVs) for methane, adjusted for DMI were significantly ($P < 0.05$) higher in Crossbred than J or F. Heterosis effects should be investigated. To validate the approach including the use of bulls for phenotyping, 350 daughters are being generated from the 25 highest and 25 lowest BV bulls to determine if the differences in methane observed in bulls are also observed in lactating dairy cattle.

Novel formulas to calculate methane production from concentrations while using sniffersC.I.V. Manzanilla-Pech¹, M.H. Kjeldsen², T. Villumsen¹ and J. Lassen^{1,3}¹Center for Quantitative Genetics and Genomics, Faculty of Science and Technology, Aarhus University, C. F. Møllers allé 3, 8000 Aarhus C, Denmark, ²Department of Animal Science and Veterinary Science at Aarhus University, Blichers Allé 20, 8830 Tjele, Denmark, ³Viking Genetics, Ebeltoftevej 16, Assenstoft, 8960 Randers, Denmark, Denmark; coralia.manzanilla@qgg.au.dk

Sniffers are widely used to measure methane emissions in dairy cattle. However, sniffers measure concentrations of methane (MeC) and carbon dioxide. To be able to compare animals across countries and other methane recording methods, it is needed to transform MeC to methane production in g/d (MeP) that is the gold standard trait. Madsen *et al.* formula has been widely used to calculate MeP in dairy cattle from MeC and carbon dioxide concentration. Though, this formula was developed based on a limited number of animals, not similar to modern dairy cows. Recently, Kjeldsen *et al.* have developed couple of formulas based on a data set with larger number of animals (n=1,502) in different countries (n=12) and production systems. The first formula uses ECM and BW as the Madsen *et al.* formula, however the coefficients have been re-estimated based on the new data set. The second formula has DMI and BW as main drivers of methane emissions, this formula could be convenient when DMI is available. However, these new formulas have never been tested for genetic purposes, only for nutritional purposes, where their correlations with respiration chamber and GreenFeed data is from 0.68 to 0.76. Thus, the general aim of this paper is to test these formulas in a large database, 24k methane records from 650 cows measured during 7 years in Danish Cattle Research Center, Aarhus University, Denmark. The specific objectives are: (1) to calculate MeP with these updated formulas; and (2) estimate genetic parameters including genetic correlations with the previous formula; (3) to calculate EBV correlation between the formulas. Preliminary results showed similar heritabilities (0.19-0.23) to the previous formula (0.21) and high genetic correlation (0.79-0.82) between the new formulas and the previous formula. The genetic correlation between these two new formulas was close to unity (0.99).

Predicting methane production and intensity from milk mid-infrared spectraS. Fresco^{1,2}, A. Vanlierde³, R. Lefebvre¹, M. Gaborit⁴, D. Boichard¹, R. Bore⁵, S. Fritz^{1,2}, N. Gengler⁶ and P. Martin¹¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²Eliance, 149 Rue de Bercy, 75012 Paris, France, ³Walloon Agricultural Research Centre, Valorization of Agricultural Products, 9 Rue de Lioux, 5030 Gembloux, Belgium, ⁴INRAE, UE326 Domaine Expérimental du Pin, l'Ermite, 61310 Exmes, France, ⁵Institut de l'Élevage, 149 Rue de Bercy, 75012 Paris, France, ⁶ULiège – GxABT, 2 Passage des déportés, 5030 Gembloux, Belgium; solene.fresco@eliance.fr

Selecting dairy cows against methane (CH₄) emissions is one of the solutions to reduce greenhouse gas emissions. However, as large-scale phenotyping is challenging, proxies have been developed to supply the amount of data necessary to genetic analyses. One of them is predicting CH₄ emissions from milk mid-infrared spectra. This study aimed at comparing prediction equations developed from two reference CH₄ for two CH₄ traits: MeP (g/d) and MeI (g/kg of fat- and protein-corrected milk [FCPM]). Methane emissions were recorded using GreenFeed devices, for 278 cows from nine different experiments. These reference CH₄ emissions were averaged over 1 or 2 weeks and were associated to 1,035 and 680, respectively. Equations were derived using Partial Least Square regression. A second dataset including 104 spectra and 1-week or 2-week CH₄ averages from 46 cows was used as an external validation to assess the performance of each equation based on R² and % of RMSE/observations mean (E). Performance was similar for both reference CH₄ time periods. Equations calibrated on 2-week CH₄ averages tended to have lower R² and E than the one on 1-week CH₄ averages. The average R² (E) were 0.28 (17.7) and 0.43 (17.3) for MeP and MeI, respectively. Indirectly predicting MeP by multiplying predicted MeI by FPCM was found to be as accurate as MeI and more accurate than predicting directly MeP. As selection of MeI presents two disadvantages – lower efficiency when selecting a ratio than the two traits separately and a potential increase of milk production at a given MeP, which would be detrimental to high producing cows' fertility and health – using CH₄ predicted from MeI multiplied by FPCM can be of great interest in genetic selection.

Genetic parameters for enteric methane emissions of dairy cows using random regression models

A.E. Van Breukelen¹, M.N. Aldridge¹, R.F. Veerkamp¹ and Y. De Haas²

¹Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands,

²Wageningen University & Research, Animal Health & Welfare, P.O. Box 338, 6700 AH Wageningen, the Netherlands; anouk.vanbreukelen@wur.nl

To reduce the environmental impact of dairy farming, there is considerable interest in applying selective breeding to mitigate enteric methane emissions of cattle. To add methane to breeding programs, models need to be developed that accurately estimate breeding values for individual cows. The objective of this study was to apply a random regression model to long-term recorded methane emissions, which estimated genetic parameters across the lactation curve. Methane concentrations were measured with sniffers in milking robots. The data comprised of 20,768 weekly mean methane concentration measurements from 1,587 cows, with recording periods ranging from 1 to 17 months, on 14 commercial dairy farms in the Netherlands. Genetic parameters were estimated using a single-trait restricted maximum likelihood model in ASReml. The model included fixed effects for farm, year, week of measurement, parity and second order Legendre orthogonal polynomials for days in milk (DIM). In addition, the model included random regressions on the genetic and permanent environmental effect, using second order Legendre orthogonal polynomials, and a heterogeneous residual effect with four classes. The heritability was moderate at the start of the lactation (0.25 ± 0.09 , at 5 DIM), peaked in mid lactation (0.41 ± 0.06) and decreased to a low heritability in late lactation (0.06 ± 0.04 , at 305 DIM). The repeatability was approaching one at the start of lactation (<10 DIM), and reduced steeply between 15 and 25 DIM, after which it stabilized but remained high at 0.74 ± 0.02 . Genetic correlations between the first 25 days of lactation and later lactation stages were moderate to high (ranging from 0.38 ± 0.19 to $1 \pm <0.01$). The results confirmed that using a random regression model is more appropriate than using a model that would assume that genetic correlations between different DIM are one. A novel dataset is currently being recorded, which will increase recording to 100 dairy farms with around 15,000 cows. The results will be used to improve the accuracy of the estimations and to confirm the results presented here.

Session 15

Theatre 6

Heritability of methane emission in dairy cows estimated from GreenFeed measures in commercial herds

B. Heringstad^{1,2}, K.A. Bakke¹ and G. Difford²

¹Geno Breeding and A.I. Association, Storhamargata, Hamar, Norway, ²Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Faculty of Biosciences, Ås, Norway; bjorg.heringstad@nmbu.no

The aim of this study was to estimate heritability of methane emissions (CH_4) for Norwegian Red dairy cows. Measures of CH_4 from 15 GreenFeed units installed in commercial herds was available. We used data from 2020 and 2021 and the final dataset had a total of 370,642 records of GreenFeed visits from 814 Norwegian Red cows. The trait analysed was CH_4 , gram per cow per day, computed as the average of the cow's individual visits each day. The mean (standard deviation) CH_4 was 422 (96) gram per cow per day. A linear animal repeatability model with fixed effects of parity and lactation week, and random effects of herd-testday, animal, and permanent environment was used to estimate variance components. The estimated heritability (standard error) was 0.34 (0.04) and repeatability 0.42. The predicted breeding values for cows with phenotype varied from -123 to 143, with standard errors between 22 and 34. Results so far are promising. The genetic variation for CH_4 in the Norwegian Red breed indicates that breeding for lower CH_4 is feasible.

Rapid measurements for breeding low methane cattle

Global warming attributed to methane emissions from livestock presents a significant global challenge to the agricultural sector. Although opportunities in intensive systems for feeding additives exist, the only proven tool for permanent mitigation at a national level, across sectors is breeding. The greatest challenge to incorporating methane emissions into breeding schemes is the difficulty of direct measures on selection candidates. A single measure of methane emissions from a portable accumulation chamber in sheep has been shown rank animals for their lifetime. These measures have successfully been employed to show a 2% reduction in methane emissions per year without affecting productivity. To extend this to cattle, a portable accumulation chamber was designed and built by engineers at AgResearch. To test the design, thirty Holstein-Friesian heifers at approximately 10 months of age and averaging a weight of 250 kg were evaluated. Heifers were fed *ad libitum* baleage for two weeks prior to the start of measures. Heifers were measured over a 5-day period. On the day of measure, a group of 6 heifers were removed from feed. After one-hour heifers were placed one at a time into the chamber for forty-five minutes. Methane (CH₄), Carbon-dioxide (CO₂) and Oxygen (O₂) measures were taken every 5 minutes using an Eagle II analyser. After two weeks the trial was repeated. Results were very similar on a liveweight basis to those seen in sheep per kg liveweight for CH₄ after a 40-minute measure. Importantly, no behavioural issues were observed while the animals were restrained in the chambers. We conclude that the portable accumulation chamber is potentially a suitable measurement technology for the lifetime ranking of cattle for enteric methane emissions for breeding schemes under any management regime. We will present protocols, behaviour observations, variances and phenotypic repeatabilities.

¹Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus C, Denmark, ²Aarhus University, Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, ³VikingGenetics, Ebeltoftvej 16, 8960 Randers, Denmark; tmv@qgg.au.dk

The EU Green Deal has made the target of no net emissions of GHG by 2050. This requires reduction of GHG from the livestock sector and particularly from dairy. Genetic selection for low methane (CH₄) emitting dairy cows can be one of the important mitigation strategies. The methane sniffer typically installed in an automatic milking system (AMS) makes it possible to record individual CH₄ concentrations from many cows. However, to achieve a high-quality CH₄ phenotype for genetic evaluation, we need a sniffer setup with high operational reliability and an automated data handling pipeline for data quality control. In Denmark, we currently record gas emission from cows with 14 sniffers based on the Guardian NG methane sensor and an additional carbon dioxide (CO₂) sensor. Each sniffer has a multiplex setup with two channels which makes it possible to switch recordings between two AMS units. Our database currently holds CH₄ records of ~8,500 dairy cows from 22 farms. Each day we get ~1.1 mil. new data points from the sniffers currently installed in five farms with ~1,600 dairy cows. The sniffer setup requires daily monitoring of Wi-Fi connections, data transfer, and concentrations as well as technical assistance on farms when irregularities in data flow are observed. The subsequent handling pipeline includes several steps hereunder. (1) A check of time alignment of AMS data and gas data to pair cow and gas concentrations. For this, and quality control of CO₂ concentrations, we use a matched filter approach (doi.org/10.1016/j.compag.2022.107299). (2) Discard data with irregularities in CH₄, e.g. due to instrument breakdowns, duplicated and obvious bad data. (3) Correct for baseline gas concentrations due to diurnal changes and random drift of sniffers. (4) Overall pruning of early and late gas data during milking, to keep part of gas data where concentrations are the highest. These steps are to be integrated and automated for routine genetic evaluation.

Methods and tools for automated processing of sniffer-based methane emission data from dairy cows

V. Milkevych, R.K. Nielsen, T.M. Villumsen, P. Løvendahl and G. Sahana

Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus C, Denmark; vimi@qgg.au.dk

Mitigating methane emission from livestock production is one of the crucial factors for sustainable agricultural food production. To ensure the demanded sustainability level of agricultural food production, a continuous monitoring and efficient implementation of diverse emissions mitigation strategies are required. Hence, a proper emission measurement technique is crucial, which fulfils three basic requirements: cheap and easy-to-operate; scalability and mobility of measurements; and high level of reliability of a measured data and resulting precise emission phenotypes. Overall, the sniffers are cheap, mobile, and relatively easy-to-operate technique. However, due to the intrinsic properties, mostly associated with technique's hardware and the related data acquisition set-up, the quality and reliability of measured gas emission data are of great concern. This leads to the significant difficulties in drawing reliable (statistical) estimates, such as methane phenotypes which, in fact, are highly important for establishing methane emissions mitigation strategies and animal breeding schemes. Hence, there are several major data-related sniffers-technique's issues: alignment (synchronization), reliability detection, and the great level of measurement (embedded) noise. Here we focus on the methods and software aimed to solve these issues. The methods are based on the general approach developed using the linear filtering theory. The algorithmic implementation of the developed approach allows fast and efficient automated data processing. Besides the methodology, we provide its complete software implementation. Our implementations were verified on the massive bulk of the gas emission data from the multiple commercial dairy farms in Denmark. These were analysed and discussed in terms of the methods accuracy and performance. Our findings support the conclusion that the proposed overall solution is robust, applicable to the problem of cattle gas emission data, and convenient for an automated large-scale data processing. The methods and tools are ready for routine phenotyping for use in both management and genetic evaluation to reduce emission from dairy cattle production.

Recently, there has been an increase in interest in the reduction of methane (CH₄), and the genetic selection of cows with low CH₄ emissions has drawn attention for sustainable livestock production. Thus, it is necessary to identify selection indicators that can be measured in a large number of samples at low cost in commercial farms. One of the strategies for measuring CH₄ at low cost is the sniffer method, in which the air near the animal's nostrils is sampled through a fixed tube in a feed trough in an automatic milking system (AMS). Here, our objective was to evaluate whether the CH₄ to carbon dioxide ratio (CH₄/CO₂) and methane-related traits obtained by the sniffer method can be used as indicators of genetic selection for lower CH₄ emissions in Holstein cows. First, we investigated the impact of the model with and without body weight (BW) on the lactation stage and parity for predicting methane-related traits using an on-farm dataset (Farm 1; 400 records for 74 Holstein cows). Second, we estimated the genetic parameters for CH₄/CO₂ and methane conversion factor (MCF) using a second on-farm dataset (Farm 2; 520 records for 182 Holstein cows). Farm 1 results revealed that MCF can be reliably evaluated during the lactation stage and parity, even when BW is excluded from the model. Furthermore, the CH₄/CO₂ and MCF could be evaluated consistently during the lactation stage and parity on both farms. Estimates for genetic parameters revealed low heritability for CH₄/CO₂ (0.12) and MCF (0.13) on Farm 2, but moderate repeatability for CH₄/CO₂ and MCF on both farms (ranging from 0.38 to 0.46). This study demonstrated the applicability of the sniffer method for the genetic selection of cows with low CH₄ emissions at the farm level.

Reducing methane emissions: foundations for genetic evaluations for sustainable Irish beef cattleC.V. Ryan^{1,2}, S. Conroy², T. Pabiou², D.C. Purfield¹ and R. Evans²¹Munster Technological University, Bishopstown, Co. Cork, T12 P928, Ireland, ²Irish Cattle Breeding Federation, Ballincollig, Co. Cork, P31 D452, Ireland; cryan@icbf.com

Livestock production globally is a significant contributor to anthropogenic greenhouse gas emissions, particularly methane. Animal breeding provides a potential solution for reducing enteric methane emissions in a cost-effective, permanent, and cumulative manner. Before adding methane to a selection index, correlations with economically important traits already included in breeding goals must be evaluated. This study aimed to estimate genetic parameters, including heritability and genetic correlations between methane and feed intake, using a large quantity of GreenFeed Emission Monitoring system data. The data available in this study consisted of methane measurements of steers, heifers and young bulls in a commercial feedlot environment, with methane measurements recorded via GreenFeed Emission Monitoring units. To date, 1,450 animals, ranging from 368 to 910 days of age have undertaken methane measurement cumulating in 216,921 methane measurements. The test period duration for measurement ranged from 20 to 83 days. Additional measurements available on the population include detailed feed intake records recorded using Insentec feed boxes. Informative animals (n=1,155) were used to derive heritability estimates for methane and feed intake using DMU, ensuring sire representation across contemporary groups. Multiple definitions of the methane trait were analysed due to the varying length of test periods. The resulting six trait definitions included individual observations, 1-day average, 5-day average, 10-day average, 15-day average and a full test average methane trait. Methane heritability estimates ranged from 0.09 to 0.43 depending on trait definition, with larger averaging periods yielding greater heritability estimates. Each of the methane definitions was moderately correlated with dry matter intake ranging from 0.38 to 0.62. The results from this study will aid in the development of breeding values for greenhouse gas traits and the creation of a novel methane trait for future selection of sustainable livestock.

Determining relative values of genetic traits of Chinese dairy cattle in greenhouse gas mitigationY. Wang¹, R. Shi^{1,2,3}, A. Van Der Linden¹, B.J. Ducro³, Y. Wang², Y. Hou⁴, S.J. Oosting¹ and C.E. Van Middelaar¹¹Wageningen University & Research, Animal Production Systems group, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ²China Agricultural University, College of Animal Science and Technology, Beijing, 100193, China, P.R.,³Wageningen University & Research, Animal Breeding and Genomics group, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ⁴China Agricultural University, College of Resources and Environmental Sciences, Beijing, 100193, China, P.R.; yue3.wang@wur.nl

Breeding is considered a promising greenhouse gas (GHG) mitigation option for dairy sector. Compared with other mitigation options such as nutrition interventions, the effect of breeding is permanent and cumulative. Using a typical Chinese dairy farm as a case, this study builds on a novel method to determine the relative values of genetic traits in dairy cows to reduce GHG emissions. Life cycle assessment was conducted to calculate emissions from the farm (expressed in kg CO₂-eq per ton fat-and-protein-corrected milk (FPCM)). Results were combined with an existing bio-economic model to determine GHG values of six genetic traits, i.e. milk yield (MY), protein yield (PY), fat yield (FY), productive life (PL), calving interval (CI) and clinical mastitis (MAS). Next, an environmental breeding goal (minimizing GHG emissions) and an economic goal (maximizing farm profit) were formed, and relative weights of the traits under different breeding goals were calculated. Then the environmental and economic consequences of two goals were compared. Results showed that, with an improvement of one genetic standard deviation, MY, PY, FY, PL and MAS resulted in a reduction of 27, 6, 2, 6, and 1 kg CO₂-eq per ton FPCM, respectively, while CI resulted in an increase of 10 kg CO₂-eq per ton FPCM. As the goal shifted from economic to environmental focus, relative weight of MY doubled, meanwhile the weights of PY, FY and CI decreased. Under environmental goal, the reduction in emissions is 59% higher than that of economic goal, while the increase in profit is 37% less than that of economic goal. The study provides insights into trade-offs between economic and environmental gains that can be achieved via breeding. Results can be used by breeding organizations to contribute to a more environmentally friendly dairy sector.

Effects of breeding for feed efficiency on carbon footprint of milk – LCA approachS. Hietala¹, A. Astaptsev², E. Negussie³, M.H. Lidauer³ and T. Mehtiö³¹Natural Resources Institute Finland, Bioeconomy and environment, Paavo Havaksen tie 3, 90570 Oulu, Finland, ²Valio Ltd, Meijeritie 6, 00370, Finland, ³Natural Resources Institute Finland, Production systems, Myllytie 1, 31600 Jokioinen, Finland; sanna.hietala@luke.fi

The climate change impacts of cattle production are well acknowledged. Enteric fermentation and feed crop production are responsible for a large share of the carbon footprint (CF) of milk. Recent studies have shown a medium to high genetic correlation between feed utilization efficiency (FE) and methane (CH₄) emission implying selection for FE lowers CH₄ emission. However, the magnitude of the achievable effects is not clearly known. The aim of this study was to assess the size of correlated response on CH₄ emission due to selection for FE in Nordic Red cattle. The quantified impacts due to breeding for FE were assessed using life cycle assessment (LCA) method. The assessment for the Finnish dairy production ('business-as-usual', BAU) was conducted utilizing data collected from 700 Finnish dairy farms. The data included herd composition, feed composition, own feed crop production details (crops, yields, fertilizer inputs, crop protection), manure management system and the yields of raw milk and meat from cull cows. LCA model was constructed by following product environmental footprint category rules (PEFCR) of dairy products (EC 2018) and IPCC (2006, 2013) guidelines. These frameworks were complemented by national emission prediction models. System boundary was set to farm gate and the functional unit was 1 kg fat and protein corrected milk (FPCM). The CF was assessed for BAU and for the achieved genetic response of 10% improvement in FE but considering BAU for growing replacement cows. The BAU resulted CF of 0.977 kg CO₂eq/kg FPCM. Integration of the 10% improvement in FE due to breeding resulted in CF of 0.899 kg CO₂eq/kg FPCM, which was -8% less than BAU. The reduction of emissions was clearly largest from enteric fermentation (-0.042 kg CO₂eq/kg FPCM). The results indicate that breeding can be considered as powerful tool for climate change mitigation. Breeding for better FE also directly impacted those emission sources which are responsible of largest share of carbon footprint of milk, enteric fermentation and feed crop production.

Session 15

Poster 14

Automated CT analysis to identify low emitting ruminantsS. Hitchman¹, L. Grundy², W. Bain³, T. Johnson³, M. Reis⁴, H. Gunnarsdottir³, J. McEwan³ and S. Rowe³¹Agresearch Ltd, 10 Bisley Road, Hamilton 3214, New Zealand, ²Agresearch Ltd, 1365 Springs Road, Lincoln 7674, New Zealand, ³Agresearch Ltd, 176 Puddle Alley, Mosgiel 9092, New Zealand, ⁴Agresearch Ltd, Tennent Drive, Fitzherbert, Palmerston North 4410, New Zealand; sam.hitchman@agresearch.co.nz

Genetic selection for reduced methane production has been recognized as an important tool within the agricultural industry's toolbox in achieving international targets for reduced greenhouse gas emissions. Recent research has shown that breeding for lowered methane production is associated with changes in rumen physiology (size, constituents) and feed efficiency. It was found that rumen volume was significantly lower in low methane producing animals in a flock divergently selected for methane yield. Rumen volume and composition can be measured in live animals using computed tomography (CT) of small ruminants (sheep, deer), whereby the entire animal is scanned at 5 mm intervals. CT scanning of animals is already implemented as part of a suite of imaging technologies to generate breeding values associated with desirable traits such as carcass composition. These scans also collect excellent data of the other body constituents such as the rumen, however manual processing of the CT data is a major hurdle for industry uptake. There is a need to automate this process to facilitate further research by reducing analysis costs. Recent developments in Convolutional Neural networks have led to advances in automated semantic (pixel wise) segmentation of images. Medical industry applications include tumour segmentation, classification of disease, and automated segmentation for abdominal composition. Using a dataset of 223 manually processed full body CT scans of sheep and deer, the potential to segment the rumen from the surrounding tissues and analyse its properties has been investigated. Latest models perform with Sørensen-Dice coefficients >0.90 on an independent test set, showing these techniques could soon provide unprecedented data for industry and research. This project is funded by the National Science Challenge: Science for Technological innovation. Data collection was funded through Beef and Lamb Genetics and The Pastoral Greenhouse Gas Research Consortium.

Enteric methane emission of Nellore cattle from two lines selected for yearling weight

S.B. Gianvecchio¹, M.S. Borges¹, J.A. Silva², J.P.S. Valente¹, J.O.S. Marcatto³, L.G. Albuquerque¹, J.N.S.G. Cyrillo² and M.E.Z. Mercadante²

¹School of Agricultural and Veterinarian Sciences, UNESP, 14884-900, Jaboticabal/SP, Brazil, ²Institute of Animal Science, 14174-000, Sertãozinho/SP, Brazil, ³Embrapa Environment, 13918-110, Jaguariúna/SP, Brazil; maria.mercadante@sp.gov.br

Two selection lines, established in 1980, were analysed: Nellore Control (NeC), in which animals with yearling weight (YBW) close to the average of the contemporary group are selected (stabilizing selection); and Nellore Selection (NeS), in which animals with higher YBW are selected. Young bulls (mid-test age of 340 ± 54 days) from NeC ($n=132$) and NeS ($n=238$), born from 2017 to 2021, were evaluated (60 roughage:40 concentrate diet). Enteric methane emission (g/day, CH_4) was measured by SF6 tracer gas technique. Least square means $\pm$ SE of mid-test body weight (BW), dry matter intake (DMI), average daily gain (ADG), and breeding value of YBW (estimated by ssGBLUP), for NeC and NeS, were 245 ± 7.16 vs 321 ± 6.92 kg ($P < 0.01$); 6.80 ± 0.12 vs 8.71 ± 0.11 kg/d ($P < 0.01$); 0.729 ± 0.03 vs 1.041 ± 0.03 kg/d ($P < 0.01$); and 7.14 ± 1.07 vs 69.2 ± 0.79 kg ($P < 0.01$), respectively. Concerning feed efficiency, lsmeans for NeC and NeS were -0.123 ± 0.07 vs 0.053 ± 0.05 kg/d ($P < 0.05$) for residual feed intake; 9.61 ± 0.27 vs 8.72 ± 0.25 ($P < 0.01$) for feed conversion rate; and 2.82 ± 0.06 vs $2.77 \pm 0.06\%$ ($P = 0.16$) for DMI as percentage of BW. Comparisons of methane emission traits showed that NeC emitted less CH_4 than NeS (129 ± 10.0 vs 167 ± 9.96 g/d; $P < 0.01$). However, NeC and NeS showed similar methane yield, expressed as CH_4 /DMI ($P = 0.51$), and methane emission intensity, expressed as CH_4 /BW ($P = 0.96$), although NeC had showed greater methane emission intensity, expressed as CH_4 /ADG (183 ± 13.9 for NeC vs 167 ± 13.8 g/kg for NeS; $P < 0.01$). When methane emission was expressed as a residual trait ($\text{CH}_4 = \text{DMI} + \text{res}$), it resulted in the lowest value for NeC (-4.51 ± 1.80 vs 2.30 ± 1.34 g/d; $P < 0.01$). The results showed that cattle selected for growth are more productive without loss of feed efficiency and without increase of methane per kg of body weight or methane yield. In addition, there is evidence that selection for growth traits decreases methane per kg of average daily gain. Funding: FAPESP (#2017/10630-2 and #2017/50339-5) and CAPES (Finance Code 001).

Poster 16

Genetic correlation between enteric methane emission and feed efficiency and growth traits in cattle

M.E.Z. Mercadante¹, J.P.S. Valente², S.B. Gianvecchio², J.O.S. Marcatto³, M.S. Borges², J.A. Silva¹, I.M.C. Garcia¹, S.F.M. Bonilha¹ and L.G. Albuquerque²

¹Institute of Animal Science, 14174-000, Sertãozinho, SP, Brazil, ²São Paulo State University, 14884-900, Jaboticabal, SP, Brazil, ³Embrapa Environment, 13918-110, Jaguariúna, SP, Brazil; mezmecadante@gmail.com

This study aimed to estimate genetic parameters for daily methane emission, feed efficiency, and growth traits in Nellore cattle. Data of daily methane emission (CH_4 , $n=760$ animals, 297 ± 57.3 kg of body weight, 328 ± 40.2 days of age), dry matter intake (DMI, $n=2,033$), average daily gain (ADG, $n=2,033$), residual feed intake (RFI, $n=2,033$), and selection (postweaning) weight (W_{Sel}, $n=10,393$), were analysed. Daily methane emission was also expressed as residual (CH_4res) from linear regression equation of CH_4 on DMI. CH_4 were evaluated using the tracer gas Sulphur Hexafluoride technique, in 20 sampling groups, during feed efficiency tests (GrowSafe Systems). The means of the traits studied were: 151 ± 45.9 g/d, 7.55 ± 1.53 kg/d, 1.022 ± 0.257 kg/d, 0 ± 0.661 kg/d, 303 ± 53.1 kg, and 0 ± 20.5 g/d, respectively for CH_4 , DMI, ADG, RFI, W_{Sel}, and CH_4res . The (co)variance components were estimated by the average information restricted maximum likelihood method, fitting five two-traits animal models in a single-step GBLUP analysis using the BLUPF90 family of programs. Genotype data of 2,256 animals and a pedigree file with 10,810 animals were included. The heritability estimates (h^2) for CH_4 ranged from 0.21 ± 0.06 (two-trait analysis with W_{Sel}) to 0.34 ± 0.07 (with RFI). The h^2 for DMI, ADG, RFI, W_{Sel} and CH_4res were: 0.39 ± 0.04 , 0.29 ± 0.04 , 0.20 ± 0.04 , 0.40 ± 0.02 , and 0.13 ± 0.07 . Positive and high genetic correlations were observed between CH_4 and DMI (0.83 ± 0.12) and between CH_4 and growth traits (0.95 ± 0.12 with ADG, and 0.85 ± 0.17 with W_{Sel}). Genetic correlation between CH_4 and its residual (CH_4res) was also positive and high (0.63 ± 0.29). On the other hand, a positive and weak to moderate genetic correlation was observed between CH_4 and RFI (0.31 ± 0.16). Selection for production (higher W_{Sel}, ADG and DMI) leads to higher methane emission. However, selection for negative RFI may, in the long term, lead to lower methane emissions. These are the first results in *Bos indicus*. Funding: FAPESP (#2017/10630-2 and #2017/50339-5), and CAPES (Finance Code 001).

Heritability of predicted enteric methane emission in Japanese Holstein cows

R. Tatebayashi¹, A. Nishiura¹, F. Terada¹, Y. Uemoto², M. Aihara³, T. Suzuki⁴, I. Nonaka¹ and O. Sasaki¹

¹Institute of Livestock and Grassland Science, NARO, Tsukuba, Ibaraki, 305-0901, Japan, ²Graduate School of Agricultural Science, Tohoku University, Sendai, Miyagi, 980-0845, Japan, ³Livestock Improvement Association of Japan, Koto, Tokyo, 135-0041, Japan, ⁴Institute of Livestock and Grassland Science, NARO, Nasushiobara, Tochigi, 329-2793, Japan; tatebayashir014@affrc.go.jp

To achieve sustainable livestock farming, reduction of greenhouse gas emissions in the livestock production is needed. Dairy cattle emit methane, a greenhouse gas, on rumen fermentation. It is required to reduce methane emission genetically in dairy cattle, but it is difficult to collect a large number of data necessary for the accurate genetic evaluation. We developed an equation to predict enteric methane emission in dairy cows based on information such as lactation stage, body weight, and milk composition. This study aimed to predict enteric methane emission and estimate the heritability of methane production using large data sets. Enteric methane production at 6-305 days in milk (DIM) was predicted using 118,402 records of Holstein cows in the 1-5 lactation collected by the Livestock Improvement Association of Japan in 2020-2021. Lactation stage, body weight, energy-corrected milk, milk fat percentage, and milk fatty acid composition were used to predict enteric methane emission. A random regression test-day model was used to estimate heritability of predicted enteric methane emission, including herd-test day-milking frequency, region-calving month and parity-calving age as the fixed effects, and additive genetic and permanent environmental effects as the random effects. The Gibbs sampling method was used to estimate variance components. The mean value of predicted enteric methane emission was like that of measured enteric methane emission in previous reports. The mean values of predicted enteric methane emission were increased around 60 DIM and then gradually decreased from 80 DIM during the lactation period. Heritability was estimated 0.070 to 0.21 from 6 to 305 DIM, which was slightly lower than that previously reported. Heritability estimates were low soon after parturition and in early lactation, and then increased until reaching a maximum at 305 DIM.

Session 15

Poster 18

Using genomic markers and microbiome data to predict methane emissions from Holstein cows

N. Saedi, M.S. Lund and E. Karaman

Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, bld. 1130, 8000 Aarhus, Denmark; naghsa@qgg.au.dk

The emission of Methane, which is produced by microbial activities in livestock, contributes to global warming. Microbiome composition and host genetic markers have an impact on the methane emissions of dairy cows. Our objective is to evaluate genomic prediction accuracy for methane emission, by using microbiome composition together with genetic markers. We used a joint model (GMBLUP), which models methane as a function of microbiome data and genetic markers, and microbial OTUs as a function of genetic markers. The phenotype, genotype, and microbiome data of 692 Holstein cows were used. The microbiome data included relative abundances of 3,894 bacterial operational taxonomic units (OTUs) and 189 archaeal OTUs, for each individual. We compared prediction accuracies from GMBLUP with pedigree-based (PBLUP) and genomic (GBLUP) best linear unbiased prediction methods. Heritability of methane from GMBLUP, GBLUP, and PBLUP was 0.22, 0.22, and 0.15, respectively. The proportion of phenotypic variance explained by microbiome data (microbiability) using GMBLUP was 0.05. The low microbiability demonstrated that the rumen OTUs did not explain a large proportion of phenotypic variance in methane phenotypes. Both GBLUP and GMBLUP provided a prediction accuracy of 0.17, whereas PBLUP provided a prediction accuracy of 0.13. In conclusion, the joint model (GMBLUP) combining microbial OTUs and genotype data, did not improve genomic prediction of methane, over a standard GBLUP method.

Non-traditional feed ingredients in diets for pigs*H. Stein**University of Illinois, Department of Animal Sciences, 1207 West Gregory Dr. Urbana, IL 61801, USA; hstein@illinois.edu*

Non-traditional feed ingredients that may be used in diets for pigs include, but are not limited to, bakery meal, rice bran, field peas, and yeast products. Bakery meal consist of dried former foods and is produced after collection of non-saleable bread, pastries, cookies, and confectionary products. Generally, companies that produce bakery meal are able to supply meals that are consistent in chemical composition, whereas the variability in digestibility of amino acids and for metabolizable energy is considerable among sources. Bakery meal has low digestibility of lysine, but excellent digestibility of phosphorus, and bakery meal may be included in diets for weanling pigs by up to 25%. Rice bran is the co-product produced when bran is removed from de-hulled paddy rice and the product usually contains 20 to 30% starch, 12 to 15% crude protein, and 20 to 25% total dietary fibre. Rice bran contains 15 to 20% acid hydrolysed ether extract, but the product may be defatted, in which case the fat content is around 2%. The metabolizable energy in defatted rice bran is less than in maize, but full fat rice bran contains more energy than maize. Rice bran may be included in diets for weanling or growing-finishing pigs at up to 30% without negative impacts on growth performance. Field peas contain around 40% starch and 20% crude protein. The protein is high in lysine, but low in sulphur-containing amino acids. However, amino acids and phosphorus in field peas have excellent digestibility and the metabolizable energy is close to that in maize. Field peas may be included in diets for weanling pigs by up to 36% and in diets for growing and finishing pigs, field peas may replace all soybean meal. Yeast is a single cell protein that may be produced on different substrates and there is, therefore, some variability in the nutritional value among sources of yeast. Protein concentration is between 40 and 50%, but digestibility of amino acids vary considerably among sources. High quality sources of yeast may be included in diets for weanling pigs by up to 14%. In conclusion, there are many non-traditional feed ingredients available to the swine feed industry, but it is critical that each ingredient is assessed in terms of nutritional composition, energy and nutrient digestibility and impact on growth performance of pigs.

Session 16

Theatre 2

Effect of genotypes on agronomic and antinutritional traits of *Lupinus albus* L. for livestock*M. Oteri, D. Scordia, R. Armone, V. Nava, F. Gresta and B. Chiofalo**University of Messina, Department of Veterinary Sciences, Via Palatucci, 98168, Italy; marianna.oteri@unime.it*

Lupin species (*Lupinus* spp.) could represent a realistic and sustainable alternative protein source in both monogastric and ruminant feeds, capable of replacing soy without loss of quantity and quality of livestock products. However, a drawback of lupin seed quality are the antinutritional factors (ANFs), namely the alkaloid compounds. Aim of this study was to explore the productive traits and the quinolizidine alkaloids (QAs) in four genotypes of *Lupinus albus* L. grown in the Mediterranean environment. Two recently released varieties (Volos and Luxor) and two ecotypes from South-Italy (Ecotype F and Ecotype G) were compared in a field trial. Seed yield (SY) and thousand seed weight (TSW) were evaluated at seed physiological maturity. QAs analysis was performed by HR-GC/MS (LOQ: 0.01 mg/100 g). Data were subjected to a one-way ANOVA and means were separated by the Tukey HSD test ($p \leq 0.05$). SY was the significantly highest in Luxor and Ecotype G (2.27 and 1.81 Mg/ha), and the lowest in Volos (1.02 Mg/ha). On the contrary, the TSW was the highest in Volos (347.2 g) and the lowest in the two Ecotypes (315.4 g, on average). Luxor (6 mg/100 g) and Volos (5 mg/100 g) showed very low concentrations of total QAs, while Ecotype F (250 mg/100 g) and G (202 mg/100 g) showed the highest values. Lupanine and angustifoline were significantly higher in Ecotypes F (183 and 39 mg/100 g) and G (146 and 29 mg/100 g) than in Luxor (5 and 0.3 mg/100 g) and Volos (4 and 0.2 mg/100 g). Other QAs (sparteine, multiflorine, 13- α -hydroxylupanine, 13- α -hydroxymultiflorine and angeloxylupanine) were below the limit of toxicity (0.02%) for animal consumption, nonetheless, the two ecotypes showed the highest content. This study underlines the importance of genotype selection for a safe and sustainable animal nutrition. Among tested genotypes, present findings suggests Luxor well balanced between productive and ANFs traits, while Volos was characterized by a low productivity and the two ecotypes by too high ANFs content. Further effort is needed to breed new white lupin genotypes well adapted to a wide range of climatic conditions and resilient to abiotic adversities.

Dietary effects of xylanase and flaxseeds on performance, meat quality and bone health in broilersD. Lanzoni¹, M. Skřivan², M. Englmaierová², M. Marounek², E. Skřivanová², A. Baldi¹ and C. Giromini¹¹Università degli Studi di Milano, Department of Veterinary and Animal Science (DIVAS), Via dell'Università 6, 29600 Lodi, Italy, ²Institute of Animal Sciences, Department of Nutritional Physiology and Animal Product Quality, Pratelství 815, 104 00 Prague, Czech Republic; davide.lanzoni@unimi.it

The need to increase the nutritional profile of wheat and to study new crops that can ensure both food/feed safety and environmental protection are nowadays primary objectives in the feed industry. Wheat-treatment with xylanase (XL) and the use of flaxseeds (FSs), recognised for their high lipid profile rich in n-3 fatty acids (FAs), are potential candidates. For this, the aim of this experiment was to test the effects of XL and FSs in broiler chickens fed a wheat-based diet, on performance, nutrient retention, quality of breast meat, and bone health. 720 one-day-old broiler Ross 308 were divided into four experimental groups: (Control, basal diet), FSs (80 g/kg), XL (0.1 g/kg), and XF received FSs + XL combination. Experimental period lasted 35 days. XL not only reduced feed intake by improving feed conversion and reduced mortality, but also significantly increased ($P<0.05$) retention of dry matter, crude protein, and ash (56.9; 11.2; 55.1 g/kg, respectively), values not observed following FSs treatment. XL significantly increased ($P<0.05$) fat in the breast meat (12.1 g/kg) than in the control group (10.6 g/kg), also improving its oxidative stability. At the same time, FSs significantly increased the n-3 FAs content (65.5 mg/100 g) than control (24.3 mg/100 g) and XL treatment (29.6 mg/100 g). Higher values were obtained for XF group (97.2 mg/100 g). HSs resulted in a better n-6/n-3 ratio in the diet (1.96 mg/100 g), also in combination with XL (1.81 mg/100 g), showing statistically significant differences compared to the control (7.66 mg/100 g) and XL treatment (6.96 mg/100 g). FSs and XL treatment significantly improved bone health than the control group ($P<0.05$). Although further studies are needed to investigate the best level of FSs inclusion in the diet of broilers, these data suggest how their use in combination with XL can achieve positive levels in broilers. These results are enhanced by the sustainable impact of FSs to ensure environmental protection.

Session 16

Theatre 4

The effect of hydrolysed yeast on production performance and gastrointestinal health in broilers

N. Irshad, V. Perricone, S. Sandrini, C. Lecchi, P. De Faria Lainetti, A. Agazzi and G. Savoini

University of Milan, Department of Veterinary Medicine and Animal Sciences, Via dell'università 6, 26900 Lodi, Italy; nida.irshad@unimi.it

The goal of the present study was to ascertain the effects of dietary inclusion of hydrolysed yeast (HY) on the growth performance, meat quality, and gastrointestinal health of broilers. A total of 320 male 1-day-old chicks (ROSS 308) were used in this experiment. The animals were homogeneously separated into two groups and given either the basal diet (CTR) or the basal diet supplemented with yeast (TRT, 500 mg/kg HY). Each experimental group was composed of 160 birds, which were distributed among eight replicates (20 birds per replicate). Growth performance and body lesions (hock burn and foot pad dermatitis) were evaluated at the beginning, at each feeding phase change, and at the end of the trial (i.e. 0, 10, 21, 42). On day 42, all the animals were taken to a slaughterhouse for slaughter and sample collection to further determine meat quality (water holding capacity, pH, or colour) and gastrointestinal health (gene expression). Statistical Analysis System software (SAS version 9.4; SAS Institute Inc., Cary, NC, USA) applying a MIXED procedure, the GLM procedure, and PROC FREQ was used for the analysis of the data. Differences between groups were considered statistically significant at $P<0.05$, whereas a trend for a treatment effect was noted for $0.05\leq P<0.10$. The results revealed no difference between the CTR and TRT groups both in terms of production performance and meat quality ($P>0.05$). Furthermore, the mRNA expression studies on the Adiponectin system genes (AdipoQ, Adipo Receptor 1, and Adipo Receptor 2) and tight junctions (Zonula occludens ZO-1, Occludin, Claudin-3) showed no significant difference ($P>0.05$) between the CTR and TRT groups. This study was carried out within the Agritech National Research Center and received funding from the European Union Next-Generation EU (Piano Nazionale di Ripresa e Resilienza (Pnrr) – Missione 4 Componente 2, Investimento 1.4 – D.D. 1032 17/06/2022, CN00000022). This manuscript reflects only the authors' views and opinions, neither the European Union nor the European Commission can be considered responsible for them.

Yoghurt acid whey effects on broiler performance, meat oxidative status and caecal barrier integrity

V.V. Paraskeuas, G. Papadomichelakis, A. Pappas, P. Simitzis, E.C. Anagnostopoulos, I.P. Brouklogiannis, E. Griela, I. Palamidi, G. Theodorou, I. Politis and K.C. Mountzouris

Agricultural University of Athens, Animal Science, Iera Odos 75, 11855, Greece; v.paraskeuas@aua.gr

In this research, the investigation of broilers' response to dietary supplementation of yoghurt acid whey (YAW) at 4 different dietary levels (0, 25, 50, and 100 g/kg of diet) was conducted on growth performance, nutrient digestibility, breast meat oxidative stability and quality traits as well as caecal barrier integrity. A total of 300 male 1 d old Ross 308 broilers were randomly allocated in 4 experimental treatments with 5 replicates of 15 broilers each. All experimental treatments received a maize-soybean meal basal diet following a two-phase feeding plan. The 4 experimental treatments were as follows: control was fed with basal diet with no YAW addition (W0), the other three treatments were fed basal diet supplemented with YAW at 25 g/kg of diet (W25), 50 g/kg of diet (W50) and 100 g/kg of diet (W100), respectively. At the starter period (1-10 d) increasing YAW inclusion level resulted in reduction ($P<0.05$) of body weight (BW) and body weight gain (BWG) in treatments W50 and W100, compared with W0. Breast meat oxidative stability was improved ($P<0.05$) during refrigerated storage for 1 and 3 d in all treatments and only at W25 birds at 6 and 9 d. From breast meat quality traits, yellowness appeared to increase ($P<0.05$) in treatments W50 and W100 compared to W0. The relative expression levels of occludin and claudin-1 in caecal mucosa were increased ($P<0.05$) with the addition of YAW at 25 g/kg of diet compared with those of W0 treatment. The results suggest that YAW inclusion at 25 g/kg of diet did not impair the performance, extended meat shelf life by reducing lipid oxidation and enhanced caecal gut barrier. This research has been co-financed by the European Regional Development Fund of the European Union and Greek national funds through the Operational Program Competitiveness, Entrepreneurship, and Innovation, under the call RESEARCH – CREATE – INNOVATE (project code:T2EDK-00783).

The effect of *Citrus unshiu* peel on growth performance, digestibility and immunity in weaning pig

A.S. Sureshbabu¹, A.K. Adhimoolam² and T.M. Min³

¹Jeju National University, Department of Animal Biotechnology, 102 Jejudaehak-ro, 63243, Korea, South, ²Jeju National University, Subtropical Horticulture Research Institute, 102 Jejudaehak-ro, 63243, Korea, South, ³Jeju National University, Department of Animal Biotechnology, Bio-Resources Computing Research Center, Sustainable Agriculture, 102 Jejudaehak-ro, 63243, Korea, South; anjbio9@stu.jejunu.ac.kr

Mandarin orange (*Citrus unshiu*) is one of the important fruits widely cultivated in Jeju Island, South Korea. *C. unshiu* peels (CUP) account for nearly half of the fruit body and are the main waste used to produce a vast amount of by-products. CUP rich in nutrients/ active compounds, therefore, it is potential feed additives instead of antibiotics for the husbandry of both livestock and poultry. We characterized the biologically active compounds from CUP and studied their beneficial effects (Anti-inflammatory and antioxidant effects). Further, we used it as a feed additive in weaning pigs and examined their growth performance, digestibility, and immunity in weaner pigs. A total of 75 weaning pigs [(Yorkshire × Landrace) × Duroc], with an average body weight of 6.5 ± 0.05 kg, were used in a three weeks feeding trial. Pigs were examined for initial body weight and gender and randomly allotted into experimental treatments (5 replicates pens per treatment, 5 pigs per pen). The dietary treatments were as follows: (1) Control; (2) CUP1; and (3) CUP 2. After three weeks and during the overall period, dietary CUP supplementation showed a positive effect on growth performance, digestibility, and immunity. In another experiment, we also investigated the combined effect of CUP and curcumin nanospheres in weaning pigs and obtained positive results. Taken together, CUP and curcumin nanospheres supplementation can be beneficial in enhancing the performance of weaning pigs.

The effect of replacing grains with bakery by-products on performance and pigs' diet preferenceF. Veldkamp^{1,2}, H.M. Vermeer², J. Kater², A. Ten Berge², J.M.J. Rebel¹ and I.C. De Jong²¹Wageningen University, Adaptation Physiology Group, De Elst 1, 6708 WD, Wageningen, the Netherlands, ²Wageningen Livestock Research, Animal Health & Welfare, De Elst 1, 6708 WD, Wageningen, the Netherlands; fleur1.veldkamp@wur.nl

Around one-third of all food produced in the world is lost or wasted. Part of this can be re-used in animal diets to reduce the usage of grains, making it a good diet ingredient for improved livestock sustainability. The aim of this study was to test the effect of replacing feed grains in weaned pig feed with bakery by-products on growth performance, health, welfare and behaviour (data latter three not yet analysed) and pigs' diet preference. The first part of the study was carried out in eight pens with ten weaned piglets per pen (initial starting weight = 7.95 ± 0.9 kg) until a body weight of 25.7 ± 2.5 kg during four batches. Pigs received either standard (PS, based on grains) or circular (PC, based on bakery by-products) feed and were offspring from sows that were fed standard feed (SS, based on grains) during the first two batches or circular (SC, based on bakery by-products) feed during the last two batches. Body weight at pen level was measured at the start and end of each batch. Feed provision was determined daily. Average daily gain (ADG, in grams), average daily feed intake (ADFI, in grams) and feed conversion ratio (FCR) were calculated. The ADG was higher for PC than for PS (451 ± 42 vs 423 ± 57 , $P=0.03$) and the ADFI showed a tendency to be higher for PC than PS (624 ± 63.1 vs 583 ± 60.7 , $P=0.05$) whereas FCR ($PC=1.50 \pm 0.09$ vs $PS=1.49 \pm 0.07$, $P=0.97$) did not differ significantly. No interaction between pig feed and sow feed was found. The second part of the study was carried out in two pens with 40 pigs per pen during four batches. Pigs had the choice between PS or PC feed (two feeding throughs per feed per pen). The results revealed that pigs consumed overall more PC than PS ($PC=52.3\% \pm 0.03$ vs $PS=47.7\% \pm 0.03$, $P=0.002$). In summary, using bakery by-products as replacements for feed grains in weaned pig feed did not negatively impact growth performance and pigs even preferred feed based on bakery by-products over feed based on grains.

Replacing hexane by 2-methyloxolane for defatting soybean meal does not impair dairy cow performanceV. Menoury¹, A. Ferlay¹, L. Jacques², V. Rapinel² and P. Nozière¹¹UCA, INRAE, VetAgroSup, UMR Herbivores, Theix, 63122 Saint Genès Champagnelle, France, ²Pennakem Europa (EcoXtract®), 224 av. de la Dordogne, 59944 Dunkerque, France; valentin.menoury@inrae.fr

Soybean meals (SMB) fed to dairy cows are obtained through mechanical and/or chemical extraction of oil from the seed. Chemical extraction consists of solvent extraction, extraction-grade hexane being the most used solvent in the industry. Concerns regarding the health effects of n-hexane residues in food and feed are driving the industry to find alternatives to extraction-grade hexane. 2-methyloxolane (2-meOx) could be one of these. However, process differences between hexane and 2-meOx defatted SBM may lead to differing nutritive values and may affect the performance of dairy cows. A 4×4 Latin-square experiment with 16 primiparous lactating Holstein cows was conducted to study the effects of 2-meOx on milk yield and composition, nitrogen use efficiency for milk production, and solvent residues in milk. Cows were fed a diet containing 14% SBM and 165 g/kg DM crude protein. The 4 treatments differed according to the inclusion level of hexane and 2-meOx defatted SBM (i.e. 100% hexane, 66% hexane – 33% 2-meOx, 33% hexane and 66% 2-meOx, and 100% 2-meOx). Results show that dry matter intake, milk yield, milk protein concentration and excretion, milk protein fractions, and milk fat excretion did not differ among treatments. Milk fat concentration tended to increase with 33% hexane – 66% 2-meOx compared to 100% hexane SBM ($P=0.07$). Nitrogen intake, milk nitrogen excretion and nitrogen use efficiency for milk production did not differ according to the treatment. N-hexane residues tended to be more often detected in the milk from 100% hexane-fed cows compared to 100% 2-meOx-fed ones ($P=0.08$). 2-meOx residues were only detected in milk from 2-meOx-fed cows, but the difference with 100% hexane-fed cows was not significant. When detected in the milk, n-hexane and 2-meOx concentrations were below the quantification threshold of 10 ng/g. These preliminary results indicate that 2-meOx-defatted SBM can replace hexane-defatted SBM without affecting milk production performance and nitrogen use efficiency. Further analyses are required to confirm results regarding the detection of solvent residues in milk.

***In vitro* rumen fermentation traits of *Mentha piperita*, and products of oil extraction**S. Massaro¹, J. Andersen², G. Secchi^{1,2}, D. Giannuzzi¹, S. Schiavon¹, E. Franciosi² and F. Tagliapietra¹¹University of Padova, DAFNAE, Viale dell'Università, 16, 35020, Legnaro (PD), Italy, ²Edmund Mach Foundation, CRI, Via E. Mach, 1, 38098, San Michele all'Adige (TN), Italy; selene.massaro@phd.unipd.it

By-products obtained from essential oil extraction could be valued as ruminant feeds for their fibre and bioactive compounds content. This study aimed to evaluate the *in vitro* rumen fermentable characteristics of *Mentha piperita* (Mp, as dry forage), the residual product achieved from a supercritical CO₂ extraction (residue: rMp), and the residual of extraction plus the extract (erMp, to reconstitute Mp). A sample of 1 gram for each of these 3 materials and a grass hay (control) were tested in 3 repeated incubations, using 3 different rumen fluids, for a total of 36 bottles and 9 blanks. DM degradability (DMd), gas production (GP) kinetic and composition, volatile fatty acid (VFA), and bacterial profile over 24 h of fermentation were investigated. A linear mixed model was run to evaluate the fermentation characteristics of these materials. Orthogonal contrasts were used to compare the control vs Mp, the Mp vs rMp and the Mp vs erMp. The control and Mp in DMd did not differ for total VFA and total GP. However, Mp decreased n-butyric acid and slightly increased acetic acid proportions, increased the GP release between 3 and 9 h, and reduced CH₄ (% v/v) emissions compared to the control. The fermentation parameters of rMp did not differ from those of Mp, except for an increase of GP between 15 and 24 h, and a slightly increase of CH₄ (% v/v) at 24 h. Also, erMp did not affected the fermentative parameters compared to Mp, except for an increase of GP rate in the first 3 h of incubation, a slight increase of branched VFA, and an increase of CH₄ proportions. The Mp caused a modification of the microbial profile in the fermentation fluid with a reduction of the diversity indexes compared to the control. The Mp degradability was similar to that of the grass hay, notwithstanding the signs of some changes in the fermentation pattern and in the rumen microbial population. The extraction of essential oil had only a limited effect on fermentative properties of mint suggesting a potential use of this residual by-product as ruminant's feed. Funded by the project: BIRD213117/21; FoodTraNet 956265.

***In vitro* rumen fermentation of mushroom-pretreated *Acacia mellifera* simulating ruminant digestion**

C. Rothmann, E.D. Cason and P.D. Vermeulen

University of the Free State, Animal Sciences, Fakulteits Road, Brandwag, Bloemfontein, South Africa; rothmann@ufs.ac.za

The increasing growth of agro-industrial activity resulting in excessive amounts of agri-waste has led to the accumulation of lignocellulosic residues all over the world, in particular, deforestation initiatives of invasive trees in South Africa. These lignocellulosic residues are rich in energy resources but considered non-digestible by ruminant animals. The use of lignolytic fungi such as mushrooms in solid-state fermentation could sufficiently degrade the indigestible lignocellulosic components and add medicinal and nutritional value to otherwise unusable, high-energy waste material. The current study presents the data of the bioconversion of lignocellulosic substrate using solid-state fermentation with the edible and medicinal mushrooms, *Pleurotus ostreatus*, *Ganoderma lucidum* and a new *Ganoderma* species, to increase digestibility and nutritional value to be applied as ruminant animal feed. Additionally, next-generation sequencing was performed to determine if the use of mushrooms as pre-treatment influenced the microbial diversity of the ruminal fermentation. The solid-state fermentation process was optimised, and the resulting product analysed for the degradation of the lignocellulosic components. Data obtained after 18 weeks of degradation indicated a significant ($P < 0.05$) reduction in the acid detergent fibre, acid detergent lignin and neutral detergent fibre fractions of the biomass, with up to 20% reduction in indigestible components. After a 48-hour *in vitro* fermentation using rumen fluid, results indicated a significant ($P < 0.001$) improvement in digestibility of all parameters tested namely crude protein, acid detergent fibre, acid detergent lignin, neutral detergent fibre, gross energy, dry matter, and organic matter when compared to an untreated control. It was also found that the species of mushroom used for pre-treatment influenced the microbial community diversity selectively. With the implementation of the AMPTS II testing system, fermentation profiles for all substrates were provided. Results indicated that the use of lignocellulose rich waste substrates, pretreated with mushrooms are suitable for use as ruminant animal feed.

Valorisation of atypical land in cattle production systems in search of self-sufficiencyD. Starling¹, A. Farruggia¹ and T. Puech²¹INRAE, ACT, UE DSLP, 545 Rue du Bois Mâche, 17450, Saint Laurent de la Prée, France, France, ²INRAE, ACT, UR ASTER, 662 Av. Louis Buffet, 88500 Mirecourt, France; thomas.puech@inrae.fr

The challenge of feeding nearly 10 billion people by 2050 in a context of climate change and increasing scarcity of natural resources requires rethinking of agricultural systems and the resources they use. Livestock are questioned on the competition for food, land use and their capacity to contribute to the nutrient cycle. This study is based on four cattle breeding systems (two dairy, two suckling) that are not representative of the dominant systems of the Western Europe such as: (1) they use minimal inputs (mineral fertilization, concentrates); (2) they rely on atypical land use providing atypical resources: woody formations, spontaneous vegetation in marshes – reed, duckweed, azolla, grasslands abandoned by conventional livestock. This study aims to understand the different uses of these resources and to quantify, from a metabolic approach of nitrogen flows, their contribution to agroecological and feed performances. Our results show that the self-sufficiency of these systems is mainly based on the use of renewable resources. Although atypical resources represent a small part of the circulating biomass, they contribute significantly to the self-sufficiency of these systems via: (1) animal feeding or nitrogen supplementation during periods of deficit in the production of ‘conventional’ fodder, particularly during summer droughts; (2) the supply of winter stocks; and (3) the production of biomass for animal bedding, particularly when the land is not well adapted to cereal crops. In addition their composition in antioxidants and micronutrients potentially gives them a role in terms of animal health and tolerance to heat stress. Finally, these resources can offer flexibility of management to systems because they can be used for two purposes: feed or bedding. However, the valorisation of these atypical lands requires harvesting practices that respect the life cycle of the resources generated to ensure their renewal but also the habitats that they provide for many wildlife species.

Theatre 12

Growth of black belly ewe lambs ingesting non-conventional feeds in the form of complete feed blocksD. Barde¹, E. Traore², R. Arquet¹, N. Minatchy¹ and H. Archimede¹¹INRAE, Prise d'eau Petit-bourg, 97170, Guadeloupe, ²ISRA, saint louis, 24005, Senegal; dingamgoto.barde@inrae.fr

The co-products of crops and agro-industry are biomasses that can be used for animal feed. This reduces the need for land for animal feed and the associated carbon footprint of meat production. Various constraints limit the application of this strategy, including seasonal availability, nutritional imbalances and practicality of use. The development of low-tech technologies on the farm, including complete feed blocks, is a solution that should be evaluated considering the socio-economic contexts of the territories and countries. The objective of this study is to compare the feed value of 4 complete feed blocks composed of crop coproducts and agro-industry relative to a conventional feed based on hay grass and concentrate. A fattening trial involving 50 ewes lambs Black belly for 3 months was conducted. Five diets were evaluated: (1) Diet 1, control consisting of a 2-month-old tropical grass hay distributed *ad libitum* and 300 g of concentrate; (2) Diet 2, sorghum straw/molasses/cottonseed; (3) Diet 3, sorghum straw/sorghum grain/cottonseed ration; (4) Diet 4, sorghum straw/sorghum grain/*Leucaena leucocephala*; (5) Diet 5, sorghum straw/molasses/*Leucaena leucocephala*. The diets were formulated to be isoenergetic and isoproteic. The growth potential of Black belly ewe lambs recorded at INRAE is 150 g/day. Intakes and daily growths (g/d) were 955 and 91, 1,219 and 116, 1,233 and 110, 1,223 and 79, 1,167 and 66 for control, diets 1, 2, 3 and 4 respectively. The differences in intake were not significant. Growth was lower with diets 3 and 4 compared to the other rations ($P < 0.05$). The daily growth rates recorded with the control diet are lower than the growth potential of Black belly ewe lambs. This result is attributable to the poor quality of the hay and its low intake. Lowest growth observed with diets 3 and 4 are probably due to the insufficient protein intake with *Leucaena leucocephala* compared to cotton seed.

Diet effect of *Hermetia illucens* on proximate and fatty acid composition of broiler meatR. Berrocal^{1,2}, E. Molinero², S. Rueda^{2,3}, M.M. Campo¹ and L. Mur^{1,2}¹Instituto Agroalimentario IA2, Miguel Servet, 177, 50013 Zaragoza, Spain, ²UVESA, Pol Montes del Cierzo km86, 31500 Tudela, Spain, ³Venttus, Pierre Gassier, 23C, 50018 Zaragoza, Spain; rberrocal@uvesa.es

Poultry production development in recent decades and increasing costs make it necessary to study new sources of protein. *Hermetia illucens* meal is offered as an alternative to soybean meal due to its high animal protein content (CP=50%) and amino acid profile. But it is important to know the effect on productive parameters and the final product quality. The aim of this study was to assess the influence of including this source of protein in the diet on the chemical composition and the fatty acid profile of the breast in broilers. A total of 1440 one-day-old chicks were housed in 24 boxes (60 birds/pen). Three groups were defined with 8 replicates each one: control group (CG) with soybean meal as the main protein source, a second and third groups with 5% of *Hermetia illucens* meal included in the diet until 21 (H21) and 42 (H42) days, respectively. Animals were slaughtered at 42 days and 12 randomly carcasses were sampled per treatment. Breast proximate composition and fatty acid profile were analysed in frozen samples kept in vacuum packaging. Data were analysed with a General Lineal Model with SPSS (26.0) and differences between treatments were assessed with a Tukey test. No differences were found in the protein or fat content of the breast due to the inclusion of *H. illucens*. The percentage of saturated fatty acids was higher in animals fed with *H. illucens* meal ($P \leq 0.05$), especially due to the higher percentage of lauric and myristic acids ($p \leq 0.001$). Nevertheless, palmitic acid was lower in H42 because part of the dietary palm oil in the last lifecycle days was replaced by *H. illucens* meal (22.7 vs 23.7% in CG and 24.0% in H21, $P \leq 0.001$). Also, the inclusion of *H. illucens* tended to reduce the percentage of monounsaturated acids (39.7 vs 41.3 and 42.3%, $P = 0.07$, in H42, H21 and CG, respectively) especially due to the reduction of oleic acid ($P \leq 0.05$). However, the evolution of linoleic and α -linolenic acids follow the opposite way, increasing in H42 vs the other two groups ($P \leq 0.001$). It is essential to continue researching alternative feed ingredients beyond profitability because they may change the final product composition.

Antioxidant and rumen microbiota shift of Holstein cows by aquatic plant silage in Tibetan plateauB. Li¹, X. Huang¹, X. Yang¹ and Y. Wang²¹Tibet Academy of Agricultural and Animal Husbandry Sciences, Institute of Animal Husbandry and Veterinary, Lhasa, 850000, China, P.R., ²China Agricultural University, College of Animal Science and Technology, Beijing, 100000, China, P.R.; xukesuolilin@163.com

The Qinghai-Tibetan Plateau is a region with a unique geographical environment and abundant natural resources. However, due to harsh environmental conditions, forage production in the region is limited. To tackle the issue of feed scarcity, the use of non-conventional feedstuffs as a substitute for conventional feed has emerged as a sustainable solution for animal husbandry. In this study, the aquatic plant silage with optimal performance was selected instead of corn silage and applied in a dairy cow feeding experiment ($n=24$, 74 days) in the plateau. We evaluated the growth and lactation performance of Holstein cows in the aquatic plant silage treatment groups and the corn silage control group. Milk fatty acid and blood indicators were analysed, along with the rumen microbial response as community, functions, and metabolic profiles through metagenomics. Results showed that the milk fat, lactose, total solids contents and milk fatty acid content varied among different treatment groups. Additionally, the milk somatic cell counts in the formula 1 group was significantly lower than those in the control group, indicating anti-inflammatory activity driven by possible higher bioactive compounds. The blood biochemical indexes of dairy cow among groups also revealed that the addition of aquatic plant silage improved host antioxidant activity and immunity. Metagenomic analysis of the rumen microbiota showed significant enrichment of specific taxa among different groups which is align with rumen metabolism as shown in VFAs and metabolome analysis. These findings suggest that different rumen microorganisms may play important roles in regulating the immune and antioxidant capacity of Holstein cows, as well as affecting the production performance of the animals. Overall, the study provides evidence that substitution of corn silage with aquatic plant silage could improve the production performance, immunity and antioxidant capacity of Holstein cows in the Tibetan plateau, highlighting the potential of using aquatic plants as substitute for ruminant feed.

Feeding olive cake alters the mRNA of SREBF1 in adipose tissue of cows

M.C. Neofytou¹, D. Miltiadou¹, E. Sfakianaki², S. Symeou¹, D. Sparaggis³, A.L. Hager-Theodorides² and O. Tzamaloukas¹

¹Cyprus University of Technology, Department of Agricultural Sciences, Biotechnology and Food Science, P.O. Box 50329, Limassol, Cyprus, ²Agricultural University of Athens, Department of Animal Science, Iera Odos, 11855 Athens, Greece, ³Agricultural Research Institute, P.O. Box 22016, Nicosia, Cyprus; ouranios.tzamaloukas@cut.ac.cy

This study evaluated the use of ensiled olive cake (EOC) on yield, composition, fatty acid (FA) profile of milk and expression of selected genes involved in mammary and adipose lipid metabolism. Mid-lactating cows were randomly assigned to two feeding treatments (12 animals/ group), named the control (C) and the olive cake diet (OC), where EOC was at 10% DM, for a four-week period. Mammary and perirenal adipose tissues were sampled for gene expression analysis using quantitative RT-PCR at the end of the trial. The expression of 11 genes, involved in FA synthesis (ACACA, FASN, G6PDH), FA uptake and/or translocation (VLDLR, LPL, SLC2A1, CD36, FABP3), FA desaturation (SCD1) and transcriptional regulation (SREBF1, PPAR γ), was assessed. The findings showed that EOC feeding increased the milk fat yield (kg/day) and improved the FA profile of bovine milk by significantly decreasing the concentration of de novo synthesized FA and saturated FA, and increasing long – chain, monounsaturated FA concentration as well as the content of specific FA like C18:1 cis-9, the sum of C18:1 trans-10 and trans-11 and CLA cis-9, trans-11 acids. Concerning gene expression results of adipose tissue, only SREBF1 was significantly upregulated in the perirenal fat of OC group in response to the increased level of C18:0 and C18:1 cis-9 in the OC diet, while the mRNA expression of the genes involved in FA synthesis and desaturation was unaffected. Additionally, the decreased proportion of the de novo C<16 FA noticed for the OC group was not accompanied by changes in mammary lipogenic gene expression. The increased secretion of LCFA observed in the milk of OC group did not affect the mammary LPL mRNA abundance, or in mRNA abundance of genes involved in the uptake, transport and trafficking of FA in the cells (CD36, FABP3, VLDLR, SLC2A1). Overall, 10% DM of EOC could be included in cow diets without adversely affecting milk traits or the expression of genes involved in lipid metabolism in cows.

Poster 16

Improving gut functions and egg nutrition with stevia Residue in laying hens

M.X. Tang^{1,2}, Y.L. W², C. Y¹, C. P², H.G. L², Y. L¹, Y.D. C³, W. L³, X. X^{2,3} and X.F. K^{2,3}

¹Hunan Agricultural University, Hunan Key Laboratory of Traditional Chinese Veterinary Medicine, Changsha, Hunan province, Changsha 410128, China, P.R., ²Chinese Academy of Sciences, Institute of Subtropical Agriculture, Hunan province, Changsha 410125, China, P.R., ³Fuyang Normal University, School of Biology and Food Engineering, Anhui Province, Fuyang, 236000, China, P.R.; xx@isa.ac.cn

The objective of this study was to investigate the effect of stevia Residue (STER) on the production performance, egg quality, egg nutritional value, antioxidant ability, immunity, gut health, and microbial populations of laying hens during the peak laying period. To this end, 270 Laying hens (35 weeks of age) of the Yikoujingfen 8 were randomly divided into 5 treatment groups, including the control group and 2, 4, 6 and 8% STER added groups. The results showed that STER had no statistically significant effect on egg quality and production performance of laying hens ($P>0.05$), but it could significantly improve the yolk colour, amino acid content (alanine, proline, valine, ornithine, asparagine, aspartic acid, and cysteine) of egg whites ($P<0.05$), and the content of acetate and cis-13, 16-docosadienoic acid in egg whites ($P<0.05$). Moreover, the addition of STER increased the levels of serum immunoglobulin G (IgG) and interleukins 2, 4, and 10 ($P<0.05$), improved the antioxidant ability of the liver and oestradiol level in the oviduct ($P<0.05$), and decreased the level of cortisol ($P<0.05$). Further research showed that STER could enhance the height of the villi and crypt depth in the jejunum ($P<0.05$) and increase the abundance of *Actinobacteriota* in the gut ($P<0.05$), while inhibiting the abundance of harmful bacteria such as *Proteobacteria*, *Desulfobacterota*, and *Synergistota* ($P<0.05$). Among all the treatment groups, the 6% addition of STER showed the best results. In conclusion, STER has great potential as a plant-based additive in the feed of laying hens.

***In vitro* evaluation of olive stones and sorghum used as forage in ruminant diets**N. Kellali^{1,2}, N. Merino^{2,3}, E. Mata-Nicolás^{2,3}, I. Mateos^{2,3}, C. Saro^{2,3}, N. Lakhdara¹ and M.J. Ranilla^{2,3}¹Institute of Veterinary Sciences (University of Mentouri Brothers), Road of Guelma, 25100 El Khroub, Algeria, ²Universidad de León, Campus Vegazana, s/n, 24071 León, Spain, ³Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, s/n, 24346 Grulleros, Spain; mjrang@unileon.es

Tannins are secondary compounds with anti-nutritional factors. If they are present in feed ingredients they could affect ruminal fermentation of the diet. A trial was designed to test the effect of tannins present in sorghum and olive stones when these ingredients are included in diets and incubated *in vitro* for 24 hours. Two diets were formulated including 60% sorghum or olive stones, 22% wheat bran, 10.2% corn, 7.2% soybean meal and 0.4% vitamin-mineral supplement. Diets were incubated either with or without the addition of polyethylene glycol (PEG) to assess fermentation end products. Volume of gas produced was measured. Methane and volatile fatty acids were assessed by gas chromatography and disappearance of dry matter and neutral detergent fibre were determined. When sorghum was included in the diet, ml of gas produced increased by 15.8% ($P < 0.05$) when PEG was added to incubation medium. When olive stones were used as ingredient of the diet gas and methane produced increased by 29.7 and 30.4% respectively ($P < 0.05$) when PEG was added. No effect of PEG was detected for any of the diets in the volatile fatty acid production or proportions of individual fatty acids with the exception of the proportion of isobutyrate that decreased by 38% ($P < 0.05$) when PEG was added and sorghum was included as ingredient of the diet. Disappearance of dry matter or neutral detergent fibre was unaffected by the addition of PEG for both diets. Under the conditions of the present study, the effect of the tannins on ruminal fermentation was strongest in olive stones than in sorghum.

Preservation of agro-industrial co-products as silage for ruminant feedK. Paulos^{1,2}, C. Costa², J.M.S. Costa², L. Cachucho^{3,4}, P.V. Portugal², J. Santos-Silva^{2,3}, F. Lidon¹, M.R. Marques², E. Jerónimo^{4,5} and M.T.P. Dentinho^{2,3}¹Geobiotec, Departamento de Ciências da Terra, FCT Nova, Lisboa, Portugal, ²INIAV, Fonte Boa, Santarém, Portugal, ³CIISA, Avenida Universidade Técnica, Lisboa, Portugal, ⁴CEBAL, Centro de Biotecnologia Agrícola e Agro-Alimentar do Alentejo, Beja, Portugal, ⁵MED, Instituto Mediterrâneo para a Agricultura, Ambiente e Desenvolvimento, Beja, Portugal; katia.paulos@iniav.pt

Every year, considerable amounts of agro-industrial co-products are produced in Portugal that can be used in animal feed, ensuring nutritious and low-cost diets. Sweet potato (SP), brewers' grains (BG), and tomato pomace (TP) are a few examples of co-products that have great nutritional value but must be preserved for usage outside of their production season due to their high moisture content. This research aimed to characterize these co-products chemically and nutritionally and to preserve them as ingredients in silage mixtures. The silages were prepared to contain 40% dry matter (DM) and 14% crude protein (CP). Wheat bran (WB) and grass hay (GH) were added to the mixtures to attain the DM content. Sweet potato has high starch (32.8% DM) and sugar (23.3% DM), and tomato pomace and brewer's grains are good protein sources (19.6 and 29% DM, respectively). So, two silages were prepared: (1) SP/BG silage (30% SP + 35% BG + 20% WB + 15% GH); and (2) SP/TP silage (30% SP + 35% TP + 20% WB + 15% GH). After 4 months of ensiling, well-preserved silages were obtained, with low pH (4.11 ± 0.03 and 3.90 ± 0.02 in SP/BG and SP/TP, respectively), $\text{NH}_3\text{-N} < 10\%$ of total N and soluble N $< 50\%$ of total N. The CP level was 15 and 14% in DM in SP/BG and SP/TP silages, respectively. Organic matter digestibility was higher in SP/TP than in SP/BG silage (55.33 ± 1.23 vs $51.77 \pm 0.50\%$). Ensiling these co-products in mixtures is a good method of preserving them, resulting in stable and nutritionally balanced feed for ruminant nutrition. This work is funded by PRD2020 through the FEADER, project SubProMais (PDR2020-101-030988, PDR2020-101-030993) and by National Funds through FCT – Foundation for Science and Technology projects UIDB/05183/2020 (MED) and UIDP/CVT/00276/2020 (CIISA).

Combination of organic acid and heat treatment decreased ruminal protein degradation in Soybean meal

D.K. Yoo, S.W. Jeong and J.K. Seo

Pusan National University, Animal Science, Department of Animal Science, Life and Industry Convergence Research institute, College of Natural R, 50463, Korea, South; fbrjsgud@pusan.ac.kr

This study aims to evaluate the protective effects against rumen degradation when organic acid and heat are combined with soybean meal, which is widely used as a protein feed. The protected soybean meal (PSBM) was developed by adding an organic acid solution with a concentration of 1.5 M to the soybean meal, and then heating the mixture at a temperature of 160 °C for 1 h. To investigate the ruminal degradation of the PSBM developed in this study, both *in situ* and *in vitro* fermentation experiments were conducted. The *in situ* method was conducted to determine the degradability of rumen dry matter (DM) and crude protein (CP), and the results showed that the PSBM had significantly lower effective degradability than the Control group ($P<0.01$). No significant differences were observed in *in vitro* intestinal degradation between the two treatments. Consistent with the *in situ* results, the *in vitro* experimental results showed that the DM and CP degradability were significantly lower in PSBM than in the Control ($P<0.01$). The concentration of ammonia nitrogen was also significantly lower in the PSBM ($P<0.01$). The methane emission was significantly lower in the PSBM than in the Control ($P<0.01$). In conclusion, the PSBM developed in this study could potentially serve as a protein source that reduces ruminal ammonia release while increasing intestinal protein utilization.

Bakery by-products in herbage-based diets for dairy cows: effects on milk yield and reticular pHA.-M. Reiche^{1,2}, M. Tretola^{1,2}, J. Eichinger¹, A.-L. Hütten¹, A. Mürnger¹, L. Eggenschwiler¹, L. Pinotti² and F. Dohme-Meier¹¹Agroscope, Ruminant Nutrition and Emissions, Tölleure 4, 1725 Posieux, Switzerland, ²University of Milan, Department of Veterinary Medicine and Animal Sciences, Via Trentacoste 2, 20134 MILANO, Italy; anna-maria.reiche@agroscope.admin.ch

Feeding both recycled former food, such as bakery by-products (BBP) and human-inedible resources such as herbage is a key element of sustainable livestock farming. As the combination of both feed resources was not yet investigated, this work evaluated the effects of including BBP in concentrate (CONC) feed in herbage-based diets on feed intake, milk production and reticular pH of early lactating dairy cows. Twenty-three Holstein cows (days in milk: 33±15 d) were used in two seasons (n=11 in spring and n=12 in autumn). The cows were fed freshly cut grass *ad libitum* and, balanced for parity, DIM and milk yield, they were assigned to two CONC types: a cereal-based control (CON) CONC (n=11) and a CONC containing 55% of BBP (BP, n=12). The CONC were calculated for similar gross energy (19 MJ/kg dry matter (DM) for CON and 20 MJ/kg DM for BP) and crude protein contents (11% of DM). In both seasons, the CONC intake was similar for CON and BP cows. Intakes of herbage DM and ensuing total DM, CP, NDF and NEL were greater for BP than CON cows in spring, whereas they were similar in autumn (season × CONC type interaction: all $P<0.05$). The CON cows ingested more starch, irrespective of the season ($P<0.05$), and less water-soluble carbohydrates (more pronounced in spring than in autumn, interaction: $P<0.05$) than BP cows. Milk yield and composition were not altered by CONC type, except milk lactose percentage which was increased in CON compared to BP cows in both seasons ($P<0.05$). In spring, mean, min and max pH tended to be greater for BP than CON cows, while in autumn the opposite tendency was found (interaction: $P<0.10$). The time below pH 6.04 of CON cows tended to be greater in spring and lower in autumn than that of BP cows. The inclusion of 55% BBP in CONC did not show any negative effects on feed intake and milk production. The season-dependent effects on reticular pH might be related to the varying grass and BBP compositions and need further investigation, as does the relationship between pH range and rumen health.

Evaluation of legumes for fermentability and protein fractions using *in vitro* rumen fermentationB.Z. Tunkala¹, K. Digiacoimo¹, P.S. Alvarez Hess², F.R. Dunshea^{1,3} and B.J. Leury¹¹The University of Melbourne, Agricultural Sciences, Parkville campus, 3010, Parkville VIC, Australia, ²Agriculture Victoria Research, 1301 Hazeldean Road, 3821, Ellinbank VIC, Australia, ³Faculty of Biological Sciences, The University of Leeds, Leeds, LS2 9JT, United Kingdom; btunkala@student.unimelb.edu.au

A total of eight forage legumes including *Peltophorum pterocarpum*, *Neptunia monosperma*, *Acacia sutherlandii*, *Gliricidia sepium*, *Bauhinia hookeri* and three *Desmanthus* species were collected to assess their *in vitro* fermentability, degradable and undegradable protein fractions using *in vitro* fermentation technique. Soybean meal and lucerne hay were used as control. The total gas production ranged from 12.8 ml/g in *P. pterocarpum* to 127.3 ml/g in soybean meal. There was no difference in the total gas and volatile fatty acid (VFA) production between *Desmanthus* cultivars, $P < 0.001$. The total VFA concentration from *G. sepium* (117.7 mM/l) and *A. sutherlandii* (111.3 mM/l) was larger than other legumes except for soybean meal (157.1 mM/l) and lucerne hay (130.4 mM/l), $P < 0.001$. The methane gas percentage (1.98 and 2.08%) and total VFA (97.0 mM/l and 96.9 mM/l) were not different between *B. hookeri* and *P. pterocarpum*, $P < 0.001$. The maximum *in vitro* digestible crude protein (IVDP) was calculated for soybean meal (91%) and lucerne hay (85%), followed by *A. sutherlandii* (73%) and *G. sepium* (58%), $P < 0.01$. *B. hookeri* and *P. pterocarpum* showed a negative IVDP after 4 h incubation and reached 25 and 33% after 24 h, respectively. The percentage of fraction 'a' was larger in JCU9 (55.1% crude protein (CP)), and *G. sepium* (47.2%CP), and lower in *B. hookeri* (1.09%CP) and *P. pterocarpum* (1.48% CP), $P < 0.001$. Soybean meal (61.3%CP), lucerne hay (44.9%CP) and *A. sutherlandii* (38.6%CP) exceeded others in the proportion of fraction 'b', followed by *G. sepium* (27.2%CP) and JCU5 (20.7%CP), $P < 0.001$. The unavailable fraction increased with increasing phenolic content and reached more than 94% for both *B. hookeri* and *P. pterocarpum*. The findings indicate the possibility of using *A. Sutherlandii* and *G. Sepium* as a substitute for lucerne hay for their greater protein potential. However, these legumes need to be tested *in vivo* before promoting for further use to confirm the variability reported here.

Dehydration temperature- effect on physicochemical and nutritional characteristics of byproductsM. Alves¹, K. Paulos^{2,3}, C. Costa³, D. Gonçalves¹, T. Orvalho¹, J.M.S. Costa³, L. Cachucho^{4,5}, J. Santos-Silva^{3,4}, E. Jerónimo^{5,6} and M.T.P. Dentinho^{3,4}¹INOVLINIA, TAGUSVALLEY – Science and Technology Park, 2200-062 Abrantes, Portugal, ²Departamento de Ciências da Terra, Geobiotec, FCT Nova, 2829-516 Caparica, Portugal, ³Instituto Nacional de Investigação Agrária e Veterinária, Quinta da Fonte Boa, 2005-424 Vale de Santarém, Portugal, ⁴Centro Investigação Interdisciplinar em Sanidade Animal, University of Lisbon, 1300-477 Lisboa, Portugal, ⁵Centro de Biotecnologia Agrícola e Agro-Alimentar do Alentejo, IPBeja, 7801-908 Beja, Portugal, ⁶Mediterranean Institute for Agriculture, Environment and Development, CEBAL, 7801-908 Beja, Portugal; teresa.dentinho@iniav.pt

The aim of this work was to test the dehydration conditions of sweet potato (SP) and carrot (C) wastes and tomato pomace (TP) with temperature and air speed control for use as animal feed. The effects on colour, water activity (a_w), chemical and nutritional composition and cost were evaluated. Carrot was dehydrated at 60, 70 and 80 °C and SP and TP were dehydrated at 70 and 80 °C. Dehydration was conducted until weight loss stabilized. Freeze-dried samples were used as Control for chemical and nutritional composition. Except SP at 70 °C the moisture in all samples was reduced to values below the critical limit that ensures microbial stability. In SP dehydrated at 70 °C the value was 0.7% above the critical limit. However, all samples had a low a_w (≤ 0.35), which suggests microbiological and chemical stability. Organic matter digestibility was not affected by temperature but in SP, starch was significantly reduced (24, 19 and 13% in dry matter in Control, 70 and 80 °C, respectively). The energy cost to process 1 kg of fresh by-products was lower at 60 °C for C (€0.39-0.44), 70 °C for SP (€0.51-0.57) and 80 °C for TP (€0.80), assuming an electricity cost of €0.15/kWh. With these dehydration conditions, it is possible to ensure product stability at a lower cost. In an industrial setting, process, costs can be reduced by increasing the scale of production and with more efficient dehydrators. This work is funded by PRD2020 through the FEADER, project SubProMais (PDR2020-101-030991, 030988, 030993) and by National Funds through FCT-Foundation for Science and Technology projects UIDB/05183/2020 (MED) and UIDP/CVT/00276/2020 (CIISA).

Bacterial ecology and silage quality improvement upon treatment with microbial inoculantsI. Nikodinoska¹, M. Franco², M. Rinne² and C.A. Moran³¹Alltech European Headquarters, Summerhill Road, A86X006, Dunboyne, Co. Meath, Ireland, ²Natural Resources Institute Finland (Luke), Tietotie 2, FI-31600 Jokioinen, Finland, ³ALLTECH SARL, Regulatory Affairs Department, Rue Charles Amand, 14500, Vire, France; ivana.nikodinoska@alltech.com

Microbiota composition in grass silage produced under two fermentation conditions, spontaneous or controlled via microbial inoculant addition, was examined. A second cut timothy (*Phleum pratense*) and meadow fescue (*Festuca pratensis*) grass was harvested (August, 2022) in Jokioinen, Finland, using a farm scale precision chopper. The raw material contained 27.4% dry matter (DM) and 2.95% water-soluble carbohydrates on a fresh matter basis, and thus classified as moderately difficult forage to ensile. The grass was inoculated with silage additive composed of *Lactiplantibacillus plantarum* IMI 507026 and *Pediococcus pentosaceus* IMI 507025 at a dose of 1×10^6 cfu/g of fresh matter, or with water (control). Five replicates per treatment were prepared in 12 l capacity cylindrical silos at a density of 160 kg DM/m³. After 90 days of ensiling at 20 °C, samples of each replicate were collected. Freeze-dried and ground silages (0.25 g) were subjected to DNA extraction using QIAamp DNA Stool Mini Kit (Qiagen; Sollentuna, Sweden). Amplicon metagenomic sequencing (2×250 bp), targeting 16S rRNA gene V4 region, according to Novogene's pipeline was used for sequencing and bioinformatic analysis. QIIME2's classify-sklearn algorithm was used for species annotation of each amplicon sequence variants (ASV) and Silva database for bacterial ASV taxonomy assignment. T-test was performed to determine species with significant variation between groups (P -value<0.05). Microbiota analysis evidenced *Lactobacillaceae* and *Leuconostocaceae* as dominant families, with *Pediococcus-Lactobacillus* and *Weissella-Pediococcus* as dominant genera in treated and control silage, respectively. T-tests confirmed higher (P <0.05) *Pediococcus-Lactobacillus* and lower (P <0.05) *Weissella-Lactococcus-Leuconostoc-Enterococcus* abundance in treated compared to control silages. These findings suggest that the microbial inoculation used in this study can dominate and modulate silage fermentation, inhibiting the growth of heterofermentative strains such as *Weissella*, which may alter silage losses and quality.

Session 16

Poster 24

Growth performance, carcass and meat quality of pigs fed *Chlorella vulgaris* supplemented dietsJ.M. Almeida^{1,2,3}, M. Parreiras³, R. Varino³, A. Sequeira³, R.J.B. Bessa^{1,2} and O. Moreira^{1,2,3}¹AL4AnimalS, Associate Laboratory for Animal and Veterinary Sciences, FMV-UL, Lisboa, Portugal, ²CIISA – Centre for Interdisciplinary Research in Animal Health, FMV-UL, Av Universidade Técnica, 1300-477 Lisboa, Portugal, ³INIAV – National Institute for Agricultural and Veterinary Research, Rua Prof Vaz Portugal, 2005-424 Vale de Santarém, Portugal; joaoalmeida@iniav.pt

Microalgae are being highlighted as new and alternative ingredients for animal feed. *Chlorella vulgaris* has been used to supplement monogastric diets, but its administration could impact growth and meat quality. The current study assessed the impact of adding 1.5 and 3% of dried *C. vulgaris* to an iso-energetic and iso-protein conventional diet on growth performance during the finishing period of 72 pigs F1 [Pietran × (Large White × Landrace)]. Males and females with initial weights of 48.4 and 49.4 kg, respectively, were allocated to 24 pens of 3 animals, and within each pen, allocated to one of the diets. The pens allowed individualised feeding during two 30-minute periods (morning and afternoon), and water access was free all day. Live weight was checked weekly, and animals were slaughtered when they reached 100 kg. Carcass and meat parameters were evaluated immediately after slaughter and at 24 h post-mortem, when longissimus lumborum (LL) samples were collected for further analysis. The dietary inclusion of *C. vulgaris* increased the time to reach the target slaughter weight (P <0.05), reduced the voluntary dry matter intake and average daily gain and tended (P <0.10) to decrease hot and cold carcass weight but did not affect (P >0.10) the feed conversion rate. Dietary *Chlorella* supplementation did not affect the weight or proportion of the abdominal adipose deposits nor the backfat layers' thickness. However, females showed significantly lower values for most of these variables. The dietary treatments did not affect the longissimus and semimembranosus muscles' pH, LL weight losses, shear force or meat and backfat colour parameters. Ingestion of up to 3% *C. vulgaris* did not change the carcass or meat quality traits, aside from a slight but considerable impact on intake and slaughter weight. Funding: Project: ALGAVALOR: POCI-01-0247-FEDER-035234; LISBOA-01-0247-FEDER-035234; ALG-01-0247-FEDER-035234.

Inclusion of slow-release ammonia-treated barley in concentrates – feed intake and milk productionK.S. Eikanger¹, M. Eknæs¹, I.J. Karlengen², J.K. Sommerseth³, I. Schei³ and A. Kidane¹¹Norwegian University of Life Sciences, Faculty of Biosciences, Arboretveien 6, 1430 Ås, Norway, ²Norgesfôr AS, Akershusstranda 27, 0150 Oslo, Norway, ³TINE SA, BTB – NMBU PB. 5003, 1432 ÅS, Norway; katrinee@nmbu.no

The need to utilize alternative protein sources for sustainable milk production, plus the ability of the rumen microbiome to convert dietary non-protein nitrogen into high-quality microbial protein, has led to an increasing interest in locally produced cereal grains treated with slow-release ammonia as a replacement for conventional protein ingredients. We assessed the effects on feed intake and milk production of two slow-release ammonia (Home'n Dry, FiveF Alka Ltd) treated concentrates with high contents of locally produced barley differing in pre-pelleting particle size (i.e. Alka mjolk-fine=Alka-F, and Alka mjolk-coarse=Alka-C) against a negative control based on the Alka ingredients mixed with urea (Urea-F) and a soy-based positive control (Soya-F). The concentrates were roughly iso-nitrogenous and iso-energetic. Eight multiparous early lactation Norwegian Red dairy cows with initial daily milk yield (MY±SD) of 30.5±5.94 kg were used in a 4×4 duplicated Latin square design experiment (4 diets over 4 periods of 35 d each) accommodated in a tie-stall housing with *ad lib* access to grass silage and water. The concentrates were fed in optimized amounts based on Soya-F (w/w replacement) in 3-split portions per day. Feed intake, MY, milk composition, energy corrected MY (ECM), and ECM efficiency were analysed using a linear mixed model in R (Version 4.2.2) with treatment, period, and week within a period as fixed effects and cow as random effect. Covariance structure was selected based on Bayesian information criterion. Feed intake was not affected ($P \geq 0.05$) by concentrate type. But MY, ECM, and ECM efficiency were higher ($P < 0.05$) for Alka-F and Soya-F than Urea-F, while Alka-C was intermediate. Milk fat (%) tended to be lower ($P = 0.10$) in Soya-F, and milk protein (%) was significantly lower ($P = 0.007$) for Alka-C compared to others. Milk lactose (%) did not differ among treatments ($P = 0.27$). In conclusion, slow-release ammonia-treated concentrates, based on local ingredients, can potentially replace soy-based concentrates without adverse effects on milk production.

Reducing aggression in finishing pigs through short application liquid calming herbal blendC. Nicolás-Jorrillo¹, D. Carrión¹, D. Escribano², A. Brun³ and E. Jiménez-Moreno¹¹Cargill Animal Nutrition, Polígono Industrial Riols s/n, 50170 Mequinenza, Spain, ²University of Murcia, Animal Production, Campus de Espinardo s/n, 30100 Murcia, Spain, ³IRTA, Food Quality and Technology Program, Finca Camps i Armet, 17121 Monells, Spain; carlos_denicolas@cargill.com

The aim of this study was to evaluate the effects of the inclusion of a calming herbal extract blend in liquid form (BehavePro® L) varying in dosage and in application length on feeding and aggressive behaviours and carcass quality. BehavePro is a nutritional solution containing natural compounds and plant extracts added to drinking water. Four hundred seventy-two [Pietrain × (Landrace × Large White)] pigs, were sexed (entire males and females) and allotted randomly to two treatments (group A; 0.25% solution for 15 days, and group B; 0.8% solution for 5 days period) with twenty-four conventional pens of 17 pigs each and six pens of 12 pigs each with one automatic feeding system per pen. Four days before adding the solution (day 118), pigs weighed 115±2.0 and 116±4.5 kg per pig for the group A and B, respectively. Pigs were slaughtered at day 137 and 146 for the evaluation of carcass quality and skin lesions, and the feeding behaviours after fasting, respectively. After the first load, group A continued receiving 0.25% while group B, was maintained at 0.8% for 2 days following by 0.25% till slaughter. All pigs had free access to water until transportation to the abattoir. Fasting lasted for 21 h and the transportation and lairage time was 4 h. Feed intake of pig was affected for the first 2 days after fasting with higher values in the group B than in the group A ($P < 0.05$). Cortisol concentration was reduced with the use of BehavePro and the time of application ($P < 0.05$). Final pig BW was not affected by the treatment ($P > 0.1$). Hot carcass tended to be 1.5 kg heavier in group B than A ($P = 0.08$). The incidence of the skin lesions was lower in the group B than in the group A in the front (68.1 vs 77.3% pigs with less than 2 scratches for the group A and B, respectively) and middle regions of the carcass ($P < 0.05$). In conclusion, the addition of 0.8% of BehavePro via water for the last 5 days of fattening reduced the skin damage at slaughter due to its calming effect on aggressive behaviour.

Evaluating fermentative profile in corn silage using chemical and biological additivesC. Mastroeni¹, S. Van Kuijk², F. Ghilardelli¹, S. Sigolo¹, E. Fiorbelli¹ and A. Gallo¹¹Università Cattolica del Sacro Cuore, Department of Animal Science, Food and Nutrition (DIANA), Via E. Parmense 84, Piacenza 29121, Italy, ²Selko, Stationsstraat 77, 3800 AG Amersfoort, the Netherlands, the Netherlands; antonio.gallo@unicatt.it

Silage additives are widely used to reduce dry matter loss, decrease temperature, and enhance quality of ensiled fodder. The objective of this work was to evaluate the effects of chemical and biological silage additives on the fermentative profile of ensiled corn. After harvesting, fresh-chopped corn was ensiled directly (control, CTR) or sprayed with one of two mixes of organic acids before ensiling, Fyvalet Silage (FS, Selko) at a concentration of 3 g/kg of freshly-chopped forage or Selko TMR (ST, Selko), at a concentration of 2 g/kg of freshly-chopped with a combination of *L. hilgardii* CNCM I-4785 and *L. buchneri* NCIMB 40788 (Magniva Platinum 1 or MP1, Lallemand SAS), at recommended concentration of 150,000 cfu/g of freshly-chopped forage. Corn silage was ensiled in 20 l mini-silos, stored at room temperature and opened after 12 or 20 weeks. There were differences in dry matter, pH, lactic acid, acetic acid, propionic acid, and ethanol between treatments ($P < 0.05$), but all treatments showed an adequate fermentative profile. The MP1 mini-silos had higher ($P < 0.05$) acetic acid content than the other groups, whereas the highest ($P < 0.05$) value of ethanol was measured in FS mini-silos. No differences were observed for LAB, mould, and yeast counts, indicating that chemical or biological additives in ensiled corn allow achieving a safe and well-fermented product. Evaluation of fermentative profiles of corn silage with chemical and biological additives included shows that both solutions improve the final quality of the fodder.

Effect of *Chlorella vulgaris* incorporation in pig diets on pork chemical composition and fatty acidsJ.M. Almeida^{1,2,3}, A.P. Portugal³, R.J.B. Bessa^{1,2} and O. Moreira^{1,2,3}¹AL4AnimalS – Associate Laboratory for Animal and Veterinary Sciences, FMV-UL, Lisboa, Portugal, ²CIISA – Centre for Interdisciplinary Research in Animal Health, FMV-UL, Av Universidade Técnica, 1330-477 Lisboa, Portugal, ³INIAV – National Institute for Agricultural and Veterinary Research, Rua Prof Vaz Portugal, 2005-424 Vale de Santarém, Portugal; joaoalmeida@gmail.com

Supplementing diets for finishing pigs with microalgae may affect the nutritional value of their meat. The current study assessed the impact of adding dried *Chlorella vulgaris* to iso-energetic and iso-protein conventional final diet on the nutritional composition and meat fatty acid (FA) profile. The experimental design involved 36 males and 36 females [Pietran × (Large White × Landrace)] to study the three experimental diets with 0%, 1.5 and 3% incorporation of *C. vulgaris*. The animals, separated by sex, were assigned to 24 pens of 3 animals and allocated to one of the diets within each pen. The pens allowed individualised feeding during two 30-minute periods (8:00; 16:00), and water access was free all day. The animals were weighed weekly and slaughtered when they reached 100 kg live weight. Longissimus lumborum muscle samples were collected 24 h *post-mortem*, vacuum packed and stored at -20 °C until analytical procedures. Including *C. vulgaris* in the diets increased linearly ($P < 0.001$) the ash content but not the calcium, sodium, phosphorus, potassium or magnesium content. The intramuscular fat (IMF) content was lowest, and the meat protein content was highest with the dietary treatment with 1.5% of *Chlorella* (Quadratic contrast $P < 0.05$). Females showed a lower ($P < 0.05$) IMF content than males, 1.88 vs 1.38%. The FA composition of the longissimus muscle was little affected by the diets but differed with sex, reflecting the IMF differences. Due to their higher IMF, males had higher saturated FA and lower polyunsaturated FA (PUFA). Neither the omega-3 PUFA nor the omega-6 PUFA were influenced by the inclusion of microalgae in the diet. Similarly, the diets did not affect monounsaturated fatty acids, although 16:1c9 and 18:1c11 showed higher levels in animals fed the 1.5% *Chlorella* diet. Funding: Project: ALGAVALOR: POCI-01-0247-FEDER-035234; LISBOA-01-0247-FEDER-035234; ALG-01-0247-FEDER-035234.

Bacillus fermentation products of hog hair waste serve as potential animal feed additives

W.J. Chen, K.C. Chang, Z.J. Zhuang, Y.H. Cheng and Y.H. Yu

National Ilan University, Department of Biotechnology and Animal Science, No.1, Sec.1, Shennong Rd., 26047, Taiwan; wjchen@niu.edu.tw

We isolated three *Bacillus* strains from livestock waste: *Bacillus licheniformis* (BL), *Bacillus amyloliquefaciens* (BA) and *Bacillus subtilis* 25 (BS25). The crude enzyme produced by BA, BL and BS25 showed protease activity at 40-70 °C and pH 8-12. Heating at 90 °C for 2 hours, the enzyme activity still retains about 90%, and it will not be inhibited by EDTA, iodoacetic acid and PMSF. In zymogram assay, we confirmed that the molecular sizes of these three keratinases were mainly distributed between 17 and 52 kDa. When testing the fermentation conditions, the intact hog hair and hog hair powder were both tested, and BA strain with the best keratinase activity was selected for further study and its optimal fermentation conditions established. We performed acid hydrolysis on the product obtained from intact hog hair fermented for 5 days to analyse the amino acid composition of hog hair before and after fermentation with BA strain. The results showed that in the fermentation products of hog hair, the contents of essential amino acids such as methionine (Met), tryptophan (Trp), phenylalanine (Phe), lysine (Lys) and other non-essential amino acids were all significantly increased. We further established the optimal fermentation conditions for BA to decompose intact hog hairs as follows: fermentation temperature of 37 °C, adding 2% molasses as carbon source, 4% intact hog hair as nitrogen source, and the initial bacterial concentration of 10^{11} cfu/ml. Then, soybean meal, a raw material commonly used in broiler's feed was applied as an adsorbent, and the hog hair fermentation product is sprayed on it using a fluidized bed dryer, serving as broiler feed additive. The results of the animal experiments on broiler showed that 2.5 and 5% substitution of soybean meal with hog hair fermentation product can effectively improve the growth performance of broilers, such as body weight, average daily weight gain and feed conversion rate, in a dose-dependent manner with statistically significant difference. Based on our current findings, BA has the potential for decomposing hog hair waste and the value-added usage as novel feed additives, thus achieving the goal of circularity in agriculture.

Effect of coffee grounds on digestibility, ruminal fermentation, and microbial protein synthesisM. Medjadbi¹, I. Goiri¹, R. Atxaerandio¹, S. Charef¹, C. Michelet¹, J. Ibarruri², B. Iñarra², D. San Martín² and A. García-Rodríguez¹

¹NEIKER – Basque Institute for Agricultural Research and Development, Department of Animal Production, Agroalimentary campus of Arkaute, s/n, N 104, km355, 01192 Arkaute, Álava, Spain, ²AZTI, Food Research, Basque Research and Technology Alliance (BRTA), Technology Park of Bizkaia, Astondo Bidea, Building 609, 48160, Derio, Bizkaia, Spain; mmedjadbi@neiker.eus

Coffee grounds (CG), through their phenolic compounds, can contribute to modulating rumen fermentation towards more efficient fermentation routes and decreasing enteric methane production. This study evaluated the effect of 4 levels of CG inclusion in concentrate on enteric methane production, feed intake, apparent digestibility, ruminal fermentation, and microbial protein synthesis. In a replicated 4×4 Latin square design, 8 non-productive Latxa ewes were randomly assigned to a concentrate that differed in the level of CG: 0, 10, 15, and 20%. In each period, 15 days of adaptation were allowed, followed by 7 days in metabolic cages, and two days in respiration chambers. To avoid a carry-over effect a minimum of 7 days were allotted in which ewes consumed concentrate with 0% CG and forage. Total organic matter intake and CH₄ emissions (g/d) presented a quadratic response ($P < 0.050$) to increasing levels of CG in the feed. However, when CH₄ emissions were corrected for a kg of organic matter intake (OMI), a linear decrease was observed with increasing levels of CG in the concentrate ($P = 0.009$). This reduction in CH₄ emissions (g/kg OMI) could be explained by the linear decrease ($P = 0.034$) observed in apparent digestibility with increasing levels of CG in the concentrate. No significant response was found in CH₄ emissions corrected for digestible organic matter input or individual VFA ratios. For microbial N flux, a linear increase in microbial protein supply efficiency ($P = 0.008$) was observed with increasing levels of CG in the concentrate. In conclusion, increasing doses of CG in the concentrate linearly reduced methane emissions per kg of OMI, due to a decrease in digestibility, and increased the efficiency of microbial synthesis.

Environmental impact of former food estimated through life cycle assessmentM.G.D. Azzena¹, A. Luciano², L. Pinotti² and A.S. Atzori¹¹University of Sassari, Department of Agricultural Science, via E De Nicola 9, 07100 Sassari, Italy, ² University of Milan, Department of Health, Animal Science and Food Safety, VESPA, Via Celoria 10, 20134 Milano, Italy; asatzori@uniss.it

The livestock sector is called to improve resource utilization moreover minimizing the direct food-feed competition in land use. Former food products (FFPs), i.e. food products for human consumption that comply with EU food legislation but cannot be used for human consumption must be found for inclusion as a supplementary food in the diet of farm animals, as an alternative to cereals. Due to their variability in composition, they are classified according to origin into bakery and confectionary products. There is little information on life cycle assessment of FFPs in animal feed. This study aimed to retrieve information on the environmental impact of bakery and confectionery products obtained with the complete life cycle assessment (LCA) from the point of production to incorporation into feed for animal nutrition. Existing environmental product declaration (EPD) of edible foods can be adopted as environmental impact of FFPs in animal diets. The EPD system considers: Upstream, which involves calculating the LCA of individual ingredients used in the formulation; Core, which calculates the energy expended, including water, electricity and methane emitted; and Downstream, which considers the LCA analysis from when the product leaves the factory until it arrives on the shelf. Assuming that the final product is used in animal feed, emissions produced as they undergo further processing might increase in energy expenditure and methane produced. Literature evidences gathered from scientific databases showed that variations in emissions depends on the origin of the product, with values ranging on average from 1.323 kg CO₂eq/kg (crackers), 1.577 (rusks), 1.277 (bread), 1.173 (pasta), 1.645 (shortbread), 2.710 (filled cookies), 2.982 (snacks) 2.922 (puff pastry), and 1.478 (breakfast cereals) kg of CO₂eq/kg per 100 g of bakery product. Considering the variations in product emissions, the addition of LCA information would help the feed industry reconsider environmental policies and promote more sustainable feed production by reducing environmental impact.

Session 16

Poster 32

Effect of coffee grounds on productive performance, milk fatty acid profile and methane productionM. Medjadbi¹, I. Goiri¹, R. Atxaerandio¹, S. Charef¹, C. Michelet¹, J. Ibarruri², B. Iñarra², D. San Martín² and A. García-Rodríguez¹¹NEIKER – Basque Institute for Agricultural Research and Development, Department of Animal Production, Agroalimentary campus of Arkaute, s/n, N 104, km355, 01192 Arkaute, Álava, Spain, ²AZTI, Food Research, Basque Research and Technology Alliance (BRTA), Technology Park of Bizkaia, Astondo Bidea, Building 609, 48160, Derio, Bizkaia, Spain; mmedjadbi@neiker.eus

Coffee grounds (CG) are one of the food wastes that have been studied as an alternative in livestock feeding in the last decade. These studies have proved that the addition of up to 10% of CG in the concentrate does not have a negative effect on the productive performance of dairy ruminants. This study evaluated higher levels of inclusion of CG (0, 10, 15, and 20%) in the concentrate on milk yield and quality, milk fatty acid profile, and methane production. In this trial of 6 weeks of duration, 48 Latxa dairy sheep were used. Ewes were divided into blocks according to parity, milk yield and days in milk. All the concentrates were formulated to be isoenergetic, isoproteic, isofat and to meet the production needs. The concentrate was given in two doses of 450 g of dry matter/milking and fescue hay was offered *ad libitum*. The increase of CG doses in concentrate up to 20% did not affect milk yield or milk quality but affected the milk fatty acid profile. The increase in CG doses resulted in a linear increase in the content of C18:0, C18:1 trans-11, total n-3, total n-6, conjugated linoleic acid, total monounsaturated fatty acids, and total polyunsaturated fatty acids. In contrast, decreased linearly the content of C16:0 and total saturated fatty acids. Methane production (g/d) and methane intensity (g/l of milk) decreased linearly with increasing levels of CG inclusion in the concentrate. In conclusion, increasing the inclusion level of CG up to 20% in concentrate in dairy sheep did not have a negative effect on milk production and its quality, but modified the milk fatty acid profile towards a healthier profile and decreased methane production and intensity.

Effect of including fresh pears as feedstuff in lactating ewes' diet on the ewes' milk curd strength

I. Caro¹, J. Mateo², S. Kasaiyan², N. Merino^{2,3}, E. Mata-Nicolás^{2,3}, I. Mateos^{2,3}, C. Saro^{2,3}, A. Martín³, F.J. Giráldez³ and M.J. Ranilla^{2,3}

¹Universidad de Valladolid, Av. Ramón y Cajal, 7, 47005, Spain, ²Universidad de León, Campus Vegazana, s/n, 24071 León, Spain, ³Instituto de Ganadería de Montaña (CSIC-Universidad de León), Finca Marzanas, s/n, 24346 Grulleros, Spain; nmerb@unileon.es

Spain is the one of major European producers of fruit and vegetables and almost half of the initial production of fruits and vegetable is lost or wasted at different stages of the food chain supply. The inclusion of discarded fruits in animal feed would allow minimizing this impact and reducing the costs of livestock production. The aim of this research is to assess the eventual effect of using pears in the diet of lactating ewes on a relevant milk quality trait. Two groups of ten lactating Assaf ewes on the 2nd third of lactation were fed on two different isoproteic and isoenergetic diets (total mixed rations) for 35 days. One included pear, at a level of 116 g/kg dry matter, as ingredient (PEAR) and the other did not contained pear (CONTROL). The last day of the trial, the milk from each ewe was sampled, skimmed. to avoid the effect of fat, and samples (in duplicate) were used for composition analysis and texture analysis. For the texture, 100 ml of skimmed milk were poured into 150 ml beaker and tempered to 35 °C and 4 ml of diluted (1/10) rennet (1:100,000 force) were added to the milk and mixed. The beaker was incubated at 35 °C for 40 min and then refrigerated at 4 °C for 24 hours. Afterwards, the curd in the beaker was tempered at 22 °C and the gel strength was determined by a penetration text using a texture analyser (TA-XT2, Stable Micro Systems Ltd, Surrey, UK) equipped with metallic cylindrical probe (SMSP/40) which penetrated the curd 15 mm at 0.2 mm/s. The maximum force (firmness) was recorded. Neither the protein content nor the curd firmness was affected by the diet. The protein contents (%) of CONTROL and PEAR ewe milk were (mean ± standard deviation) respectively 5.30±0.43 and 5.50±0.63 ($P=0.418$), and the curd strengths (N) 2.55±0.80 and 2.88±1.11 ($P=0.767$). The curd strength was highly correlated with the protein content in the milk from both ewe groups (the regression coefficient, r^2 , for CON and PEAR was 0.817 and 0.857, respectively).

Upcycling of Citrus and Vinification by-products' bioactive compounds for broiler diets

A. Mavrommatis and E. Tsiplakou

Agricultural University of Athens, Laboratory of Nutritional Physiology and Feeding, Department of Animal Science, Iera Odos 75, 11855 Athens, Greece; mavrommatis@aua.gr

Although carotenoids and polyphenols derived by *Citrus* and vinification by-products, respectively, generally possess vital antimicrobial and antioxidant properties their *in vivo* impact in animals diet have not been thoroughly studied. For this purpose, 300 one-day-old as hatched chicks (Ross 308) were assigned to five treatments, with four replicate pens and 15 birds in each pen. Birds were fed either a basal diet (CON) or a basal diet supplemented with 25 g/kg ground grape pomace (GGP), or 2 g/kg wine lees extract rich in yeast cell walls (WYC), or 1 g/kg starch including 100 mg pure grape stem polyphenolic extract/kg (PE), or 1 g/kg starch including 25 mg carotenoid extract (CCE) for 42 d. Procyanidin B1 and B2, gallic acid, caftaric acid, (+)-catechin, quercetin, and trans-resveratrol were the prevailing compounds in vinification by-products while β -Cryptoxanthin, β -Carotene, Zeaxanthin, and Lutein in *Citrus reticulata* extract. The CCE feed additive exerted inhibitory properties against *Staphylococcus aureus*, *Klebsiella oxytoca*, *Escherichia coli*, and *Salmonella typhimurium in vitro*. Body weight and feed consumption were not significantly affected. The mRNA levels of *GPX1* and *SOD1* tended to increase in the liver of WYC-fed broilers. SOD activity in blood plasma was significantly increased in WYC and PE groups. The total antioxidant capacity showed significantly higher values in the breast muscle of PE-fed broilers, while the malondialdehyde concentration was significantly decreased in WYC-, PE-, and CCE-fed broilers. The mRNA levels of Interleukin 1 β and tumour necrosis factor (*TNF*) were downregulated in the livers of the CCE-fed broilers, while *TNF* and interferon γ tended to decrease in the spleens and bursa of Fabricius, respectively. Our study provided new insights regarding the beneficial properties of bioactive compounds present in *Citrus* and vinification by-products in broilers' immune-oxidative status. These promising outcomes could be the basis for further research under field conditions.

Simplified method developed for estimating the on-farm EFGHG and NH₃ – presentation & results

Estimating the greenhouse gas (GHG) and ammonia (NH₃) emission factors (EF) of cattle farming is challenging in open barn production systems since ventilation rates are very difficult to do in such situations. To overcome this difficulty, we developed a method based on: (1) indoor/outdoor CO₂, CH₄, N₂O and NH₃ concentration measurements; and (2) a farm questionnaire estimating the carbon mass balance at the building scale. This 'Simplified Method' has been applied in an international study including eight European countries totalizing over 50 dairy farms with seasonal repetitions and the results of the questionnaire were also used to characterize the farm diversity. The dairy population in the barn where the air samplings were done ranged from 8 to 979 cows. The feeding quantity was between 14 and 31 kg DM/animal/day and the milk production between 18 and 50 kg milk/animal/day. Most of them had concrete or slatted floors (40 and 35% respectively) and one fourth were separated urine and faeces. The 'Simplified Method' will be shortly described and examples of the results per countries, farms and seasons will be presented.

Simulation of three farming strategies on ammonia and GHG emissions and economics

P. Galama and H. Pishgarkomileh

Wageningen University and Research, Livestock research, De Elst 1, 6700 AH Wageningen, the Netherlands; paul.galama@wur.nl

Tackling climate change and other environmental concerns is a global challenge. Given the high contribution of livestock sector on the greenhouse gas (GHG) emissions, this industry has come into focus. Efforts have been initiated by introducing many mitigation strategies. However, still there are debates about effectiveness of them. Given the complexity of dairy system, quantifying the impacts is a challenge. In this study some of the available mitigation strategies have been models using a farm model (DairyWise). The assessment had two parts: (1) individual assessment of mitigation strategies; (2) combination of mitigation strategies as different production systems. For individual assessments, five mitigation strategies including increasing milk production level (6,000, 8,500, and 10,000 kg milk/cow), increasing longevity by changing the young stock ratio (5, 6.7, and 8 young stock per 10 dairy cow), increasing area of long-term grasslands (20:20, 33:6, 39:0 grass area:maize area), sowing clover on grasslands, and increasing grazing intensity (900, 1,600, and 3,600 hours/year) were selected and evaluated at three levels. To have a better overview, three production systems including extensive-regular (ER), extensive-organic (EO), and high-tech (HT) dairy systems were compared with the baseline to show the technical, environmental, and economic differences. The production systems differed from the point of view of the stocking rate, milk production level, grazing intensity, cultivation of clover, available land area, and type of stall. For comparisons, environmental (GHG and ammonia emissions), technical (nutrient balance), and economic aspects were considered. Obtained results showed that the total GHG emission of baseline, ER, EO and HT were 1.21, 1.18, 1.14 and 1.20 kg g CO₂-eq per kg milk, respectively. Results of ammonia emission showed the lowest emissions for EO while the highest emissions were reported for HT. Economic results showed that HT is the most attractive system. Results showed that moving towards more extensive and organic production system reduces the environmental impacts and can be attractive for farmers in term of economic aspect.

Exploring the effect of dairy cow replacement decisions on feed efficiency and sustainability

A. De Vries

University of Florida, 2250 Shealy Drive, Gainesville, FL 32608, USA; devries@ufl.edu

An important metric for the impact of dairy farming on climate sustainability is the amount of milk produced per unit of enteric methane. Enteric methane emissions in dairy cattle are strongly related to dry matter feed intake. Therefore, the amount of milk produced per unit of dry matter intake is relevant. This should include dry matter eaten by all dairy cattle on the farm, including growing replacement heifers, dry cows, and lactating cows. Increasing the productive life of dairy cows implies fewer replacement heifers are needed but may also result in keeping low milk producing cows in the herd longer. The objective of this study was to explore how economic replacement decisions affect feed efficiency and thereby the climate sustainability of dairy farming. We developed and used a stochastic dynamic programming model of a dairy herd consisting of heifers and cows. The model optimizes voluntary replacement and insemination decisions for millions of states of animals but can also simulate scenarios with non-optimal decisions. Animal states are defined by parity, week in milk, week of pregnancy, week of oestrous cycle, and levels of milk production. Each state is associated with relevant performance, such as milk yield, dry matter intake, fertility, and cash flow. Herd inputs were chosen to represent a typical herd in the USA. Initial results showed that a scenario with optimal replacement decisions led to a 36% annual cow replacement rate with profit of \$332/cow per year. Average milk yield was 36.5 kg/cow per day. Herd feed efficiency, calculated as all milk yield divided by all dry matter intake in the herd, was 1.42. Lifetime milk yield was 37,278 kg produced in 1,729 days of lifetime, or 21.49 kg per day of life. A scenario where cows were kept longer led to an 28% annual cow replacement rate with a profit of \$265/cow per year. Average milk yield was 35.2 kg/cow per day and herd feed efficiency was also 1.42. Lifetime milk yield was 46,548 kg produced in 2023 days of lifetime, or 22.89 kg per day of life. In conclusion, initial results show that trade-offs exist between profitability, longevity, and climate sustainability. Extending the productive life of dairy cows does not necessarily improve climate sustainability.

Session 17

Theatre 4

Practical monitoring of individual methane production rates in dairy cows: an alternativeC.M. Levraut¹, J.T. Eekelder¹, P.W.G. Koerkamp¹, C.F.W. Peeters², J.P.M. Ploegaert³ and N.W.M. Ogink^{1,3}¹Wageningen University & Research, Farm Technology Group, P.O. Box 16, 6700 AA Wageningen, the Netherlands,²Wageningen University & Research, Mathematical & Statistical Methods Group, P.O. Box 16, 6700 AA Wageningen, the Netherlands, ³Mathematical & Statistical Methods Group, Livestock & Environment, P.O. Box 338, 6700 AH Wageningen, the Netherlands; cecile.levraut@wur.nl

Over the past decades, the potent greenhouse gas emissions from cattle farming have kept rising, and reducing the impact of the sector on the environment has become crucial. While reduction strategies have already been identified, the evaluation of the performance of these measures remains limited by the available assessment methods. Several devices have already been developed in an attempt to quantify the individual methane production rates (MPR) of dairy cows under barn conditions. Unfortunately, they are often inaccurate, laborious, or expensive. The newly developed Cubicle Hood Sampler (CHS) could offer a way to compensate for this shortcoming. The principle of the CHS is to collect, in a non-intrusive manner, the gas mixtures produced by cows when lying down through the use of extraction hoods that are positioned above the cubicles. Additional RFID sensors allowed each measurement to be assigned to a specific cow. Camera vision was used to monitor cow postures and filter out biased observations. Due to the physiological rhythm of cattle and the location of the system, individual monitoring of up to 12-h per day can be achieved. To investigate the ability of the CHS to estimate MPR and build a ranking index to select cows based on their methane production levels, the methane emissions of 28 lactating Holstein cows were monitored using, alternatively, climate respiration chambers (CRC, 4-d) and CHS (7-d). Using a partially-pollled hierarchical model we developed, the estimations made by the CHS were converted from discrete measurements to continuous methane production curves. Comparisons with the MPR estimated by the CRC showed that the CHS can sense variability between cows, and that its estimates are moderately correlated with the CRC ones. These first results position the CHS as a promising system to monitor the MPR of cows in practical conditions.

Air filtering as alternative approach to combat emissions from cattle facilities

A. Kuipers, P. Galama, R. Maasdam, S. Spoelstra and P. Groot Koerkamp

Wageningen University & Research, De Elst 1, 6708 WD, the Netherlands; abele.kuipers@wur.nl

Various strategies can be applied to reduce ammonia and methane emissions. One strategy is to adapt the animal to the environment, like adding methane blockers to the feed or selecting for low methane animals, and the other is to adapt the environment to the animal. We study the simultaneously capturing of methane and ammonia from air, a practice belonging to the 2nd strategy. In some intensive livestock areas, air scrubbers are common in pig houses to capture ammonia from the air. This technique has not been adopted in cattle housings, mostly because these facilities have an open structure. Moreover, capturing of methane from air in cattle houses is complicated due to the very low concentration in barns (in 60 farms spread over Europe ranging from 5 to 80 ppm at 2 m height) and low solubility of methane in water. In a dairy housing about 30% of methane comes from the manure and 70% from the mouth of cows through the process of rumen fermentation. We examined several options to remove ammonia and methane from dairy barns by use of a survey based on scientific literature, contacts with experimenting farmers and farms and experimentation on capturing more concentrated methane (with aid of a hood mounted over the lying place of cows and recirculating of air). We found no feasible technology to capture ammonia and methane simultaneously, because of the low concentrations and chemical and physical inertness of methane. We conclude that two separate technologies need to be applied for capturing ammonia and methane, respectively. When stored manure is a significant source of ammonia and – temporarily- methane, both emissions can be guided to an air scrubber to remove ammonia by acid. For higher levels of methane, a biobed depending on consortia of methanotrophs could be considered. The methane concentration of ventilation air of dairy barns is too low to be treated. No technologies based on activity of methanotrophs or physical-chemical methods involving adsorption and oxidation of methane have been identified until now. Concentration to around 300-500 ppm seems to be a way out. Technologies like catching methane near the head of the animal, e.g. by a hood or designing new ventilation systems, seem a direction to be further explored.

Session 17

Theatre 6

UAV-based approaches for gaseous emissions assessment in cattle farming

V. Becciolini¹, A. Mattia¹, M. Merlini¹, G. Rossi¹, F. Squillace¹, G. Coletti², U. Rossi² and M. Barbari¹

¹University of Florence, Department of Agriculture, Food, Environment and Forestry (DAGRI), via San Bonaventura 13, 50145 Firenze, Italy, ²Project & Design S.r.l.s., via Livorno 8/28, 50142 Firenze, Italy; valentina.becciolini@unifi.it

The use of unmanned aerial vehicles (UAVs) as in-flight sensing platforms for atmospheric chemical research is rapidly growing, with an increasing number of field studies published in the past 5 years and with the appearance on the market of gas sensors specifically designed for UAVs. Nevertheless, the main applications are connected to air quality and emission monitoring in urban or industrial contexts. Aiming to provide a comprehensive view on the perspectives of application in dairy farming, we investigated and tested UAV-based approaches for gaseous emissions assessment focusing on equipment (drones, sensors), technical solutions and methods for fluxes estimation. While rotorcrafts represent the primary option, due to their manoeuvrability and autonomous GPS-based hovering, drone size choice largely varies depending on the utilized gas sensing equipment. Non-Dispersive Infrared Sensors (NDIR) are considered suitable for measuring CO₂, with small-sized and low-cost options available and providing sufficient accuracy. Measuring CH₄ in farming contexts requires sensors with appropriate limit of detection and accuracy. Finding miniaturized and low-cost options on the market with such performances is currently challenging since most available sensors, both electrochemical and NDIR, have limits of detection of 100 ppm. Methane sensing over livestock facilities, thus, requires high accuracy sensors that can be used in-flight. Ground-based analysers (e.g. CRDS analysers) are also used to measure methane and N₂O concentrations using UAVs as mobile platforms for air sampling. When coming to fluxes estimation using UAVs, current methods rely on mass balance or on the use of plume inversion techniques. Both approaches require the simultaneous collection of accurate gas measurements and atmospheric data as temperature, relative humidity, atmospheric pressure and wind measurements. Together with literature information, the outcomes of an experimental application of a prototype multi-sensor platform for UAV and ground gaseous measurements in cattle dairy farms is presented and discussed.

Reducing N leaching by adapting N application timing and quantities to weather and grass growthL. Bonnard^{1,2}, E. Ruelle², M. O'Donovan², M. Murphy¹ and L. Delaby³¹MTU, Department of Process, Energy and Transport Engineering, Cork, Ireland, ²Teagasc, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy, Cork, Ireland, ³INRAe, Institut Agro, PEGASE, Saint-Gilles, 35590, France; laetitia.bonnard@teagasc.ie

The EU Green Deal Farm to Fork strategy has set a target to reduce nutrient losses by at least 50% and fertilizer use by at least 20% by 2030. This will require more appropriate management of Nitrogen (N) fertiliser increasing N use efficiency leading to a reduction of N available for loss. A modelling exercise has been conducted, using the MoSt GG model, to highlight the potential for N precision management to reduce N leaching. Four scenarios were simulated over 19 years (2003 to 2021) using weather data recorded by the Met Eireann synoptic weather station, located in Moorepark Co. Cork, Ireland. The base fertiliser application had a total annual N fertilisation of 225 kg N/ha/yr. Then, the following rules were set to adjust the timing and quantity of the fertilisation: The N application had to be delayed if (1) the average temperature recorded over the preceding and/or the coming week dropped below 5 °C, (2) heavy rainfall occurred in the four preceding days or if it was expected in the three coming days, (3) from April onwards, if the predicted grass growth for the following week was below 30 kg DM/ha/d, fertilisation was cancelled. In each case, if the N application was delayed by more than seven days, the N application was reduced (or even cancelled if over 21 days). For each scenario, four paddocks cut every four weeks in rotation with a total of 10 cuts/yr/paddock were simulated. The precision N management led to an average reduction in N leaching of 3%, associated with an average reduction of 10 kg of N applied/ha/yr and a grass dry matter (DM) yield decrease of 1%. While the highest impact on the amount of N leached was the weather (yearly effect), the positive impact of precision fertiliser application has been shown on specific years. In 2014, for example, the N leaching decrease of 7% with 5 kg DM less grass produced. The years with the greatest N leaching reduction due to the reduction of N applied are often associated with a loss of grass DM production, highlighting that trade-offs will have to be found.

Session 17

Theatre 8

Reducing greenhouse gases in dairy cattle farming through innovative technologies

A. Svitojus and E. Gedgaudas

Chamber of Agriculture of the Republic of Lithuania, K. Donelaičio g. 2, 44239, Lithuania; arunas_svitojus@yahoo.com

The presentation will provide an overview of the situation of Lithuanian dairy farms, the capacity of the Lithuanian dairy industry, and the volume of milk produced in Lithuania and its imports from other countries. Information will be provided on milk purchase prices in Lithuania – the different prices paid for raw milk to small and medium-sized dairy producers and large dairy producers. It will also provide information on the average milk procurement prices in the EU in 2022 and the average milk procurement prices in Lithuania. Information will be provided on changes in prices of dairy products sold by Lithuanian dairy companies, structural changes in dairy farms, the main indicators of milk production in Lithuania and the situation of co-operation, as well as measures to reduce the greenhouse effect and increase milk profitability. One of the way to reduce the greenhouse effect is milk production. Lithuanian dairy farms include in selection programs bulls with high milk production indexes, health traits, longevity. In Lithuanian we increase milk production from 5,601 kg in 2017 until 6,425 in 2021 per cow and we still have a lot potential. Farmers have big interest in female sexed semen and beef on dairies management technology.

Annual quantification of GHG and NH₃ emissions coming from compost-bedded pack housing systems

E. Fuertes, G. De La Fuente, J. Balcells and R. Seradj

University of Lleida, Animal Science, Av. Alcalde Rovira Roure, 191, 25198, Lleida, Spain; esperanza.fuertes@udl.cat

Traditionally, dairy cattle in Spain has been housed on freestall cubicles system, where manure is stored on an open air pool. Nevertheless, compost-bedded pack systems (CBP) are gaining popularity due to its benefits on animal health and welfare, and its use is being extended. In this system, the animals rest on a bed made up by their own manure, which is daily composted *in situ*. As emission of pollutant gases such as certain GHG or NH₃ coming from this system have not been quite studied yet, the need appears to evaluate the effect that the composting process has on emissions from CBP dairy systems. Moreover, as gas emission are not constant along the year due to temperature variations, annual emissions were registered to evaluate differences between seasons. Measurements were taken every two months during a whole year on a CBP farm. Two distinct emission phases were differentiated: static emission (SE), corresponding to the period of the day when the compost bed is kept at rest; and dynamic emission (DE), happening during and afterwards the mechanical composting of the bed. To determine emissions, an airtight structure was located on the surface of the bed. An air flux was performed inside the structure, counting with an air entry where clean air come in and an outlet way where the air inside the simulator was taken to an analysis station in order to collect the gases of interest. During DE, surface of the bed was composted by means of a rototiller, simulating in time and depth the composting work performed on the rest of the barn. Emission was calculated as the difference between entry and outlet concentrations. GHG and NH₃ emissions were significantly higher during DE compared with SE for all gases under study (CH₄: 0.55 vs 0.07 g/m²&h; CO₂: 1.5 vs 0.21 g/m²&h; N₂O: 7.6 vs 1.1 mg/m²&h; NH₃: 0.28 vs 0.12 g NH₃/m²&h). NH₃, N₂O and CO₂ showed clearly how their emissions decreased during the cold months of the year and increased constantly as temperatures warmed up, while CH₄ showed the opposite trend. Despite being a positive system when it comes to animal health and welfare, CBP composting phase would present an important contribution to pollutant gas emissions generated from manure.

A study of the building-integrated photovoltaic cattle houses application scenario in China

Q. Wang, X. Du and Z. Shi

China Agricultural University, NO.17 Tsing Hua East Road, Beijing, 100083, China, P.R.; qiawang@cau.edu.cn

For the sake of sustainably meeting the growing demand for livestock products, it is essential to improve resource efficiency and reduce the corresponding emissions, which highlights the significance and necessity of harnessing the renewable energy. The use of building-integrated photovoltaic (BIPV) system can be well optimized on the barn, so that the solar radiation received by the roof of the barn can be fully utilized. This study conducts a feasibility study on the application of BIPV cattle houses in various provinces in China (counting the data for 31 mainland provinces without Hong Kong, Macao and Taiwan). In the study, a virtual standard barn was applied to each province in China, with setting the solar radiation and electricity price differently for each province. The results showed that the application of BIPV cattle houses in all provinces could help to achieve self-sufficiency in the power of the barn. The cattle houses in most provinces could generate a large amount of surplus electricity feeding in the grid, which may reduce most of (over 95%) the annual greenhouse gas (GHG) emissions of the cattle houses in each province. From the perspective of generating electricity power, Tibet had the highest amount of photovoltaic electricity generation, the largest proportion of electricity saved and the biggest number of the gross annual GHG emission reduction, 866,569 kWh, 251% and 546.9 tCO₂, respectively. Seven provinces, including Beijing, Hebei, Shanxi, Inner Mongolia, Jilin, Qinghai and Ningxia, were relatively higher among all provinces, with averages of 665,202 kWh, 193% and 418.8 tCO₂. The financial viability of the above-mentioned results showed that the equity payback of six provinces including Beijing, Hebei, Shanxi, Inner Mongolia, Jilin and Ningxia were shorter, with an average of 3.8 years, while Tibet and Qinghai were longer, with an average of 5.2 years. In general, the photovoltaic electricity generation effect and the income of BIPV cattle houses applied in six northern provinces reached a better result. With the finding, this study certainly provides a preliminary basis for the application of BIPV cattle houses.

Effect of manure management and environmental temperature on microbial communities in dairy manure*E. Fuertes, R. Seradj, J. Balcells and G. De La Fuente**University of Lleida, Av. Alcalde Rovira Roure, 191, 25198 Lleida, Spain; esperanza.fuertes@udl.cat*

Lleida region is home to some of the largest dairy farms in Spain; this intense farming generates a great amount of manure to be managed, which is known to act as a source of pollutant gases. The two main dairy housing systems which stand out from others are compost-bedded pack (CBP) and cubicles system (CUB), each one with a different manure management procedure. Since pollutant gas production depends on the activity of certain microbial communities, understand the connection between manure microbiota and housing system might help to characterize the microbial dynamics involved in the emission of pollutant gases in dairy manure as well as the impact of the environmental temperature on such communities. Manure samples (n=81) from both housing systems (CBP, n=3; CUB, n=3) were collected during two seasons: summer and winter. Samples were frozen and the bacterial genomic DNA was extracted, using a commercial kit. Then, high-throughput sequencing of the V3-V4 hypervariable region of 16S rRNA was conducted on Illumina MiSeq system. Taxonomic assignment of phylotypes was performed using a Bayesian Classifier trained with Silva database; both microbial alpha and beta diversity as well as the taxonomic profiles of the samples were analysed using 'vegan' and 'mixomics' packages from R software. CBP showed higher microbial biodiversity than CUB, and both systems presented higher index values during summer season. Community structure was also clustering by system and season although separation between seasons was more remarkable in CPB systems. In CUB systems, higher abundance of methanogenic archaea such as *Methanobrevibacter* (9%) was found, explained by the favourable anaerobic conditions provided by the storage pool compared to CBP. Some urease producer bacteria, like *Corynebacterium* and *Pseudomonas*, were more abundant on CBP systems, especially on summer, results in accordance with literature showing higher NH₃ volatilization from CBP systems compared to CUB. Results obtained show that manure microbiota changes between housing systems and highlights the importance of environmental temperature on microbial activity, and in consequence on the gas emissions produced in these scenarios.

Session 17

Simultaneous comparison of 5 methods to quantify enteric methane emitted by lactating dairy cows*A. Vanlierde, F. Dehareng, O. Christophe and E. Froidmont**Wallon Agricultural Research Center, 5030 Gembloux, Belgium; a.vanlierde@cra.wallonie.be*

Different techniques to estimate methane (CH₄) emissions from livestock are available. This study aimed to compare simultaneously 5 methods. Two measurement techniques were considered: SF₆ tracer gas and automated head-chamber system (AHCS – Greenfeed system); as well as three indirect predictive models: based on milk fatty acids obtained by gas chromatography (GC), on milk mid infrared (MIR) spectra and on faecal near infrared (NIR) spectra. The focus was on the ranking of animals in function of their level of CH₄ emissions depending of the technique. Variability is needed between animals (parity, milk yield, level of CH₄ emissions, corresponding spectral information, etc.). Ten animals were chosen based on CH₄ predictions from milk MIR spectra and zootechnical characteristics. The basal diet was a classical RTM. After 3 weeks of adaptation (W1 to W3) to the AHCS device, 4 weeks of measurement with the AHCS were performed (W4 to W8) and an individual representative milk sample (proportional mix of am and pm milking) was collected daily to obtain the MIR spectra. SF₆ tracer technique was used to obtain a double daily measurement of CH₄ emission per cow during 3 days both on W5 and W7. During the same days a spot faecal sample (to obtain NIR spectra) and an additional mix of am/pm milk sample was collected to perform GC analyse. Two cows obtained CH₄ values with SF₆ technique with more than 20% of difference between W5 and W7 which is physiologically questionable as no health trouble was noticed and the diet is stable. Consequently, the cows have been removed of the analyse. The range of CH₄ values obtained by SF₆ tracer technique was about 563 to 872 g/d (mean ± SD=674±82) while it was between 530 and 717 g/d for the AHCS (618±56 g/d). Values obtained from milk MIR spectra were about 25% lower than the AHCS values while the predictions from the very first model based on faecal NIR spectra dedicated to dairy cattle were about 50% lower. However, due to the know errors of the prediction models the variability of CH₄ emissions between animals was too low to conclude about the ranking of animals between techniques.

Meeting consumer expectations: a 3G global beef eating quality predictive model for EuropeA. Neveu¹, R. Polkinghorne², R. Watson³, H. Cuthbertson² and J. Wierzbicki⁴¹SARL Birkenwood Europe, Lanon, 03240, France, ²Birkenwood Pty Ltd, Blandford, 2338 Murrurundi, Australia, ³Melbourne University, Department of Mathematics and Statistics, University of Melbourne, 3010, Australia, ⁴IMR3G Foundation, Smulikowskiego 4, 00-389 Warsaw, Poland; neveu.alix@gmail.com

The meat industry faces several challenges and consistent, predictable eating quality is one of them. In Europe, the actual EUROP commercial grading system for carcass conformation and fat distribution doesn't align with consumer's meal experiences. This was proven over the past 15 years with meat eating quality research trials using untrained consumers across Europe. Since 2017 the collaborative platform hosted by the International Meat Research 3G Foundation (IMR3GF) has compiled the data collected using UNECE Beef Eating Quality protocols. The IMR3GF members comprise leading scientists from several countries who have collaborated extensively to assemble consumer and animal data across many countries and over 25,000 European consumers. The approach was to work with UNECE to create common standards for meat products and sensory evaluation to ensure data were compatible and able to be merged to create sufficient scale from which reliable consumer sensory estimates could be developed. These data have enabled the Foundation to develop a European predictive model based on research trials. The database contains data connecting cattle, carcass treatments, cuts and cooking styles to consumer answers on eating quality. This represents consumer studies conducted in total on 11 muscles over the last decades in European countries (Poland, France, England, Northern Ireland, Wales, Ireland). The database contains a considerable number of variables characterising the carcass using the 3G Chiller Assessment method and the consumers sensory testing according to the UNECE standards. The predictive model is an evolutive tool with further eating quality accuracy and scope developed with greater data. As all industry revenue directly relates to the consumers judgement of value, with the most critical component meal satisfaction, industry profitability can be enhanced by delivering consistent eating quality through strong commercial brands built on a solid scientific foundation.

Development of a carcass grading system for South African beefM.S. Faulhaber¹, P.E. Strydom² and N. Hall¹¹Cavalier Foods, 83 Performance road, Farm Tweefontein, Cullinan, 1000, South Africa, ²University of Stellenbosch, Stellenbosch Central, Stellenbosch, 7602, South Africa; michaela@cavalier.co.za

The South African red meat industry is diverse in terms of production systems, landscape, climate, breeds, age, sex, feeding regimes, external parasite loads, growth stimulant use (hormonal and beta-agonists) and management practices; each providing its own influence on the quality of meat provided to the consumer. This diversity in conditions often makes it difficult to identify strong correlations between single intrinsic factors and meat quality attributes. Due to this complexity, there is paucity in the understanding the exact factors which influence meat quality. Currently, no method exists which can effectively and consistently predict or ensure the eating quality of the meat which is produced within South Africa. To develop a quality grading model within South Africa, a developing country, the effect of animal inputs unique to South Africa on the eating experience of the consumer, needs to be determined. These unique inputs include local breeds (Sanga types), growth stimulant use (beta-agonists and hormonal growth promotants), sexes (predominantly young bulls) and traditional production methods (grass-fed & feedlot raised) which have not been included in the Meat Standards Australia (MSA), International Meat Research 3G Foundation (IMR3GF) or other international grading model developments, yet. A matrix of animals (n=276), inclusive of the above-mentioned attributes, were slaughtered as per current South African standards and data recorded utilising registered UNECE protocols. A total of 1,980 beef cuts of varying quality were harvested to be subjected to consumer testing to determine eating quality as experienced by the South African population. Subsequent grading prediction scores were compared to the South African consumer's eating experience. The results will update the existing grading models of the International Meat Research 3G Foundation, Meat and Livestock Australia and be utilised to develop the first of its kind grading system for South Africa. Once developed, the model will be implemented within one of the leading red meat value-chain companies and food retailers (the exclusive owner of the South African IP) within South Africa.

French consumer evaluation of eating quality of Limousin beef

M. Kombolo¹, J. Liu¹, I. Legrand², F. Noel³, P. Faure⁴, L. Thoumy², D. Pethick⁵ and J.-F. Hocquette¹

¹INRAE, UMR1213, Theix, 63122, France, ²IDELE, Bd des Arcades, 87000 Limoges, France, ³IDELE, Rte d'Epinay sur Odon, 14310 Villers-Bocage, France, ⁴INRAE, Herbipôle, Theix, 63122, France, ⁵Murdoch University, Food Futures Institute, Perth, 6150, Australia; moise.kombolo-ngah@inrae.fr

The aim of this study was to evaluate the eating quality of 2 beef cuts (striploin and rump) from 102 Limousin cows. Carcasses were first graded according to the Meat Standards Australia (MSA) methodology at the 5th and 10th rib 24 h post-mortem by 2 chiller assessors. This allowed the prediction of the MSA index for the whole carcass, which is an indicator of beef potential eating quality. Muscle samples were then collected, sliced with a thickness of 2.5 cm, aged for 10 days and finally grilled according to the MSA protocol. A total of 480 consumers scored beef for tenderness, juiciness, flavour and overall liking on a 0 to 100 scale. In addition, consumers were asked to assign a quality rating to each sample: 'unsatisfactory' (2*), 'good everyday' (3*), 'better than everyday quality' (4*) or 'premium quality' (5*) with an average of 3.03 and 2.9 for striploin and rump. Observed MQ4 scores were calculated combining scores of tenderness, juiciness, flavour and overall liking according to the MSA protocol. MQ4 values for the 2*/3*, 3*/4* and 4*/5* boundaries were 54, 62 and 76 respectively. The MSA index ranged from 45.5 to 58.5 and had a median value of 51.33. The marbling scores at the 5th and 10th ribs were positively correlated with the MSA index (0.34 and 0.47 respectively). Finally, beef carcasses were divided into two equal groups (under or above the median MSA index). The MSA index and the marbling score were 13 and 15% higher respectively in the second group of carcasses while ribfat thickness was 88% higher. Scores for tenderness, juiciness, flavour and overall liking as well as MQ4 were on average 9 to 13% higher for the rump and 5-10% higher for striploin in the second group compared to the first one. Overall, the results showed that the Australian MSA model might be relevant for Limousin cows but may require improvements for carcass grading at the 5th rib.

Session 18

Theatre 4

BeefQ – testing a beef eating quality prediction system for Wales and England

P.K. Nicholas-Davies¹, R. Polkinghorne², A. Neveu², H. Cuthbertson² and T. Rowe³

¹Aberystwyth University, Department of Life Sciences, Penglais Campus, SY233DA Aberystwyth, United Kingdom, ²Birkenwood Pty Ltd, 45 Church Street, Hawthorn, Victoria, 3122, Australia, ³Celtica Foods, Heol Y Plas Cross Hands Food Park, Cross Hands, SA146SX Llanelli, United Kingdom; neveu.alix@gmail.com

The BeefQ project was implemented to address industry and consumer concerns around beef eating quality consistency. To adapt the Meat Standards Australia (MSA) model for UK conditions, consumer taste testing beef was conducted using the standard protocol developed in Australia. Four cuts (sirloin, tenderloin, salmon and feather blade) from 90 sides of beef were evaluated as grilled steak by 1,200 Welsh and English consumers. Carcase suspension method and 7 and 21 days maturation were also tested. Cuts were collected in two seasons from cattle types typical of the Welsh herd (beef breed steers and heifers, dairy cross steers and heifers, young bulls and cows). Discriminate analysis determined the relationship between the individual consumer scoring scales of tenderness, juiciness, flavour and overall liking and provided a measure of the relative importance of each scale in determining the final quality decision. Overall eating quality scores (an aggregation of scales above (1-100)) were used to determine cut off values for what consumers consider to be good everyday, better than every day and premium quality beef. The relative importance of each variable was 0.3 tenderness + 0.1 juiciness + 0.3 flavour + 0.3 overall liking. These weightings were similar to current MSA 30:10:30:30 ratios indicating that the two consumer populations were similar. The cut off scores for better than every day and premium quality, respectively, were slightly lower (37 vs 41) and slightly higher (79 vs 77) than current MSA values, indicating that BeefQ consumers may discriminate more for both unsatisfactory and premium beef. This is important for brands where any inconsistency may impact value. These analyses provide strong evidence that Welsh and English consumers clearly differentiate eating quality from unsatisfactory to premium and that a universal set of sensory weightings and cut off values can adequately define these categories.

Assessment of untrained consumers on eating quality in Zebu and crossbred cattle at aging times

A. Barro^{1,2}, M. Coutinho³, G. Rovadoscki³, A.M. Bridi² and J.F. Hocquette¹

¹INRAE Vetagro Sup, UMR1213, Theix France, 63122 Theix, France, ²Londrina State University, Highway Celso Garcia Cid, 86057970 Londrina, Brazil, ³Research and Development Department, Brazil Beef Quality Ltd, Piracicaba, Sao Paulo 13415-000, Brazil; amandagbarro@gmail.com

Crossbreeding has been used to improve the sensory quality of Zebu animals, and aging time improves meat tenderness. The objective of this study was to evaluate the effects of aging times on beef eating quality in Zebu and crossbred cattle. Two experiments are reported in this study. The first one was based on carcasses of Nellore and crossbred (Nellore × Angus) animals at 3 aging times (5, 15 and 25 days) for Longissimus thoracis et lumborum (LD). The second experiment involved 6 muscles from Nellore and Brangus at 2 aging times. Sensory analysis with untrained consumers was conducted with a neighbour-balanced Latin square design (6×6) with two block factors, consumer, and assessment order. Consumers rated tenderness, juiciness, and overall liking on a non-structured scale (0-100). The t test was used to evaluate the difference between breeds and aging times in first experiment. A variance analysis was performed for muscle comparison with the post-hoc test including Bonferroni correction for pairwise comparisons. In the first experiment, breed had no effect on sensory traits of the LD muscle. However, beef aged 25 days had on average eating scores 13-20% higher compared to 5-day aged beef. In the second experiment, at 5 days of aging, Brangus cattle presented better scores for all sensory traits (+11-20%). However, increasing ageing time from 5 to 15 days did not improve sensory scores of beef from Brangus. On the opposite, increasing ageing time improved sensory scores of Nellore beef by 11.6-15.4%. At 5 days, muscles showed a difference in tenderness, with the highest grade for rumpsteak. The striploin improved in flavour and the top Sirloin improved in beef eating quality after 15 days of ageing. As a consequence, there was no more difference between cuts in sensory traits at 15 days of ageing. In conclusion, the crossbred animals need shorter aging time compared to Zebu animals to produce good beef. Increasing aging time in Nellore may be a strategy to improve eating quality of beef.

Session 18

Theatre 6

Loin residual glycogen and free glucose do not affect Australian lamb loin eating quality

S.M. Moyes, D.W. Pethick, G.E. Gardner and L. Pannier

Murdoch University, 90 South Street, Murdoch 6150, Australia; s.moyes@murdoch.edu.au

Post-slaughter, muscle pH declines through anaerobic metabolism of muscle glycogen to lactic acid. An ideal pH of at least 5.7 is achieved within 24 hours *post-mortem* when sufficient levels of glycogen are available at slaughter. The inactivation of enzymes that breakdown glycogen occurs as muscle pH lowers, inhibiting further production of lactic acid and thus pH decline, resulting in residual glycogen remaining in muscles. During ageing, concentration of free glucose increases from hydrolysis and diffusion of residual glycogen. Both free glucose and residual glycogen may positively affect lamb eating quality through the Maillard reaction during cooking. However, the link between untrained consumer eating quality and residual glycogen has yet to be demonstrated, nor whether this link varies between ageing times. Loin samples were collected from 139 lamb (Maternal, Merino, Terminal) and 40 yearling (Merino) carcasses 24 hours post-slaughter and aged for either 5, 14 or 21 days, prior to grilled sensory testing for overall liking by untrained consumers. An additional 5 g sample was collected at each ageing time and assessed for residual glycogen and free glucose. Consumer responses (n=1,790) were modelled using ageing time as a fixed effect, and residual glycogen or free glucose tested one at a time as covariates. Unadjusted mean residual glycogen concentration was 14.83, 13.81 and 13.39 µmol/g at 5, 14 and 21 days. Unadjusted mean free glucose was similar across the ageing times ranging from 12.27 at 5 days to 12.22 µmol/g at 21 days ageing. Results showed no association ($P>0.05$) of loin residual glycogen with loin overall liking scores at any of the ageing times. A similar finding was observed for free glucose on loin overall liking. Despite this lack of effect, further research is warranted to explore the impact of residual glycogen or free glucose on other sensory traits (tenderness, juiciness, flavour liking). Additionally, residual glycogen and free glucose levels vary between muscles due to fibre type and other anatomical differences, therefore their impact on eating quality within other cuts should be explored.

Combining eating quality and individual cut tracking to maximise value and decrease waste in beef*H. Cuthbertson¹, R. Polkinghorne¹ and A. Neveu²**¹Birkenwood International Pty Ltd, Murrumbidgee, NSW, Australia, ²SARL Birkenwood Europe, Lanon, 03240, Saint-Sornin, France; holly.cuthbertson1@gmail.com*

Typically, processors are limited to how many ways cattle can be sorted as they come into the boning room. In most cases, individual identification is lost as cuts fall onto the belt. This affects the ability to maximise individual carcass value and often results in better quality carcasses or cuts being downgraded because of their pre-assigned batch. Yield based measurement systems are becoming popular in processing facilities. These systems can individually identify and track cuts, whilst collecting multiple yield measurements along the boning line, enabling processors to segregate product of consistent weight and size into specific brands. Eating quality is an important value for calculating consumer satisfaction across multi-cuts, cook types and days ageing on varying cattle populations. Produced from the IMR3GF 3G grading Model, an eating quality matrix provides processors with the ability to differentiate their product into trusted brands based on EQ cut off scores. By facilitating an accurate interpretation of 3G's eating quality matrix and feeding this into a cut tracking system combined with yield results, it enables individual cut sorting to happen in real-time at chain speed. This system would eliminate the need for extensive pre-sorting of carcasses, decrease capture losses and generate increased carcass value through the uplifting of cuts into better valued brands. Using Birkenwood's MEQ Toolkit and Marel's StreamLine system, a case study on generic data reported on the potential benefit of this system over a 3-month period. The processor was previously using basic cut offs for its brands across a small number of cuts. The analysis only looked at the system improving what was currently in place at the processor. Results from the case study revealed an large increase in product capture into the top brand (average 82.5%, range 28-175%) and increased the average \$/Hd across the entire dataset from \$996.43 to \$1,223.14. Potential value and cut capture would only increase if expanded to look at multi-cuts.

Session 18

Theatre 8

Changing the Australian trading language for beef and lamb to adapt to new measurement technologies*G.E. Gardner^{1,2}, S. Stewart^{1,2}, P. McGilchrist¹, C. Steele¹, H. Calnan^{1,2}, S. Connaughton^{1,2}, K. Mata^{1,2} and R. Apps¹**¹Advanced Livestock Measurement Technologies, (ALMTech), Australia, ²Murdoch University, College of Science, Health, Engineering and Education, Murdoch, 6150, Australia; g.gardner@murdoch.edu.au*

Since 2016 an Australian project (ALMTech) has accelerated the development and implementation of technologies that predict traits describing eating quality and saleable meat yield %. Initially these technologies were trained to predict traits that are commercially traded upon within industry. However, it soon became apparent that the existing industry trading language was limiting, as evidenced by the following 3 scenarios. The first is an example of where technologies can measure a trait that was not legislated for trading. In this case we introduced intramuscular fat % (IMF%) into the lamb industry trading language – a crucial step given the importance of this trait for predicting eating quality. This was underpinned by a Soxhlet laboratory method as the gold standard. In the second scenario, we introduced an alternative trait for one that poorly describes carcass value. In this case GR tissue depth in lamb was the historical measurement used to reflect saleable meat yield %. We introduced the alternative whole carcass lean % as a better indicator of saleable meat yield %, using computed tomography as the gold standard measurement. In the third scenario we provided an alternative to an existing trait that performed poorly as a calibrating standard for technologies. In this case we introduced IMF% into the beef industry to act in parallel with visual marble scores which have proven too erroneous for accrediting technologies. Conversion equations have also been established enabling these values to be interchanged. These new traits calibrated against robust gold standards have delivered multiple benefits. Firstly, technology provider-companies were instilled with the confidence to commercialise due to the provision of achievable accreditation standards. Secondly, processors had the confidence to invest in these technologies and establish payment grids based upon their measurements, knowing that reliable accuracy standards had been met. And lastly, data flow into genetic databases, industry data systems (MSA), and as feedback to producers was enhanced because of these technologies.

The precision and accuracy of the Q-FOM grading camera predicting rib eye traits in beef carcassesS.M. Stewart¹, M. Christensen², H. Toft², T. Lauridsen² and R. O'reilly¹¹Murdoch University, 90 South Street, Murdoch 6150, Australia, ²Frontmatec A/S, Smørum 2765, Smørum 2765, Denmark; r.o'reilly@murdoch.edu.au

The Q-FOM is a non-contact, rechargeable device specifically designed for ribeye grading according to AUS-MEAT and MSA grading standards, either in the chiller or at a grading station. The Q-FOM is able to grade in real-time MSA and AUS-MEAT marble score, AUS-MEAT eye muscle (EMA), AUS-MEAT meat colour, AUS-MEAT fat colour, MSA sub-cutaneous rib fat and chemical intramuscular fat (IMF%). A total of 4,677 commercial carcasses from two Queensland export abattoirs were graded and imaged using 3 cameras. A diverse range of carcass categories (Wagyu, grain fed (long, medium, short), organic, grass-fed, dairy, cull cow) were targeted to achieve a broad phenotypic range in rib eye traits. Visual ribeye grading was performed by two MSA expert graders and one commercial grader according to the AUS-MEAT chiller assessment language guidelines and used as reference. Precision (R², RMSEC/RMSEP) accuracy (bias) were reported for both calibration and validation analyses. The performance of the camera against the AMILSC accreditation standards were also reported. In addition, a high level of repeatability and reproducibility of Q-FOM Beef cameras was demonstrated across all traits.

Session 18

Theatre 10

Predicting IMF% and visual marbling scores on beef portion steaks with a Marel vision scanner systemL. Pannier¹, T.M. Van De Weijer², F.T.H.J. Van Der Steen², R. Kranenbarg² and G.E. Gardner¹¹Murdoch University, College of Science, Health, Engineering and Education, South Street, 6150 Murdoch, Australia,²Marel Meat B.V., Handelstraat 3, 5830 AD Boxmeer, the Netherlands; l.pannier@murdoch.edu.au

Marbling score is an important factor in many beef carcass grading schemes to classify carcass quality grades. Under the current Meat Standards Australia (MSA) and AUS-MEAT grading system, marbling score is visually assessed by accredited graders on the caudal surface of the m. longissimus thoracis et lumborum (loin) at a rib site between the 5th and 13th rib. The marbling score assessed at the grading site, is assumed to adequately represent the entire loin. Contrary to this assumption some studies have indicated that marbling varies within the beef loin. Therefore the grading of individual steaks could enhance classification of marbling grades for individual portions and could underpin an enhanced marbling specification for portion-cut product entering premium markets. This study describes the performance of a Marel conveyer vision scanner system in its ability to predict MSA and AUS-MEAT marbling scores of portion steaks from the cube roll. The capacity to predict the new AUS-MEAT trait of IMF% that has been approved as the gold-standard-trait for accreditation of objective measurement technologies was also assessed. Vision scanner marbling scores were acquired on fresh-cut steaks of beef carcasses (n=102) that represented a wide range in visual marbling score. The vision scanner predictions were tested using a leave-one-out cross validation method, which demonstrated precise and accurate predictions of IMF% (R²=0.87; RMSEP=1.16; slope=0.09; bias=0.22), MSA (R²=0.82; RMSEP=70.11; slope=0.09; bias=17.08) and AUS-MEAT marbling (R²=0.79; RMSEP=0.75; slope=0.16; bias=0.08). The Marel vision scanner prediction of visual grader scores was relatively less precise and accurate than its prediction of IMF%, likely due to random error in subjective grader scores. These results indicate that the Marel Vision Scanner could be used to underpin a market for premium portion-cut steaks where enhanced product description and consistency is required.

Improved analysis of dual energy x-ray absorptiometry images enhances lamb eating quality prediction*F. Anderson^{1,2}, L. Pannier^{1,2}, C. Payne^{1,2}, S. Connaughton^{1,2}, A. Williams^{1,2} and G.E. Gardner^{1,2}**¹Advanced Livestock Measurement Technologies, Murdoch, 6105, Western Australia, Australia, ²Murdoch University, School of Agricultural Sciences, Murdoch, 6105, Western Australia, Australia; f.anderson@murdoch.edu.au*

Dual energy x-ray absorptiometry (DEXA) is used in commercial abattoirs in Australia to predict carcass composition. Images captured using DEXA are at two different energy levels, with the pixels captured at low energy expressed as a ratio (R value) to those captured at a high energy, and relate to the atomic mass of the tissue. The mean R values from DEXA images have previously been used to predict lamb eating quality using isolated bone regions from the images, however this was in a small number of lambs and also demonstrated correlation with intramuscular fat content. Improvements in image analysis have enabled better isolation of the entire lamb skeleton, enabling calculation of the mean bone DEXA R value. This technique has been applied to a larger dataset from 2 abattoirs for lambs that varied in age/maturity (n=198). As the bone DEXA R value increased there was a decrease in the eating quality of some cuts, as evaluated by untrained consumers on a scale from 0 to 100. The relationship between bone DEXA R and eating quality was most consistent in the loin grill where overall liking scores decreased by 10 units ($P < 0.05$) at both abattoirs. This relationship was independent of loin intramuscular fat % and carcass lean %, which were tested simultaneously in models alongside bone DEXA R values. Similar associations were also found in other cuts, although the magnitude of effect varied. The improvements to DEXA image analysis enables chain speed DEXA scanning of lamb carcasses to rapidly predict aspects of lamb eating quality. Given the large proportion of the Australian lambs that undergo DEXA scanning at slaughter ($\approx 50\%$), this represents the ability to provide information on a large proportion of the lambs processed in this country. DEXA eating quality predictions may be incorporated along-side other production traits and carcass measures that could better allow for in-plant carcass sorting and recognition of carcass quality on which to base payment.

Session 18

Theatre 12

Aligning upper and lower commercial beef DEXA images to predict CT composition*H.B. Calnan^{1,2}, A. Williams² and G.E. Gardner^{1,2}**¹Advanced Livestock Measurement Technologies, Murdoch, 6160, Australia, ²Murdoch University, College of Science, Health, Engineering and Education, Murdoch, 6160, Australia; honor.calnan@murdoch.edu.au*

The Australian beef industry is focused on improved measurement of beef carcass composition and valuation along the supply chain. The first commercial dual energy X-ray absorptiometry (DEXA) system has been installed in Rockhampton Australia to measure computed tomography (CT) composition in entire beef sides scanned at line speed. The system is comprised of two DEXA units positioned vertically that scan the entire length of hanging beef sides to produce upper and lower images that overlap centrally. For established DEXA CT prediction equations to be aligned with and outputted by this commercial DEXA system, an automated method of stitching the beef DEXA images is needed that accounts for the duplicated central section and thereby maintains a consistent measure of whole side composition. Two approaches were explored to achieve this: (1) using an anatomical landmark; and (2) based on the number of duplicated pixel rows in carcass DEXA images. The caudal aspect of the 13th rib was identified as an anatomical landmark in the overlapping section of both DEXA images that could guide image stitching. An advantage of this method is that upper and lower DEXA images become a good approximation of the carcass 'forequarter' (lower image) and 'hindquarter' (upper image). However, difficulties were encountered in the ability of an operator to consistently identify the 13th rib landmark in both upper and lower DEXA images, making this method inconsistent and unreliable. Alternatively, the number of pixel rows duplicated in upper and lower DEXA images was determined using scans of plastic calibration blocks. This method of image stitching is advantageous in that it can be consistently applied to beef DEXA images regardless of carcass size or length and can be easily automated. This method has therefore been adopted to produce a single DEXA value for each beef side for use in pre-existing DEXA CT prediction algorithms to output an estimate of carcass composition. However direct calibration of this commercial DEXA system against CT measures of beef composition will further refine this image stitching method.

Calibration of chain-speed DXA units using synthetic phantom blocks in two Australian lamb abattoirsS.L. Connaughton^{1,2}, F. Anderson^{1,2}, A. Williams^{1,2} and G.E. Gardner^{1,2}¹Advanced Livestock Measurement Technologies, Murdoch, 6150, Australia, ²Murdoch University, College of Science, Health, Engineering and Education, Murdoch, 6150, Australia; s.connaughton@murdoch.edu.au

Dual Energy X-ray Absorptiometry (DXA) technology has been developed for chain-speed predictions of carcass composition in Australian lamb abattoirs, capable of predicting fat %, lean muscle % and bone % with high precision and accuracy. With multiple DXA units in operation across the country, a simple yet reliable method of calibrating them against one another was required. A synthetic phantom constructed of three different plastics (acrylic, high molecular weight polyethylene, and nylon) of varying mixtures and thicknesses is installed at each DXA site and is scanned at the commencement of every production day. The thickness of the plastic sections, as determined by the individual DXA, is compared to the thicknesses at one DXA site in Western Australia operating as the reference. Similarly, the predicted fat % composition of each plastic block is compared to that from the reference site, generating a calibration curve for the R-values of the DXA images. The thickness and R-value differences between the test site and the reference site are applied to all pixels in the DXA image through linear transformations, allowing the test site to calculate the carcass composition using the same algorithm as that applied at the reference site. The predictions of carcass composition can be validated against the computed tomography (CT) determination of fat, muscle, and bone %. The application of this cross-site calibration resulted in an increased precision for the prediction of CT fat % ($R^2=0.86$, RMSE=1.71%) from the uncalibrated values ($R^2=0.82$, RMSE=2.77%), while the accuracy was also increased (slope=0.96, bias=-0.12%) from the uncalibrated values (slope=1.24, bias=11.43%). This calibrated precision of CT fat % prediction was well aligned with the precision at the reference site ($R^2=0.94$, RMSE=1.10%), as was the accuracy (slope=0.97, bias=-1.19%). This method of calibration is suitable for calibration of DXA systems between abattoirs, as it is quickly calculated and applied, and enables DXA to be accredited for trading across Australia.

Theatre 14

Objective carcass measurement from commercial supply chains contributing to genetic improvementD.J. Brown¹, R. Alexandri¹, S.F. Walkom¹, D.W. Pethick², P. McGilchrist³, S. Stewart², W.S. Pitchford⁴ and G.E. Gardner²¹University of New England, AGBU, Armidale, 2351, Australia, ²Murdoch University, School of Veterinary and Life Sciences, Murdoch, 6150, Australia, ³University of New England, School of Environmental and Rural Science, Armidale, 2351, Australia, ⁴University of Adelaide, School of Animal and Veterinary Sciences, Roseworthy, 5371, Australia; dbrown2@une.edu.au

Australia's meat supply-chains are investing in a range of new technologies to improve productivity across the whole value-chain. This has been a collaborative effort aiming to transform industry competitiveness by creating feedback and decision support systems linked to accurate carcass measurements. The Australian sheep industry has also been developing tools for sheep breeders to make simultaneous improvements in the proportion of carcass saleable meat (lean meat yield: LMY) and its eating quality (EQ). Lean meat yield and eating quality attributes are antagonistically related and 'difficult to measure' for seedstock selection purposes. Objective carcass measurements from commercial supply chains offer an important tool for seedstock breeders, and the genetic validation of new technologies for assessment of LMY and EQ can increase opportunities to improve genetic progress. Genetic analysis of both LMY and EQ traits, recorded using several new technologies, demonstrated excellent accuracy. This analysis provided the platform for the new measures to be used in routine genetic evaluation and fast-track genetic progress. Furthermore, our existing genomic selection protocols coupled with objective carcass measurements from commercial lambs offer new opportunities to increase the reference population size and reduce the current reliance on expensive resource populations. New LMY and EQ measuring technologies can also help seedstock breeders by using the collected data and developing platforms to underpin pricing signals for commercial sheep producers. Currently there are limited pricing signals for both LMY and EQ but their development can help seedstock breeders to invest in these traits within their breeding objectives.

Potential of deep learning video image analysis for automated SEUROP-classification

T. Rombouts, M. Seynaeve and S. De Smet

Ghent University, Department of Animal Sciences and Aquatic Ecology, Coupure Links 653, 9000, Belgium; toon.rombouts@ugent.be

In cattle slaughterhouses in Europe, video image analysis (VIA) combined with linear regression (LR) modelling is widely used to assist or replace human SEUROP-classifiers. During the authorization procedure of the VBS 2000 (E+V) in Belgium in 2022, a deep learning (DL) algorithm was evaluated as an alternative for LR in terms of correct classification as well as other potential advantages. In Belgium, carcasses are classified into 18 different subclasses for conformation (SEUROP with subclasses +, = and -), 15 subclasses for fat cover (12,345 with subclasses +, = and -) and 7 animal categories (ABCDEZV). For the authorization test, a sample grid of 650 carcasses was made according to the distribution of category, conformation and fat cover in the Belgian carcass population. A jury of 5 assigned classification experts (2 from Belgium and 3 from other EU member states) were positioned next to the VBS 2000 and independently graded 1,123 bovine carcasses, of which 650 were finally used to fill in the grid on a first come, first served basis. The carcass classification was predicted by a previously developed VBS 2000 DL algorithm as well as a LR model, and these scores were compared with the median score of the jury. Correct classification was defined as having the same subclass or one subclass difference compared with the median expert score. For conformation, DL and LR resulted in high and comparable correct classification (90.9 and 92.0% respectively). Differences of 2 and 3 subclasses were observed for 8.9 and 0.2% respectively of the carcasses for DL, and 7.4 and 0.6% for LR. For fat cover, the correct classification was meaningfully larger for DL than for LR (95.7 vs 86.6%). A difference of 2 subclasses was found for 1.3 and 12.0% of the cases respectively, whereas DL had no scores with 3 subclasses difference and LR had 1.4%. Unlike LR, DL does not need the animal category nor the hot carcass weight as input, meaning it can operate separately from other software. In addition, DL was able to grade carcasses as S+, which LR couldn't, and produced less errors due to damage of carcasses. In conclusion, DL offers advantages compared to LR for bovine carcass classification.

Poster 16

Hand-held NIR device predicting chemical intramuscular fat% in pork

M.T. Corlett, F. Anderson and G.E. Gardner

Murdoch University, 90 South Street, Murdoch, 6150, Australia; f.anderson@murdoch.edu.au

The use of fast growing, muscular genotypes of pigs in Australia has been shown to result in some genotypes having intramuscular fat (IMF) as low as 1%. The SOMA S-7090 NIR is an AUS-MEAT accredited device for measuring chemical IMF% in sheep meat. This study tested the SOMA using a lamb algorithm to predict pork chemical IMF%. Chemical IMF% and SOMA measures were taken from the same location on the exposed loin eye surface (*M. longissimus lumborum*). Pork carcasses were collected from 3 sites; site 1 in New South Wales (n=120), site 2 in Queensland (n=115) and site 3 in Western Australia (n=104). The SOMA predicted pork IMF% with low precision ($R^2=0.10$, RMSEP=0.63) and accuracy (bias=-0.15). This work demonstrated the sheep meat IMF% algorithm currently installed in the device was not transferable to predicting pork IMF%. However, nearly 70% of the chemical IMF data was below 1.5%. This aligns with the national pork IMF% levels which are inherently low due to the muscular, fast growing genotypes utilised. Further work could involve training a pork specific IMF% algorithm which would likely see additional improvements in precision and accuracy.

An optimisation model for operational planning in lamb supply chainsG. Wang¹, F.L. Preston¹, C. Smith^{1,2}, D. Flanigan^{1,3}, S.M. Miller¹, W.S. Pitchford¹ and D. Meehan^{1,4}¹University of Adelaide, Davies Livestock Research Centre, Roseworthy, 5371, SA, Australia, ²Agbiz Solutions, RMB 539, Natimuk, 3409 Vic, Australia, ³Meat Data Logic, Horsham, 3400, Vic, Australia, ⁴Meehan Consulting, Brisbane, 4000, Qld, Australia; vince.wang@adelaide.edu.au

A Carcase Optimisation Tool was developed for use by the lamb processing industry to sort carcasses into boning groups by optimally allocating them to cutting plans using lean meat yield and weight, and to maximise profit. Processors are challenged to design cutting plans and sort carcasses into groups to fabricate the most efficient and profitable combination of cuts from each carcass whilst satisfying market specifications. Currently, carcasses are grouped using hot weight as the primary sortation criteria. As technologies that precisely and accurately measure carcass yield have become available, such as dual-energy X-ray absorptiometry (DXA), carcass lean meat yield percentage (LMY%) may be used with carcass weight to predict individual cut weights to allocate 'the right carcass' to 'the right cutting plan'. This task is well suited to be solved using mathematical optimisation models. The tool uses an Integer Linear Programming model to allocate carcasses of varying weight and LMY% to cut plans to maximise profit. The tool does this by: • specifying multiple cut plans; • using cut weight ranges (min and max) and piece counts to constrain and shape the allocation of carcasses to plans to meet market orders; • accounting for the differential cost of labour to process individual carcasses based on their weight and LMY%. The potential for the tool to improve profit was tested in a case study in an Australian domestic lamb supply chain. An optimised scenario using carcass weight and LMY% was compared to: (1) carcasses randomly allocated to cut plans; and (2) carcasses allocated to cut plans by weight; as is the current industry standard practice. Using cut weight alone, profit was 4.1% greater than when carcasses were randomly allocated to cutting plans. Optimisation yielded an additional 1% profit when compared to the carcass weight scenario. This work provides a pathway whereby DXA technology, combined with cut weight prediction and optimisation algorithms, and carcass sortation may improve the profitability of lamb supply chains.

Session 18

Poster 18

Predicting P8 fat depth in hot beef carcasses using a handheld microwave system

J. Marimuthu, R.K. Abraham and G.E. Gardner

Advanced Livestock Measurement Technologies Project, School of Veterinary and Life Sciences, Murdoch University, Murdoch, WA 6150, Australia; jayaseelan.marimuthu@murdoch.edu.au

Non-destructive and non-invasive methods of measuring live animal and carcass fatness on genotypically and phenotypically diverse cattle are crucial as they enable optimised carcass boning, producer feedback, and value-based trading. However, the suitability of the technology that takes these measurements depends upon numerous factors including accuracy, reliability, cost, portability, durability, speed, ease of use, safety, and for *in vivo* measurements the need for fixation or sedation. Working within these constraints a portable microwave system has been developed at Murdoch University to measure fat depth. This study details the accuracy of this system to predict P8 fat depth of hot beef carcasses at commercial abattoir chain speeds. Beef carcasses (n=1,304) were scanned hot using the Microwave System at the P8-site 30 min *post-mortem* and simultaneously measured for P8 fat depth by the in-house grader. The average carcass weight of these cattle was 476±30 kg and ranged between 156 and 5.48 kg, while the average P8 fat depth was 16±5 mm and ranged between 2 and 35 mm. The microwave system operated at frequencies of 100 MHz to 5.4 GHz with output power of -10 dBm coupled with a prototype broadband Vivaldi patch antenna. The reflected microwave signals were recorded at 10 MHz intervals across 531 frequencies. The magnitude of the frequency domain signals was used to predict the P8 fat depth, with the model trained using an ensemble stacking technique in WEKA and tested using 5-fold cross validation. The average precision was high with average R² of 0.81, with root-mean-square-error of the prediction of 2.78. The average bias (difference between the predicted and actual values at the mean of the dataset) was 0.12, while the average slope between predicted and actual values deviated from 1 by 0.02. This study demonstrates that the microwave system can precisely and accurately predict hot P8 fat depth across divergent phenotypes. Given that these measures were captured at commercial chain speed, these results suggest that the hand-held device has the potential for commercial deployment as a simple cost-effective technology for measuring carcass fatness.

Meat@ppli, a smartphone application to predict fat content of beefJ. Normand¹, B. Meunier², M. Bonnet² and B. Albouy-Kissi³¹Institut de l'Élevage, Carcass and Meat Quality, 69007 Lyon, France, ²INRAE, Université Clermont Auvergne, VetAgro Sup, UMR Herbivores, 63122 Saint-Genès-Champagnelle, France, ³Institut Pascal, Université Clermont Auvergne, 43009 Le-Puy-en-Velay, France; jerome.normand@idele.fr

Fat has a major economic importance in the beef sector. It affects all the meat food chain steps: from the farmer to the consumer. However, nowadays, the monitoring of fat, and especially marbling, in beef is difficult, due to the lack of a suitable assessment tool, i.e. reliable, simple, fast, non-destructive and inexpensive. The exponential growth of smartphones equipped with high quality imagers and high computing power has provided tremendous opportunities for measuring fat on bovine carcasses. The Meat@ppli project aimed: (1) to predict intramuscular and total fat content of 6th rib from its image captured under non-standardized and uncontrolled conditions, using image analysis methods and deep learning; (2) to embed the algorithms in a smartphone application. For this purpose, cross section images of the 6th rib of 164 carcasses chosen to be representative of the beef marbling variability, were captured with a smartphone Samsung® Galaxy S8 fitted with polarizing filters. The ribs were then removed to determined gold standard measures: total fat content by dissection and weighing, and intramuscular fat content (IMF) by the Soxhlet method. From more than 3,500 images of 6th ribs and gold standard measures, several artificial neural networks were trained to segment the rib, the ribeye, IMF in the ribeye and total fat in the rib. The correlations between the gold standards and the parameters from the image analysis were strong, with correlation coefficients of 0.91 and 0.79 for IMF and total fat content, respectively. The prediction models were then embedded in the Meat@ppli application. The application starts by taking a picture of the cross section of the 6th rib. The captured image is then displayed and submitted for validation. In less than 10 seconds, the application calculates IMF and total fat content. The Meat@ppli application remains a proof-of-concept that, in the future, could be used by the beef industry to route carcasses to the most suitable distribution channels and to perform massive phenotyping for the selection of bovines with appropriate marbling.

Computed tomography vs chemical composition for determination of Australian lamb carcass composition

K. Mata, G. Gardner and F. Anderson

Murdoch University, College of Science, Health, engineering and education, 90 South street, 6150, Australia; g.gardner@murdoch.edu.au

Computed tomography (CT) is commonly used as the gold standard measure of carcass composition in Australian lamb. For industry acceptance, experimentation against its predecessor, chemical composition was undertaken to demonstrate its comparability. A group of 30 lambs with a wide phenotypic range were sectioned into fore, saddle and hind and CT scanned at 36 hrs *post-mortem*. The 3 sections including bones were minced post scan through a 5 mm grinding plate until a uniform and homogenous mix was produced. Five samples were obtained in each of the fore(F), saddle(S), and hind(H) sections of the carcass and tested for their chemical composition of protein, lipid, and ash. These values expressed as percentages were then compared to the CT estimates of fat %, lean % and bone %. There was a strong association between chemical protein % and CT lean % with the R² and RMSE values for each section 0.86 and 2.82% (F), 0.92 and 2.82% (S) and 0.91 and 2.20% (H). A similar association was found with chemical lipid % and CT fat % across all carcass sections showing R² and RMSE values of 0.93 and 2.11% (F), 0.93 and 3% (S), and 0.89 and 2.05% (H). These strong associations demonstrate the relative equivalence between these two values as indicators of carcass composition. There was a weaker association found with chemical ash % and CT bone % showing R² values of <0.67 across all three sections and highlighting the well documented difficulty in homogenizing bone in a multi-tissue sample. Chemical analysis for protein, lipid and ash all showed marked sub-sample variation. Despite extensive mixing, the average deviation of each rep from the sample mean was 1.15 protein % units, an amount which represents 3.42% of the average protein value. Comparatively, for CT, the average deviation from the mean for each rep was 0.01 CT lean % units, which represents 0.02% of the average CT lean value. Similar findings were found for lipid and CT fat %, and ash and CT bone %. This variation in chemical sampling makes calibration of objective measurement tools against chemical analysis an unreliable method when compared to CT.

Assessing dual-energy X-ray absorptiometry prediction of intramuscular fat content in beefC.L.N. Nunes¹, R.S.R. Vilela¹, E.B. Schultz¹, M.I. Hannas¹, C.M. Veloso¹, M.M. Ladeira² and M.L. Chizzotti¹¹Universidade Federal de Viçosa, Department of Animal Science, Av PH Rolfs, s/n. Campus Universitário, 36570900 Viçosa, Brazil, ²Universidade Federal de Lavras, Trevo Rotatório Professor Edmir Sá Santos, 37203202 Lavras, Brazil; mariochizzotti@ufv.br

This study assessed the capability of dual-energy X-ray absorptiometry (DEXA) to predict intramuscular fat (IMF) content of beef longissimus steaks against chemical IMF as the gold standard. DEXA performance of fat prediction was assessed using a leave-one-out cross validation method among Angus and Nelore steaks, which generated a chemical fat range of 14.05-36.82% and 2.46-7.84%, respectively. There was a significant positive association between DEXA predicted fat and chemical fat content. However, higher precision was found for pooled data ($R^2=0.95$, RMSECV=1.95) and Angus ($R^2=0.75$, RMSECV=2.39) than Nelore ($R^2=0.15$, RMSECV=1.22) group. Accuracy also had the same response with average slope values close to one for pooled data and Angus and a lower value (0.42) for Nelore group. DEXA precisely predicts IMF content across a wide range of fat content. However, its precision and accuracy of prediction within low-fat content samples are lower than in high-fat content beef steaks. Funding: supported by Fundação de Amparo à Pesquisa de Minas Gerais (FAPEMIG) #APQ-02403-2017; RED-00172-22, Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), # 443718/2018-0; 308241/2022-3, and Instituto Nacional de Ciência e Tecnologia de Ciência Animal (INCT-CA).

Session 18

Poster 22

In-abattoir 3D image parameters of beef carcasses for predicting carcass classification and weightH. Nisbet^{1,2}, N. Lambe², G. Miller², A. Doeschl-Wilson¹, D. Barclay³ and C.A. Duthie²¹The University of Edinburgh, The Roslin Institute, Easter Bush, Midlothian, EH259RG, United Kingdom, ²Scotland's Rural College, The Roslin Institute Building, Easter Bush, Midlothian, EH259RG, United Kingdom, ³Innovent Technology Ltd., Northern Agri-Tech Innovation Hub, Easter Bush, Midlothian, EH259RG, United Kingdom; holly.nisbet@sruc.ac.uk

Imaging technology can extract measurements from beef carcasses, allowing for objective grading. However, many abattoirs still rely on manual grading due to the infrastructure and cost required, making the technology unsuitable. This study explores 3-Dimensional (3D) imaging technology, requiring limited infrastructure and its ability to extract automated measurements from beef carcasses to predict cold carcass weight (CCW), and EUROP conformation and fat class on the 15-point scale. Time-of-flight cameras captured 3D images of beef carcasses in a commercial abattoir in Scotland over 6-months. Up to 35 frames were captured per carcass, with 74 measurements (lengths, widths, and volumes) extracted from each image using machine vision software. Values were averaged across frames giving one data row per carcass (9,577 steers, 8,323 heifers). The data were randomly split into training and validation datasets (70:30). The training dataset was used to build multiple linear regression and stepwise selection models, using fixed effects, (sex, breed type, kill date (and CCW for conformation and fat class predictions)) or a combination of fixed effects and 3D measurements. Including 3D measurements substantially improved the fit of models for conformation ($R^2_{Adj}=0.25_1, 0.54_2$, RMSE=1.18₁, 0.93₂), fat class ($R^2_{Adj}=0.20_1, 0.30_2$, RMSE=1.55₁, 1.38₂) and CCW ($R^2_{Adj}=0.2_1, 0.74_2$, RMSE=31.14₁, 21.02₂). Validation of the best fitting models had low, moderate, and high accuracy, respectively, for fat ($R^2=0.3_2$, RMSE=1.36₂), conformation ($R^2=0.54_2$, RMSE=0.93₂), and CCW ($R^2=0.74_2$, RMSE=21.28₂). Mapping predictions on to the traditional EUROP grid used in the UK showed that 95% of fat classes and 81% of conformation classes were classified within the correct or one neighbouring grade. The 3D measurements were found to add value to the models, improving accuracy, indicating the potential for technology requiring limited infrastructure to predict carcass traits.

Prediction of liveweight from linear conformation traits in beef cattle*M. Meister¹, L. Speiser² and A. Burren¹*¹Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences HAFL, Länggasse, 85, 3052, Switzerland, ²Mutterkuh Schweiz, Staperferstrasse 2, 5201 Brugg, Switzerland; marc.meister@students.bfh.ch

In the present study, live weight in beef cattle was modelled using linear conformation traits. For this purpose, Mutterkuh Schweiz provided data from a total of 26,374 beef cattle (♀: 17,920; ♂: 8,454) of 19 different breeds from years 2015-2023. For each animal, the first linear description was used in each case. In the linear description, the live weight of the animal was also determined with a scale in each case. The relationship between live weight and linear conformation traits was investigated using a linear mixed model. The model included the fixed effects sex, breed, age and month at the measurement, height at withers (cm), top line (score:1-9), body length (cm), length of rump (cm), rump angle (score:1-9), chest depth (cm), width at hips (cm), muscularity (score:60-99), BCS (score:1-9), muscularity shoulder side view (score:1-9), thickness of loin (score:1-9), thigh rounding side view (score:1-9), thigh length (score:1-9) and final score (score:60-99), as well as expert as random effects and residual effect. This model resulted in a coefficient of determination of 87.7% and a root mean squared error of 38.26 kg. The largest fixed effects were observed for sex ((♀-♂: 37.97±1.17 kg) and the breeds Grauvieh-Charolais (36.51±2.00 kg), Grauvieh-Aubrac (33.55±1.97 kg), Grauvieh-Dexter (24.51±3.64 kg), Grauvieh-Galloway (16.80±4.00 kg) and Grauvieh-Simmental (16.08±1.85 kg). The main estimated fixed effects for linear conformation traits were 8.51±0.49 kg/score, 7.92±0.49 kg/score, 6.26±0.12 kg/cm, 6.17±0.12 kg/cm, 5.80±0.43 kg/score and 5.55±0.67 kg/score for thigh rounding side view, muscularity shoulder side view, width at hips, chest depth, BCS and rump angle, respectively. In conclusion, linear conformation traits can be used to estimate live weight of beef cattle.

Session 18

Poster 24

Beef marbling assessment by accredited graders and a hand-held camera device*M. Kombolo-Ngah¹, N.S.R. Mendes¹, A. Neveu², A. Barro¹, M. Christensen³ and J.F. Hocquette¹*¹INRAE, VetAgroSup, UMRH, 63122 Theix, France, ²IMR3GF, Smulikowskiego St. 4, 217 00-389 Warsaw, France,³Frontmtec A/S, A/S, Smørum 2765, Denmark; moise.kombolo-ngah@inrae.fr

Marbling is one of the most important traits of beef related to eating quality. According to the MSA (Meat Standards Australia) methodology, marbling should be evaluated visually in the chiller by accredited graders although various technologies have been developed. The aim of this study was to evaluate the performance of a hand-held camera (Q-FOM Beef) to predict MSA marbling scores (MSA-MS) between the 5th and the 6th rib. The MSA-MS ranged from 100 to 1,190. Two MSA trained graders were used for this study, one being an expert grader. A total of 285 carcasses were assessed in the chiller by these 2 graders. The R² of prediction between scores from the expert grader and the second grader was 0.78 with a RMSE of 47.9 MSA marbling points. Then, 779 images from the same carcasses were acquired with the Q-FOM Beef camera (i.e. between 2 and 3 images per carcass). In a first analysis with the 285 carcasses, a Q-FOM Beef calibration model using expert grader MSA-MS as reference was developed. This calibration model was applied to one image per 285 carcasses resulting in a R² of prediction 0.75 and the RMSEP was 44.9 MSA marbling score points. To be accredited in Australia, the requirements are that ≥49% of the samples must be within 50 MSA-MS from the expert grader, ≥79% of the samples must be within 100 MSA-MS and ≥97% must be within 200 MSA-MS. The grader-to-grader comparison showed 75.9% were within 50 MSA-MS, 97.1% were within 100 MSA-MS and 100% were within 200 MSA-MS. This indicates that the graders performed well when comparing their scores. In a second analysis, a subset (n=124) of the 285 carcasses were also assessed on-screen by the expert grader. The R² of prediction between in chiller and on-screen MSA-MS was 0.78 with a RMSE of 48.7. The in-chiller and on-screen comparison showed that 79.8% were within 50 MSA-MS, 96.8% were within 100 MSA-MS and 100% were within 200 MSA-MS. This suggests that on-screen assessment would be an acceptable method to develop a marbling calibration model, although more investigations would be required.

Beef on dairy – meat quality and prediction of intramuscular fat on the slaughter line

F.F. Drachmann and M. Therkildsen

Aarhus University, Department of Food Science, Agro Food Park 48, 8200 Aarhus n, Denmark; margrethe.therkildsen@food.au.dk

Increased use of beef semen on dairy cows in Denmark is the consequence of focus on sustainable beef production, where beef on dairy has less CO₂ emission than beef from purebred beef breeds. However, this also leads to a larger variation in the carcasses at the slaughterhouse and an interest in optimizing the meat quality from these cross-bred calves. No tools have previously been implemented on the slaughter line to quantify meat quality in Denmark. However, Q-FOM, a handheld camera solution, designed to predict intramuscular fat (IMF) could be a solution to quantify IMF in the carcasses, and a way to generate a large number of meat quality data, which could be used in genomic selection of breeding stock. The aim of the study was to characterize the meat quality of cross-bred calves from Holstein cows sired with Danish Blue (DB), Charolais (CHA) or Angus (ANG) bulls and to evaluate the Q-FOM to predict IMF in the loin on carcasses split between 5th and 6th thoracic vertebra. 335 cross-bred calves were included in the study, representing 126 DB, 100 CHA and 109 ANG including both heifers and bulls. They were slaughtered at the age of approximately 9.5 months. One day *post mortem*, the carcass was split between the 5th and 6th thoracic vertebra and a Q-FOM image was captured of the loin at 5th thoracic vertebra side. At the same time, 7 cm of the loin was removed and aged for additional 2 days before analysis. The Q-FOM prediction model was developed based on the chemical IMF analysis of 261 samples of these cross-bred calves and in addition 111 samples representing loins from cattle with IMF between 6 and 23%. The carcasses from the DB cross-bred calves were the heaviest (221 kg) followed by CHA (216 kg) and ANG (210 kg), and the bulls were on average 15 kg heavier than heifers, although the heifers were 21 days older at slaughter. The amount of IMF measured chemically was highest in ANG (3.5%) vs CHA (3.0%) and DB (2.5%), and with a clear difference between heifers (3.7%) and bulls (2.3%). The Q-FOM model had a RMSEC of 1.5% ($R^2=0.89$), however if the model was used only on cross-bred calves below 6% IMF, the RMSEC was 1.4%. The study was supported by the GUDP (J. 34009-18-1434), Ministry of Food, Agriculture and Fisheries of Denmark.

Pig carcass and cuts lean meat content determined by X-ray computed tomography

M. Font-I-Furnols, A. Brun and M. Gispert

IRTA-Food Quality and Technology, Finca Camps i Armet, 17121 Monells, Spain; maria.font@irta.cat

Currently, the value of the pig carcass is determined by its lean meat content (LMP). At slaughterhouse, LMP is determined objectively by means of manual, automatic or semi-automatic devices. These devices need to be previously calibrated and calibration is carried out by performing a cut-test, using as a reference the manual dissection of the carcass or the virtual dissection by means of a computed tomography (CT) equipment. In Spain an old fixed CTf (GE HiSpeed Zx/I) was calibrated to determine carcass LMP. However, a new mobile CTm unit (Philips Brilliance 16) has recently become available, and it is necessary to validate this new equipment to be used as a reference. Therefore, two different tests have been carried out, (1) adapting the old CTf formula to the new CTm and, (2) calculating a new formula for the CTm. For both approaches, a total of 20 carcasses and its 4 main cuts (ham, belly, shoulder and loin) had been scanned with the new CTm and, after that, they have been fully dissected to determine the LMP. In the first test, when the equation of the old CTf was applied to the images of the new one (CTm) and regressed against the LMP obtained by full dissection, R^2 was 0.97. As a second test, a preliminary and simple new formula for LMP determination with the new CTm has been obtained calculating the volume associated to Hounsfield values between 0 and 120 and divided it by the carcass (or cuts) weight. A correction factor of 1.072 has been found to be applied to adjust the LMP to the dissection with an accuracy of $R^2=0.99$. This formula has also been applied to the images obtained from the cuts ($n=20 \times 4$) scanned with the CTm and the relation between LMP obtained by CTm and by dissection is $R^2=0.99$. Thus, it can be concluded that with these preliminary results, it is possible to have a good determination of pig carcass LMP with the new CTm either by applying the calibration formula of old CTf with a correction factor or by determining the LMP considering the volume associated to lean and the carcass weight, also with a correction factor.

Relationships between ultimate pH, weight, conformation and fatness of carcasses

N. Silva Rodrigues Mendes^{1,2}, R. Rodrigues Silva², T. Ferreira De Oliveira², P.F. Rivet³, M.P. Ellies-Oury^{1,4}, S. Chriki^{1,5} and J.F. Hocquette¹

¹INRAE, VetAgro Sup, UMRI1213, Theix, 63122, France, ²Federal University of Goiás-UFG, Campus Samambaia, Rodovia Goiânia, Goiânia, 74690-900, Brazil, ³Beauvallet, 18 rue de l'abattoir, Limoges, 87000, France, ⁴Bordeaux Sciences Agro, CS 40201, Gradignan, 33175, France, ⁵ISARA, 23 rue Jean Baldassini, Cedex 07, Lyon, 69364, France; nathaliasrm@gmail.com

We hypothesized that the transportation of cattle prior to slaughter causes stress that results in lower quality carcasses due a higher final ultimate pH. Therefore, the objective of this study was to investigate the effects of stress during transport to slaughter from farms located in different geographical areas in France, specifically the effects on ultimate pH for Limousin cattle. Cold carcass weight, age, and the EUROP conformation and fatness scores were recorded from 3,809 Limousine carcasses from a private slaughterhouse in Limoges, France, which were evaluated 24 h *post-mortem*, from May 2021 to November 2021. We performed statistical analyses of the relationships between ultimate pH, geographical areas (<50 km; between 50 and 150 km; and between 150 and 250 km from the slaughterhouse), cold carcass weight, conformation and fatness of carcasses. European conformation score was correlated with cold carcass weight ($r=0.76$, $P<0.001$) and fat score ($r=0.57$, $P<0.001$). Similarly, fat score was correlated with cold carcass weight ($r=0.57$, $P<0.001$). As expected, the variability in cold carcass weight can be explained in part by the variables studied (mainly age, European conformation, and fat score), explaining approximately 60% of the variability in carcass data. The variables studied (area, age, European conformation, and fat scores) explained only 2.45% of the total variability in pH data. Values of ultimate pH were lower in the geographical area farthest from the slaughterhouse (5.74 vs 5.78, $P<0.05$) because cattle were transported the day before slaughter in contrast to the first two areas. In conclusion, long distances slightly affect beef pH, with consequences on beef eating quality that remain to be studied but are likely to be small.

Elite Dairy Beef – a pathway for male dairy calves into the premium beef market

H. Cuthbertson¹, R. Polkinghorne¹, A. Neveu², T. Maguire¹, O. Catalan³ and R. Law⁴

¹Elite Dairy Beef Pty Ltd, Hawthorn, VIC, Australia, ²SARL Birkenwood Europe, Lanon, Saint-Sornin, France, ³Inzar S.L, Zaragoza, 50018, Spain, ⁴Anupro Ltd, Omagh, BT78 1TS, Ireland; hcuthbertson@elitedairybeef.com

The Elite Dairy Beef program is based on consumer eating experience from dairy beef raised under a unique tightly controlled nutritional program. The program is aimed at changing industry perception of 'dairy beef' from the traditional lower quality manufacturing image to a high value premium product that justifies the raising of male dairy calves. A requirement for cattle marketed under this brand requires animals to be antibiotic, hormone and ionophore free. The nutritional program was initially developed in Spain and is widely used in Europe and the UK in the premium beef programs. A locally adapted program utilising key ingredients from Spain in conjunction with local sourcing has since been tested and proven in Australia. The milk replacer and rations are of extremely high quality and specifically targeted at superior early life nutrition to rapidly develop the calf immune system and rumen function, thereby maximising health and avoiding the use of antibiotics. Contrary to conventional rearing systems, this system is based on a low milk replacer intake and immediate concentrate consumption from birth. The critical and interlinked aims are to avoid negative energy balance, optimise gut health, and fast-track rumen development. Calves are purchased at 5 days of age and transported to a rearer. They have *ad lib* access to concentrate Quickstart, plus specialised milk powder InzarMilk, fed at 2 l twice a day for 3-4 weeks. After 2 weeks, calves transition onto a grower ration Papincalf enabling early weaning of the calf. This ration is fed until 14 weeks after which cattle are transitioned onto the final ration Econbeef until slaughter. Cattle are finished at 12-13 months of age with a liveweight of 500-550 kg and a carcass weight of 280-300 kg. Optimal fat cover on these animals is observed for minimal trimming and little waste, with straight Holsteins yielding similar to their beef cross counterparts. Cattle also carry a positive carbon story, with the calf primarily offset by the cow coupled with a highly efficient animal capable of good conversion and fast finishing times.

The contribution of Daniel Sauvant to modelling in animal science*J. Van Milgen and P. Faverdin**INRAE, Institut Agro, Pegase, Le Clos, 35590 Saint-Gilles, France; jaap.vanmilgen@inrae.fr*

Mechanistic modelling in animal science started in the 1980s with researchers from the USA, the UK, Australia, and New Zealand leading this. In France, Daniel Sauvant was a 'driving force' in the development of a culture of modelling in research and education. Most animal scientists perceived modelling as somewhat mysterious, more related to complicated mathematics than to biology. An important contribution of Daniel has been the conceptualization of biological systems through an operating system (i.e. the flow of nutrients and metabolites through compartments) and a decisional system (the control of the flows). Furthermore, he integrated concepts proposed by Bauman and Currie of homeorhesis (a long-term trajectory) and homeostasis (short-term controls) in the models. The concept of a long-term trajectory was applied to protein and lipid deposition during the productive life of a growing animal, but also to the management of priorities by the animal during its entire life (e.g. to grow and mature, to reproduce and care for newborns, and eventually to die). In 1994, Daniel stated that 'to progress further in metabolic modelling, it will be necessary to have a better knowledge of the interaction of the metabolic effects of homeorhetic and homeostatic regulations'. He modelled this by comparing the actual situation of an animal with its position on the homeorhetic trajectory, to use the difference (e.g. due to the nutrition or sanitary conditions) as a regulatory mechanism to return towards the trajectory. He applied the concepts an operating and a decisional system not only to animals, but also to livestock production systems in which homeorhesis can be perceived as a long-term goal of a farmer, and homeostasis as his management practices of the herd. Many of us who worked with Daniel may have been frustrated one day because our model did not predict what we expected, to which Daniel could reply "but it goes in the right direction". There is probably not a better way to illustrate the limitations and potential of modelling in animal science. Daniel's approach to structure complicated and complex systems and his skills to make this accessible have been a great source of inspiration for many of us.

Systemic modelling of nutrient partitioning: from the seed sown by D. Sauvant to future prospects*L. Puillet**Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 91120 Palaiseau, France; laurence.puillet@inrae.fr*

Predicting how nutrients are channelled to biological functions and eventually converted into animal products has always been a key issue in nutrition models. Many progresses were made to quantify the biochemistry of nutrition and then model metabolic functioning. In this view, the animal is a passive convertor and regulations are short-term homeostasis mechanisms. The role of long-term regulations, that play a key role in coordinating changes in metabolism to support physiological stages, was known but remained a challenge for modellers. A major innovation enabled by the work of Daniel Sauvant was to propose an operational framework for implementing these long-term regulations, with the concept of meta-hormones reflecting priorities among functions. The objective of this presentation is to illustrate how this pioneer systemic proposal was further developed in modelling works. A first type of work is the explicit implementation of animal's priorities. Combining a dynamic theoretical model of priorities among functions (growth, lactation, gestation and reserves) with a model of energy partitioning allows the simulation of multi-traits lifetime trajectories. Interactions among functions are taken into account throughout the succession of reproductive cycles. This consistent biological building-block, proposed as a virtual animal, has contributed to improve herd simulators. A second type of work is the use of systemic view when interpreting time-series data. Pure statistical models are very efficient to capture dynamics but interpreting outputs may be difficult due to their lack of biological meaning. Using a systemic view based on animal's investment into functions is powerful to better interpret trajectories and study individual variability. A third type of work is the implementation of acquisition-allocation framework. This theory, grounded in ecology, has started to be more and more used in animal science, especially with all the issues related to robustness and the need to better account for trade-offs among functions. The examples presented here, not exhaustive, illustrate how powerful the systemic approach is to address challenging issues in animal science, a view that Daniel Sauvant has always defended during his career.

Mechanistic model of the dynamics of body retention and utilization of phosphorus and calcium in sow*J. Heurtault^{1,2}, P. Schlegel¹ and M.P. Létourneau-Montminy²**¹Agroscope, Route de la Tioleyre 4, 1725, Posieux, Switzerland, ²Université Laval, 2425 rue de l'Agriculture, G1V 0A6, Québec, Canada; julien.heurtault.1@ulaval.ca*

A better understanding of the fate of dietary phosphorus (P) use by sows will allow its optimization and enhance sustainable practices. Current models for predicting P and calcium (Ca) requirements of sows are extrapolated from growing pig models in which the driving force is the body weight or the protein gain. Furthermore, recent data, of bone mineralization kinetics in sows and its evolution during the production cycle, have shown the ability of the sow to mobilize part of her body P and Ca reserves in lactation to cover her high requirements and also to replenish her body reserves at the beginning of the next gestation period, when her requirement is lower. Thus, a new mechanistic approach could simulate the dynamics of retention and utilization of body P and Ca reserves during lactation. The model includes 3 sub-modules. First, the digestion sub-module considers the sources of dietary minerals including responses to microbial and plant phytase and Ca and P interactions and predicts absorption and faecal excretion. Then, protein and lipid compartments growth sub-module is based on InraPorc model principles. The third one is the body ash sub-module that simulates the partitioning of absorbed Ca and P into the bone, milk, protein, and lipid compartments as well as urinary losses. The P and Ca deposited into soft tissue and excreted into milk have priority over bone deposition and if dietary supply is not sufficient bone are mobilized. This approach aims at precisising the understanding and prediction of the fate of dietary P and Ca to then inversed it to calculate precisely the requirements and then optimize the use of P and reduce the losses. The next step will be validation with the generation of a new set of data.

Session 19

Theatre 4

Modelling the digestive utilization of calcium and phosphorus in laying hens*F. Hervo^{1,2}, B. Méda¹, A. Narcy¹ and M.-P. Létourneau-Montminy²**¹INRAE, Université de Tours, BOA, 37380, Nouzilly, France, ²Sciences Animales, Université Laval, G1V 0A6, Québec city, Québec, Canada; fabie.hervo@inrae.fr*

Laying hens require a massive daily quantity of calcium (Ca) to form the eggshell. Calcium is provided by the diet and resorption of medullary bone. Calcium mobilization from the skeleton simultaneously leads to the release of phosphorus (P) which is excreted in the urine. Thus, the levels of P and Ca in the feed must be finely balanced to ensure eggshell and bone quality while reducing P excretion in manure. Nevertheless, the fate of P and Ca in the gastrointestinal tract (GIT) and effects of the main modulating factors are not well understood in laying hens. Thus, the aim of this study was to develop a mechanistic model predicting the digestive fate of these minerals in a producing hen (34 weeks of age) considering dietary Ca and non-phytic P (NPP) levels, as well as phytase and coarse limestone particles incorporation. The model consists in 2 compartments with 5 sub-compartments representing the anatomical sections of the GIT: (1) the pre-intestinal compartment with crop and gizzard; and (2) the intestinal compartment with the duodenum, jejunum, and ileum. Because of the expression of a specific appetite for Ca, Ca and P intake were parametrized dependently of the photoperiod. In the pre-intestinal compartment, solubilization of Ca and P and complexation between Ca and phytic P (PP) or NPP are modelled depending on the pH in the compartment. Furthermore, the conversion of PP into NPP depends on the presence of microbial and plant phytases. A longer retention time and a slower solubilization of coarse limestone particles in the gizzard are also represented. In order to consider hormonal regulations occurring at the intestinal level, Ca and P absorption flows are modelled depending of the eggshell formation cycle. In the intestinal phase, the propensity of Ca to form insoluble complexes with PNP or PP as well as the effect of intestinal phytase on PP hydrolysis were parametrized. The sensitivity analysis and external validation of the model are currently in progress. This model provides a promising tool to easily evaluate different feeding strategies to optimise Ca and P utilization in laying hens, and reduce P excretion while maintaining the eggshell and skeleton quality.

A dynamic mechanistic model to forecast the oscillatory feeding behaviour of lactating dairy cowsE. Fiorbelli¹, A.S. Atzori², A.T. Büşra², L. Tedeschi³ and A. Gallo¹¹Università Cattolica del Sacro Cuore, Department of Animal Science, Food and Nutrition (DIANA), Via E. Parmense 84, Piacenza 29121, Italy, ²Università di Sassari, Dipartimento di Agraria, Viale Italia 39, Sassari 07100, Italy, ³Texas A&M University, Department of Animal Science, College Station, TX 77843-2471, USA; antonio.gallo@unicatt.it

The aim of this study was to evaluate the ability of the model proposed by Fischer (1996) and reproduced by Tedeschi and Fox (2020) to predict the oscillatory feeding behaviour of lactating dairy cows. The model used the stock and flow diagram (Vensim ver 9.2.4, Ventana Systems) and included compartments for potentially degradable proteins, soluble carbohydrates, slowly digestible fibres, and very slowly digestible fibres fractions. The intake regulation included feedback structures for distention, chemostatics and protein effects. Inputs to the model were limited to protein (CP), 48-hour IVDMD corrected for residual microbial mass, and NDF. In the experimental facility (CERZOO srl, Piacenza, Italy), 20 Holstein dairy cows were randomly selected and the feeding behaviour was monitored for four consecutive days using the Roughage Intake Control System automatic recorder (Hokofarm Group, Marknesse, The Netherlands). The average age was 38±7 months and the average milk yield was 33.3±4.36 kg/cow/day. Oscillation differences in frequency and amplitude (meals per day and amount eaten per meal) and the variability of the observed meals (kg/hour) were discussed in relation to the average meal eaten by each animal during the experimental period. On average, the animal consumed 7±2 meals/cow per day, the intake per meal was 3.60±1.12 kg, the daily dry matter intake (DMI) was 23.81±2.73 kg/cow per day and the time spent eating was 21.0±4.6 minutes per meal. In this experiment, the animal components had a significant influence on the variation in DMI. New feedback loops in the structure of the stock and flow diagram were included to improve the model in simulating the daily oscillatory system of the lactating cow's behaviour and the daily DMI.

Session 19

Theatre 6

A dynamic *in silico* model of rumen microbial fermentation and methane productionR. Muñoz-Tamayo¹, S. Ahvenjärvi², A.R. Bayat² and I. Tapio³¹Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 91120, Palaiseau, France, ²Animal Nutrition, Production Systems, Natural Resources Institute Finland (Luke), 31600, Jokioinen, Finland, ³Genomics and Breeding, Production Systems, Natural Resources Institute Finland (Luke), 31600, Jokioinen, Finland; rafael.munoz-tamayo@inrae.fr

Mathematical (*in silico*) models have been developed to enhance understanding of rumen function. Model evaluations have shown that there is still room to enhance their accuracy for predicting volatile fatty acids (VFA) concentration and methane production. Previously, we developed an alternative model of rumen fermentation under *in vitro* conditions aimed at better representing the rumen microbiota and hydrogen dynamics. In the present work, we extended the previous model to account for *in vivo* conditions. We performed an experiment with four Nordic-Red dairy cows equipped with rumen fistulas to provide dynamic data to support model construction. The experiment determined animal daily patterns of feed intake, rumen fermentation and enteric methane production. Feed intake and methane emissions were measured in respiration chambers during two days after an adaptation period. Rumen liquid was collected every three hours for determination of VFA concentration. In the model, the rumen microbiota is represented by three functional groups namely sugar-, amino acids- and hydrogen-utilisers. The feed is expressed in three pools as neutral detergent fibre, non-structural carbohydrates and proteins. The model consists of 18 compartments. The model performance was satisfactory as evaluated by the coefficient of variation of the root mean squared error, which was 9% for acetate, 11% for butyrate, 13% for propionate and 21% for methane. Our model has the potential to be used as virtual platform to simulate rumen fermentation dynamics. Acknowledgements. The authors acknowledge funding from the MASTER project, an Innovation Action funded by the European Union's Horizon 2020 research and innovation programme under grant agreement No 818368.

Future directions in ruminant feeding systems: opportunities and challenges for sustainability

L.O. Tedeschi

Texas A&M University, Department of Animal Science, 230 Kleberg Center, 2471 TAMU, College Station, TX 77843, USA; luis.tedeschi@tamu.edu

Ruminants have a specialized digestive system that allows them to extract nutrients from fibrous plant material through microbial fermentation in their rumen. Mathematical models simulate the complex interactions between animal nutrition, digestion, metabolism, and production to optimize feed formulations, predict nutrient requirements, and evaluate the effects of different feeding strategies on animal performance and health. Advancements in decision support tools (DST) must incorporate data from multiple sources (sensors and satellite imagery) to improve predictability and provide real-time recommendations for feeding strategies based on animal performance, feed availability, and environmental conditions. DST will require advanced modelling techniques (machine learning and agent-based models) to enhance the adoption of big data. The real-time decision-making recommendations require multi-objective optimization based on animal performance, environmental impacts, and economic feasibility. An overhaul of the mathematical models is needed to support the DST directives by revising the underlying principles of ruminant nutrition, revamping existing submodels, and incorporating novel concepts. Must-improve topics are nutrient utilization by gut microbes: producing metabolites such as volatile fatty acids, ammonia, and microbial protein; developing environmental impact assessment tools to evaluate the environmental and economic impacts of different feeding strategies and identify opportunities for improvement: genetic/genomics and animals stress/disease/metabolic disorders to enhance prediction of animal performance, feed efficiency, nutrient utilization, and strategic medication. Data quality is the most critical issue in the success of DST and model predictability. The evolution of nutrition models for ruminants will depend on technological advances, data collection, scientific knowledge, and the livestock industry's and society's changing needs and priorities. The increased predictive accuracy of nutrition models for ruminant animals requires a multi-disciplinary approach involving collaboration among scientists, producers, and industry stakeholders and using advanced technologies and modelling techniques.

Session 19

Theatre 8

Meta-analysis in animal science: a valuable tool to generate new knowledge from previous experimentsM.P. Létourneau Montminy¹, C. Loncke², P. Schmidely², M. Boval², J.B. Daniel³ and D. Sauvant²¹Laval University, Animal Science, 2425 rue de l'Agriculture, G1V0A6, Canada, ²AgroParisTech, UMR MOSAR, 22 place de l'Agronomie, CS 20040, France, ³Trouw nutrition R&D, P.O. Box 299, 3000, Amersfoort, the Netherlands; marie-pierre.letourneau@fsaa.ulaval.ca

Meta-analysis is a useful tool to analyse large sets of heterogeneous data that gain popularity in animal science since the 2000s. Meta-analysis has proven to be efficient to create new knowledge based on already published data through empirical models, allowing progress in both understanding, highlighting research effort and lack of information, and obtain improve prediction. Review on this tool in animal science by Sauvant *et al.* have first focus on good practices namely graphical interpretation, the way of considering the experiment effect (i.e. fixed or random), and then interfering factors. Meta-analysis has then been used for updating feed unit systems (e.g. 'Feeding System for Ruminants'). Another important use of meta-analysis is for the development of mechanistic models to simulate fluxes, parameterization or external validation database. Based on these years of experience, the current review will paint a portrait of the evolution of meta-analysis, followed by a description of the key steps including study objectives well defined to preform exhaustive search of the literature, article filtering to select or discard publications, database construction, coding, and statistical analysis. A focus will also be done regarding the good practices and the potential pitfalls in the conduct of meta-analyses in animal sciences. These include traceability and criteria used to select/discard publications in a way that one could reproduce the final selection of data which is know require by most journals. Then, some key elements for statistical processing such as the coding step of selected data to isolate specific experimental factors, the study of the meta-design, the accurate consideration of study, and the post-analytic study that most often allows the analysis to be re-run to improve the quality of the procedure. Several examples of meta-analysis types will be presented to demonstrate the advantages and the limits of the approach.

Global sensitivity analysis of INRAtion®V5 for dairy cows: Sobol' indicesS. Jeon¹, S. Lemosquet², T. Senga Kiese³ and P. Nozière¹¹INRAE-VetAgro Sup, UMR Herbivores, Saint-Genès-Champagnelle, 63122, France, ²INRAE-Institut Agro, UMR Pegase, Saint Gilles, 35590, France, ³INRAE-Institut Agro, UMR SAS, Rennes, 35000, France; seoyoung.jeon@inrae.fr

The effective ruminal degradability (ED6_N) and true intestinal digestibility (dr_N) of nitrogen measured *in sacco* are used to describe the nutritive values of feedstuffs in the INRA 2018 feeding system for ruminant and its rationing software (INRAtion®V5). In the perspective to move from *in sacco* to *in vitro* tests, a global sensitivity analysis (GSA) was conducted to measure the sensitivity of the INRAtionV5 to variations in input variables: gross energy (GE) and crude protein (CP) contents, organic matter digestibility (OMd), ED6_N and dr_N. We used Sobol' indices that calculated input's contribution to each output with interactions among inputs (St_i). The GSA was performed with 6 diets varying according to forages (corn silage, grass fresh/hay/silage) and concentrates (cereals and oil seed meals). These diets were formulated for a multiparous dairy cow at week 14 of lactation, and contained 14 to 18% CP. Then, 10,000 quasi-random samples of the 5 input variables were generated per diet using Sobol' sequences. Variations on predicted dry matter intake were on average mainly due to GE (St_{GE}=53±5.3%), but with grass hay and grass silage diets, OMd was the main contributor (St_{OMd}=52 and 51%, respectively). The contribution of OMd was the highest for milk yield (MY; 63±11.0%), protein yields (MPY; 68±8.7%) and protein contents (MPC; 79±7.2%). With grass silage and fresh forage diets (14% CP), ED6_N was the second contributor to MPY (24 and 16%, respectively) and MY (2 and 18%, respectively). Urinary N flow was most affected by CP (60±8.4%), and faecal N flow (FN) by GE (35±9.6%) and OMd (33±14.4%). The ED6_N was the second contributor to FN in corn silage diet (33%) and grass hay diet (41%). Interaction among the input variables was the highest (>35%) on MPY and MY with grass hay diets with oil seed meal, but was the lowest (<5%) with grass hay diet without oil seed meal. In conclusion, with diets containing 14 to 18% CP, protein-related inputs less contributed than energy related inputs to changes in DMI and milk production. But with 14% CP diets, production responses are sensitive to ED6_N.

Session 19

Theatre 10

Effects of housing or feeding practice in dairy goats estimated by the INRAtion®V5 feeding system

S. Giger-Reverdin, V. Berthelot and D. Sauvant

Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 Place de l'Agronomie, 91120, Palaiseau, France; sylvie.giger-reverdin@agroparistech.fr

Effects of housing or feeding practice were tested on outputs of the INRAtion®V5 rationing system based on results obtained at MoSAR's unit. Dairy goats were housed either in individual crates (CRA) or in collective pens (PEN). They were fed either separate feed ingredients (SF) or total mixed ration (TMR) with individual measurement of feed intake. Individual weekly mean values of all results were pooled to obtain groups receiving the same basal roughage at similar stages of lactation, housing and feeding practice. Mean values were weighed by the number of observations within a group. The saturation coefficient is the ratio between the dietary fill value and the intake capacity corrected for the level of refusals that is specific to goats, because they exhibit a higher sorting behaviour than other ruminants. Observations with a level of roughage refusal below 7% were discarded. The saturation coefficient of the CRA group (1.04±0.021, ngroups=41) was close to 1 and lower than for the PEN group (1.20±0.024, n=16). The model is accurate for the CRA group and underestimates saturation coefficient for the PEN group. This might be due to data used for the setting up of the model (Caprinut database) obtained with animals in individual crates. In the CRA group, the saturation coefficient was higher for TMR (1.08±0.026, n=23) than for SF (0.96±0.035, n=18). It was quite low (0.80±0.108) for the 8 groups fed corn silage. Standard milk yield did not differ between CRA (3.28±0.179 kg/day) and PEN (3.42±0.203), but predicted milk yield was lower for CRA (2.83±0.174 kg) and higher for PEN (4.35±0.197). The non-producing requirements might be overestimated by the lack of activity for CRA goats. For PEN, an increase in passage rate due to a higher intake might overestimate the feed values. Another explanation might be the evolution of the genetic of the herd, as the trials for CRA were performed between 1978 and 2017 and for PEN after 2018. Animals might exhibit a higher intake capacity. This first test on a large number of rations is quite promising and must be extended to a larger number of diets and in other locations.

Dynamic models to inform precision supplementation of heifers grazing dormant native grasslands*H.M. Menendez Iii, J.R. Brennan, A.K. Dagel and K. Olson**South Dakota State University, Animal Science, 711 N. Creek Drive, 57703, USA; hector.menendez@sdstate.edu*

Decreasing supplementation cost while optimizing animal intake is critical to maintaining cow-calf operation viability. Precision livestock technologies (PLT) can be used to target supplementation to meet individual animal nutrient requirements on extensive grasslands. However, real-time animal performance data and animal nutrition models are needed to dynamically adjust precision supplementation levels. The objectives of our study were to: (1) Develop a precision systems model (PSM) that leveraged real-time weight data and nutrient equations to dynamically inform individual heifer supplementation (kg hd/d); and (2) compare differences in predicted and observed rates of gain (kg/d). Angus heifer calves [n=60, initial body weight (BW)=237.6±15.5 kg] were assigned to one of two treatments, control or precision, and grazed dormant native grass. Both treatments were provided 2.27 kg hd/d of pelleted supplement. The control group was supplemented using a bunk feeding method and the precision group was offered supplement via the Super Smartfeed Producer™. Individual daily BW was measured using SmartScales™ and used to calculate daily rate of gain. The PSM was developed in Program R and utilized equations for metabolizable energy intake (MEI), net energy for maintenance (NEm) and gain (NEg) requirements (Mcal/d) at two-week intervals to program precision supplementation to obtain 60% mature BW (381 kg) at time of breeding. Results indicate that of 893 individual animal two week feeding periods, animals were overfed 69% of the time and underfed 31% of the time. Performance gap was calculated between observed and modelled (optimal) rates of gain, resulting in significant differences between the control (0.39±0.05) and precision (0.13±0.05) groups ($P<0.01$). This study suggests precision supplementation can decrease heifer development costs by reducing intake variation and supplement overconsumption without negatively influencing heifer performance. Refining PSM to integrate real-time data with animal nutrition models will be essential to reduce feed costs and meet individual nutrition requirements and performance targets.

Session 19

Theatre 12

Comparison of measured enteric methane emission with model calculations of commercial dairy diets*L. Koning and L.B. Šebek**Wageningen Livestock Research, Animal Nutrition, P.O. Box 338, 6700 AH Wageningen, the Netherlands; lisanne.koning@wur.nl*

According to the international climate agreement the Dutch dairy sector is obligated to reduce methane (CH₄) emissions substantially. To determine enteric CH₄ emission on commercial dairy farms model estimations are used. The model used in the Netherlands (Annual Nutrient Cycling Assessment; ANCA) is (indirectly) based on data from respiration chambers and underlying principles of rumen fermentation and it is important to know how well the model fits the wide variation in diets fed on farms. Measurements of enteric CH₄ on commercial farms to validate the model are however limited. This study fills that gap and thereby enabling a comparison between measured CH₄ emission and model estimations by ANCA. On ten commercial dairy farms in the Netherlands enteric CH₄ emission of a subset of lactating dairy cows (between 16 and 53 cows per farm) was measured for twelve weeks between June 2020 to January 2022, divided into three periods of four weeks (two weeks of adaptation and two weeks of measuring period). In each period a different diet was fed (n=29, of one farm only two periods were measured). Enteric CH₄ emission was measured using the GreenFeed Emission Monitoring system (GEM, C-lock Inc. Rapid City, SD, US), an adapted feeding station that measures both continually CH₄ concentration and the quantitative airflow. Additionally, individual milk samples were taken to analyse milk composition and feed intake data on herd level (including feed composition and quality) were collected. Based on feed intake and feed composition CH₄ emission was calculated using ANCA and compared with measured CH₄ in a lack of fit regression analysis. The lack of fit analysis indicated a large fitted bias ($F=76.92$, $P<0.001$). The measured CH₄ yield (g CH₄/kg DMI) was not significantly related to the calculated CH₄ yield ($P=0.669$). Overall the difference between measured and calculated CH₄ yield was less than 5%. The results suggest that the model is accurate on national level and for a select range of diets, but lacks factors that are necessary to estimate CH₄ more accurately on individual farms in practice.

Optim'Al can optimize dairy cow rations on economic cost and protein autonomy with INRA 2018 system

P. Chapoutot¹, G. Tran¹, V. Heuze¹ and A. Berchoux²

¹AFZ, 22 place de l'Agronomie, 91120 Palaiseau Cedex, France, ²IDELE, 23 rue Jean Baldassini, 69364 Lyon Cedex 7, France; patrick.chapoutot@zootechnie.fr

The low-cost formulation by linear programming (LP) is not widely used in ruminants, unlike in monogastric production. The novelties brought by the INRA 2018 system do not simplify its adaptation to the LP: on the one hand, the calculations implement many iterative processes and, on the other hand, the animals' responses are not linear. Moreover, taking into account protein autonomy of farms is more and more important to increase metropolitan sovereignty for the supply of protein to livestock. In this context, Optim'Al v2 is an optimization tool for dairy cow rations based on LP and integrating nevertheless the principles of the new INRA system, in which feed values and animal requirements depend on the ration characteristics. Different simulations, implementing an iterative calculation process, reveal the interest of a sensitivity analysis of the optimized solutions, useful to reflect on feed valorisation and purchase strategies for dairy farmers. A post-optimization calculation phase takes the non-linear responses of the animals into account and allows a technical-economic diagnosis of dairy cow rations based on feed cost margin and on their environmental values. In addition, a protein-dependency value of feeds according to their supply perimeter, can be used instead of feed cost as an optimization function to obtain 'autonomous' rations. Moreover, both 'economy' and 'protein autonomy' approaches can be combined in an optimization multi-objective function. This tool, designed by AFZ within the framework of the French 'Cap Protéines Program', was based on a prototype proposed by Chapoutot *et al.*, and will be commercialized by Idele.

Modelling the dynamics of dairy cattle response to heat stress using system dynamics methodology

R. Cresci¹, B. Atamer Balkan¹, L.O. Tedeschi² and A.S. Atzori¹

¹University of Sassari, Department of Agricultural Sciences, Viale Italia 39, 07100, Italy, ²Texas A&M University, Department of Animal Science, 2471 TAMU Kleberg Center, 77843-2471, USA; rcresci@uniss.it

Exposure to prolonged periods of extreme heat, such as heat waves (HW), might negatively affect dairy cows' health, and productive and reproductive indices. Due to climate change, besides a possible change in the pattern of occurrence, HW are expected to rise in intensity, duration, and frequency, making heat dissipation mechanisms less effective and increasing the animal heat load. Several empirical, mathematical, and dynamic models were developed to predict the effects of heat stress (HS) in animals. However, modelling individual animal response under HS conditions is challenging because it exhibits complex system features with dynamic and nonlinear behaviour, including delayed reactions that are often misinterpreted or unaccounted. One formal mathematical modelling approach to understanding the nonlinear behaviour of complex systems over time is the system dynamics (SD) methodology. In this work, we applied SD methodology to model the dynamics of dairy cow response and observed milk yield (MY) under HS. To apply the model, we used MY and temperature-humidity index (THI) data collected from a dairy cattle farm in August 2022. From the case study farm, 20 cows were selected based on the days in milk (DIM; 70 ≤ DIM ≤ 220 d), to avoid the effects of the stage of lactation. The model calibration was performed for the relevant parameters related to selected cows' response to HS. The results showed a high accuracy (mean absolute percent error, MAPE < 5%; R² > 0.6; concordance correlation coefficient, CCC > 0.6) of the proposed model structure in capturing the effect of HS in 13 cows, which can be identified as heat-sensitive. The behaviour of the other 7 cows could not be fully captured within the defined parameter space: either they show heat-resistant behaviour, or they may experience different biological delays due to HW events. Our HS model considered nonlinear feedback mechanisms to help farmers and decision-makers quantify the animal response to HS, predict MY under HS conditions, and distinguish the heat-sensitive cows from heat-tolerant cows at the farm level.

Volatolomics for developing non-invasive biomarkers of ruminal function and health in dairy cows

E. Jorge-Smeding¹, C. Martin¹, L. Volmerange², E. Rispal³, M. Bouchon³, Y. Rochette¹, N. Salah⁴, F. Violleau² and M. Silberberg¹

¹INRAE, VetAgroSup, UMRH, Saint-Genès-Champanelle, France, 63122, France, ²INP, Toulouse, 31300, France, ³INRAE, UEH, Saint-Genès-Champanelle, France, 63122, France, ⁴Phileo by Lesaffre, Marcq-en-Baroeul, 59700, France; ejorgesmeding@gmail.com

Invasive techniques for studying ruminal function such as fistulae are being banned, and so the development of non-invasive approaches is required. Similar to biological fluids metabolomics, volatolomics propose to phenotype volatile compounds and has been shown to be successful to explore biomarkers either in gaseous samples (e.g. breath) or in the head space generated by liquid and solid samples (e.g. urine) in human. In particular, the use of single-ion flow tube coupled with mass spectrometry (SIFT-MS) has been proved to be a powerful chemometric approach when doing volatolomics due to its ability to measure thousands quickly, without requiring any sample preparation. This study aimed to test, as a proof of concept, the use of volatolomics to follow ruminal functioning. Sixteen Holstein cows (106±11 DIM) were enrolled in 2 balanced groups according to milk yield, composition and BW during a 10 weeks design based on two isoproteic diets (131 g/kg DM on average) either rich in fibre and low in starch (HFibre; 50% NDF, 12% starch) or low in fibre and rich in starch (HStarch; 40% NDF, 30% starch), the latter expected to be at risk of ruminal acidosis as a model a ruminal dysfunction. Between weeks 1 and 5, all cows received the HFibre diet, then half of the cows were progressively switched to HStarch diet (n=8) with the final diet (30% starch) being achieved on weeks 9 and 10. Milk yield and ruminal pH were measured daily, milk composition and DMI were determined twice per week. Breath air, ruminal liquid, sweat, urine, faeces and milk samples were taken on weeks 4, 5, 9 and 10 and stored at -80 °C until SIFT-MS analysis. Samples are currently being analysed and results will be presented in the meeting. In order to explore the ability of the volatolomic fingerprint to discriminate individuals between the diets, data will be submitted to univariate (repeated measure analysis) and multivariate (partial-least square discriminant analysis) analysis.

Estimation of total urinary nitrogen excretion in fattening beef cattle from urinary spot samples

C. Garcia-Vazquez¹, P. Nozière¹, L. Salis¹, R. Bellagi¹, J. David² and G. Cantalapiedra-Hijar¹

¹INRAR, URMH, Clermont-Ferrand, 63122, France, ²INRAR, URM, Clermont-Ferrand, 63122, France; cjpgvz@gmail.com

Livestock farming's impact on the environment is a contentious issue, particularly regarding pollution from N compounds. Matching protein supply to an animal's protein requirement is an effective way to reduce N excretion, evaluated through a N balance trial in metabolic cages. However, animal welfare issues limit this kind of experimental approaches. Therefore, the aim of this study was to develop prediction equations for urinary N excretion in beef cattle based on urinary biomarkers. For this, we used two independent N balance trials conducted with 48 fattening Charolais young bulls. During 10-days, the total amount of urinary N excreted was determined for each animal and spot urine samples were collected on the first and last day of the each 10d-N balance. Spot urinary samples were analysed for N (Dumas method), and creatinine and urea concentrations (colorimetric analysis). The mean urinary concentration of these three metabolites in the spot samples, as well as the weight of the animals and the amount of ingested N, were used as predictors of total urinary N excretion. Linear regression analyses were performed using Minitab® 21.3 software with various combinations of these independent variables. Two prediction equations were selected based on fitting criteria and model errors. The first equation predicted urinary N excretion (g/d) from two variables: the ratio of urinary urea-N to total N ratio in the urinary spot and the total N intake ($r^2=0.81$ and error=14%). Both predictors were uncorrelated in this first equation (VIF=1.67). The second selected equation predicted urinary N excretion (g/kg BW^{0.75}) only from the ratio of urinary urea-N to creatinine in the urinary spot ($r^2=0.71$ and error=13%). An a posteriori statistical power analysis of the developed prediction equations concluded that a total of around of 44 animals per treatment would be necessary to detect a 10% difference in total urinary N excretion regardless of the equation. The prediction equations that were developed enable practical estimation of urinary N excretion, making it possible to differentiate between treatments aimed at reducing urinary N excretion under field conditions.

Advancing mathematical modelling for equines*E.M. Leishman¹, C. Cargo-Froom¹, P. Darani², S. Cieslar² and J.L. Ellis¹**¹University of Guelph, Animal Biosciences, 50 Stone Road East, N1G 2W1, Guelph, ON, Canada, ²Mad Barn Inc., 1465 Strasburg Road, N2R 1H2, Kitchener, ON, Canada; eleishma@uoguelph.ca*

Mechanistic modelling has a long history of application in animal production systems, where it is used to synthesize knowledge, further understanding of biology, and provide decision-support. Detailed mechanistic models are used globally in dairy, swine, and poultry production, and these models have evolved along with our scientific knowledge. However, this development path has not been paralleled in equine species, and few attempts have been made to develop animal-level nutrient dynamic models in horses. While this may be due to less fundamental research being conducted in equines compared to predominant agriculture species, this gap limits the ability of the equine sector to address complex challenges such as the interactions between equine nutrition, management, health, and welfare. The aim of this large-scale research project is to develop (1) a mechanistic equine metabolism model, (2) a mechanistic equine digestion kinetics model, and (3) integrate these models together to comprehensively describe nutrient intake, digestion, and metabolism in the horse. Ultimately, the model will be expanded to consider breed and sex differences, common metabolic disorders (e.g. insulin resistance), meal and exercise patterns, and gestation and lactation. To support model development, experimental work will be ongoing, such as *in vitro* characterization of feedstuff degradability and fermentability to inform overall model inputs, and *in vivo* experiments on nutrient passage, digestibility, and absorption. This project will accelerate progress in the equine sector by leveraging decades of modelling work from other species, capitalizing on the extant equine literature, and by performing new research to develop a mechanistic model for horses. The development of this model will stimulate and assist further research, inform revisions to the nutrient requirements of horses, increase understanding of digestive and metabolic processes as well as related disorders, reduce waste via precision feeding and support the development of new products and services to improve equine health.

Session 19

Poster 18

Predicting equine voluntary forage intake using meta-analysis*E.M. Leishman¹, M. Sahar¹, P. Darani², S. Cieslar² and J.L. Ellis¹**¹University of Guelph, Animal Biosciences, 50 Stone Road East, N1G 2W1, Guelph, ON, Canada, ²Mad Barn Inc., 1465 Strasburg Road, N2R 1H2, Kitchener, ON, Canada; eleishma@uoguelph.ca*

To properly formulate diets, the ability to accurately estimate feed intake is critical since the amount of food consumed will influence the amount of nutrients delivered to the animal. Inaccurate intake estimates may lead to under- or over-feeding of nutrients to the animal. Individual differences in equine forage intake are well-known, but predictive equations based on animal and nutritional factors, from information extracted from the body of published literature, are not prevalent. The objective of the present study was to consolidate current knowledge on voluntary forage intake in equines and conduct a meta-analysis to identify driving factors and sources of heterogeneity. Therefore, a systematic literature search was used and identified 99 publications which met the inclusion criteria. From each study, the outcomes of interest (e.g. forage intake), diet composition (e.g. forage information, nutrient composition), and animal factors (e.g. sex, age, breed, bodyweight, exercise level) were extracted. Forage intake was analysed as two different outcome variables: (1) forage intake in kg/d and (2) forage intake in g/kg bodyweight. Linear mixed model analysis using a backward stepping approach was used to identify potential prediction models for both outcome variables where all terms have $P < 0.1$. The best fitting models for both outcome variables included similar factors like forage quality (i.e. NDF or crude protein content), forage composition (i.e. grass, legume, or mixed), the animals' size category (i.e. horses vs ponies), and some management factors (i.e. pasture access). As anticipated, forage intake increased when higher quality forages were fed (i.e. lower NDF or higher crude protein), potentially due to improved digestibility. In conclusion, using data gathered from multiple studies, equations to predict equine voluntary forage intake with high accuracy and precision were developed. The results of this meta-analysis confirm that animal traits and forage quality have a significant impact on the voluntary intake of equines and should be accounted for when formulating diets to meet nutritional requirements.

Score using indicators of reticulo-rumen pH kinetics to characterize subacute ruminal acidosisC. Villot¹, K. Biard², C. Martin³, A. Boudon⁴ and M. Silberberg³¹Lallemand SAS, 19 rue des Briquetiers, 31700, France, ²University Paul Sabatier, Toulouse, Toulouse, France, ³INRAE, Theix, 63122 Saint-Genès-Champagnelle, France, ⁴INRAE, Agrocampus Ouest, Saint-Gilles, France; cvillot@lallemand.com

The development of novel farm management technologies are promising strategies to improve welfare, efficiency, and productivity toward sustainable agriculture. The non-invasive and continuous recording of physiological parameters thanks to the use of biosensors, coupled to the development of dedicated data processing, make possible to precisely monitor the kinetics of specific parameters to assess rumen environment and other physiological traits. The objective of this study was to validate a set of novel indicators of reticulo-rumen (RR) pH kinetic that can better define the pattern of RR pH during a SARA challenge. Two different experimental SARA challenge studies (3-period switch-over design including a high starch diet: HSD>30% starch and <30% NDF) were conducted with 10 animals equipped individually with a RR sensor allowing a pH measurement every 10 min. Commonly used pH indicators of SARA (daily average, time spent under RR pH<6.0, area under the curve and daily amplitude) were calculated as well as descriptors modelling the pH curve. Unexpectedly, daily pH mean was not able to predict accurately the change of diet when cows were fed a HSD whereas performance and health indicators were altered confirming the susceptibility of the animals to the SARA challenge. However, indicators derived from pH kinetic significantly responded to when cows were fed a HSD compared to a low starch diet. For instance, the number of pH drops was significantly lower during the SARA challenge compared to a low starch diet (3.05 vs 4.71 drops/day, respectively for study 1 and 2.84 vs 3.27 drops/day respectively for study 2, $P<0.01$). Finally, a significant higher SARA score combining multiple daily pH indicators was able to identify when the animals were fed a HSD (3.8 vs 0.24 for study 1 and 12 vs 5.7 for study 2). Pre and post SARA challenge periods were comparable for these parameters, suggesting a good correlation with animal biology. These new indicators derived from RR pH kinetic carry additional information on pH variation; this makes them good candidates as descriptors of ruminal status.

Poster 20

The INRA mechanistic beef growth model captures feed efficiency ranking in Charolais bullsG. Cantalapiedra-Hijar¹ and S. Lerch²¹INRAE, UMR Herbivores, 63000, Clermont-Ferrand, France, ²Ruminant Nutrition and Emissions, Agroscope, 1725, Posieux, Switzerland; sylvain.lerch@agroscope.admin.ch

The INRA dynamic and mechanistic growth model predicts the daily deposition of protein and fat in growing cattle, based on metabolizable energy (ME) intake (main driven force) and animal age. Originally developed for specific animal types (breed and sex), the aim of this study was to calibrate the INRA growth model at the individual level by adjusting coefficients for either rates of protein and lipid synthesis (α and β) or degradation (γ and δ), or modulation of the ME use efficiency (cMEU). The relationship between the adjusted model parameters and residual feed intake (RFI) or feed conversion efficiency (FCE) was further assessed. Individual performance data (daily ME intake and fortnightly recording of body weight) and estimations of body composition (d0, d84, d200) were obtained from an *in vivo* trial on 32 extreme RFI Charolais bulls fed two contrasting silage-based diets (maize vs grass). The three sets of INRA growth model parameters (α and β , γ and δ , and cMEU) were adjusted for each animal using daily ME intake as input, and minimizing model deviation from body lipid and protein masses estimations (Pay-Off procedure, Vensim 7.3.5). The five adjusted parameters were analysed by ANOVA for the effects of RFI, or alternatively by ANCOVA for the covariable FCE. No effect of diet or its interaction with RFI or FCE was found ($P>0.05$). The model accuracy was higher when α and β (average RMSEP of 4.0 kg body lipids or proteins) or γ and δ (3.9 kg) were adjusted, compared to only cMEU (4.4 kg). As the FCE increased, greater synthesis (α and β) and lower degradation (γ and δ) rates for both protein ($P<0.05$) and lipids ($P<0.10$) were found. A trend for lower cMEU (greater efficiency of ME use) as FCE increased ($r=-0.30$; $P<0.10$) was also observed. The RFI ranking only impacted the protein synthesis (greater in efficient; $P<0.05$) and degradation (lower in efficient; $P<0.10$) rates in agreement with observations made during the *in vivo* study. In conclusion, based on ME intake and body composition estimates, metabolic parameters adjusted at the individual level in the INRA growth model were significantly impacted by feed efficiency ranking, especially FCE.

A framework for predicting the environmentally attainable intake of dairy cows

J.F. Ramirez-Agudelo, L. Puillet and N.C. Friggens

Université Paris-Saclay | Campus Palaiseau, 22 place de l'Agronomie – CS 80022, 91120, Palaiseau, France; nicolas.friggens@agroparistech.fr

Accurately predicting the intake of dairy cows is essential for evaluating their efficiency. However, measuring individual intake can be challenging and costly, especially in constrained environments. While mathematical models can help predict intake, they are typically designed for normal farm conditions. To overcome this limitation, this article presents a framework for predicting the dry matter intake of dairy cows allowed by constrained environmental conditions, i.e. the environmentally attainable intake (EAI, g DM/d). The framework represents EAI as the product of two main components: maximum sustainable Eating Rate (ER, g DM/min) and Eating Time (ET, min/d). The ER is determined by the physical NDF content of the food and the animal's age, which is a proxy for oral capacity. The daily time available for feeding is divided into four activities: seeking for food, ET, rumination, and additional processing time, influenced by environmental factors such as temperature, photoperiod, farm activities, and food availability. The framework includes assumptions such as a mandatory minimum amount of time for animals to sleep soundly, farm activities that prevent access to food, and the effect of heat stress. To define the most influential parameters, Bayesian inference and a database of 79 treatments from 24 published papers covering grazing and housed cows from several countries, was used for Sensitivity Analysis. The framework is sensitive to six of the 18 inferred parameters. The mean absolute errors for EAI prediction were 2.4 and 4.2 kg DM/d for grazing and housed cows, respectively. The framework separates the animal side of intake from the environmental side, enabling the study of complex phenotypes such as feed efficiency, and genotype by environment interactions. It is simple, suitable for use with resource acquisition-allocation models, and can be readily adapted for use in other livestock species. The framework is extensible to add constraints such as predation pressure, reproductive costs, competition, parasitism, or diseases. We believe this framework could provide a useful tool for designing management strategies to optimize productivity and animal welfare in dairy farms under challenging environmental conditions.

An integrated tool to apply the INRA2018 feeding system in ruminant rationing: INRAtion®V5P. Nozière¹, J. Agabriel¹, R. Baumont¹, P. Chapoutot², L. Delaby³, R. Delagarde³, A. De La Torre¹, P. Faverdin³, S. Giger-Reverdin², P. Hassoun⁴, A. Lamadon¹, G. Maxin¹, D. Sauvant², B. Sepchat⁵, P. Souvignet¹ and S. Dutoit⁶¹INRAE, UMR Herbivores, 63122 St-Genès Champanelle, France, ²INRAE AgroParisTech, UMR Mosar, 91477 Palaiseau, France, ³INRAE, UMR PEGASE, 35590 St-Gilles, France, ⁴INRAE, UMR Selmet, 34000 Montpellier, France, ⁵INRAE, UE Herbipole, 63122 St Genès Champanelle, France, ⁶SIEL, 42 rue de Châteaudun, 75009 Paris, France; pierre.noziere@inrae.fr

The INRA feeding system for rationing ruminants has been regularly updated for 40 years. Thanks to its support software, INRAtion®, it is widely used in France and in several European, African and South American countries. The recent revision of the system was aimed at developing new approaches to rationing, allowing to calculate rations at an objective different from covering animals' needs at the production potential and to predict the multiple responses of the animals in terms of production, product quality, animal health and environmental emissions. The development of the INRAtionV5 rationing system was achieved through a partnership with the SIEL association, which brings together 40 livestock adviser organizations, representing more than 50% of the dairy herd in France. INRAtionV5 calculates feed values from their laboratory analysis, predicts diet nutritive value considering digestive interactions, feed and nutrients intake including on pasture, and the multiple responses of the animals. An algorithm optimizes the rations according an «objective function» that integrates production objectives, management of body reserves, and efficiency of protein use. Other predicted animal responses allow the user to evaluate the calculated rations on several technical, environmental and economic dimensions, as a decision support tool. The current version includes feed value calculations, and ration optimizations for dairy animals (cow, ewe and goat), as well as growing and fattening cattle, and is available under license in French and English (<https://www.inration-ruminal.fr/>) for industry and academic institutions. The connection to the adviser's information systems will allow a massive feedback of results from the field, which may be used for further development of the INRA feeding system and the rationing tool.

Milk yield and mammary metabolism in response to increasing amino acids and protein suppliesS. Lemosquet¹, C. Loncke², J.C. Anger^{1,3}, A. Hamon¹, J. Guinard-Flament¹ and M.N. Haque^{1,4}¹PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France, ²Université Paris-Saclay, INRAE, AgroParisTech, UMR MoSAR, 91120 Palaiseau, France, ³Provimi, Cargill Animal Nutrition & Health, 35320 Crevin, France, ⁴Department of Animal Nutrition, University of Veterinary and Animal Sciences, Lahore, Pakistan; sophie.lemosquet@inrae.fr

The aim of this study was to understand milk yield variations in response to a balanced profile of 10 essential amino acids (EAA) at 2 levels of metabolizable protein (MP) supplies. Diets and infusions provided 14.5 vs 16.8 g/MJ for MP·NEL⁻¹ in INRA 2007 system and 128 vs 145 g/kg DM of CP, respectively in Low vs high MP. Four lactating dairy cows received 2 dietary treatments (low vs high MP) and 2 different duodenal infusions of 10 EAA (AA- and AA+), according to a 2×2 factorial design. The AA- and AA+ treatments provided (in % of MP) 1.7 vs 2.4% of Met, 5.8 vs 7.0% of Lys, 7.9 vs 9.0% of Leu and 1.9 vs 3.0% of His, respectively. Six blood samples were collected from carotid artery and mammary vein to calculate the uptakes of all the energetic nutrients using the Fick principle on Phe + Tyr for mammary plasma flow. Results were analysed using the MIXED procedure of SAS (2009) taking the effect of cows as random. Milk yield increased in AA+ vs AA- treatments (9.1 vs 8.6 kg/12 h-per half udder, $P=0.04$), with no significant difference in lactose yield between the 2 treatments (442 vs 422 g/12 h-per half udder). However, the water content in milk was higher in the AA+ vs AA- treatments (7.90 vs 7.45 kg/12 h-per half udder, $P=0.05$) and explained by a parallel increase in minerals yield (69 vs 64 g/12 h-per half udder, $P=0.05$). Mammary net uptake of glucose (GLC) tended to increase in AA+ vs AA- treatments (1,729 vs 1,562 mmol/h of C, $P=0.06$) as the difference between GLC minus lactose (504 vs. 391 mmol/h of C, $P<0.1$). This indicates that there was a shift in GLC partition towards ATP furnishing to support the increased milk protein yield (MPY; from 262 to 290 g/12 h-per half udder; $P=0.01$). In conclusion, milk volume could vary differently than lactose yield and MPY contrary to the meta-analysis of Daniel and Sauvant and the predictions of INRA (2018) model as it depends on minerals in response to EAA supplies.

Session 19

Poster 24

Ruminal fatty acid biohydrogenation pathways in lambs and kids fed a high concentrate dietV. Berthelot¹, Y.D. Yekoye¹ and L.P. Broudiscou^{1,2}¹Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 place de l'agronomie, 91120 Palaiseau, France, ²INRAE, UPPA, UMR Nutrition, Métabolisme, Aquaculture, 173 Route de St Jean De Luz, 64310 Saint-Pée-sur-Nivelle, France; valerie.berthelot@agroparistech.fr

Understanding the ruminal biohydrogenation (BH) pathways or lipid metabolism is important to improve the nutritional value of ruminant products. Differences in milk or meat fatty acid (FA) composition between sheep and goat have been shown, possibly due to species-linked differences in lipid BH processes or metabolism. In this study, *in vitro* incubations were used to compare ruminal C18 BH pathways between lambs and kids. After weaning, six lambs and six kids were fed the same concentrate diet based on wheat, rapeseed meal and dehydrated alfalfa. At slaughter, individual rumen digesta were collected to inoculate 6 dual-effluent continuous fermenters for two 8-day periods. The last 3 days, each fermenter provided fermentation medium to inoculate 75 ml culture tubes. Over an 8-hour batch incubation, the ruminal BH process was investigated via the addition of oleic, linoleic or linolenic acids. Kids had lower proportions of anteiso FA (1.62 vs 2.10% total FA, $P=0.03$) in their rumen but with a tendency to increase the proportion of iso FA (0.41 vs 0.34% total FA, $P=0.07$). These differences might be linked to a different composition of the ruminal microbiota between these two species. For both species, BH was predominantly via the t10 pathway, with t10 C18:1 being the predominant trans C18:1 isomer (50% trans C18:1). This is consistent with a typical microbiota of a high concentrate diet. Over the 8 hours of incubation, the proportion of C18:0 was significantly higher in lambs compared to kids (14.3 vs 6.5 (% of total C18) respectively, $P=0.01$) indicating a more intense BH in lambs. Lambs also showed a lower proportion of C18:1 t11 than kids ($P=0.05$), a higher C18:1 t10/C18:1 t11 ratio ($P=0.06$) and an increase in C18:2 t10,c12 for linoleic supplementation suggesting a greater orientation of BH pathways towards the t10 pathway and a higher sensitivity of lambs to high starch diets. In conclusion, these findings give evidences that there are interspecies differences in BH pathway between goat and sheep.

Can high fat concentrates offset the high methane production caused by high forage diets?N. Ayanfe¹, S. Ahvenjärvi¹, A. Sairanen² and A.R. Bayat¹¹Natural Resources Institute Finland (LUKE), Tietotie 2C, FI-31600, Jokioinen, Finland, ²Natural Resources Institute Finland (LUKE), Halolantie 31A, FI-71750 Maaninka, Finland; nisola.ayanfe@luke.fi

Increased dietary forage to concentrate ratio (F:C) would improve the sustainability of dairy production. However, high forage (HF) diets increase enteric methane (CH₄) emissions, but dietary fat supplementation may counterbalance this effect. Therefore, this study examined the effects of supplementing HF or low forage (LF) diets with two concentrates of intrinsically differing fat concentration on enteric CH₄ emission, nutrient digestibility, and milk production in lactating dairy cows. Four multiparous Nordic Red dairy cows were randomly assigned to a 4×4 Latin square design in a 2×2 factorial arrangement of treatments with four 21-d periods each consisting of 5 sampling days in metabolic chambers. The treatments comprised a total mixed ration of grass silage with F:C of 70:30 or 50:50 containing either low or high fat concentrates. Two fat concentrations of 24 and 65 g/kg dry matter (DM) were attained by replacing rapeseed meal and barley with rapeseed cake and oats at 25 and 50% of concentrates, respectively on DM basis. DM intake was higher in LF compared to HF and fat did not affect it. Interactions between F:C and fat concentration were observed for DM, gross energy and fibre digestibility coefficients with high fat concentration increasing fibre digestion ($P<0.01$) when included in LF and decreasing it in HF. Feeding high fat diet increased fat and crude protein digestibility compared to diets with low fat concentration. No interaction between F:C and fat concentration was observed on daily CH₄ production and CH₄ yield showing that the mitigating effect of fat does not depend on the F:C. Fat reduced CH₄ intensity (12.3 vs 10.6 g/kg energy-corrected milk, ECM) in LF but not in HF ($P<0.05$). However, feeding LF and high fat diets decreased CH₄ yield compared to HF (average 23 vs 21 g/kg DMI) and low fat (average 23 vs 21 g/kg DMI) diets, respectively. High fat concentrate increased the proportion of propionate in rumen VFA leading to increased ECM production only in LF. In the current study, high fat concentrate decreased daily CH₄ emissions by 7% regardless of dietary forage to concentrate ratio.

Session 19

Poster 26

Updates of the expenditures and requirements for growing dairy goats

S. Giger-Reverdin and D. Sauvant

Université Paris-Saclay, INRAE, AgroParisTech, UMR Modélisation Systémique Appliquée aux Ruminants, 22 Place de l'Agronomie, 91120, Palaiseau, France; sylvie.giger-reverdin@agroparistech.fr

A novel approach based on modelling was undertaken to update the expenditures and requirements for growing dairy goats in the INRA2018 system. It replaced former approaches based on feeding trials. Growth, growth rate of the whole body weight (BW), empty BW (eBW), the fat and protein contents of eBW were modelled along growth. The first step was to model the potential growth curves and growth rate from data obtained from the MoSAR's herd in Grignon (Alpine or Saanen breeds). Then the approach used data obtained in Brazil and in France on Alpine or Saanen growing goats using slaughtering techniques. A meta-analysis was conducted on 12 publications, with eight dealing with males, five with castrated males, and only four with females. In the second step, eBW was estimated in function of BW. The third step concerns the modelling of body lipids. The comparison of the 'three sexes' exhibited a significant 'sex' effect. A first approach was done on the males, because they were more numerous and the percentage of lipids/eBW was adjusted with a monomolecular model. Then a coefficient was calculated for the ratio of this percentage between females and males. This enables to model the body lipid component in function of age. In a fourth step, body proteins content was modelled in a similar approach using all the data as the sex effect was non significant. Growth energy requirements for young females were obtained from the body energy content due to lipids or protein deposition. It ranged from 1.55 UFL/kg BW gain around birth to 1.63 UFL (1st gestation) and to 1.80 UFL (2nd lactation). The total energy requirement increases from 0.50 (1st month) to 1.75 (end of 1st gestation) UFL/d. Growth PDI requirements are computed from the protein gain divided by PDI efficiency. It decreases with the age of the animal. Total PDI requirements include growth PDI and those related to nonproductive functions. With 'normal' diets they are around 70 g/d for a one month goat and 130 g/d at the end of 1st gestation. The new values proposed are higher than the previous ones and in agreement with other feeding systems. A more detailed description is in Chapter 21 'Dairy and growing goats'.

Feed efficiency relates to the ability of supporting lactation in dairy cows facing feed restriction

L. Barreto-Mendes, J. Pires, A. De La Torre, I. Ortigues-Marty, I. Cassar-Malek and F. Blanc

Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, 63122, Saint-Genès-Champagnelle, France; luciano.mendes@inrae.fr

We hypothesized that individual differences in prioritization of dairy cows exposed to feed restrictions (FR) are associated with feed efficiency. The objective was to explore clustered associations among adaptive responses to experimental FR and metrics of feed efficiency. 16 Holstein and 17 Montbéliarde cows, starting at 87 ± 6 DIM, underwent four 4d FR periods (50% of individual NEL). Cows were fed *ad libitum* after FR1 (during 10 d), and FR2, FR3, FR4 (during 3 d). Energy-corrected milk yield (ECMY), plasma non-esterified fatty acids (NEFA) and bilirubin concentrations were measured prior, during and after FR. Residual feed intake (RFI) and milk energy conversion efficiency (ECE) were calculated in early and mid-lactation. Individual ECMY pre-FR, and integrated areas under the curve during FR (AUC1) and recovery (AUC2) were calculated and clustered separately for FR1 (or challenge 1, CH1) and the sum of AUC responses during FR2 through FR4 (CH2). Then cluster (CL) differences were tested for RFI and ECE. For both CH1 and CH2, 3 distinct CL, each composed of both breeds, emerged: CL1 with low ECMY pre-FR, low ECMY AUC1 and ECMY AUC2, and low NEFA AUC response; CL2 with high ECMY pre-FR, average ECMY AUC1 and better ECMY recovery in terms of AUC2; and CL3 with high ECMY in pre-FR, high ECMY AUC1 and AUC2, and low bilirubin. RFI_{early} was numerically higher for cows in CL3-CH1. A concordant effect occurred for CL3-CH2 in terms of ECE_{early} where the low mobilization of body reserves may be explained by better feed efficiency to support lactation. 50% of cows changed CL typology between CH1 and CH2, suggesting that individual adaptation mechanisms are impacted when cows face multiple challenges. In conclusion, feed efficiency seems to have buffered the lower body reserves mobilization of a subgroup of cows during FR, in order to support lactation.

Effects of rumen protected calcium gluconate on hindgut dynamics and nutrient partitioningM. Hall¹ and J.G.H.E. Bergman²¹Trouw Nutrition GB, Ruminant Department, Blenheim House, Ashbourne DE6 1HA, United Kingdom, ²Nutreco, Selko, Stationsstraat 77, 3811 MH Amersfoort, the Netherlands; mark.hall@trouwnutrition.com

Rumen protected calcium gluconate (RPCG) fed as a dietary supplement has been consistently shown to increase milk and component yields in dairy cattle under both research and practical conditions. These responses are thought to be mediated by improvements in post-ruminal barrier function upon fermentation in the hindgut. Although its exact mechanism of action is currently unknown, evidence from the available studies point to beneficial effects at different levels. Gluconic acid salts have been shown to have a prebiotic effect in the lower gut of monogastric animals where it serves as a precursor for volatile fatty acids (VFA). In agreement, RPCG supplementation tended to increase both butyrate and total VFA concentrations in cecum digesta of growing lambs. Similarly, an overall increase in VFA concentrations in the hindgut was observed when supplementing RPCG to growing steers. This was accompanied by changes in the microbial population associated with gut homeostasis and health, and the formation of beneficial end products. Interestingly, models of hindgut acidosis show a decrease in milk urea nitrogen (MUN) due to increased N retention in the hindgut for microbial proliferation. This contrasts with the increase in MUN concentrations observed when feeding RPCG, which might reflect a shift in hindgut fermentation. Finally, supplementing RPCG consistently increases circulating NEFA without an increase in blood BHB, suggesting changes in postabsorptive nutrient partitioning. In conclusion, the beneficial effects of RPCG on milk performance might be partially mediated by an improved barrier function, reducing the energetic requirements of intestinal damage and leaky gut, allowing for improved whole-body bioenergetics, and ultimately increased performance.

The impact of observation frequency and duration, on resilience traits in pigs

W. Gorssen¹, C. Winters², R. Meyermans¹, L. Chapard¹, K. Hooyberghs¹, S. Janssens¹, A. Huisman³, K. Peeters³, H. Mulder⁴ and N. Buys¹

¹KU Leuven, Center for Animal Breeding and Genetics, Kasteelpark Arenberg 30, bus 2472, 3001, Belgium, ²KU Leuven, Laboratory for Biological Psychology, Tiensestraat 102, 3000 Leuven, Belgium, ³Hendrix Genetics, P.O. Box 114, 5830 AC, Boxmeer, the Netherlands, ⁴Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands; wim.gorssen@kuleuven.be

Recent studies showed pigs' resilience can be measured via deviations in longitudinal data. Recording longitudinal data in pigs has been facilitated by the introduction of automated feeding systems, generating daily records on weight, feed intake and feeding behaviour. However, feeding stations can possibly be used more efficiently. Therefore, we studied the influence of observation frequency and duration on resilience trait. This study used 324,207 daily weight measurements over a 60 day period (95-155 days) on 5,939 Piétrain pigs with known pedigree. The resilience trait *lnvar* was calculated as the natural logarithm of the variance of deviations of predicted vs observed weights after Gompertz modelling. Genetic analyses were done via blupf90 software. The impact of observation frequency was studied by lowering data density from 1 in 4 (~twice a week) up to 1 in 14 (~biweekly) records. The impact of observation duration was investigated by creating three 20 day periods: early (95-115 days), middle (115-135 days) and late (135-155 days). For both scenarios, phenotypic and genetic correlations were estimated between the full dataset and subsets. Heritability of *lnvar* was estimated at $h^2=11.0\%$. We showed that *lnvar* was robust to low observation frequencies with phenotypic correlations $r_p>0.76$ and genetic correlations $r_g>0.96$. Moreover, phenotypic and genetic correlations between 20-day periods were moderate for *lnvar* ($r_p=0.37-0.50$; $r_g=0.61-0.78$), whereas they were high between 20-day periods and the full dataset ($r_p=0.66-0.74$; $r_g=0.81-0.89$). Our findings show that *lnvar* can be used as a resilience trait in finishing pigs with as low as one recording every two weeks. Moreover, daily records on a 20-day period seemed informative to predict *lnvar* over a pigs' finishing period.

Session 20

Theatre 2

Are tail biting and tail necrosis really only a problem in the domestic pig?

I. Czycholl¹, K. Büttner², W. Baumgärtner³, C. Puff³ and J. Krieter⁴

¹University of Copenhagen, Department of Animal Welfare and Disease Control, Grønnegårdsvej 8, 1870, Denmark, ²Justus Liebig University, Unit for Biomathematics and Data Processing, Faculty of Veterinary Medicine, Frankfurter Str. 95, 35392 Giessen, Germany, ³University of Veterinary Medicine Hannover, Department of Pathology, Bunteweg 17, 30559 Hannover, Germany, ⁴Institute of Animal Breeding and Husbandry, Kiel University, Olshausenstr. 40, 24098 Kiel, Germany; ic@sund.ku.dk

Tail biting is a multifactorial problem in pig husbandry that has been linked, amongst others, to deficiencies in the health status. But which pathological findings of domestic pigs can be rated as normal and which might play a subclinical role in the behavioural disorder tail biting? 13 young wild boars, shot during normal hunting practice in Germany, were subjected to pathological examinations. The findings were compared by Chi² Tests and t-Tests to pathological findings of 17 rearing pigs from a conventional farm. Moreover, 44 additional tails of wild boars were analysed pathologically. Typical findings in wild boars were linked to parasitic infections, which were not seen in rearing pigs at all (most common findings: nematodes in the lung (11 wild boars affected; $P<0.0001$) and in the gut (8 wild boars affected; $P=0.0002$), milkspots (5 wild boars affected; $P=0.005$). However, significantly more rearing pigs were affected by parameters linked to the gut health (hyperplasia (4 rearing pigs, 0 wild boars; $P=0.05$) and crypt abscesses (7 rearing pigs, 1 wild boar; $P=0.04$) in the colon associated lymphoid tissue and crypt abscesses in the gut (5 rearing pigs, 0 wild boars affected; $P=0.03$). Moreover, significantly more rearing pigs were diagnosed to have a rhinitis (13 rearing pigs, 4 wild boars; $P=0.01$), whereas significantly more wild boars had a purulent inflammation of the mesenteric lymph nodes (3 wild boars, 0 rearing pigs, $P=0.03$). Although some pathological deviations in the tails of wild boars were seen, these can be linked to external parasites (specifically mites) but not to tail necrosis or tail biting occurrence. Overall, it can be concluded that wild boars are not healthier than rearing pigs (or vice versa), but the causes for the diseases differ. There is no scientifically proven evidence for tail necrosis or tail biting in the wild boar population.

Innovative rearing strategies for heavy pigs: weight and chemical composition of dry-cured hamsA. Toscano¹, D. Giannuzzi¹, I.H. Malgwi¹, V. Halas², P. Carnier³, L. Gallo¹ and S. Schiavon¹¹University of Padua, Dept. DAFNAE, viale dell'Università 16, 35020 Legnaro, Italy, ²Hungarian University of Agriculture and Life Sciences, Dept. Farm Animal Nutrition, Guba Sandor Utca 40, 7400 Kaposvár, Hungary, ³University of Padua, Dept. BCA, viale dell'Università 16, 35020 Legnaro, Italy; alessandro.toscano@unipd.it

To explore the influence of 4 feeding strategies on the dry-cured ham quality, 336 Goland C21 pigs, barrows and gilts of 90 kg body weight (BW), were divided into 4 groups, assigned to one of four treatments, and housed in 8 pens with automated feeders. In the control group (C), the pigs were fed restrictively medium-protein feeds and slaughtered at 170 kg BW and 257 d of age. With the older age (OA) treatment, the pigs were restrictively-fed low protein feeds and slaughtered at 170 kg BW and 273 d of age. The other two groups were fed *ad libitum* high protein feeds, the younger age (YA) group was slaughtered at 170 kg BW and 230 d of age, the greater weight (GW) at 257 d of age and 193 kg BW. According to the Prosciutto Veneto product specification the hams were dry-cured and seasoned for 607 d. Hams were weighed before and after seasoning, deboned and scored for fat cover depth. Sixty hams were sampled and sliced. The lean and the fat tissues were separated and analysed for proximate composition and fatty acid profile. The model of analysis considered sex, treatment and sex × treatment as fixed factors. With respect to C: (1) OA lowered the ham weight, the lean protein content, but increased the marbling and decreased the proportion of polyunsaturated fatty acids (PUFA) in lean and fatty tissues; (2) YA hams had thicker fat cover with lower PUFA proportion in lean and fatty tissues; (3) GW increased the deboned ham weight, fat cover depth and marbling, but reduced the PUFA proportion in lean and fatty tissues and the seasoning losses, without alteration of the lean moisture content. Sex had a negligible impact. Innovative rearing strategies had positive influences on the chemical quality of the seasoned hams. Acknowledgements: Agritech National Research Center, funded by the European Union Next-Generation EU (Piano Nazionale di Ripresa e Resilienza (PNRR) – Missione 4 Componente 2, Investimento 1.4 – D.D. 1032 17/06/2022, CN00000022) and PSR Veneto DGR 2175/2016, code 3682902.

Session 20

Theatre 4

Comparison of different non-linear growth models on post-weaning growth of pigs

K.O. Kareem-Ibrahim, O.T.F. Abanikannda and O.A. Folorunsho

Lagos State University, Department of Animal Science, School of Agriculture, Epe Campus, Lagos, Nigeria; ofabanikannda@hotmail.com

Pig growth curve models are useful tools for identifying optimum management strategies for individual grower-finisher pigs. The use of non-linear growth models in fitting the growth rate of pigs is more effective than linear models. This study aimed at evaluating post weaning growth of pigs as affected by sex and modelling of the weekly weight using various nonlinear curve fitting methods, with a view to assess and compare the efficiency and accuracy of the different models, and recommend the model of best fit for post-weaning weekly growth of pigs. A total of 43 piglets comprising 18 female and 25 male weaners were evaluated. Data was collected for a period of 12 weeks on a weekly basis from the weaners using a digital weighing scale, sensitive to 0.00 g. Preliminary analysis of variance of the effect of sex on the initial weight at weaning was not significant ($P > 0.05$), thus leading to the merger of the weaners across sex. Mean weekly weight of piglets at 0, 7, 14, 21, 28, 35, 42, 49, 56, 63, 70, 77 and 84 days were 5.69 ± 0.17 , 6.71 ± 0.17 , 7.02 ± 0.19 , 8.05 ± 0.22 , 8.28 ± 0.24 , 9.38 ± 0.28 , 10.35 ± 0.34 , 11.13 ± 0.37 , 12.51 ± 0.40 , 14.02 ± 0.47 , 15.34 ± 0.53 , 15.85 ± 0.55 and 16.51 ± 0.57 kg respectively. Seven non-linear models ranging from two to four parameters (Asymptotic Regression, Logistic, Log-logistic, Gompertz, Richards, Weibull and Mechanistic) were used to fit the growth curves. All modelling and statistical analyses were done using JMP Statistical Software. Test of goodness of fit of the various models included coefficient of determination (R^2), adjusted coefficient of determination (Adj. R^2), root mean square error (RMSE), Akaike's Information Criterion (AIC) and Bayesian Information Criterion (BIC). Out of the seven models used, the Richard growth model had the best fit for the modelling of pig growth and the least root mean square error. It is thus recommended that the Richard be further investigated for growth curve fitting of pigs at the post weaning stage.

Effect of glutamine and/or milk supplementation post-weaning on pig growth and intestinal structureE.A. Arnaud^{1,2}, G.E. Gardiner¹, S.R. Vasa^{1,2}, J.V. O'Doherty³, T. Sweeney³ and P.G. Lawlor²¹South East Technological University, Dept. of Science, X91K0EK, Waterford, Ireland, ²Teagasc, Pig Development Dept., Co. Cork, P61R966, Fermoy, Ireland, ³University College Dublin, School of Agriculture & Food Science, Belfield, D04C7X2, Dublin, Ireland; elisa.arnaud@teagasc.ie

Improving intestinal structure and function in weaned pigs will help to overcome the negative growth effects associated with weaning. This study aimed to determine the effect of providing supplemental milk and/or dietary inclusion of 1% L-glutamine on the growth and intestinal structure of newly weaned pigs. At weaning, 480 pigs were grouped into single sex groups of 10 pigs of even weight (12 pens/treatment) and randomly assigned to one of 4 treatments in a 2×2 factorial arrangement; factors being provision of supplemental milk (yes/no) and dietary supplementation with 1% L-glutamine (yes/no). Supplemental milk (167 g of Swinco Opticare milk powder/l of water) was provided from weaning to day (d)10 post-weaning (pw). L-glutamine was added at 1% to the starter feed and milk powder before reconstitution from weaning to d10pw. After d10pw, all pigs were fed the same standard diet. Group weights and feed disappearance were recorded at intervals up to slaughter. At d7pw, 40 pigs were euthanised and intestinal tissue sampled for histological analysis. Data were analysed using PROC MIXED (v9.4, SAS Institute Inc.). The pen group was the experimental unit. There was a milk × glutamine interaction on body weight (BW) at d10, d20, d28, d47 and d124pw (slaughter); at d10, d20, d28 and d47pw, milk increased pigs BW with and without L-glutamine supplementation ($P<0.05$). At d124pw, milk feeding increased BW when L-glutamine was not fed but did not when L-glutamine was fed ($P<0.05$). There was a milk × glutamine interaction for average daily feed intake (ADFI) from weaning to d10pw, d20-28pw and d28-47pw; milk feeding increased ADFI when L-glutamine was and was not fed ($P<0.05$). At d7pw, milk feeding increased duodenal, jejunal and ileal villous height by 13, 38 and 29%, respectively ($P<0.05$). In conclusion, milk supplementation increased post-weaning feed intake and intestinal villous height, leading to an increase of ~3.0 kg in BW at slaughter.

Effect of lysine level in finisher diets on performance in crossbreds from two terminal sire linesS. Goethals¹, K. Hooyberghs², N. Buys², S. Janssens² and S. Millet¹¹ILVO, Flanders Research Institute for Agriculture, Fisheries and Food, Scheldeweg 68, 9090 Melle, Belgium, ²KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, bus 2472, 3001 Leuven, Belgium; sophie.goethals@ilvo.vlaanderen.be

Adequate knowledge on lysine requirements and supplementation of free amino acids enables to reduce the dietary protein level, resulting in lower feed costs and reduced nitrogen excretion. However, a deficient supply of amino acids reduces performance. Requirements depend on sex and genotype because of the difference in capability for lean growth and feed intake. The current study evaluated the effect of lysine level in the finisher phase (80-115 kg) on growth performance in crossbred pigs from two terminal sire lines. Gilts and barrows (n=360 in total) with a different paternal genetic background (stress negative sire line selected for growth rate vs stress positive sire line selected for carcass quality) were allocated to a high or low lysine diet (6.3 vs 7.8 g standardized ileal digestible lysine per kg diet, with 12.6 and 14% crude protein, respectively and 9.3 MJ NE/kg), according to a 2×2 factorial design. The feed conversion ratio (FCR) in the finisher phase was lower for gilts compared to barrows (2.85 vs 2.93, $P=0.049$). Within sexes, there was only a significant difference in FCR between the low and high lysine diet of the crossbred selected for carcass quality (2.95 vs 2.76, $P=0.023$). Higher serum urea levels in barrows demonstrated the lower amino acid requirements compared to gilts (14.4 vs 10.8 mg/dl, $P<0.001$). In barrows, the high lysine diet resulted in 31% higher serum urea levels compared to the low lysine diet ($P<0.001$), independent of sire line, suggesting an excess of protein in the high lysine diet for all barrows. In gilts, a trend for higher serum urea levels (9% increase, $P=0.06$) was observed for the high compared to the low lysine diet, also independent of sire line. In general, both the low lysine diet and the genetic background selected for carcass quality positively affected nitrogen efficiency in the finisher phase. Only in gilts selected for carcass quality, the low lysine diet did not result in a better nitrogen efficiency compared to the high lysine diet.

Birth weight effects on performance and gut health status of weaned pigletsC. Negrini¹, F. Correa¹, D. Luise¹, S. Virdis¹, M. Mele², G. Conte², M. Mazzoni³ and P. Trevisi¹¹University of Bologna, DISTAL, Viale fanin 46, 40127, Italy, ²University of Pisa, DAFE, Via del Borghetto 80, 56124, Italy, ³University of Bologna, DIMEVET, Via Tolara di Sopra 43, 40064, Italy; federico.correa2@unibo.it

Over the past few decades, the swine industry has focused on litter size as a key production indicator. However, selecting for greater litter size has resulted in an increase in the number of piglets born with low birth weight (<1 kg). This study aims to assess the impact of birth body weight (BBW) on piglet performance, microbial profile, and gut status in after weaning. At birth, 64 piglets from 13 litters were selected for their BBW and at weaning (d0), piglets were allotted into 2 groups: NBW (>1 kg; 32 piglets) and LBW (<1 kg; 32 piglets). Piglets were weighted weekly until d21 post-weaning. Faecal score and feed intake (FI) were daily recorded. On d9 and d21, a total of 16 piglets/group were slaughtered, and jejunum tissue was collected for morphology and immunohistochemistry analysis, colon content was collected for microbiota and SCFAs analysis, and the pH of jejunum, cecum and colon was measured. Data were analysed using a linear mixed model or a generalized linear mixed model with a Poisson distribution including the class of BW and the litter as fixed and random factors respectively. Piglets from the NBW group had consistently higher BW throughout the study ($P<0.01$). From d0 to d21, the NBW group tended to have a higher average daily gain (ADG) ($P=0.07$), and a higher FI ($P=0.006$). LBW piglets tended to have a lower faecal index from d0 to d21 ($P=0.076$). At d21, the NBW piglets had a higher villus height ($P=0.05$) and tended to have higher VH:CD ratio ($P=0.07$), while LBW piglets had higher number of T-lymphocytes in the epithelium and crypts ($P<0.01$). The LBW piglets had higher concentration of iso-butyrate, butyrate, isovalerate, valerate, and the total amount of SCFAs at d21 ($P<0.05$). Alpha diversity was never different between the two groups, while Beta diversity tended to be influenced by the BW category on d9 ($P=0.068$, $R^2=0.05$) and was significantly different on d21 ($P=0.026$, $R^2=0.05$). In conclusion, the BBW affected the piglet's response to weaning and the gut health status. Selecting piglets for their BBW could represent a valid challenge model to test different feeding strategies.

Session 20

Theatre 8

Effects of sugary and salty ex-food in pigs' diets on growth performance and pork sensory traitsS. Mazzoleni¹, M. Tretola^{1,2}, C.E.M. Bernardi¹, P. Lin¹, P. Silacci², G. Bee² and L. Pinotti^{1,3}¹University of Milan, Department of Veterinary Medicine and Animal Sciences, Via dell'Università 6, 26900 Lodi, Italy,²Agroscope, Institute for Livestock Sciences, Rte de la Tioleyre 4, 1725 Posieux, Switzerland, ³CRC I-WE, Coordinating Research Centre: Innovation for Well-Being and Environment, 20134 Milan, Italy; sharon.mazzoleni@unimi.it

Ex-food also known as Former foodstuffs products (FFPs) are promising alternative ingredients to reduce the waste of natural resources and the environmental impact of food production. These products can be classified into two categories: (1) salty leftovers, mainly obtained by bakery products (pasta, bread and salty snacks); or (2) sugary leftovers, obtained by confectionery products (chocolate, breakfast cereals, cookies). This study investigated the effects of salty and sugary FFPs on growth performance and sensory characteristics of the loins of growing and finishing pigs. Thirty-six Swiss Large White male castrated pigs were assigned to the three grower (G) and finisher (F) experimental diets: (1) standard diets (ST-G; ST-F), 0% FFPs; (2) 30% conventional ingredients replaced by sugary FFPs (SU-G, SU-F); (3) 30% conventional ingredients replaced by salty FFPs (SA-G, SA-F). The grower and finisher diets were iso-energetic and iso-nitrogenous. Body weight was measured weekly. Feed intake (FI) was determined daily. Average daily gain (ADG), average daily feed intake (ADFI), feed conversion ratio (FCR) and gain to feed were calculated for both the growing and finishing phases. The pork loins were assessed for sensory attributes. Feed efficiency in terms of FCR was improved ($P<0.05$) in ST-G than SA-G and SU-G. However, when considering the overall mean of the entire period BW, ADFI, ADG and FCR were similar ($P>0.05$) between the three groups. The loin from SU pigs was perceived as significantly sweeter ($P<0.001$) than the control, while the loin from SA pigs was perceived as significantly sweeter ($P<0.001$) and more tender ($P<0.001$) than the control. This study confirmed that inclusion of FFPs had no detrimental effects on growth performance in growing and finishing pigs and did not impair the sensory characteristics of the loin, further analyses on the chemical composition of the meat and the fatty acid composition of the intramuscular fat are planned.

Performances, milk quality, and piglet growth in lactating sows fed former food productsP. Lin^{1,2,3}, G. Bee¹, S. Neuenschwander² and M. Girard¹¹Agroscope, Route De La Tioleyre 4, 1725 Posieux, Switzerland, ²ETH Zurich, Institute of Agricultural Sciences, Universitätsstrasse 2, 8092 Zurich, Switzerland, ³Current address: University of Milan, Department of Veterinary Medicine and Animal Sciences, Via dell'Università 6, 26900 Lodi, Italy; peng.lin@unimi.it

Due to their nutrient composition, former food products (FFPs) can replace grains in pig diets. Therefore, we hypothesized that including FFPs in a sow's lactation diet wouldn't affect their lactation performance. However, the FFPs' richness in saturated fatty acid (FA) and scarcity in unsaturated FA will impact the FA profile of sow milk. As unsaturated FAs have immunomodulatory effects, one could expect effects on piglet growth. After farrowing, twenty Swiss Large White sows were allocated to either a diet with 25% FFPs (FFP) or a diet with 15% linseed cake (LIN) during lactation (n=10 per group). The two groups were balanced for body weights (BW), backfat thickness (BF), and parity. Litters were standardized to 13 piglets on average. Individual BW and BF of sows were measured at farrowing and at weaning and feed intake was recorded daily. Milk samples were collected on d17 post-partum to evaluate the chemical composition and the immunoglobulin (Ig) content. Piglet individual BW was measured at several time points until 5 weeks post-weaning. Although FFP sows ingested daily less ($P<0.05$) feed, BW and BF of FFP and LIN sows at weaning was similar ($P>0.05$). The contents (g/kg) of dry matter, protein and fat in milk were or tended to be higher ($P<0.10$) while that of lactose was lower ($P<0.001$) in the FFP than in the LIN group. The percentage (g/100 g milk FA) of lauric acid was higher ($P<0.001$) whereas the percentage of linoleic acid, alpha-linolenic acid, and eicosapentaenoic acid was lower ($P<0.01$) in the FFP group compared to the LIN group. The concentrations of milk IgG and IgA were unaffected ($P>0.05$) by the diets. The FFP piglets tended ($P\leq 0.10$) to grow slower in the pre-weaning and overall period and consumed less feed ($P<0.05$) from 3 to 5 weeks post-weaning. The inclusion of 25% of FFPs in the lactation diet may be too high as it reduced the daily feed intake, which may have impaired milk yield and ultimately hindered piglet growth.

Session 20

Theatre 10

Effect of arginine supplementation on the productive performance of gestating sows: a meta-analysis

S. Viridis, D. Luise, P. Bosi and P. Trevisi

University of Bologna, Department of Agricultural and Food Sciences, Viale Fanin 46, 40126 Bologna, Italy; sara.viridis3@unibo.it

The supplementation of Arginine (Arg) to gestating sows could play a primary role in litter development. The aim of this study was to investigate the effects of the concentration of dietary standardized digestible Arg (SID Arg) on productive performance of gestating sows using a meta-analytical approach. A total of 19 studies conducted between 2007-2020 were collected from literature. Data regarding backfat thickness, total number of piglets born and born alive, number of stillborn piglets, litter weight at birth and weaning were extrapolated from each experimental group and expressed as a percentage of the value of the control group (CO) within the studies. The SID Arg supplementation was expressed as the percentage of SID Arg in the treated group (TRT) minus that included in the CO group within each study (Additional SID Arg %). Linear and quadratic models were built using a mixed procedure by Minitab® software including Additional SID Arg %, parity and feed intake classes and the period of Arg supplementation as fixed factors, and the study as random factor. The SID Arg in CO groups was higher than the doses suggested by the NRC (2012; 4.20-8.90 g/kg of feed vs 2.02-3.10 g/kg, respectively). A quadratic response of Additional SID Arg % was observed for placental efficiency (PE; $P=0.003$; $a=0.0019$), number of total piglets born ($P=0.027$; $a=-0.0003$), number of piglets born alive ($P=0.005$; $a=-0.0006$) and backfat thickness loss ($P=0.057$; $a=0.0029$). A linear increase in plasma concentration of Proline ($P=0.004$; $b=0.120$), Ornithine ($P=0.002$; $b=0.284$), Arg ($P=0.001$; $b=0.425$), and a decrease in the concentration of urea ($P=0.037$; $b=-0.063$) was observed with an increasing level of Additional SID Arg %. There was no effect on placenta weight, alive litter birthweight, individual piglet birthweight and parameters at weaning. The estimated requirements of SID Arg for improving PE, reducing backfat thickness loss, increasing the total number of piglets born and born alive were 11.17 g/kg, 13.03 g/kg, 14.83 g/kg and 15.71 g/kg of feed, respectively. This meta-analysis highlighted the importance of redefining the Arg requirements of gestating sows to improve their productive performance.

Are pre-weaning piglet and sow parameters a proxy for uniformity and daily gain?

K. Hooyberghs¹, S. Goethals², W. Gorssen¹, L. Chapard¹, R. Meyermans¹, B. Chakkingal Bhaskaran¹, S. Millet², S. Janssens¹ and N. Buys¹

¹Center for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30 bus 2472, 3001 Leuven, Belgium, ²ILVO, Scheldeweg 68, 9090 Melle, Belgium; katrijn.hooyberghs@kuleuven.be

Body weight uniformity within a batch of pigs is important from different viewpoints: economic purposes but also to lower environmental and social costs. The objective of the UNIPIG project is to identify factors associated with uniformity and to research the evolution of uniformity from birth until slaughter. Data were collected during an observation trial in two Belgian sow farms where 1,177 crossbred pigs born in 70 litters were recorded. Uniformity was assessed as the coefficient of variation (CV; standard deviation/mean) of body weight at several time points between birth and slaughter. CV per litter was calculated at birth (CV= 0.20), weaning (CV= 0.19), 1 (CV= 0.19) and 2 weeks (CV= 0.18) after weaning, at the start (9-11 weeks) (CV= 0.17) and in the middle (17 weeks) (CV= 0.13) of the finishing period. Furthermore, the association between variables such as sow condition (body weight, chest circumference and back fat thickness), order of birth and litter size, and body weight and CV of body weight was studied. Our results show that litters with a higher number of live-born piglets have a higher CV of body weight throughout life, especially at birth ($r=0.43$, $P<0.001$). Litter size was also moderately correlated to a lower average birth weight per litter ($r=-0.40$, $P<0.001$) and a higher percentage of gilts at birth ($r=0.26$, $P=0.02$). Furthermore, the time between the birth of piglets was found to be lowly correlated with birth weight ($r=0.11$, $P<0.001$). Moreover, other factors that contribute to the variation in body weight in a biological litter and in a batch were evaluated. At this moment, pairwise relationships are reported but in the next step, several factors will be examined together. Our study contributes to more insight into body weight uniformity within a litter and within a batch of pigs and this could help to arrive at a more sustainable and efficient pig production.

Session 20

Theatre 12

Dietary polyphenol extracts improve the performance of broilers challenged with necrotic enteritis

S.A. Salami¹, L. Chew², B.S. Lumpkins³ and B. Tas¹

¹Mootral Ltd, Roseheyworth Business Park North, Abertillery, United Kingdom, ²Mootral SA, Jalan Kiara, Kuala Lumpur, Malaysia, ³Southern Poultry Feed & Research Inc., Roquemore Road, Athens GA, USA; ssalami@mootral.com

Necrotic enteritis (NE) is a common intestinal disease in poultry and imposes significant economic loss due to the poor productivity of birds. Polyphenols are natural bioactive compounds that can be used in poultry nutrition to improve birds' gut health and productivity. This study investigated the effects of supplementing proprietary polyphenol extracts (IQV10-3) on the performance of broilers challenged with NE. A total of 400-day-old chicks were assigned to five groups (10 replicates/group) that were all challenged with NE: T1, control; T2 received IQV10-3 dose A; T3 received IQV10-3 dose A + coccidiostat; T4 received IQV10-3 dose B; T5 received IQV10-3 dose B + coccidiostat. The trial lasted for 28 d and NE was induced by inoculating all birds with *Eimeria maxima* on d 14 and *Clostridium perfringens* on d 19-21. IQV10-3 was administered via drinking water (dose A: 0.8% from d 0-2 and 0.2% from d 3-28; dose B: 0.8% from d 0-2, 0.4% from d 3-10 and 0.2% from d 11-28) while in-feed coccidiostat (125 ppm Amprolium on d 13-21) was administered to T3 and T5. Feed intake (FI), body weight gain (BWG) and feed conversion ratio (FCR) were evaluated at d 13-21 (challenge phase) and d 13-28 (challenge+recovery phase), and mortality was measured on d 0-28. On d 21, NE lesions were scored, and gut permeability was determined by the levels of serum fluorescein isothiocyanate-dextran (FITC-d). Contrast analysis was used to evaluate the effects of IQV10-3 without (T2+T4) or with (T3+T5) coccidiostat compared to the control (T1). For the challenge phase, T2+T4 and T3+T5 significantly increased BWG and reduced FCR. For the challenge+recovery phase, T2+T4 tended to increase ($P=0.08$) BWG and reduce ($P=0.06$) FCR whereas T3+T5 increased ($P<0.01$) FI and BWG without affecting FCR. No treatment effect on FITC-d was observed. However, T2+T4 and T3+T5 reduced mortality and lesion scores. These results suggest that IQV10-3 without or with coccidiostat had similar performance improvements compared to T1. Overall, IQV10-3 could be an effective nutritional solution for ameliorating the negative impacts of NE on broiler performance.

Effects of *Bacillus subtilis* DSM 32315 or *Bacillus velezensis* CECT 5940 on chicken PBMCsF. Larsberg^{1,2}, M. Sprechert², D. Hesse², G. Loh³, G.A. Brockmann² and S. Kreuzer-Redmer¹¹Veterinärmedizinische Universität Wien, Institute of Animal Nutrition, Nutrigenomics, Veterinärplatz 1, 1210 Vienna, Austria, ²Humboldt-Universität zu Berlin, Albrecht Daniel Thaer-Institute, Breeding Biology and Molecular Genetics, Unter den Linden 6, 10099 Berlin, Germany, ³Evonik Operations GmbH, Research, Development & Innovation Nutrition & Care, Kantstr. 2, 33790 Halle, Germany; filip.larsberg.1@hu-berlin.de

Feeding probiotic *Bacillus subtilis* DSM 32315 (BS) and *B. velezensis* CECT 5940 (BV) has been described to promote health in chicken. One of the most plausible mechanisms underlying the beneficial effects is the modulation of the immune system. Here, we explored direct interactions of chicken peripheral blood mononuclear cells (PBMCs) and probiotics *in vitro*. We performed cell culture experiments with PBMCs of Cobb500 broiler chicken in a co-culture with vital BS or BV in a ratio of 1:3 (PBMCs:*Bacillus*) for 24 hours. The effects on PBMCs were analysed using flow cytometry, RNA-sequencing, and chicken cytokine array Q1 (RayBiotech). We found a higher Δ (difference between treatment and control) relative cell count of CD4⁺ T-helper (Th) cells ($P < 0.05$) and CD4⁺CD25⁺ activated Th cells ($P < 0.01$) after treatment with BS. Accordingly, RNA-sequencing of BS-treated PBMCs revealed higher Δ normalized counts of T cell-related genes CD4, CD28, IL2Ra (CD25), and IL10. Consistently, we found an increased Δ protein concentration of IL10 and decreased levels of pro-inflammatory IL16. However, the RNA-sequencing and cytokine array results were not statistically significant. Furthermore, the Δ relative cell count of CD8⁺ cytotoxic T-cells (CTLs, $P < 0.05$) and CD8⁺CD25⁺ activated CTLs ($P < 0.05$) was increased in PBMCs exposed to BS. After treatment with BV, we found a higher Δ relative cell count of CD4⁺ Th cells ($P < 0.1$) as well as CD4⁺CD25⁺ activated Th cells ($P < 0.05$). Correspondingly, the RNA expression of CD4, CD28, and CD25 was elevated. Furthermore, the expression and Δ protein concentration of IL16 decreased after BV treatment. However, those differences were not significant. Our results suggest a modulation of the T cell immune response by BS and BV in chicken PBMCs *in vitro* and, therefore, provide evidence of a direct immunomodulatory effect on the cellular immune response.

Session 20

Theatre 14

Effect of creatine monohydrate *in ovo* feeding on progeny performance of young breeder flocksC.A. Firman¹, V.K. Inhuber², D.J. Cadogan³, W.H.E.J. Van Wettere¹ and R.E.A. Forder¹¹The University of Adelaide, School of Animal and Veterinary Sciences, Roseworthy Campus, 5371 Roseworthy, South Australia, Australia, ²Alzchem Trostberg GmbH, Animal Nutrition, Dr.-Albert-Frank-Straße 32, 83308 Trostberg, Germany,³Feedworks Pty. Ltd., 13 High st, 3434 Lancefield, Victoria, Australia; vivienne.inhuber@alzchem.com

Broilers hatched from young broiler breeder hens (<30 weeks of age) have higher first week mortalities and lower final bodyweights compared to broiler chickens from older breeder hens. This may be due to the fact that younger breeder hens produce smaller eggs with smaller extraembryonic yolk sacs. Hence, less energy-rich components are available during embryonic development and hatch. The aim of this study was to evaluate if IOF of Creatine Monohydrate, with Creatine (Cr) being a cellular energy storage, positively influences post-hatch growth performance of broilers hatched from young breeder flocks. Four hundred eggs (Ross 308 breeder hens, 27-29 weeks) were collected and at embryonic d14 evenly assigned to three experimental groups: (1) no IOF (CON); (2) 0.75% saline injection (IOF-CON); (3) 8.16 mg CrM in 0.75% saline (IOF-CrM). At hatch, 72 birds (n=24/treatment) and at d42, 96 (n=32/treatment) birds were euthanized and dissected. Birds were reared in a total of 24 pens with 8 pens/IOF treatment until d42. Hatch rate was not statistically different between the three treatment groups. However, a notable difference could be observed between IOF-CrM (93.5%) vs both CON and IOF-CON (88.8 and 88.6%, respectively). Early post-hatch mortality was numerically reduced in the CrM group as compared to both CON and IOF-CON (weeks 4 and 5). *In ovo* feeding of CrM led to increased ($P < 0.05$) Cr concentrations on both liver and heart tissue at hatch as compared to both CON and IOF-CON. There were no treatment effects on growth performance over the whole rearing period. Enhanced energy status at hatch may have improved hatching rate in the CrM group, but was only leaving little resources for post-hatch overall performance. This research indicates that improved energy status at hatch enables producers to place more robust chicks and therefore, has immense application to the industry.

Statistical modelling and estimation of pig body weight based on its linear body measurements

O.T.F. Abanikannnda, K.O. Kareem-Ibrahim and Z.A. Ahmad

Lagos State University, Department of Animal Science, School of Agriculture, Epe Campus, Lagos, Nigeria; ofabanikannnda@hotmail.com

Body weight is an essential index used by producers to determine market-ready pigs, and its accurate estimation before the finishing stage helps reduce losses in pig production. However, since most pig farms at the smallholder level have limited or no access to weighing scales, this study aimed at statistical modelling of linear body measurements to estimate pig body weight. The study involved 83 weaners from a commercial farm at three different ages (4, 5 and 7 weeks) from four breeds comprising Camborough (CB), Large White (LW), and crosses of Camborough with Large White (CB × LW) and Landrace (CB × LR). Body weight was measured using digital weighing scale sensitive to 0.00 g, while the eight linear body measurements were taken using a flexible graduated tape, for the points of reference. Nine parameters including body weight (BW), total body length (BL), thoracic circumference (TC), palette length (PL), shank length (SKL), shank circumference (SC), hip circumference (HC), heart girth (HG) and standard body length (SL) were measured, with mean values of 23.12±1.04 kg, 65.24±3.95 cm, 39.66±3.93 cm, 21.49±0.29 cm, 16.16±1.00 cm, 12.96±0.81 cm, 47.12±2.95 cm, 44.77±2.79 cm and 46.78±2.78 cm, respectively. Breed and age exerted significant ($P<0.05$) influence on each of the nine variables measured, while multiple correlation of variables was mostly highly significant ($P<0.01$) except for palette length and other variables which was mostly not significant ($P>0.05$). Four of the variables, BW, TC, HG and HC had highest loadings in the eigenvalues obtained from the two principal components, which accounted for 99.1% of the total variation. The general model describing body weight in the study was $\text{Body Weight} = -18.69 - 1.19 \text{ TC} + 1.46 \text{ HG} + 0.50 \text{ HC}$ which explained 88.26% of the total variation in body weight. The study confirmed the accuracy and reliability of body weight estimation using linear body measurements in pigs, and thus it is recommended that a quick appraisal of the thoracic circumference, heart girth and or hip circumference can give a fair estimate of the pig body weight.

The potential of insects in sustainable agri-food systems

K.B. Barragán-Fonseca

Universidad Nacional de Colombia, Faculty of Veterinary Medicine and Animal Sciences, Animal Production Department, Carrera 45 # 26-85 Bogotá, 11132, Colombia; kbbarraganf@unal.edu.co

Insects play an important role in sustainability of agri-food systems, as they provide numerous ecosystem services that benefit humans and the environment, including pollination, decomposition, and pest control, as well as serving as a source of food and feed. To evaluate the potential of insects in sustainable agri-food systems, we must consider the following: the objective of insect use; climatic and ecological factors; biological and behavioural traits of the insect species; ways of obtaining the insects; and the scale of their use. Insect farming is rapidly expanding on all continents, and sustainability dimensions vary across small, medium, and large scales of operation. A current societal tendency exists to develop an economic vision that not only focuses growth of the gross domestic product, but also on ecological and social factors. This vision emphasizes the importance of optimizing how insects contribute to various Sustainable Development Goals, including food security, circular economy, and social transformation. While use of insects has the potential to transform societies, not all insect species are suitable for all purposes, and the way in which they are obtained as well as scale of use may vary depending on a variety of factors, including community needs, ecological settings, local regulations, and investment trends. To address these challenges, a comprehensive and interdisciplinary approach is needed to scrutinize the social, economic, and environmental sustainability of insect utilization, assessing various forms of use (gathering, semi-rearing, and production) and their scale. Furthermore, mapping the global use of insects, including current 'hotspots' of their use, can help identify suitable species, forms of production, and scale by region, integrating insects into food systems in an economically, socially, and environmentally sustainable manner.

Sustainability potential of insect production systemsS. Smetana¹, A. Bhatia^{1,2}, U. Batta¹, N. Mouhrim³ and A. Tonda^{3,4}¹DIL German Institute of Food Technologies (DIL e.V.), Professor-von-klitzing-straße 7, 7, 49610, Germany, ²University of Osnabrück, Neuer Graben 29, 49074, Osnabrück, Germany, ³INRAE, Université Paris-Saclay, UMR 518 MIA-PS, 91120 Palaiseau, France, ⁴Institut des Systèmes Complexes de Paris Île-de-France (ISC-PIF), UAR 3611 CNRS, Paris, France; s.smetana@dil-ev.de

The current food systems face severe sustainability problems, e.g. climate change, deforestation, and biodiversity loss. This study aims to assess the potential of insect production to improve sustainable food systems in Europe. Using a comprehensive approach that models key sustainability aspects as defined in FAO SAFA guidelines, the study determined that environmentally beneficial insect value chains can reduce the impact of livestock production systems by 40-97% in categories of global warming potential, land use, and fossil resource scarcity. This reduction is achievable by substituting meat (beef, pork, and poultry) with efficiently produced insect biomass. However, substituting compound feed production with insect value chains would only be environmentally beneficial in cases where extremely efficient production systems are used (e.g. insects grown on waste or low-cost feeds, relying on side-stream heat and alternative energy sources). In such cases, up to 93% of the impact of compound feed production in categories such as global warming potential, land use, and fossil resource scarcity can be eliminated. Insect biomass did not show benefits in the categories of water footprint and animal welfare. This is partly due to the lack of assessments carried or lack of specialized methods (e.g. animal welfare for insects). It is important to consider various factors, such as social acceptability, economic feasibility, and scalability of production, when evaluating the sustainability of insect production chains to fully evaluate the potential of insect production as a sustainable food system at a European level. This project received funding from the European Union's Horizon 2020 research and innovation program under grant agreement no. 861976 (Project SUSINCHAIN). This document reflects only the authors' views, and the Commission is not responsible for any use that may be made of the information it contains.

Session 21

Theatre 3

Maximizing sustainability in insect production: a multi-objective optimization approachA. Anita^{1,2}, N. Mouhrim³, A. Green⁴, D. Peguero⁴, A. Mathys⁴, A. Tonda³ and S. Smetana²¹University of Osnabrück, Osnabrück, 49074, Germany, ²German Institute of Food Technologies (DIL e.V.), Quakenbrück, 49610, Germany, ³UMR 518 MIA-Paris, INRAE, Paris, 75231, France, ⁴Laboratory of Sustainable Food Processing, ETH, Zurich, 8092, Switzerland; S.Smetana@dil-ev.de

Determining the sustainability of insect production is a complex and challenging task. The life cycle sustainability assessment (LCSA) of insect production can estimate social, economic, and environmental impacts. To use insects as feed and food, several aspects of sustainability must be considered, including food and feed production regulations, nutrition factors, social acceptance, and greenhouse gas regulation. Multi-objective optimization (MOO) can consider three competing goals: maximization of economic, social benefits and minimize environmental impacts. The MOO-decision support system is based on: (1) modular LCA and scenario-based life cycle inventory (LCI) that analyse environmental, social, and economic performance of insect species (*A. domesticus*, *M. domestica*, *H. illucens*, *T. molitor*); (2) non-dominated sorting genetic algorithm (NSGA-II) to obtain pareto-optimal solutions covering all sustainability indicators to compare insect production scenarios and test the sensitivity of results with different feeds, processing, utilities, end product type, packaging, and scaling options. This MOO-DSS is developed in the scope of SUSINCHAIN project grant agreement no. 861976 to examine the insect production chains in Netherlands, Germany, France, and the United Kingdom. According to findings, *H. illucens* should be the most used insect for food/feed production, followed by *T. molitor*, *M. domestica*, and *A. domesticus*. *H. illucens* is the most versatile species in terms of feed types (poultry feed, fruits, vegetables, and brewer's-spent-grains). *T. molitor* and *A. domesticus* should be fed on fruits, vegetables, and plant residues, whereas *M. domestica* on fruits, vegetables, and brewer's-spent-grains. The study shows that the scaling potential of each species varies, with *H. illucens* having the highest potential for scale-up. The feed types used to rear insects vary depending on region and production scalability. This data can assist farmers and researchers in determining the best feed types and insects for their region and needs.

Lowering impacts of chicken meat through *H. illucens* larvae supplementation in the feed?D. Ristic^{1,2}, S. Kechovska^{2,3}, C.L. Coudron⁴, A. Schiavone⁵, J. Claeys⁴, F. Gai⁶ and S. Smetana²

¹University of Nat. Resources and Life Sciences (BOKU), Institute of Food Technology, Muthgasse 18, 1190 Vienna, Austria, ²German Institute of Food Technologies (DIL e.V.), Prof-von-Klitzing-St 7, 49610 Quakenbrück, Germany, ³University of Ss. Cyril and Methodius, Faculty of Technology and Metallurgy, Ruger Boskovic 16, 1000 Skopje, Macedonia, ⁴Inagro, Ieperseweg 87, 8800 Rumeke-Beitem, Belgium, ⁵University of Turin, Veterinary Sciences, L.go Paolo Braccini 2, 10095 Grugliasco, Italy, ⁶National Research Council, Institute of Sciences of Food Production, L.go Paolo Braccini 2, 10095 Grugliasco, Italy; d.ristic@dil-ev.de

Feed production is responsible for most environmental impacts in poultry production chains. Environmentally friendly sources of protein for feed are required to reduce the ecological footprint of poultry production. The slow-growing Label Naked Neck chickens were divided into 2 groups: one, reared on commercial organic feed and 10% BSFL substitution, and the other, reared on commercial organic feed. The modular, attributional life cycle assessment (LCA) was developed to assure a structured and quantitative approach. The results are based on experimental data collected from the project partners, extended by the background data and data from the literature. This study followed the cradle-to-slaughterhouse gate perspective with further extensions to waste treatments, thus including feed production, larvae production, hatchery, poultry production, and slaughterhouse. The endpoint results show major impacts on ecosystem quality and human health, followed by climate change, while resource depletion was the least impacted. Crucially, there was no significant difference in the environmental impact of chicken meat introduced by the inclusion of 10% of BSFL into the chicken diet; the differences can rather be attributed to the difference between the sexes. The midpoint results reveal major impacts in Land occupation (male 1.1725 and 1.1553, female 0.9924 and 0.9187 mPt), Global warming (male 1.1718 and 1.1417, female 1.1095 and 0.9924 mPt) and Respiratory inorganics (male 1.0382 and 1.0171, female 0.938 and 0.8856 mPt). Better results might be expected if insect feed were adjusted to overproduced fruits and vegetables, and if the portion of BSFL in broilers' diets were increased.

Session 21

Theatre 5

Use of locusts as feed and food: turning threats into opportunitiesH.P.S. Makkar¹, V. Heuze² and G. Tran²

¹University of Hohenheim, Schloß Hohenheim 1, 70599 Stuttgart, Germany, ²AFZ, AFZ/AgroParistech, 22 place de l'Agronomie, 91120 Palaiseau, France; valerie.heuze@zootechnie.fr

Locusts cause massive destruction of crops and pastures and adversely affect livelihoods and food security of farmers and pastoralists. Locusts are rich in protein (50-65% in dry matter). Their essential amino acid composition is good. In the diets of poultry, pigs and fish, replacement of up to 25% of the conventional protein-rich feed resources such as soymeal and fishmeal is possible with locusts. Among 10 species of locusts have been traditionally consumed by humans for millennia in 65 countries. Their nutritional composition is comparable or superior to that of conventional meat. Main constraint in their use as food/feed is the presence of insecticides, sprayed for controlling outbreaks. Only insecticide-free locusts must be used as a feed/food. Locusts rearing techniques have not been upscaled; however, harvesting approaches are available: use of nets, light and sound. Upscaling of harvesting techniques could offer opportunities to enhance feed/food availability in many developing countries during the locust plague. However, use of harvesting approaches has not been fully considered by the locust controlling agencies. A concern has also been raised that people actively collecting locusts during nights puts them at risk from wildlife/other rural population. Communication of advantages of locust harvesting to the community: prevention of animal/human health deterioration because of insecticide spray would help overcoming the resistance. Locust harvesting using light and sound would deter wild animals from coming near. Alternatively, collection can be done in the mornings when the locusts are numb. An integrated approach that strategically uses insecticides and employs mass harvesting techniques must be considered to control these pests. This would decrease use of pesticides and their associated negative effects. The people should be educated on collection of only live locusts for use as food/feed. The dead ones could be used for composting. Advance preparation of the locust control emergency units towards use of the integrated approach would be a triple-win for smallholder farmers, environment, and human/animal health.

***Chrysomya chloropyga* in broiler feed: valorising abattoir waste for sustainable feed**

E. Pieterse, E.Y. Gleeson and L.C. Hoffman

Stellenbosch University, Animal Sciences, Merriman avenue, Stellenbosch, 7600, South Africa; elsjep@sun.ac.za

Insects in animal feed have been extensively researched over the past decade and interest in the field has grown exponentially over the past few years. Larvae from different fly species, most notably *Hermetia illucens*, have gathered a great deal of attention as they represent possible avenues for more sustainable feed ingredients by valorising a vast array of waste and by-products. The various species have different dietary preferences and attributes that determine the substrates on which they thrive. Therefore, it is important to determine the best suited species to work with depending on the waste or by-product that would be used as substrate. *Chrysomya chloropyga*, otherwise known as the copper bottom blow fly, is a fly species that is particularly well suited to valorising abattoir waste as it is a carnivorous species commonly associated with carrion. The *C. chloropyga* larvae are rich in protein and represent a promising protein and iron source for broiler nutrition. This paper will present data gathered over several studies where *C. chloropyga* larvae were raised on abattoir waste and processed into a meal. The studies determined digestibility of the meal, evaluated the effect of inclusion level on production parameters, assessed carcass and meat quality characteristics and established the viability of the use of the meal as an iron source for broiler production. It was concluded from these studies that *C. chloropyga* can be successfully used to valorise abattoir waste and that the resultant larvae have a high digestibility, fits the ideal amino acid profile of poultry closely, can serve as an iron source for broilers. It was also established that the use of the larvae in broiler feeds has no negative impact on carcass- or meat quality characteristic. The addition of *C. chloropyga* to the list of insect species used as animal feed ingredients will contribute to creating more dynamic insect production schemes that are aimed at optimizing the valorisation of various wastes and by-products and moving towards circular economies in the animal production sector.

Session 21

Theatre 7

Waste side story: a success role for mealworms

C. Ricciardi, L. D'Orleans, C. Oundjian, M. Leheup, T. Lefebvre and F. Peyrichou

Ynsect, 1, rue Pierre Fontaine – Genopole Campus 3 – Batiment 2, 91000 Evry Courcouronnes, France; carmelo.ricciardi@ynsect.com

Today, one third of all food produced for human consumption is wasted. According to FAO's Food Loss Index (FLI), half of that amount is lost from post-harvest to sale and the other half from sale to consumers. In this context insects can be a powerful resource to reduce and valorise the food wastes. Insects, specifically *Tenebrio molitor*, can be reared in vertical farms, reducing the surface needed, and are able to convert the feed given more efficiently than common livestock. Inclusion of wastes in the diet of *Tenebrio molitor* presents two major benefits: reducing the use of more noble ingredients to provide nutrients of interest, and so decreasing the diet price, and improving the global sustainability of the rearing by reducing the carbon footprint of the feedstock. Ynsect conducted several trials in order to assess the effect of including different types of food wastes on the rearing performances. Different diets were formulated according to specific constraints and tested during the exponential growth phase of larval stage, until the harvest. The results obtained were significant: (1) Average reduction of both the developmental time and the FCR when a mixture of humid wastes was provided to the larvae; (2) Stability in the performances for isoproteic and isoenergetic diets formulated incorporating wastes of different origin (Cereals based foods, Vegetables, Processed foods); (3) Reduction of the environmental impact of the formulated diets, estimated as kg of CO₂ equivalent for kg of larvae produced (values obtained from the software Simapro). The trials made proved that the inclusion of different type of food wastes allows to maintain the same, or improved, rearing performances of the standard diet and to decrease the environmental impact and the cost of the diet. The use of food wastes opens new opportunities for feedstock sourcing and outsourcing. These are indeed more environmental friendly and at a cheaper cost than traditional ones. It appears surely feasible and desirable to formulate diets optimized for the industrial rearing of *Tenebrio molitor*.

Ammonia emissions of *Hermetia illucens* larvae grown on different dietsC.L. Coudron¹, S. Berrens², M. Van Peer², J. Claeys¹ and D. Deruytter¹¹Inagro vzw, Ieperseweg 87, 8800 Rumeke-Beitem, Belgium, ²Thomas More University of Applied Sciences, Radius, Kleinhofstraat 4, 2440 Geel, Belgium; carl.coudron@inagro.be

The impact of ammonia emissions and associated depositions from intensive livestock farming on eutrophication leads in some countries to specific measures to reduce emissions. The production of black soldier fly larvae is a novel activity that could similarly lead to ammonia emissions. Several studies have already examined this topic, but new studies are still needed due to the huge array of potential substrates and nuances in rearing techniques, that could all influence ammonia emissions. Better understanding of this topic can only help clarifying which measures, if any, need to be taken so that local decision makers can make appropriate decisions on the matter. A study was performed using an accumulation chamber, a stainless steel box wherein the concentration of ammonia is monitored. A crate (60×40 cm) with growing larvae (15,000) in their feed is placed inside of the accumulation chamber for a short period (10 minutes up to 1 hour) every 24 h. An exponential function $f(t)=a(1-b*\exp(-ct))$ is fit on the ammonia evolution in the accumulation chamber and derived at time zero to determine the momentaneous ammonia emitted by a crate at the time the larvae were put inside. The combined data throughout larval growth can be used to determine peak and total ammonia emissions. This method was performed on a total of four diets (Gainesville diet, chicken feed, swill and brewers spent grains). In addition, both swill and brewers spent grains were enriched with casein protein or protein was diluted using straw pellets in order to vary the protein content between 12 and 25% crude protein on a dry matter basis. This gives an indication of how protein content influences ammonia emissions. Simultaneous with the ammonia measurement, the nitrogen balance of each crate was determined via chemical analysis of the feed, larvae and frass, the inner crate conditions were monitored by measuring pH and temperature of the substrate daily as well as the insects growth parameters. The combination of these parameters gives better insights on how and when ammonia is produced and how it can be reduced.

Session 21

Theatre 9

Chemical & microbiological safety of insect rearing on yet to be legally authorised residual streamsE.F. Hoek- Van Den Hil¹, A.F.G. Antonis², Y. Hoffmans¹, K. Van Zadelhoff¹, R. Deurenberg², O.L.M. Haenen², M.E. Bruins³, J.W. Van Groenestijn³, A. Borghuis⁴, F. Schaafstra⁴, T. Veldkamp⁵, P. Van Wikselaar⁵ and M. Appel¹¹Wageningen Food Safety Research (WFSR), Akkermaalsbos 2s, 6708 WB, the Netherlands, ²Wageningen Bioveterinary Research (WBVR), Houtribweg 39, 8221 RA Lelystad, the Netherlands, ³Wageningen Food & Biobased Research (WFBR), Bornse Weiland 9, 6708 WG Wageningen, the Netherlands, ⁴HAS Den Bosch University of Applied Science, Onderwijsboulevard 221, 5223 DE 's-Hertogenbosch, the Netherlands, ⁵Wageningen Livestock Research (WLR), De Elst 1, 6700 AH Wageningen, the Netherlands; elise.hoek@wur.nl

Insects can convert low quality residual streams into protein-rich ingredients for food and feed. However, chemical residues, pathogens and viruses could be present in these residual streams. Under current European law, it is not permitted to use residual streams that contain animal products or manure for insect rearing. Therefore necessary safety data is needed to provide a basis for enforcement of legalization. Within the project SAFE INSECTS, black soldier fly larvae (BSF, *Hermetia illucens*) and yellow mealworms (YMW, *Tenebrio molitor*) were reared on supermarket mix (food products that passed the expiration date or are unsaleable for other reasons), category 2 meat meal from animal rendering, organic waste from household kitchens, and poultry manure. Chemical and microbiological safety parameters were investigated in the residual streams that were used as substrates, the insects and the frass. Chemical safety parameters were heavy metals, other elements, pesticides, veterinary drugs, dioxins, and PCBs. Residual packaging materials and microplastics were also studied. Microbiological parameters were *Listeria monocytogenes*, *Bacillus cereus*, *Clostridium perfringens*, *Campylobacter*, *Salmonella*, *Staphylococcus aureus*, parasites, the viruses HEV and AIV, and antimicrobial resistant genes. During this presentation, safety results will be shown for both BSF and YMW with a focus on hazards which were present in the residual streams, and on possible accumulation or absence of safety hazards in the insects. With these data, we aim to contribute to possible adaptation of legalization on the permitted use of these residual streams as substrates for insects rearing.

Growth and chemical composition of insects reared on 'yet to be legally authorised' residual streams

S. Naser El Deen¹, P. Van Wikselaar¹, A. Rezaei Far¹, I. Fodor¹, E.F. Hoek - Van Den Hil², Y. Hoffmans², M.E. Bruins³, J.W. Van Groenestijn³, A. Borghuis⁴, F. Schaafstra⁴ and T. Veldkamp¹

¹Wageningen Livestock Research (WLR), Wageningen University & Research, De Elst 1, 6700 AH Wageningen, the Netherlands, ²Wageningen Food Safety Research (WFSR), Wageningen University & Research, P.O. Box 230, 6700 AE Wageningen, the Netherlands, ³Wageningen Food & Biobased Research (WFBR), Wageningen University & Research, Bornse Weilanden 9, 6708 WG Wageningen, the Netherlands, ⁴HAS Den Bosch University of Applied Science, Onderwijsboulevard 221, 5223 DE 's-Hertogenbosch, the Netherlands; somaya.nasereldeen@wur.nl

Insects can be used to increase the circularity of agriculture. Underutilized residual streams such as food waste, slaughter by-products, and animal manure are a source of nutrients and insects can convert these residual streams into high-quality products for animal and human consumption. It is not permitted to use residual streams that contain animal products or manure for insect rearing according to current EU legislation. In the project SAFE INSECTS the aim is to complete the necessary food safety data to enable the application of legally prohibited residual streams to grow insects. Next to the safety data also the growth performance of the insects and the chemical composition of the insects and frass harvested from these residual streams were studied to see if these residual streams are promising substrates for insect rearing. Black soldier fly larvae (BSF; *Hermetia illucens*) and yellow mealworms (YMW; *Tenebrio molitor*) were reared on supermarket mix (food products that passed the expiration date or are unsaleable for other reasons), category 2 meat meal from animal rendering, organic waste from household kitchens, and poultry manure. The growth performance and the chemical composition of the substrates, the starting and harvested larvae, and the frass were determined in order to calculate the conversion of nutrients such as nitrogen (protein) and fat. These data will indicate if the organic residual streams are promising substrates as such to grow insects or if these should be further optimized to get satisfactory results for insect-rearing companies.

Safety and production performance of insects reared on catering waste

E.F. Hoek- Van Den Hil¹, S. Naser El Deen², K. Van Rozen³, P. Van Wikselaar², H.J.H. Elissen³, R.Y. Van Der Weide³, A. Rezaei Far², I. Fodor², N. Meijer¹ and T. Veldkamp²

¹Wageningen Food Safety Research (WFSR), Akkemaalsbos 2, 6708 WB, the Netherlands, ²Wageningen Livestock Research (WLR), de Elst 1, 6700 AH, the Netherlands, ³Wageningen Research – ACRRES, Edelhertweg 1, 8219 PH Lelystad, the Netherlands; elise.hoek@wur.nl

Farmed insects intended for food or feed are considered as 'farmed animals', and the EU has established restrictions on the type of feed (substrate) that these insects may be reared on. Consequently, such insects may only be fed with materials of vegetal origin or certain specified animal products such as milk, eggs, etc. – but no meat or fish. Catering waste or former foodstuffs which can contain meat, however, are a very promising substrate compared to other residual streams. These products were food grade and can therefore be considered safe, presuming the risks had been correctly managed in the chain. However, 'intra-species recycling' ('cannibalism') should be avoided: including 'indirect' recycling with insects acting as intermediary. Therefore, the objective of this study was to determine the presence of animal DNA (pig/poultry/bovine) and pathogens in insects reared on substrates containing animal proteins. Black soldier fly larvae (BSFL, *Hermetia illucens*) were reared for one week on catering waste stored until usage at room temperature (18-22 °C) or cool conditions (4-8 °C). The different types of catering waste tested were: (1) fresh French fries, (2) fried French fries, (3) mix location 1 (bread, fries, and meat), (4) mix location 2, and (5) mix location 3. Larval performance in terms of growth rate, waste reduction index, and efficiency of conversion of ingested substrate were determined as well as the chemical composition of the substrate, the larvae, and the frass; to calculate the conversion of nitrogen and fat. Microbiological safety (*Salmonella*, *B. cereus*, and *S. Aureus*) was assessed. Furthermore, data suggests that gut emptying is an effective measure to reduce the level of animal DNA below detectable limits in the larvae. All results will be presented. With these data we hope to contribute to possible legalization of the use of catering waste for rearing insects.

Mycotoxin accumulation and metabolism by insects: an overviewK.C.W. Van Dongen¹, K. Niermans^{1,2}, E.F. Hoek-Van Den Hill¹, J.J.A. Van Loon² and H.J. Van Der Fels-Klerx¹¹Wageningen Food Safety Research, Akkermaalsbos 2, 6708 WB Wageningen, the Netherlands, ²Wageningen University, Department of Plant Sciences, Laboratory of Entomology, Droevendaalsesteeg 1, 6708 PB Wageningen, the Netherlands; katja.vandongen@wur.nl

Animal feed production needs novel protein sources, and insects are seen as a promising feed ingredient. In particular when insects can be reared on substrates of low quality, that cannot directly be used as feed ingredient. When insects could upgrade waste or side streams into high quality proteins, insect production would contribute to an economic viable and sustainable food system. When rearing insects on waste and side streams, potential safety issues could arise, and these should be studied in advance, using a safe-by-design approach. In particular, mycotoxin contamination is seen very often, around the world, in all sorts of plant-based commodities. These contaminants can have very severe adverse health effects, so possible accumulation in insects, from the substrate, should be investigated. In this presentation, a state of the art overview will be given on research into the possible accumulation of mycotoxins in insects, in particular black soldier fly and (lesser and yellow) mealworm larvae, as well as impacts of mycotoxins on insect growth and survival. General findings are: (1) mycotoxins have no or very low effects on insect growth and survival; (2) accumulation of mycotoxins was low in black soldier fly and lesser and yellow mealworm larvae; (3) mycotoxins are metabolized within the larvae to some extent. The degree of metabolization depends on the particular insect species and respective mycotoxin. Results of the studies performed so far provide valuable findings to use insects as a means to use commodities contaminated with mycotoxins in a valuable way. However, since full routes of metabolization are not known yet, care must be taken, and more research is needed.

Session 21

Theatre 13

Manure as a substrate for insect rearing: ecological progress or health risk?A. Anselmo^{1,2}, A. Cordonnier², L. Plasman², J. Maljean², C. Aerts², D. Evrard¹, A. Marien², E. Janssen², V. Ninane², S. Gofflot², P. Veys², M.-C. Lecrenier², V. Baeten² and D. Michez¹¹University of Mons, Research Institute for Biosciences, Laboratory of Zoology, Place du Parc 20, 7000 Mons, Belgium,²Walloon Agricultural Research Centre, Chaussée de Namur 24, 5030 Gembloux, Belgium; a.anselmo@cra.wallonie.be

Insect rearing represents a food and ecological issue that could help solve future challenges of human societies. Insects are known to be very rich in protein, very easy to produce and require minimal maintenance. These various advantages make them a serious alternative protein for food and feed. However, as the insect sector is not yet sufficiently developed, the price of insect meal is to high. To further develop the insect meal market, the European Union has authorised the use of 8 species in aquaculture since 2017 and, more recently, for pig and poultry feed. Insects are known for recycling organic waste and can transform a low-quality material into a very high protein product. Several studies have tested the use of organic waste substrates to raise insects intended for animal feed. This type of experimentation highlights the crucial issue of the health risk of using waste to produce feed for animals. To address this issue, *T. molitor* larvae were reared on a substrate adulterated with 5, 15 or 25% bovine manure. At the end of the experiment, these larvae were recovered, cleaned and ground to obtain a larval meal. The different insect meals were evaluated by multiple analyses. Firstly, microscopic analyses were carried out according to Annex 6 of Commission Regulation (EC) No 125/2009. Secondly, real-time PCR and proteomic analyses were conducted to check for the presence of ruminant DNA and proteins to assess the potential risk of BSE transmission. Thirdly, microbiological analyses focused on faecal indicator bacteria. Finally, protein and lipid analyses were performed to evaluate a possible modification of the insect nutritional value. The aim of this study was to get a comprehensive overview of the potential health risk associated with the use of organic waste and, if the results are encouraging, to consider circular production in the insect sector. The results of this study will be presented and discussed during the lecture.

Quality characteristics of black soldier fly produced by different substrates

A.R. Hosseindoust, S. Ha, J. Mun, H. Tajudeen, S. Park and J. Kim

Kangwon National University, Department of Animal Industry Convergence, Chuncheon, 24341, Korea, South; hosseindoust@kangwon.ac.kr

Insects as a source of livestock feed, such as the black soldier fly (BSF; *Hermetia illucens*), have high accumulations of essential nutrients, particularly protein and fatty acids. BSF is therefore regarded as a new option for sustainable agriculture and a source of animal feed. There were 3 treatments including tofu by-product, food waste, and vegetables. This study was conducted to assess the effectiveness of these botanical waste substrates for BSF growth, conversion efficiency, nutrient accumulation, and fatty acid profiles. Tofu by-product treatment showed the greatest weight at d 14 and the harvest period, compared with food waste and vegetable treatments. Moreover, BSF larval weight was greater in the food waste treatment compared with the vegetable treatment at d 14 and harvest. The larval length was increased in the food waste and tofu by-product treatments. Larvae yield result was greater in the vegetable treatment compared with the food waste. The content of DM and CP were increased in BSF fed with tofu by-product, and the EE content was greater in the food waste and tofu by-product treatments compared with the vegetable treatment. The bioconversion rate was higher in the tofu by-product treatment compared with the vegetable. The waste reduction rate was higher in the tofu by-product treatment compared with the food waste and vegetable treatments. Moreover, the waste reduction rate was higher in the food waste treatment compared with the vegetable. The protein conversion rate was the highest in the food waste treatment. Lipid conversion rate, protein yield, and lipid yield were greatest in the tofu by-product treatment. The content of lauric acid was increased in BSF fed tofu by-product compared with the food waste treatment. The concentration of C16:1 was the highest in the tofu by-product treatment. The content of oleic acid and α -linolenic acid were higher in BSF fed tofu by-product compared with the vegetable treatment. In conclusion, tofu by-product shows benefits of larvae growth and nutrient accumulation, which can improve larval quality for livestock feed ingredients.

Poster 15

The value of organic fertilizer from *Hermetia illucens* frass in the sustainable agriculture

S. Kaczmarek and K. Dudek

HiProMine S.A., Poznańska, 12F, 62-023 Robakowo, Poland; krzysztof.dudek@hipromine.com

With the challenges of climate change and the global environmental crisis, sustainable agriculture is becoming increasingly important. In this context, frass from the larvae of the fly *Hermetia illucens*, also known as 'black gold', is gaining importance as an organic fertilizer that can reduce the use of chemical fertilizers, improve soil quality and increase yields. Fertilizer made from *H. illucens*, insect frass, is a valuable source of nutrients for plants. Due to its origin, insect frass contains chitin in its composition, which provides additional application benefits – in addition to improving plant productivity, it can also result in induced plant resistance to abiotic stresses. Chitin can also improve plant resistance to pathogens and diseases. Thus, it can be used to promote crop and soil health on farms, thereby reducing the need for chemical crop protection products. Studies have shown that the use of frass improves soil structure and increases the content of nitrogen, phosphorus, potassium and other elements in the soil. In addition, the use of this fertilizer contributes to reducing greenhouse gas emissions and organic waste. There is also evidence that frass improves the physiological state of plants and their nutritional value, especially for crops under drought stress. Research indicates that the use of frass can contribute to the development of sustainable agriculture, as well as provide a valuable resource for agriculture by using it as a source of plant nutrients and improving soil structure. Insect frass-based organic fertilizer is a product that can be safely applied to all fields, gardens, parks and green spaces, nurseries, hobby gardens, greenhouses, orchards, or ornamental plants. This work was supported by an Szybka Ścieżka grant titled 'Development of a technology for the production of organic fertilizer (in the form of pellets/granules) based on the *H. illucens* frass and testing its impact on selected plants' (no. POIR.01.01.01-00-1503/19), which was financed by the Narodowe Centrum Badań i Rozwoju (Poland).

Effects of rearing substrates and processing methods on black soldier fly meal quality

S. Ha, A.R. Hosseindoust, Z. Khajehmiri, J. Mun, H. Tajudeen, S. Park and J. Kim

Kangwon National University, Department of Animal Industry Convergence, room 201, Animal Resources dep, (409), 24341, Korea, South; hosseindoust@kangwon.ac.kr

Insects as a source of livestock feed, such as the black soldier fly (BSF; *Hermetia illucens*), have high accumulations of essential nutrients, particularly protein and fatty acids. BSF is therefore regarded as a new option for sustainable agriculture and a source of animal feed. The study included six treatments, comprising three different substrates (tofu by-product (TF), food waste (FW), and vegetables (VEG)) and two drying methods (hot air (HA) and microwave (MW)). This study was conducted to assess the effectiveness of these botanical waste substrates for BSF growth, conversion efficiency, nutrient accumulation, and fatty acid profiles. The TF treatment showed a higher crude protein and gross energy content compared with the VEG. There was a tendency for higher ether extract in the FW compared with the VEG. The dry matter was higher in the MW but ether extract was higher in the HA treatment. The *in vitro* pepsin digestibility of BSF meal was the lowest in the VEG. Among processing methods, the *in vitro* pepsin digestibility of BSF was higher in the HA. The thiobarbituric acid reactive species analysis showed higher values in the TF and FW compared with the VEG. The thiobarbituric acid reactive species was decreased in the MW compared with the HA. The content of C12:0 in BSF meal in the TF was higher than in FW. The content of C16:1 was higher in the TF compared with the FW and VEG. The content of C18:1 in BSF meal in the TF was higher than VEG. In conclusion, tofu by-product and food waste show a high potential for larvae growth and nutrient accumulation, which can improve larval quality for livestock feed ingredients.

The use of insect meals for broiler feeds with a lower environmental footprintP. Chantzi^{1,2}, I. Giannenas², E. Bonos³, E. Antonopoulou⁴, C. Athanasiou⁵, A. Grigoriadou⁶, A. Tzora³ and I. Skoufos³¹Aristotle University of Thessaloniki, Department of Physical & Environmental Geography, Thessaloniki, 54124, Greece,²Aristotle University of Thessaloniki, School of Veterinary Medicine, Thessaloniki, 54124, Greece, ³University of Ioannina,Department of Agriculture, Arta, 47100, Greece, ⁴Aristotle University of Thessaloniki, Department of Biology, Thessaloniki,54124, Greece, ⁵University of Thessaly, Department of Agriculture, Plant Production and Rural Development, Volos, 38446,Greece, ⁶HAO-Demeter, Institute of Plant Breeding and Genetic Resources, Thessaloniki, 57001, Greece; ebonos@uoi.gr

Recent awareness has led to the transition to alternative sources of protein as feeds and foods. The use of insects in animal nutrition is possible environmentally-friendly approach as insects: (1) do not have a high demand of energy to maintain their body temperature; (2) have a high rate of food conversion into edible meal protein; (3) have great potential of reuse food waste; (4) have lower land use and water requirements than traditional systems. There are different models to study the environmental footprint of insect use such as the Life Cycle Assessment (LCA) of carbon footprint estimation. This initial study evaluated whether the environmental footprint of insect meal production for feed use in broiler systems was improved compared the production of common feeds such as soybean meal. Also, a short literature review on GWP values of broiler, insect, and soybean meal production based on previous LCA studies was conducted to create a dataset for further analysis. LCA results were presented as kg CO₂-eq per kg protein and the FU was nutrient based. The first step was to estimate the GWP of feed ingredients. The mean ratio of soya meal in the basal diet was about 30% and the insect replacement was about 5-10%. The FCR factor was about 1.67. Preliminary data analysis provided a wide range of GWP values without clear evidence yet that GWP of insect protein in broiler systems could result in a reduced environmental footprint. Acknowledgments: Research was co-financed by Greece and EU in context 'Research–Create–Innovate' within the Operational Program Competitiveness, Entrepreneurship and Innovation of the NSRF 2014-2020, Project Code: T2EAK-02356. Acronym: InsectFeedAroma.

Diet mediated PUFA accumulation and $\omega 6/\omega 3$ ratio improvement in mealworm larvae (*Tenebrio molitor*)

S. Yoon, C. Ricciardi, C. Oundjian, M. Leheup, T. Lefebvre and F. Peyrichou

Ynsect, 1, rue Pierre Fontaine – Genopole Campus 3 – Batiment 2, 91000 Evry Courcouronnes, France; carmelo.ricciardi@ynsect.com

Edible insects being recognized as a promising alternative ingredient for both animal and human consumption, being able to adjust the final composition of insects through their nutrition may open new products and markets opportunities. As one of the current challenge in human nutrition is the supply of polyunsaturated fatty acids (PUFA), the aim of this study is to optimize the $\omega 6/\omega 3$ ratio of Yellow Mealworm by substituting fixed percentages (5% or 10%) of the standard production diet with oilseeds: chia seeds, flax seeds, rape seeds, soybean, hemp seeds. 9 diets were formulated and tested for 25 days during the exponential growth phase of the larvae until harvest. The results showed that there is a positive correlation between the nutritional composition of the diets and the body composition of larvae, without negatively impacting the survival, growth rate and feed conversion ratio. The PUFA content of the larvae was positively correlated to the PUFA content of the diets. Larvae fed with the standard diet had a $\omega 6/\omega 3$ ratio of 19.07. Chia and flax seeds had the best $\omega 6/\omega 3$ (0.33 and 0.26) among oilseeds. Larvae fed with the diet substituted by 5 and 10% of chia seeds obtained a omega 6 to 3 ratio of 1.4 and 0.9 respectively, approaching the 1:1 ratio, beneficial to human health. By 5 and 10% flaxseed substitution, larvae obtained ratio of 1.6 and 1.0. In addition, rearing performance was positively improved by the addition of those two seeds, compared to the standard diet. It would therefore seem that it is possible to modulate the fatty acid profile of the larvae by accordingly formulate the diets, while improving the production system.

Session 21

Poster 19

Agro-industry by-products for *Tenebrio molitor* rearing to generate a new aquaculture feed ingredientI. Vieira¹, D. Murta² and M.V. Santos¹¹Thunder Foods, Santarém, 2005-332, Portugal, ²EntoGreen, Santarém, 2005-079, Portugal; marisa.santos@thunderfoods.pt

The progressive increase in world population and animal protein consumption is propelling the growth of animal food production and consequently, the production of compound feeds. For aquaculture, feed formulations, composed of fishmeal, fish oil, soybean and various types of seeds and grains, represent around 60-70% of the production costs and present several sustainability challenges. This situation boosts the search for sustainable alternatives to conventional nutritional sources, essential to support the growth of aquaculture sector. Insects are a possibility, being suitable for large scale production, with positive environmental impact, high feed conversion efficiency and functional properties. Research on this field has recently demonstrated that insect larvae can improve the health of animals, which makes them a promising ingredient for dietary supplementation, with potential to replace the conventional proteins. Within the insect species, *Tenebrio molitor* usually produced using dry grain flours, presents high nutritional quality. The use of other agri-food by-products in insect production could contribute to develop a circular economy approach, encompassing production, consumption and by-products management, which could lead to the development of a secondary market for new raw materials. To test this approach, different agro-industrial by-products, such as olive pomace and beer bagasse, were tested with levels of incorporation varying from 50 to 100%. Positive results were obtained for both by-products used, with surprising production parameters observed for 50 and 60% olive pomace, in the preliminary assays. Considering the water content above 80% in olive pomace and that *T. molitor* is highly impacted by moisture conditions, these results are very promising. The best conditions are being scaled-up to an industrial production environment, to assess the viability of using these agro-industrial by-products for the production of new protein feed ingredients for aquaculture. Acknowledgments: The InFishMix project (PT-INNOVATION-0094) is funded by Iceland, Liechtenstein and Norway through the EEA and Norway grants.

Transfer of veterinary drug residues from substrate to black soldier fly larvae and frass

K.C.W. Van Dongen, E. De Lange, L. Van Asseldonk and H.J. Van Der Fels-Klerx

Wageningen Food Safety Research, Akkermaalsbos 2, 6708 WB Wageningen, the Netherlands; katja.vandongen@wur.nl

Insect production for food or feed is increasing in Europe, and is expected to further increase in the near future. To evaluate food and feed safety aspects, quantitative information on transfer of possible contaminants from substrates to larvae is needed, especially when low quality organic substrates or residual streams (e.g. manure) are (to be) applied as substrate to contribute to a more sustainable food system. Veterinary drugs applied to e.g. chicken and pigs, which are regularly detected in manure, were included in this study and evaluated for their transfer to black soldier fly larvae (*Hermetia illucens*). These included three different antibiotics (enrofloxacin, oxytetracycline, sulfamethoxazole), three coccidiostats (narasin, salinomycin, toltrazuril) and one antiparasitic drug (eprinomectin). The veterinary drugs were spiked to the substrate in final concentrations ranging from 0.5 and 5 mg/kg or 5 and 50 mg/kg (depending on the particular drug residue). Black soldier fly larvae were reared for one week on the spiked substrates and the transfer of the veterinary drugs to the respective larvae and frass was quantified using LC-MS/MS. Transfer of the spiked veterinary drugs to the larvae, relative to the spiked amount, was on average 9.5% for narasin, 3.9% for salinomycin, 4.2% for toltrazuril, 12% for enrofloxacin, 19.2% for oxytetracycline, 0.2% for sulfamethoxazole and 8.1% for eprinomectin. Quantified concentrations were compared to the most relevant and available maximum residue limit (MRL). Mass-balance calculations showed that the larvae seem to metabolize the spiked veterinary drugs at least to some extent. As compared to the control, exposure to eprinomectin affected the growth of the larvae significantly, while other veterinary drugs did not affect larvae growth. In conclusion, differences in the transfer of the tested veterinary drugs were observed and their presence in substrates used for insect rearing requires evaluation for feed or food safety purposes as well as for insect growth.

Drinking heated water improves the growth performance and rumen microbiota of beef cattle in winter

T. He, S. Long, X. Wang, T. Liu and Z. Chen

China Agricultural University, College of Animal Science and Technology, No. 2, Yuanmingyuan West Road, Haidian District, Beijing, 100194, Beijing, China, P.R.; hetengfei@cau.edu.cn

Drinking heated water is essential for resisting cold stimulation and improving the growth performance of beef cattle in winter. The effects of drinking different water temperature on growth performance, serum stress hormones, rumen microbiota, and nutrient digestibility of fattening beef cattle was conducted in winter. Fifty Simmental fattening bulls with an average ($\pm$ SD) body weight of 647 ± 7.25 kg were randomly assigned according to body weight to five drinking water temperature treatments: 4.39 ± 2.54 , 10.6 ± 1.29 , 18.6 ± 1.52 , 26.3 ± 1.74 and 32.5 ± 1.28 °C. The trial lasted for 60 days with an average environmental temperature of 5.65 ± 3.68 °C. Results showed that increasing drinking water temperature linearly and quadratically increased the average daily gain (ADG) and apparent digestibility of neutral detergent fibre (NDF) ($P < 0.01$). A quadratic linear-parabolic model revealed that the maximum ADG of 1.23 kg/d ($R^2 = 0.84$) was obtained at a drinking water temperature of 29.0 °C. The 26.3 ± 1.74 °C group significantly reduced ($P < 0.05$) serum cortisol, insulin, and creatinine concentration, enhanced ($P < 0.05$) the mRNA expression levels of ZO-1, Occludin, and Claudin-4 in the rumen epithelium, and increased ($P < 0.05$) the concentrations of propionate and total volatile fatty acids, as well as the relative abundances of phylum Bacteroidetes and genus *Prevotella*, whereas decreased ($P < 0.05$) the relative abundances of genus *Streptococcus* in the rumen fluid compared to the 4.39 ± 2.54 °C group. In addition, the net meat rate tended to increase ($P = 0.07$) and the drip loss of longissimus dorsi muscle tended to decrease ($P = 0.09$) in the 26.3 ± 1.74 °C group compared to the 4.39 ± 2.54 °C group. Therefore, using heated drinking water at an appropriate temperature (29 °C) in winter is recommended to improve the rumen microbiota composition and function, increase NDF digestibility, and enhance the anti-cold stress ability and growth performance of fattening beef cattle.

Elevated temperature induces transcriptional and epigenetic changes in the lungs of chickensD. Schokker¹, J. De Vos², P.B. Stege¹, O. Madsen², H.J. Wijnen³, S.K. Kar⁴ and J.M.J. Rebel¹¹Wageningen Bioveterinary Research, Houtribweg 39, 8221 RA Lelystad, the Netherlands, ²Wageningen University, Droevendaalsesteeg 4, 6708 PB Wageningen, the Netherlands, ³HatchTech, Innovatielaan 3, 6745 XW De Klomp, the Netherlands, ⁴Wageningen Livestock Research, De Elst 1, 6708 WD Wageningen, the Netherlands; dirkjan.schokker@wur.nl

Health and resilience against respiratory diseases are important features for broiler chicken. In this study, epigenetic and transcriptomic changes in the lungs of broiler chickens of different ages during rearing that were either exposed to elevated egg shell temperature (HIGH) of 38.9 °C during mid-incubation or normal egg shell temperature (control; CON). The objective was to better understand how environmental challenges, such as heat stress during egg incubation, affect the development of the immune system and health of broiler chicken at later age. To this end we generated both epigenetic and transcriptomic data of lung tissue of elevated HIGH and CON chicken, furthermore these chicken were challenged by introducing either an infectious *E. coli* or an IBV vaccination to monitor the respiratory response. Thousands of differential methylated sites were observed at days 15 and 33, when comparing HIGH vs CON. Pathway enrichment analysis of HIGH vs CON showed that differentially expressed genes were mainly involved in cilium, cytoskeleton, and immune processes. These findings provide insight into the underlying biological mechanisms of early life conditions, like elevated EST, and their potential role in health of broilers.

Session 22

Theatre 3

Supplementing heat stressed cows with plant extract affects performance welfare and oxidative stressJ.R. Daddam¹, D. Daniel², I. Pelech³, G. Kra^{1,2}, H. Kamer¹, U. Moallem¹, Y. Lavon⁴ and M. Zachut¹¹Volcani Institute, Ruminant Science, Rishon LeZion, 7528809, Israel, ²the Robert H. Smith Faculty of Agriculture, Food and Environment, the Hebrew University, Rehovot, 76100001, Israel, ³Extension Service, Ministry of Agriculture, Rishon LeZion, 7528809, Israel, ⁴Israeli Cattle Board Association, Caesarea, 38900, Israel; mayak@volcani.agri.gov.il

We examined the effects of a supplement comprised of plant polyphenols extracts of green tea, capsicum and fenugreek, and electrolytes [(Na⁺, K⁺), AXT; Axion ThermoPlus, CCPA, France] during summer heat load on production, welfare, and on oxidative stress proteins in adipose tissue (AT) of dairy cows. Forty-two multiparous mid-lactation cows were divided into 3 groups during summer, and were fed for 2 wks either a standard milking cows' diet (CTL, n=14), or supplemented with 100 g/d of AXT (100AXT, n=14), or 150 g/d of AXT (150AXT, n=14), while being cooled 5 times a day; then, half of the cows from each treatment were cooled (CL) or not cooled (NCL) for 2 wks, after which the CL/NCL were switched for additional 2 wks. Cows were milked 3 times a day and milk composition was analysed at the end of each period. Vaginal temperature (VT) was measured by sensors in each period. Biopsies of subcutaneous AT were taken from 10 NCL (five CTL and five 150AXT) at the end of the period, and examined by proteomics analysis. Data were analysed with PROC MIXED of SAS; the model included the effects of treatment, cooling, and interactions. Proteomics was analysed by t-test. Milk and 4% FCM were higher in 100AXT than in CTL. DMI was higher in 100AXT than in CTL. The effect of cooling was significant for DMI, FCM 4% and Milk/DMI. The percentage of hours that VT was >39 °C was lower in 100AXT and 150AXT than in CTL. Daily rumination time was higher in 150AXT vs CTL, and lying time was increased in 100AXT and 150AXT vs CTL. Proteomics demonstrated increased abundances of peroxidase, microsomal-glutathione-S-transferase-2 and heme-oxygenase-1 in 150AXT vs CTL; the Nrf2-mediated oxidative stress response was enriched in 150AXT. AXT during heat load increased DMI and production, lowered VT, improved welfare indices, and affected the Nrf2-oxidative stress response.

Immunomodulatory effect of exosomes from the plasma of heat-stressed cows on bovine monocytes

L.G. De Matos¹, S. Dimauro¹, M. Falco¹, J.F.S. Filipe¹, C. Zamboni¹, F. Cecilian¹, V. Martini¹, A. Agazzi¹, A. Scarafoni², G.C. Heinzl², G. Sala¹, A. Boccardo¹, A. Maggolino³, P. Depalo³ and C. Lecchi¹

¹Università degli Studi di Milano, Department of Veterinary Medicine and Animal Science, Via dell'Università, 6, 26900 Lodi, Italy, ²Università degli Studi di Milano, Department of Food, Environmental and Nutritional Sciences, via Celoria 2, 20133 Milan, Italy, ³Università degli Studi di Bari A. Moro, Department of Veterinary Medicine, SP per Casamassima, km 3, 70010, Valenzano, Italy; luiz.dematos@unimi.it

The impact of climate change is expected to negatively affect human and animal health. From the one health point of view, hyperthermia induces impairment of immune cell functions, increasing the risk of infection, morbidity, and mortality, and represents one of the main issues in the livestock industry. Exosomes are nano-sized extracellular vesicles (30-150 nm) involved in cell-to-cell communication, and regulation of immune response and found in many biological fluids, delivering several molecules released into target cells, including immune cells, inducing a change in cellular response. This study aimed to assess the immunomodulatory effects of plasma exosomes purified from cows exposed to thermal comfort conditions (TC, THI<68) and after a natural four-day (heatwave hyperthermia, HS, THI_{max}=84, THI_{min}=69) on bovine monocytes (CD14⁺). Exosomes were isolated from the blood of three healthy multiparous Holstein cows during TC and HS. Monocytes (CD14⁺) were isolated from the blood of 6 clinically healthy multiparous Holstein cows during TC, sorted by Magnetic Activated Cell Sorting (MACS), and cocultured with exosomes (200 exosomes/cell) for 20 h at 37 °C and 5% CO₂. To test the influence of exosomes on the immune activity of bovine monocytes, viability, apoptosis, phagocytosis, and chemotaxis assays were performed. Results demonstrated that the phagocytosis ability significantly decreased ($P=0.008$) in monocytes cultured with HS- compared to TC-exosomes, while exosomes did not affect viability, apoptosis, and chemotaxis of bovine CD14⁺ monocytes. In conclusion, the exosomes released into the bloodstream during HS significantly impaired monocytes' phagocytosis, exposing cows to a greater risk of developing infections.

Late gestation heat stress: programming effects on three generations

J. Laporta

University of Wisconsin, Department of Animal and Dairy Sciences, 1675 Observatory Dr, 53706, USA; jlaporta@wisc.edu

In dairy cows, the dry period is a 6 to 8-week non-lactating phase between two subsequent lactations intended to regenerate mammary epithelial senescent cells with new ones for the next lactation. The dry period also overlaps with a portion of the last trimester of gestation, a period of exponential foetal growth. Exposure to environmental elevated temperature and humidity leading to heat stress during this period can impact three generations: (1) the dam (F0); (2) the developing daughter (F1), and (3) her germline (future F2). We have previously shown that dry-period heat stress disrupts the highly coordinated cellular processes during mammary gland involution and redevelopment phases (i.e. cellular turnover) and derails the expression of critical genes and pathways (i.e. ductal branching morphogenesis and cell death), resulting in lower milk production during the dam's subsequent lactation. Intrauterine hyperthermia also affects offspring growth, physiology, and performance into adulthood. Experiencing intrauterine hyperthermia for several consecutive weeks affects many tissues, cells, and entire organ systems vital for productivity and maintaining physiological functions. This presentation will highlight the phenotypical, histological, and molecular adaptations of the daughter's mammary gland to in-utero heat stress. We will also discuss the impact of in-utero heat stress on other tissues and organs, including the adrenal glands and the ovaries. Last, carry-over effects on the granddaughters' survival and milk production will be presented. This presentation will provide insights into the molecular underpinnings of disrupted organ structure and function arising from prior exposure to heat stress, leading to lower milk yields for at least three generations.

Temporal patterns of environmental heat stress in Holstein heifers: association with age at calvingV. Tsiamadis¹, G.E. Valergakis¹, A. Soufleri¹, G. Arsenos¹, G. Banos^{1,2} and X. Karamanlis³¹Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Laboratory of Animal Husbandry, Box 393, 54124, Thessaloniki, Greece, ²Scotland's Rural College, Roslin Institute Building, University of Edinburgh, Easter Bush Campus, EH25 9RG Midlothian, United Kingdom, ³Faculty of Veterinary Medicine, Aristotle University of Thessaloniki, Laboratory of Ecology and Environmental Protection, Box 393, 54124, Thessaloniki, Greece; asoufler@vet.auth.gr

A retrospective study was conducted to evaluate temporal patterns of environmental heat stress (EHS) during in-uterus (IUD) and 3-month post-natal (PN) period of dairy heifers as well as to estimate their association with age at first calving (AFC). Data from 30 dairy herds in Northern Greece including 9,098 heifers were extracted from National Cattle Database. Moreover, 230,100 farm-specific daily temperature and relative humidity records, were obtained from ERA5-Land during 2005-2019. Average monthly THIs were calculated and matched for each heifer to their IUD and PN (IUDM and PN, respectively). They were categorized as: low ≤ 68 and high > 68 , and then entered in Hierarchical and Two-Step Cluster Analysis as predictors to allocate heifers to THI clusters. The association of clusters with AFC (in days) was assessed with linear regression (LR) analysis. The model included the fixed effects of herd, age of dam at conception (4 levels, age quartile 1: 292-537, 2: 537-880, 3: 881-1,375 and 4: $\geq 1,376$ days), the THI cluster category of each heifer, and adjusted for the year of heifers' conception (16 levels: 2005-2019). The association of clusters with the risk of $\text{AFC} > 787$ d (AFC median) was assessed with binary LR (logit function). Analyses were performed with SPSS 25.0. Eight clusters (HSC-1 to -8) were identified. Compared to HSC-8 (8th-9th IUDM and 1st PNM), heifers of HSC-2 (2nd IUDM and 2nd-3rd PNM), HSC-3 (2nd-3rd IUDM and 3rd PNM), HSC-4 (2nd-5th IUNM), HSC-5 (4th-7th IUDM) and HSC-6 (6th-8th IUDM) calved 14.5, 8.4, 6.4, 13.8, and 17.8 days later, respectively ($P < 0.01$ - 0.001). Furthermore, heifers of HSC-5 and HSC-6 had 1.15 ($P < 0.01$) and 1.34 ($P < 0.001$) higher risk of an $\text{AFC} > 787$ d compared to HSC-8, respectively. Heifers' exposure to THIs > 68 during IUD and PN was associated with higher AFC.

Session 22

Theatre 7

Effect of stocking density on heat stress in fattening pigsL. De Prekel¹, D. Maes¹, A. Van Den Broeke² and M. Aluwé²¹University Ghent, Unit of Porcine Health Management, Salisburylaan 133, 9820 Merelbeke, Belgium, ²ILVO, Scheldeweg 68, 9090 Melle, Belgium; lotte.deprekel@ugent.be

Lower stocking densities (SD) may protect fattening pigs from the adverse effects of heat stress (HS) through improved radiant and convective heat losses due to the ability to avoid direct contact with pen mates and greater body-to-floor contact. In the present study, we investigated whether a reduced SD can decrease the effects of HS in fattening pigs during higher heat loads. One hundred and fifty fattening pigs (crossbred Piétrain sire $\times$ hybrid sow) were randomly divided into three treatment groups: MIN (minimal SD of 1.3 m²/pig, n=12 pens), MED (medium SD of 1.0 m²/pig, n=11 pens) and MAX (maximum SD of 0.8 m²/pig, n=6 pens). All pens had partially slatted floors with a total pen surface of 4.88 m², corresponding with 4, 5 and 6 fattening pigs in the MIN, MED and MAX pens, respectively. An artificial heat wave was induced for seven days when the pigs were 21 weeks of age. In the week before (pre-heat), during (heat) and after the heat wave (post-heat), respiration rate (RR) and rectal temperature (T_{rectal}) were observed on four observation moments per period. Individual animal weight and feed intake per pen were measured weekly, to calculate average daily gain (ADG) and feed intake (ADFI). During the heat wave, the average temperature-humidity index was > 75.6 , corresponding with a mild heat wave and a warning for HS. There was no effect of the interaction of SD and period or effect of SD on RR or T_{rectal} . However, independent of SD, RR significantly increased with ± 20 bpm and T_{rectal} with 0.1 °C during the heat period ($P < 0.001$). A significant difference in ADG between the SD was found ($P = 0.035$), regardless of period. The ADG of the MIN group was 9% higher than the MED group, possibly due to decreased stress levels as ADFI did not differ between SD. There was no significant SD or SD and period interaction on ADG and ADFI, but ADFI decreased with 15% ($P < 0.001$) and ADG with 19% ($P < 0.001$) in all groups during the heat period. In conclusion, a lower SD (1.3 m²/pig) positively affected ADG but did not ameliorate the adverse effects of HS on physiological and performance parameters.

Chromium yeast alleviates heat stress in Holstein mid-lactation dairy cows

F. Ma, Y. Wo, Q. Shan and P. Sun

Institute of Animal Science, Chinese Academy of Agricultural Sciences, No. 2 Yuanmingyuan West Road, Haidian District, 100193, Beijing, China, P.R.; sunpeng02@caas.cn

Two experiments were conducted to identify the optimal dose of CY in the diet and the metabolic mechanisms whereby CY supplementation alleviates the negative effects of heat stress in mid-lactation dairy cows. Cows were experiencing heat stress as the average temperature-humidity index (THI) was greater than 72 in both experiments. In Experiment 1, twenty-four healthy Chinese Holstein mid-lactation dairy cows receiving the same basal diet containing 0.11 mg Cr/kg of DM were divided into 2 blocks according to milk yield (block 1 and block 2 for low- and high-producing cows). Cows of block 1 or block 2 each were randomly allocated to four treatments: a negative control group (without CY supplementation, CON), and groups that received CY at 0.18, 0.36, and 0.54 mg Cr/kg DM, respectively. The experiment lasted 10 wk, including a pre-feeding period of 2 wk. CY supplementation reduced rectal temperature (RT) and respiration rates (RR), and increased dry matter intake and milk lactose content ($P < 0.05$). Supplementation with CY improved the antioxidant and immune function ($P < 0.05$). The appropriate dose of CY at 0.36 mg Cr/kg DM is recommended. In Experiment 2, twelve Holstein dairy cows were fed the same basal diet containing 0.09 mg of Cr/kg DM. They were allocated randomly to 2 groups: a control group (CON, without CY supplementation) and a CY group (CY, administered 0.36 mg Cr/kg DM). The experiment was performed over 8 weeks. CY supplementation reduced RT, and increased the lactation performance of the heat-stressed dairy cows ($P < 0.05$). Supplementation with CY increased the serum glucose and thyroxine concentrations, but reduced the urea nitrogen, insulin, and triiodothyronine concentrations on d 56 ($P < 0.05$). Specifically, plasma concentration of nicotinamide was higher after CY supplementation ($P < 0.05$). In conclusion, CY supplementation reduces RT, influences metabolism by reducing serum insulin concentration and increasing serum glucose and plasma nicotinamide concentrations, and finally increases lactation performance of heat-stressed dairy cows.

Theatre 9

May anti-oxidants reduce glyphosate-based herbicides adverse effects on chicken embryo-development?

M. Fréville, A. Estienne, C. Ramé, C. Rat, J. Delaveau, P. Froment and J. Dupont

INRAe (Institut national de recherche pour l'agriculture, l'alimentation et l'environnement), UMR PRC, 37380 Nouzilly, France; freville.mathias1@gmail.com

Glyphosate is an active molecule massively used in agriculture worldwide for its herbicide properties. Numerous studies have shown that glyphosate-based herbicides (GBH) exposure can adversely affect metabolism and fertility on animal models. In avian species, our previous works have demonstrated that chronic dietary GBH exposure disturbed hens caecal microbiome, and increased the gizzard weight of animals. These effects were associated with an increase in plasma oxidative stress. GBH exposure also dramatically increased the early and late embryo mortality. The aim of the present study was to further investigate the effects of a GBH exposure on chicken embryonic development. We injected or not (non injected) growing doses of GBH (i.e. 0.03 ng/g; 0.3 ng/g; 3 ng/g and 30 ng/g of glyphosate equivalent) or PBS (control) in E13 (i.e. on their 13th day of development) eggs and weighted the organs of the subsequent E17 embryos. Surprisingly, the hearts of the embryos exposed to the weakest dose (0.03 ng of glyphosate equivalent/g egg) were significantly heavier as compared to the other embryos (i.e. all other doses and controls). By using CAM (chorioallantoic membrane) assay, we also observed that the weakest dose of GBH (0.03 ng of glyphosate equivalent /g egg) reduced significantly the neovascularization in E10 eggs. We then performed primary exposed primary cardiac fibroblasts and Gizzard Smooth Muscle Cells cultures from chicken embryos and exposed them to GBH concentrations ranging from 0.03 to 30 ng of glyphosate equivalent/g egg. We observed that the highest dose (30 ng of glyphosate equivalent/g egg) significantly reduced the cell viability and proliferation of gizzard and heart primary cells. We are now investigating the effect of tocopherol or anti-oxidant grape seed extracts on the potential reversibility or attenuation of the negative effect of GBH on the chicken embryo development.

Bromide as a thyroid hormone disruptor

H.L. Lucht and N.H. Casey

University of Pretoria, Animal Science, Private Bag X20, 0028, Hatfield, South Africa; norman.casey@up.ac.za

Literature, which included historical and current research to provide an overview of baseline knowledge and what has since been reported, focused on the potential action of inorganic bromide (Br-) as an endocrine disrupting chemical (EDC). Many substances have been assigned a no observed adverse effect level (NOAEL) but there was none scientifically established for bromide (Br-) until the suggested NOAEL of 0.01 mg/l was validated in 2019. Br- with a concentration even mildly above the (NOAEL) has the potential to be a TDC by interfering most notably with TH and consequent metabolic processes. Evidence suggests that Br- functions as a TDC that can have an effect even at low concentrations with chronic exposure. Once ingested, Br- moves easily through the body water spaces in the body by means of passive and active transport using chloride (Cl-) channels. The hypothalamus-pituitary-thyroid (HPT) axis regulates TH production by means of a negative feedback loop, and energy homeostasis, growth and development depend on TH. Disruption of TH synthesis by Br- interference would potentially disrupt the negative feedback loop causing compensation mechanisms by the thyroid gland, leading to thyroid hypertrophy to mitigate the resultant hypothyroidism. Toxicity is not a sudden effect unless a critical concentration of a highly metabolically disruptive substance appears suddenly in the body. As the concentration in the body increases through further ingestion, the particular susceptible metabolic pathway becomes more exposed and offers more bonding opportunities until a threshold concentration becomes overwhelming and disrupts the metabolic pathway. The hypothesis is that Br- disrupts the deiodination process within the body and prevents the conversion of inactive T4 to the active form, T3. Br- can be considered to be a TDC when outcompeting I- and hampering T4 production in the thyroid gland, decreasing T3 levels in the body and thus disrupting the regulation of TH production in the HPT axis. The synthesis of iodinated thyronines diminishes as Br concentration rises. The implication for livestock production is that the compromised metabolic functioning of the animal will negatively affect milk production, egg production, and protein accretion of animals raised for meat.

Session 22

Theatre 11

The impact of THI on milk characteristics, productivity, and metabolism in lactating dairy cows

G. Meli, V. Fumo, G. Savoini and G. Invernizzi

Università degli studi di Milano, DIVAS, Via dell'Università 6, 26900, Italy; giovanna.meli@unimi.it

The aim of the study was to evaluate the impact of temperature humidity index (THI) on metabolic biomarkers, milk production and milk characteristics in lactating dairy cows. Ten mid lactation (139±40 DIM; average milk production 28.33±5.43 kg/day) primiparous and pluriparous Holstein dairy cows were selected and were housed in a free-stall barn at the Experimental Zootechnical Centre of the Università degli Studi di Milano, in Lodi, Italy. All the experimental animals were fed the same basal diet as total mixed ration. The trial started in May 2019 and lasted for 4 weeks. Temperature and humidity values were continuously recorded and a daily THI was calculated. The threshold for heat stress was considered when THI was above 68: no heat stress (NHS) = THI < 68 vs heat stress (HS) = THI > 68. Blood samples were collected at day 0 and 28 and milk samples every two weeks. Milk yield was recorded weekly and feed intake was recorded daily. Collected data were analysed by mixed procedure of SAS. Heat stress significantly ($P < 0.05$) decreased dry matter intake (DMI; HS = 21.15±1.33 vs NHS = 23.27±1.31 kg/day), milk yield (HS = 25.54±2.15 vs NHS 28.86±2.15 kg/day), protein yield (HS = 0.87±0.07 vs NHS = 1.0±0.07 kg/day) and lactose content (HS = 5.03±0.04 vs NHS 5.1±0.04 g/100 ml). Long chain fatty acids increased significantly (HS = 27.61±0.84 vs NHS = 25.36±0.84 g/100 ml; $P < 0.05$) and medium chain fatty acids tended to increase ($0.05 < P < 0.1$). Plasma glucose decreased significantly (HS = 3.63±0.09 vs NHS = 3.91±0.09; $P < 0.05$). DMI reduction could have affected blood glucose concentration and subsequent conversion to lactose in the mammary gland. In conclusion, heat stress negatively impacted DMI, milk yield, milk characteristics and caused several physiological changes in lactating animals. Acknowledgments This study was carried out within the Agritech National Research Center and received funding from the European Union Next-GenerationEU (Piano Nazionale di Ripresa e Resilienza (Pnrr) – Missione 4 Componente 2, INVESTIMENTO 1.4 – D.D. 1032 17/06/2022, CN00000022). This manuscript reflects only the authors' views and opinions, neither the European Union nor the European Commission can be considered responsible for them.

A selected phytogetic solution improves performance and thermal tolerance of heat stressed pigsA. Morales¹, P. Sakkas², M. Soto¹, N. Arce¹, N. Quilichini² and M. Cervantes¹¹ICA, Universidad Autónoma de Baja California, 21100 Mexicali, Mexico, ²DELTAVIT, CCPA Group, Z.A. du Bois de Teillac, 35150 Janzé, France; nquilichini@ccpa.com

Pig exposure to high ambient temperature (AT) penalises their performance. Dietary supplementation with phytogetic solutions containing specific plant secondary metabolites, may lower body temperature (BT) and increase the upper critical temperature threshold level, thus improving thermal tolerance. Herein, we investigated the effects of offering a phytogetic solution based on selected and characterized plant extracts including *Capsicum* spp. (PHY; 0.2%) on performance and thermal tolerance of heat-stressed (HS) pigs. Forty-two individually housed pigs (BW 27±3 kg) were randomly allotted to three treatments: TN-C, thermoneutral (TN, 22±2 °C) pigs fed a control diet based on wheat and soybean meal; HS-C and HS-PHY, pigs housed under HS conditions (29-36 °C) fed control diet without or with PHY, respectively. Following 8 days of adaptation, all pigs were fed *ad libitum* for 8 days (twice daily, 07:00 and 19:00). Thermographs were implanted subcutaneously in five pigs per treatment to record BT every 5 min. Respiration rates were assessed in the morning (07:00) and in the afternoon (17:00). Performance, respiration rates and average BT following morning and evening feedings were analysed using the Statistix software. The TN-C pigs had increased ADG and ADFI in comparison with HS-C ($P<0.01$) and HS-PHY pigs ($P<0.05$), and reduced FCR in comparison to HS-C pigs ($P<0.01$). However, HS-PHY pigs had greater ADFI ($P<0.01$), ADG ($P<0.05$) and tended to have improved FCR than HS-C pigs ($P=0.07$). Respiration rates were higher for HS pigs than TN-C during the afternoon ($P<0.01$), when AT was higher, while additive supplementation had no effect. Higher BT was observed in HS pigs compared to TN pigs ($P<0.01$), while the BT increment observed after the evening meal (from 20:00 to 03:00 next day) in HS-PHY pigs was smaller than that of HS-C pigs ($P<0.05$). In conclusion, dietary phytogetic supplementation partially alleviated the adverse effects of HS on pig performance and reduced BT after the afternoon feeding. Further research should reveal whether observed effects of dietary PHY supplementation are associated with improved intestinal health.

Effects of Met, Lys and His supplementation on the metabolic response to heat stress in dairy cowsÁ. Kenéz¹, E. Jorge-Smeding^{1,2}, Y.H. Leung¹, A. Ruiz-González^{3,4} and D.E. Rico³¹City University of Hong Kong, Department of Infectious Diseases and Public Health, Hong Kong, China, P.R., ²Universidad de la República, DPAP, FAGRO, Montevideo, Uruguay, ³Université Laval, Quebec, QC, Canada, ⁴Centre de Recherche en Sciences Animales de Deschambault, Deschambault, QC, Canada; akos.kenez@cityu.edu.hk

Low-protein diets were shown to decrease heat production, thus providing a potential avenue to alleviate metabolic effects triggered by heat stress (HS). However, Met, Lys and His must be supplemented according to requirements as they are the common limiting AA. Twelve lactating Holstein cows (primiparous, P, n=6; multiparous, M, n=6; 83±28 DIM) were enrolled in a Latin square design with 14-days treatment periods: Heat stress (HS; maximal THI 84; 17% crude protein (CP); 1,715 metabolizable protein (MP), 107 Lys, 34 Met, and 37 His (g/d)); pair feeding in thermoneutrality (TN; maximal THI 64; CP, MP and AAs supply equal to HS); and HS with a balanced AA diet (HS+AA; maximal THI 84; 17% CP, 1,730 g/d MP, 178 Lys, 64 Met, and 43 His (g/d)). Blood plasma was sampled on the last day of each period and analysed with the AbsoluteIDQ p400 metabolomics assay (Biocrates, Innsbruck, Austria). ANOVA was used to evaluate the treatment (TN, HS, HS+AA), parity (P, M) and their interaction as fixed effects, and the cow as random effect. *P*-values were adjusted by false discovery rate (FDR) correction. A total of 15 plasma metabolites differed (FDR≤0.048) between treatments but no metabolite was affected by the interaction between treatment and parity. Several of them increased in HS+AA compared with TN and HS (including α -amino adipic acid, Met, Lys, Val, Phe, Trp and sarcosine). Further, some lipid compounds had lower concentrations in HS than in TN but intermediate concentrations in HS+AA (including phosphatidylcholine (PC) 40:7, PC 40:9, PC-O 34:1, PC-O 40:6, and diglyceride (DG) 39:0). Our results suggest that a relatively greater availability of Met in HS+AA stimulated PC synthesis, recovering it to similar levels to TN. Increased Lys availability in HS+AA likely led to increased oxidation of Lys and to lower catabolism of other essential AA (such as Val, Phe, Trp). The potential signalling function of the affected lipids will be further investigated.

Evaluation of earwax and hair cortisol level in relation to environmental stressors in Hanwoo cattle*M. Ataallahi, G.W. Park, E. Nugrahaeningtyas, M. Dehghani, J.S. Lee and K.H. Park**Kangwon National University, College of Animal Life Sciences, Chuncheon, Gangwon, Republic of Korea, 24341, Korea, South; ataallahim@kangwon.ac.kr*

Recently, global warming issues in the cattle industry received more attention. The severity of heat stress on cattle can be evaluated through the measurement of cortisol secretion. In this study earwax cortisol concentration (ECC) and hair cortisol concentration (HCC) of native Korean cattle (Hanwoo) were compared to evaluate their usefulness in reflecting the chronic stress from environmental temperature and humidity. Earwax samples (n=70) were collected from the left ear and hair samples (n=70) were collected from the forehead of each cattle with an age ranging from 1 to 72 months in the livestock research farm at the Kangwon National University from April to July 2022. Temperature-humidity index was calculated based on microclimate data from the Korea Meteorological Administration. The ECC ranged from 7.1 to 55.3 pg/mg (average: 29.5 ± 11.1), while the HCC ranged from 1.1 to 25.7 pg/mg (average: 6.7 ± 4.5) via enzyme immunoassay. The ECC was higher in July than April, May, and June ($P < 0.05$), whilst it was lower in June in comparison to April and May ($P < 0.05$). The HCC was higher in July than May ($P < 0.05$). However, the comparison of HCC was not different between April, May, and June, nor between July with April and June ($P > 0.05$). Overall, the concentration of cortisol in earwax and hair can be suitable indicators of long-term heat stress in Hanwoo. However, factors such as earwax buildup and earwax collection procedure may affect the production rate of earwax that eventuates inaccuracy of earwax cortisol measurement as a reliable chronic stress indicator.

Session 22

Poster 15

Effects of energy levels and heat stress on growth performance and blood metabolites in Hanwoo calves*Y.H. Jo¹, J.G. Nejad¹, J.S. Lee¹, K.K. Park¹, E.J. Kim² and H.G. Lee¹**¹Konkuk university, Animal Science & Technology, 120, Neungdong-ro, Gwangjin-gu, Seoul, Republic of Korea, 05029, Korea, South, ²Kyungpook National University, Department of Animal Science and Biotechnology, 2559, Gyeongsang-daero, Sangju-si, Gyeongsangbuk-do, Republic of Korea, 37224, Korea, South; hglee66@konkuk.ac.kr*

This study investigated the effects of dietary energy levels on growth, blood metabolites, and expression of heat shock proteins in Hanwoo calves subjected to heat stress (HS). Twenty-four calves (BW: 221.5 ± 24.9 kg; age: 162 ± 4.8 d) were randomly housed in climate-controlled chambers using a 3×2 factorial design. There were three energy treatments, including low (LE=2.53), medium (ME=2.63), and high energy levels (HE=2.72 Mcal/kg of DM) and two stress levels (threshold: THI=70-73; severe: THI=89-91). The calves were adapted to 22 °C for 7 days, then to the target THI level for 14 days. Energy intake, average daily gain, and gain to feed ratio were determined to decline ($P < 0.05$) under severe HS compared with the threshold. Under severe HS, the rectal temperature was increased by 0.67 °C compared with the threshold. Severe HS increased glycine, ammonia, and 3-methylhistidine levels compared with the threshold ($P < 0.05$). Gluconeogenic AAs in the blood were increased among the various energy levels regardless of HS. In PBMCs, the expression of the HSP70 gene was increased in the LE group ($P < 0.05$), and the HSP90 gene expression was increased in LE and ME groups ($P < 0.05$) under severe HS. However, the expression of genes HSP70 and HSP90 in the HE group did not differ under severe HS ($P > 0.05$). HE may mitigate ATP depletion in PBMCs. No differences in growth performance were found when increasing energy intake with high protein (CP 17.5%) under HS. However, the increase in energy levels resulted in increased gluconeogenic AAs but decreased urea and 3-methylhistidine in the blood. In conclusion, increased energy levels are thought to improve HS adaptability by inhibiting muscle degradation and glucose production using gluconeogenic AAs, which may improve the health of calves under HS conditions.

The effect of a summer diet on heat stress in lactating sows and their piglets

A. Van Den Broeke¹, L. De Prekel², D. Maes² and M. Aluwé¹

¹ILVO, Scheldeweg 68, 9090 Melle, Belgium, ²University Ghent, Unit of Porcine Health Management, Salisburylaan 133, 9820 Merelbeke, Belgium; alice.vandenbroeke@ilvo.vlaanderen.be

Heat stress is an emerging problem in pig farming, especially in lactating sows. High temperatures and relative humidity rates can negatively affect the sow's health, productivity, and reproduction. Feeding strategies can help alleviate the effects of heat stress in lactating sows. Apart from changes in the energy, fat and protein levels of the feed, addition of minerals, vitamins and electrolytes can help to maintain the sow's body condition and milk production during times of heat stress. The aim of this trial was to compare the effect of a standard vs a summer lactation diet supplemented with vitamin E (200 ppm), vitamin C (200 ppm), Selenium (organic formula), Betaine (0.1%) and adjusted electrolyte balance on physiological and performance parameters of 50 lactating sows and their piglets during the summer of 2022. To examine the effect of the diet on physiological parameters affected by heat load, observations were performed at control days (temperature-humidity index (THI) below 75) and at days with a high heat load (THI at least 6 hours above 75). Independent of diet, sows had an increase in respiration rate (68 vs 39 breaths per minutes) and rectal temperature (39.6 vs 38.7 °C) on hot vs control days, but there was no significant difference due to diet. Global effects of diet on reproduction parameters like total born piglets, weaned piglets, mortality rate of piglets were also not observed. At the end of the nursery period however, piglets of the standard group had a higher weight (20.7 vs 20.1 kg, $P=0.042$), higher growth rate (391 vs 368 g/day, $P=0.003$) and a better feed conversion ratio (1.33 vs 1.37, $P=0.030$) compared to piglets of the summer diet group, although the latter group had numerically a higher weight at weaning compared to piglets from standard diet sows. To conclude, this study did not observe effects of a summer diet on reproduction or physiological parameters but lactation diet had a significant impact on the performance of the piglets after weaning.

Session 22

Poster 17

Physiological implication of omega-3 fatty acid supplementation on animal welfare in laying hens

S.K. Kang

Graduate School of International Agricultural Technology, Seoul National University, 1447, Pyeongchang-daero, Daehwa-myeon, Pyeongchang-gun, Gangwon-do, 25354, Korea, South; kangsk01@snu.ac.kr

In general, the lipid mediators which derived from omega-6 fatty acids enhance inflammatory reaction whereas omega-3 fatty acid-derived lipid mediators relieve it. Thus, the balance of omega-6 and omega-3 fatty acid in animal's body is crucial to maintain immune homeostasis. However, most of modern livestock animals considered to be suffered from the chronic inflammation because of the imbalance in omega-6 to omega-3 fatty acid ratio majorly due to the feeding system depending on omega-6 fatty acid-biased resource such as corn. In this study, it is hypothesized that supplementation of dietary flaxseed, an omega-3 fatty acid-rich feed ingredient, to livestock animals could alleviate the chronic inflammation and stress conditions during their feeding by altering the lipid mediators profile. 33-week-old laying hens in their intensive production period were chosen for the investigation, then lipid mediator profiles, indices of inflammation (serum pro-inflammatory cytokines), and stress indices (corticosterone level and heterophils to lymphocytes ratio) in serum have been monitored after feeding 0, 0.9, 1.8, or 3.6% (w/w) dietary flaxseed for 4 weeks. As results, significant increment of several omega-3 fatty acid-derived lipid mediators, reduction of pro-inflammatory cytokine level such as TNF- α , alleviation of stress indices, and improvement of overall laying performance have been observed. So far, in livestock industry, flaxseed supplementation in feed just has been focused on the production of omega-3 fatty acid-fortified animal products. This study newly suggests that the supplementation of omega-3 fatty acids to livestock animals could be helpful to reduce chronic inflammation and stress during their production period associated with animal welfare issues.

The effect of different bedding materials on dust and toxic gas concentrations in calf housing

D. Witkowska, A. Ponieważ and D. Murawska

University of Warmia and Mazury, Oczapowski Str. 5, 10-719 Olsztyn, Poland; dorota.witkowska@uwm.edu.pl

The type and quality of the bedding material is an important aspect of the health status of the calves. One of the most popular bedding materials in many countries is straw. Nevertheless, some research indicate that contamination levels can be significantly higher in facilities using straw, in comparison with alternative bedding materials. Given that calves' immunity builds for a relatively long time and that long-term exposure to aerial contaminations predisposes them to respiratory system health disorders, a given type of litter may improve the results of calves breeding. For this reason, the aim of our study was to determine the effect of classic straw and six alternative bedding materials (light pellets, medium sawdust, peat, chopped straw, flax, hemp) on the levels of dust fraction (particulate matter/PM1, PM2.5, PM4, PM10 and total suspended particulate/TSP) and toxic gas (ammonia/NH₃, hydrogen sulphide/H₂S) concentrations in the air of calf housing. The calves were kept in accordance with the EU and Polish standards in identically equipped and separated boxes (8 calves on each type of bedding). Analyses of contaminations were conducted every day at 6 am (before calves handling) for a period of 2 weeks at 5 locations in each box, using a gas detector (Nanosens DP-24 VET) and gravimetric apparatus (DustScan 3020). The data were normally distributed (Kolmogorov-Smirnov test) and analysed by ANOVA (StatSoft). Considering dust concentration, the most contaminated air (by each fraction, apart from PM1) was registered using traditional straw ($P<0.01$; PM2.5=13.02, PM4=50.48, PM10=285.21, TSP=477.78 µg/m³). In case of PM4-10 and TSP the lowest concentrations ($P<0.01$) characterized light pellet and sawdust. Chopped bedding materials: straw, flax, and hemp, and peat had an intermediate effect. Whereas, in the case of PM1-2.5, pellets had the worst impact on the quality of air ($P<0.01$; PM1=2.91, PM2.5=11.36 µg/m³). The toxic gas concentrations were the lowest using light pellets ($P<0.01$; NH₃=0.25 ppm; H₂S=0.5 ppm) and the highest in case of sawdust ($P<0.01$; NH₃=1.17 ppm; H₂S=1.29 ppm). It could be concluded that alternative bedding materials, especially pellet, significantly improve air quality and hygiene standards in calf housing.

Poster 19

Mitigate density stress by using a proprietary orange essential oilA.N. Nalovic¹, A.A. Auvray² and J.G. Gabarrou²¹Réseau Cristal, 23 Rue Olivier de Serres, 85500 Les Herbiers, France, ²Laboratoires Phodé, 8 avenue de la Martelle, 81150 Terrassac, France; aauvray@phode.fr

Tail biting in pig farm is a major welfare issue that is also impacting farm profitability. Even when on farm policies are taken to reduce risk factors, uncontrolled variables remain like density stress. The aim of this study was to measure the effect of an antistress functional feed additive on gilt stress level and its impact on tail biting. Four successive batches between 120 and 140 gilts each were monitored from post-weaning to fattening, alternating control and experimental batch every 4 weeks: two of them were control batches while the two others received the feed additive, VeO® (Phodé, France) at the dose of 100 ml per 1000 l of drinking water and for the whole duration of the trial. Gilts activity was daily measured through video recording analysed by group scan sampling, using BORIS®. Tail lesions were scored every 15 days, following a scoring system derived from Honeck *et al.* Saliva have been taken on sixteen identified animal 3 times: before and after the transfer (=stressor) and the day after, to measure the cortisol rate. All the data were analysed on SPSS® and using an analysis of variance (General Linear Model) or Khi-square test when appropriate. For the all period, experimental gilts expressed more eating, drinking and digging behaviour ($P<0.001$) and less manipulating objects or other gilts ($P<0.001$). The total number of tail lesions was lower in the experimental group (4.7 vs 13.4%; $P<0.001$) as was the severity of these lesions (14.0 vs 46.9%; $P<0.001$). Regarding the evolution of the tail lesions, we observed a substantial increase 45 days after the entrance in fattening stage 20.6% for the control and 11.2% for the experimental batches supposing a higher density stress. In addition, and just after the stressor, cortisol rate of control group was higher compared to experimental group (8.06 vs 82.67 mg/ml; $P<0.01$). Animals receiving VeO showed a better resilience to stressful situation. Normal behaviour has been maintain longer in experimental group. As a consequence, lower tail biting lesions has been counted. This cerebral approach seems key in an ending of tail docking practise.

The effects of heating drinking water or calcium propionate on fattening beef cattle in winter

T. He, Z. Chen and S. Long

China Agricultural University, College of Animal Science and Technology, No. 2, Yuanmingyuan West Road, Haidian District, Beijing, 100194, Beijing, China, P.R.; tenghe@ethz.ch

The effects of heated drinking water (HDW) or calcium propionate (CaP) supplementation on growth performance, nutrient digestibility, and rumen microbiota in finishing beef cattle during winter (Average ambient temperature 6.47 ± 3.52 °C) were evaluated. Ninety-six Simmental finishing bulls with an average body weight of 613 ± 16.5 kg were randomly allocated into four treatments with six replicates per treatment and four bulls per replicate, with a 2×2 factorial arrangement of treatments for 60 d periods. Factors were drinking water temperature (room temperature of 5.12 ± 2.01 °C or heated water temperature of 28.63 ± 3.25 °C) and CaP (0 or 200 g/d per head, dry matter basis). The results showed that HDW significantly increased average daily gain, average daily feed intake, and average daily water intake ($P < 0.05$), while the CaP supplementation significantly decreased the feed-to-gain ratio ($P < 0.05$). No significant interaction was observed between HDW and CaP supplementation on growth performance and water intake. HDW and CaP supplementation significantly increased the digestibility of neutral detergent fibre and crude protein and significantly interacted on cellulase and xylanase concentration in rumen ($P < 0.05$). Moreover, CaP supplementation increased the concentration of total volatile fatty acids, acetate, and propionate in rumen, and had an interactive effect on rumen propionate concentration with HDW ($P < 0.05$). HDW significantly reduced serum cortisol and thyroid hormone concentrations ($P < 0.05$), while no significant effect was observed on CaP supplementation in serum stress hormone levels. HDW significantly reduced the ratio of Firmicutes to Bacteroidetes and increased the relative abundance of *Prevotellaceae_ucg_003* and decreased the relative abundance of *Lachnospiraceae* ($P < 0.05$) in rumen. CaP supplementation did not significantly affect rumen microbial populations but significantly increased the relative abundance of *Succinivibrionaceae* ($P < 0.05$). In conclusion, HDW or supplementing CaP in a cold environment could improve growth performance, rumen fermentation function, and nutrient digestibility, enhancing the overwintering ability of Simmental finishing bulls.

Water quality in dairy cattle farms: impact on animal production, reproduction and health

V. Resende

Universidade Évora e Instituto Mediterrâneo para a Agricultura, Ambiente e Desenvolvimento, Departamento de Zootecnia, Pólo da Mitra, Apartado 94, 7002-554 Évora, Portugal, Portugal; vjgr33@gmail.com

Climate change is currently one of the great global challenges, affecting in particular the water sector, namely the lack of precipitation and consequent periods of prolonged drought. Drinking water is a scarce resource in many regions of the world. Water is essential for the life of animals, since it intervenes in various metabolic processes. An inadequate water supply could reduce the health and performance of the animals. In dairy farms, the use of quality water is essential to maximize the milk production of animals. The objective of this study is to verify: (1) the importance of water quality on intensive dairy farms; (2) water quality affects animal production, reproduction and health. Presentation of the preliminary results of (2) biochemical analysis and toxicology. Serum samples were tested for Urea, Creatinine, ASL, ALT, Alkaline F. and Manganese. Urine samples were tested for urea, creatinine, and manganese. Milk samples were tested for manganese, calcium and copper. The requirements of cattle are not precisely known, but Hartmans recommended 25 mg Mn/kg DM for Dutch dairy cattle. Marginal bands for manganese concentrations in diet (10-20 mg/kg DM), blood ($\mu\text{g/l}$) and serum ($\mu\text{g/l}$) in cattle. Toxic levels Mn 1000 mg/kg DM and symptoms of toxicity: Slow growth, anaemia, gastrointestinal lesions and occasionally neurological signs. Values were found for the untreated group of ALT=31.5 and 36.2 IU/l (min 6.9 and max 35.3). AST=201.1-269.1 (min 45.3 and max 110.2). GGT= 32.9-135.7 (min 4.9 and max 25.7). GGT – elevated values related to liver disease of toxic origin. This study helps to verify the importance attributed by national dairy cattle producers to the availability and quality of water on their farms.

Study on the effect of improving the pig gut microbiota of *Rhodobacter sphaeroides*

D. Shin¹, J. Park², S. Son¹, H. Lee¹ and J. Kim³

¹Jeonbuk National University, Jeonju-si, Jeollabuk-do, Korea, 54932, Korea, South, ²Jeju National University, Jeju-si, Jeju-do, Korea, 63243, Korea, South, ³Chung-Ang University, Anseong-si, Gyeonggi-do, Korea, 17546, Korea, South; sdh1214@gmail.com

Pig is attractive to consumers due to its characteristics such as tenderness and supercilious taste. Recently, in the case of pigs, not only the taste of pork but also the importance of animal welfare is increasing. In particular, health is very important in the process of raising pigs. Recently, several previous studies reported that intestinal microbiome was closely related to health and immunity of the host. Herein, we explored a possible relation between pig gut microbiota composition and *Rhodobacter sphaeroides* as feed additive. A feeding experiment was conducted on 20 hybrids (Landrace × Yorkshire × Duroc) with an average weight of 7.73±0.13 kg (10 control group, 10 *Rhodobacter* treatment group), and this experiment was conducted for 2 weeks. After collecting faeces, the pig gut microbiota was characterized by the V3-V4 region of 16S rRNA using an Illumina Miseq. We identified 4,198 OTU-level core bacteria mainly belonging to the kingdom bacteria. Results showed that feeding additives affect the composition of pig gut microbiota. Compared with the control group, *R. sphaeroides* treatment group showed a higher proportion of the putative beneficial bacteria. Also, at the genus level, this feed additive increased *Olsenella*, whereas *Bacteroides* were enriched in the control group. Collectively, our study suggested that the *R. sphaeroides* might improve pig health by modulating gut microbiota.

Algae-based beta-glucan mitigates the adverse effects of heat stress in lactating sows

J. Mun, A. Hosseindoust, S. Ha, S. Park, H. Tajudeen, S. Oh and J. Kim

Kangwon National University, Department of Animal Industry Convergence, room 201, Animal Resources dep, (409), 24341, Korea, South; 202016455@kangwon.ac.kr

Heat stress has negative effects on sow performance, but proper nutritional strategies may help alleviate the consequences. This study aimed to investigate the interactive effects of algae-based beta-glucans (BG) on reproductive performance and metabolic response in lactating sows under heat stress. Thirty multiparous sows at day 112 of gestation were randomly assigned to one of three treatments: control (CON), 50 g BG/kg (BG5), and 100 g BG/kg (BG10), for 21 days. Results showed that sows fed BG5 and BG10 had reduced respiratory rates compared to CON. Sows in the BG10 group had higher feed intake ($P<0.01$) than CON. Body weight loss and weaning to oestrus interval tended to be lower in the BG5 and BG10 groups during lactation. Piglet weight ($P<0.05$) was higher in the BG10 group at weaning compared to CON. Sows in the BG10 group had significantly lower hair cortisol levels, and the lowest ($P<0.01$) TNF- α levels in blood. In contrast, a higher ($P<0.01$) concentration of TNF- α was observed in the BG5 group compared to CON. The blood concentration of lipopolysaccharide was decreased ($P<0.01$) in sows fed the BG10 diet compared to CON. The lipopolysaccharide-binding protein concentration in the jejunum tended to be lower ($P<0.01$) in the BG10 group compared to CON. Sows in the BG10 group showed higher ($P<0.05$) superoxide dismutase in the blood. However, there were no significant differences in reactive oxygen species, hydrogen peroxide, total antioxidant capacity, malonaldehyde, and catalase concentrations. Overall, the supplementation of BG at a dose of 10 g/kg was more effective than 5 g/kg, suggesting that higher doses of BG should be considered in future studies.

Effect of dietary mineral level and creep feeding on sows performance under high ambient temperature*H. Tajudeen, A. Hosseindoust, J.Y. Mun, S. Ha, S. Park, S. Yoon and J. Kim**Kangwon National University, Room 201-2, Department of Animal Industry Convergence dep, (409), 24341, Korea, South; 202016455@kangwon.ac.kr*

Heat stress is an important issue, and the dietary mineral level and supplementation of creep feed for suckling piglets may be a solution to reduce the adverse effects of heat stress. This study evaluated the interactive effect of different mineral levels and creep feeding on reproductive performance, stress level, and immune status of lactating sows during heat stress. There were a total of 4 treatments including 2 mineral levels (CON, NRC-based; HM, 200% of NRC recommendation) with or without creep feeding (CF) in a 2×2 factorial arrangement during high ambient temperature. Sows in the CF treatment showed a lower respiratory rate at days 8, 10, 11, and 14 of lactation. The rectal temperature of lactating sows was mainly over 38.5 °C indicating relatively high heat stress. Sows in the CF treatments showed a lower body weight loss during lactation. Backfat thickness, farrowing duration, weaning to oestrus interval, born alive, weaned number, weaned weight, and litter weight was unaffected. The CF treatment showed a higher litter uniformity compared with suckling pigs without creep feeding. The survivability of piglets was increased in the CF treatment. Sows in the CF treatment showed a lower hair cortisol concentration. However, hair cortisol was not affected in the HM group. Sows in the CF treatments showed a lower tumour necrosis factor- α during lactation. The concentration of lipopolysaccharide and lipopolysaccharide-binding protein were not different in the CF and HM treatments. In conclusion, creep feeding is recommended for suckling pigs during heat stress due to reducing weight loss, stress level, and inflammatory response in sows.

Session 23

Theatre 1

Pre-weaned dairy calf welfare: from the ‘End the Cage Age’ movement to the EFSA mandate*M. Brscic**University of Padova, Department of Animal Medicine Production and Health (MAPS), Viale dell’Università 16, 35020 Legnaro, Italy; marta.brscic@unipd.it*

Aim of this contribution is to analyse the outcomes of the European Food Safety Authority (EFSA) mandate in regards to pre-weaned dairy calf and veal calf welfare and the risks associated with individual housing and insufficient space, in particular. Before an in-depth analysis of the contents of the EFSA scientific opinion on the welfare of calves adopted in February 2023, an overview of the state of the art at European level will be given starting with the ‘End the Cage Age’ movement, the large European Citizens’ Initiative that in June 2021, that has obtained the response from the Commission to phase out cages for a number of farm animal species and categories and has risen the lack of science-based knowledge to fully respond to it. The campaign and the EU Farm to Fork Strategy, core of the Green Deal, are promoting rapid changes in the EU food production chains with implications as raising standards of animal welfare to improve animal health and food quality, reduce the need for medication and promote biodiversity preservation. The contribution will progress with a SWOT analysis on the importance of implementing a whole sector approach from farm to fork in order to guarantee higher levels of animal welfare still maintaining food safe and accessible, and the need to support farmers to upgrade their farms to more animal-friendly facilities meeting needs of several: animals, consumers and citizens, farmers and stakeholders. In this context, some major concerns related to dairy calves farming as the abrupt early calf-cow separation at birth (within minutes to 1-2 days), the actual housing systems used for pre-weaned dairy calves and veal calves and their space allowances will be analysed and the respective recommendations from the EFSA scientific opinion will be described. The contribution will end with a discussion on the potential impact that recommendations might have on dairy and veal calves sectors.

Impact of individual pens removal on veal calves' behaviour*D. Bastien and V. Lefoul**Institut de l'Elevage, Qualité des carcasses et des viandes, Monvoisin, 35650 Le Rheu, France; virginie.lefoul@idele.fr*

The European Commission plans to phase out the use of cages for farm animals from 2025. In this context, a trial was conducted to study the impact of the removal of individual pen in veal calf production. 60 male Prim Holstein calves aged 20 days and weighing 49.0 kg were divided into 3 batches and housed for the first 28 days in individual pens (control, IP28), by pair (pair housing, PH28), or in groups of 5 calves (GROUP). The calves were then fattened in collective pen of 5 calves. The total fattening period last 24 weeks. Drinking from buckets in collective pens requires the presence of headlocks that allow the calves to be blocked during milk drinking. Continuous sampling observations were carried out from 6 am to 8 pm on 4 days (D13, D27, D112 and D156). The use of headlocks for the PH28 and GROUP caused stress in the calves (35% of calves stressed in the first two days and 20.7% at 2 weeks). At D13, cross-sucking of the foreskin was more frequent in PH28 and GROUP (8.2 and 11.1% of their daytime vs 0.4% for IP28, $P<0.01$). 65% of this activity occurred between 1.5 hours before and 1.5 hours after milk drinking. At D27, this cross-sucking behaviour was still very present for PH28 (3.2% of their daytime, with 65% calves affected compared to 0.0% for IP28, $P<0.01$, and 1.6% for GROUP being intermediate with 56% of calves affected, NS). In the GROUP batch, 2 calves with high cross-sucking behaviour had to be isolated (at D54 and D133) because they were no longer drinking their milk and were losing weight. Positive interactions such as grooming, or muzzle and ear sucking were equivalent between the 3 batches (representing 1.3% of the day's activities). Nevertheless, IP28 spent more time expressing PICA behaviour on D13 (7.8 vs 1.5% for the PH28 and GROUP batches, $P<0.01$). These differences are balanced out during the rest of the fattening period. Furthermore, no significant differences were observed on the number of health treatments per batch (1.7 treatment/calf, NS) or on live weight at slaughter, despite 10 kg difference between IP28 vs PH28 and GROUP (IP28=262.7 kg, PH28=252.5 kg, GROUP=251.9 kg). These results show that collective management of male calves at their arrival at the fattening farms can lead to fatal decline of their welfare.

Session 23

Theatre 3

Quarter level milk yield in dairy cows before and after separation in a cow-calf contact system*S. Ferneborg¹ and S. Agenäs²*

¹Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, P.O. Box 5003 NMBU, 1432 Aas, Norway, ²Swedish University of Agricultural Sciences, Department of Animal Nutrition and Management, P.O. Box 7070, 75007 Uppsala, Sweden; sabine.ferneborg@nmbu.no

There is an increased interest among consumers, farmers and other stakeholders, to facilitate cow-calf contact (CCC) systems in dairy production, where cow and calf are kept together for an extended period of time. However, research on the effects of the system on milk yield before and after separation is scarce. Farmers report milk ejection difficulties in CCC cows during the time together with their calves and also low milk yield after separation. The aim of this study was to investigate quarter level milk yield prior to and after separation among cows kept in a CCC system with automatic milking. In total 35 cows were enrolled in the trial and assigned to CCC ($n=17$) until the calves were 127 ± 6.6 d old, or control ($n=18$) that were separated from their calves within 12 h after calving. All cows were milked in an AMS and individual quarter level records were obtained from each milking during one lactation. Analysis of variance was performed using the mixed model function in SAS Studio, with a model including the fixed effects of treatment, separation, quarter and the random effect of cow. Milk yield delivered to the robot was higher in control cows per quarter and milking than in CCC cows before separation ($P<0.001$) but not after ($P=0.92$). In CCC cows, average milk yield per quarter and milking increased from 2.1 ± 1.12 before separation to 2.7 ± 0.93 kg/milking (mean $\pm$ SD) after separation, while control cows decreased from 3.9 ± 1.10 to 3.0 ± 1.00 kg/milking over the same period. Within-cow variation was higher in CCC cows before ($CV=58\%$) than after separation ($CV=38\%$). Collectively, these results indicate that milk yield per quarter and milking is similar between control and CCC cows after separation and that in turn suggests that total yield is similar between the groups also before separation. The lower milk yield recorded by the robotic milking is therefore more likely an effect of calf milk intake than of impaired milk ejection.

Two different training protocols to encourage dam-reared calves to drink supplemental milkJ. Sørby¹, S. Ferneborg¹, S.G. Kischel² and J.F. Johnsen³¹Norwegian University of Life Sciences, Oluf Thesens vei 6, 1433, Norway, ²TINE SA, BTB-NMBU, Pb. 5003, 1432, Norway,³Norwegian Veterinary Institute, Arboretveien 57, 1433, Norway; johanne.sorby@nmbu.no

At debonding, cow-calf contact (CCC) calves' performance may be improved, and stress alleviated through encouraging the calf to drink supplemental milk (SM, e.g. automatic feeder). However, calves often struggle learning how to drink milk from a new source. This study describes the success (intake of ≥ 1.5 l SM more than once) of two different training protocols to encourage CCC calves to drink SM from an automatic feeder during debonding. In training protocol 1 calves (n=16) were pushed into the feeder where they involuntarily received whole SM from a teat bottle the first two d, thereafter assisted in drinking from the feeder the following three d regardless of success with the teat bottle. In training protocol 2, we familiarized the calves (n=14) with artificial teats and the feeder by placing two dummy teats in the creep and moving the salt lick within the feeder (i.e. race-gate). In addition, we enticed the calves with a focus on positive reinforcement during the 5 d training period using something sweet; calves could voluntarily choose to approach a teat bottle with approx. 2 dl of electrolytes and teat greased with molasses, before enticing them towards the feeder. Upon success with this first step, electrolytes were substituted with whole SM from a bottle within the feeder. Finally, calves received individual assistance in the feeder if successful with the bottle. Protocol 2 appeared gentler for the calves, and descriptive analysis showed a higher success rate compared to protocol 1 (71 and 50%, respectively). In addition, successful calves trained by protocol 2 had on average 10.4 $\pm$ 4.58 success days out of 38 possible (amounting 50.8 $\pm$ 42.7 l/calf for the period) compared to successful calves trained by protocol 1 having on average 3.4 $\pm$ 2.34 success days (18.4 $\pm$ 21.08 l/calf). Experiences from this study confirm that CCC calves struggle to learn how to drink SM during debonding, but familiarity with an artificial teat and enticement during training can be promising tools.

Session 23

Theatre 5

Effects of automatic TMR feeding system on the health status of finishing bulls and heifers

O. Martinić, L. Magrin, P. Prevedello, G. Fabbri, G. Cozzi and F. Gottardo

University of Padova, Department of Animal Medicine, Production and Health, Viale dell'Università 16, 35020 Legnaro, Italy; oliver.martinic@phd.unipd.it

The aim of this study was to evaluate the effects on the health status of Limousine finishing bulls and heifers of automatic feeding systems (AFS) with dynamic total mixed ration (TMR) distribution in comparison to the conventional feeding system (CFS). Two feeding systems (FS) prepare and distribute the same composition TMR: the CFS consisted of a TMR prepared and distributed by a mixer wagon in a single daily distribution; AFS consisted of an automatic system that prepared and delivered TMR dynamically several times daily according to animals' intake observed by feeding delivery robot sensor which measured feed leftovers in the bunk. A total of 1,440 bulls and 1,129 heifers regularly imported in 75 batches from France were monitored during the experimental period from January 2020 to March 2022 in a farm located in the province of Treviso, Italy. After an adaptation period, animals were separated into groups of 10 animals based on sex, batch, and initial weight, and were transferred to two identical fattening barns with different FS. Animals were slaughtered when they reached a suitable finishing status evaluated by a slaughterhouse expert. The individual health status of the animals was daily checked by the farm veterinarian throughout the fattening period. The trained veterinarian inspected the rumen mucosa of a random sample of animals of each batch at the slaughterhouse. The percentage of treated animals was greater for CFS heifers ($P < 0.01$) and bulls ($P < 0.05$) than AFS. The number of treatments for respiratory disorders in heifers was greater for CFS than for AFS ($P < 0.05$). Furthermore, the number of treatments received per bull for locomotor disorders was greater for CFS than AFS ($P < 0.05$). The FS affected the prevalence of hyperkeratosis, plaques, and signs of ruminitis both in bulls and heifers, being lower for AFS than CFS. Rumens' mucosa belonging to AFS heifers showed a lower prevalence of star scars than those belonging to CFS ($P < 0.005$). Collected data showed that an increasing frequency of feed deliveries over the day could improve the rumen health status of bulls and heifers.

Associations between feed push-up frequency, feeding behaviour and milk yield in dairy buffaloesG. Esposito¹, E. Raffrenato², G. Bosoni¹, F. Caruso¹ and F. Righi¹¹University of Parma, Veterinary Medicine, via del Taglio, 10, 43126 Parma, Italy, ²University of Padua, Comparative Biomedicine and Animal Nutrition, viale dell'Università, 35020 Legnaro, Italy; giulia.esposito@unipr.it

The objective of this study was to assess the effects of feed push-up frequency on the feeding behaviour and milk yield of Italian Mediterranean dairy buffaloes. Lactating buffaloes ($n=95\pm6.2$, parity = 4 ± 1 ; DIM: 107 ± 8.2) were housed in a freestall, milked twice daily, and offered *ad libitum* access to water and a total mixed ration containing, on as fed basis: 25% corn flour, 17% distillers, 15% wheat silage, 15% soy, 14% haylage, 4% alfalfa and 10% mineral supplement, provided daily. Buffaloes within the pen were exposed to each of 2 treatments in a crossover design with 15-d treatment periods and a 10-d adjustment periods between treatments; treatment 1 had 3 feed push-up a day (at 7:30, 11:30 and 18:30), whereas treatment 2 had 2 feed push-up a day (7:30 and 12:30). Dry matter intake and milk yield were recorded daily whereas every five days feed samples of fresh feed andorts were collected for particle size analysis. Two separators were used: the Penn State Particle size separator, fitted with 3 screens (19, 8, and 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, fine) and a Z-box fitted with a 3.18 mm screen (for determination of the physical effectiveness factor (pef) of the TMR). Sorting was calculated as the actual intake of each particle size fraction expressed as a percentage of the predicted intake of that fraction. Treatment had no effect on milk yield (13.26 ± 0.04 vs 13.021 ± 0.05 kg/d for 3 vs 2 push-up) or feed sorting. Buffaloes sorted against long particles ($76.4\pm31.96\%$) and for short ($99.38\pm0.72\%$) and fine ($100.06\pm1.09\%$) particles. The pef of the TMR was not affected by treatment. Dry matter intake increased with increased push-up frequency (41.71 ± 0.03 kg vs 37.11 ± 0.03 kg for 3 vs 2 push-up). These preliminary results suggest that altering feed push-up frequency increases intake but doesn't affect feed sorting or milk yield in dairy buffaloes. Further studies are needed to evaluate long term effects of feeding frequency on milk yield and composition.

Comparing dairy cow welfare in loose-housing and in tie-stall systems using animal-based indicators

V. Lorenzi, L. Bertocchi, C. Montagnin and F. Fusi

Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna 'Bruno Ubertini', Italian Reference Centre for Animal Welfare, Via Bianchi 9, 25124 Brescia, Italy; francesca.fusi@izsler.it

Due to the geographical features of the territory, both tie-stall and loose-housing systems for dairy cows coexist in Italy. Tie-stall barns are more common in the mountainous areas, while loose-housing systems (free-stall or deep litter barns) are widespread in lowland areas. During the year 2022, using the ClassyFarm system of the Italian Ministry of Health (www.classyfarm.it), 10 animal-based indicators (ABIs) were collected in 1,385 tie-stall farms (range 10-656 heads, mean 51 heads) and in 4,123 loose-housing farms (range 10-700 heads, mean 223 heads). In each farm, 4 out of the 10 ABIs were collected separately for lactating cows (LC), dry cows (DC) and heifers (HF). These 4 ABIs were: avoidance distance test, body-condition score, coat cleanliness (flank, leg and udder) and integument alterations. The other 6 collected ABIs were: lameness in adult cows, milk somatic cell count, antimicrobial usage for mastitis, annual mortality rate of adult cows, annual mortality rate of calves and mutilations. For each ABI a score was assigned to the farm, based on whether or not the set warning threshold was exceeded. Results obtained in loose-housing farms and tie-stall farms were compared. Loose housing farms achieved better results for the ABIs: avoidance distance test in HF; body condition score in LC, DC and HF; coat cleanliness in LC and DC; integument alterations in LC, DC and HF; milk somatic cell count and antimicrobial usage for mastitis. Tie-stall farms showed a better score for the ABIs: lameness, annual mortality rate of lactating cows, annual mortality rate of calves and mutilations. No differences were found for the ABI 'avoidance distance test' in LC and DC and for the ABI 'coat cleanliness' in HF. In terms of animal welfare, the tie-stall housing system of dairy cows is strongly debated. On one hand, the tied system restricts the voluntary movement possibilities and the social behaviour of dairy cows; on the other it limits competition for the resources. As stated by some authors, the adverse effects of tie-stall could be reduced, when periods of exercise are possible.

Time-controlled hay racks horses: what effect on behaviour?*M. Roig-Pons and S. Briefer**Agroscope, HNS, Les Longs Prés 1, 1580 Avenches, Switzerland; marie.roig-pons@agroscope.admin.ch*

Under domestic conditions, horses are typically fed roughage 2-3 times a day in limited quantities, which differs from their natural feeding behaviour. To better regulate feeding intervals without increasing the workload, caretakers can rely on time-controlled hayracks (rack with roll-up doors opening and closing at programmed times). We studied (1) the association between lying behaviour (essential for REM-sleep) and the openings of the rack at night and (2) the evolution of aggressiveness and risk of injury between close (HC) and open (HO) hayrack. The study was conducted on 3 groups of 5 mares from the SNSF in loose housing with bedded resting area. Straw was *ad libitum* and hay was accessible for 9 hours, split into 5 meals of 1.30-2 hours using time-controlled rack. Continuous observations of social interactions were carried out for 10 hours per group and social status, aggression towards conspecifics (Specific Index of Aggression – SIA) and social tension endured (Social Tension Index – STI) were calculated for each mare. Lying behaviour was recorded with MSR accelerometers. (1) Results highlighted a significant increase of agonistic behaviours in HO compared to HC ($NbAgoBehav_{HO}/h=175.5$, $NbAgoBehav_{HC}/h=122.2$, t-test, $P<0.05$). In HO, mares displayed in average more threats (64.9% of agonistic behaviours in HO vs 53.8% in HC) and less passive displacements (27.5% HO vs 39.4% HC) (χ^2 , $P<0.05$). The average level of aggressiveness therefore increases in HO ($SIA_{HF}=3.5\pm2.4$, $SIA_{HC}=5.3\pm4.8$ paired Wilcoxon test, $P<0.05$) but injury risk behaviours (kicks, bite and chase) remained stable. STI_{HO} and STI_{HC} were similar, meaning that the mares retain their ‘initiation’ or ‘recipient’ status. Lying behaviour obtained was below the 10% of daily time reported in the literature ($\%DailyTimeSpentLying = 4\pm2.7$). A clear association between HO and lying behaviour was found ($TotNbLyingBouts_{HC} = 706$, $TotNbLyingBouts_{HO} = 8$), even though these time slots are indicated in the literature as preferable for lying phases. Five mares laid down after 8am, suggesting that some dominated mares prefer to shift their sleeping bouts to take advantage of feeding slots. These results emphasize the need of further research to find feeding management that optimizes the welfare of horses housed in groups.

Session 23

Theatre 9

Exploring techniques to mitigate heat stress in feedlot lambs*P.G. Theron¹, T.S. Brand^{1,2}, S.W.P. Cloete¹ and K. Dzama¹**¹University of Stellenbosch, Animal Sciences, Private Bag X1, Matieland, 7600, Stellenbosch, South Africa, ²Western Cape Department of Agriculture, Directorate: Animal Sciences, 80 Muldersvlei Road, 7600, Stellenbosch, South Africa; pieter.theron@westerncape.gov.za*

The increased demand for food from a growing population, linked to the projected increase in drought frequency and mean annual temperatures over Southern Africa is likely to force the predominantly extensive sheep farming industry to intensify production. Feedlotting is the commonest intensification technique but information on how to keep the method sustainable under extreme temperatures must be gathered proactively. This study explored the use of shearing and varying dietary energy levels as tools to mitigate heat stress in lambs during feedlot finishing. Fifty-six Dohne Merino ram lambs were finished on a higher (10.6 MJ ME/kg) or lower (9.1 MJ ME/kg) energy grain-based feedlot diet during summer and half of each dietary group were randomly selected to be shorn. Lambs were fed individually and production traits (growth, backfat depth, feed intake and feed conversion) and heat stress indicators (respiration rate, surface and rectal temperature) were monitored throughout the finishing period. Dietary energy level did not affect production traits or heat stress indicators, potentially due to the difference between diets not being large enough. Shorn lambs exhibited lower rectal temperatures (39.77 vs 39.91 °C) and respiration rates (140 vs 158 breaths per minute), indicating that they were more effective at coping with the high (>30 °C) environmental temperatures present during the study. Surface temperature did not differ between groups. Backfat depth was the only production trait that differed between shearing groups with unshorn lambs having greater fat depth (+0.4 mm). Growth and feed intake did not differ significantly between shearing groups, suggesting that shearing will not affect feedlot production or profitability. Shearing is thus a viable technique to improve welfare in feedlot animals as it will reduce heat stress without negatively affecting production output.

Management practices and welfare of dairy goats in GreeceG. Arsenos¹, S. Vouraki¹, V. Papanikolopoulou¹, L. V. Ekateriniadou² and I. Sakaridis²¹School of Veterinary Medicine, Aristotle University, University Campus, 54124 Thessaloniki, Greece, ²Hellenic Agricultural Organization DIMITRA, Campus of Themi, 57001 Thessaloniki, Greece; vipapani@vet.auth.gr

The objective was to assess management practices related to animal welfare in dairy goat farms in Greece. A random sample of 18 dairy goat farms located in Northern and Central Greece was used. The average farm comprised 390±448 goats with an average milk yield of 230±143.9 kg/milking period. The prevailing farming system was semi-extensive. The average grazing time and walking distance of goats was 5.9±2.35 hours and 5.5±2.88 km, respectively. There was also one intensive and one semi-intensive farm. Reared goats belonged to six indigenous Greek breeds (Eghoria, Skopelos, Chalkidikis, Paggaïou, Aridaïas, Serres; n=11 farms) and three foreign breeds (Damascus, Anglo-Nubian, Murciano-Granadina; n=5 farms) whereas two farms had composite populations of crossbred goats. Housing and management practices were recorded by a group of veterinarians using a designated questionnaire. Records included information on flock size, housing conditions and shed dimensions, milking procedures, vaccinations, and antiparasitic treatments; available space per goat was calculated. Descriptive statistical analysis was performed. Results showed that in 39 and 16% of farms, available space per goat was less than 2 and 1.5 m², respectively. In most farms (68%), machine-milking was performed; use of gloves by milkers and post-dipping were reported in 28 and 5% of cases, respectively. Moreover, 21, 42 and 84% of farmers did not vaccinate against *Clostridium perfringens*, *Mycoplasma agalactiae* and *Chlamydophila abortus*, respectively. Routine treatments for endoparasites and ectoparasites were performed in 79 and 84% of farms, respectively. Overall, results indicate that milking procedures, lack of vaccination against common diseases and limited space availability are management practices associated with the welfare status of dairy goats in Greece. Further improvement of those practices is needed to increase animal productivity and welfare. This research has been co-financed by the European Regional Development Fund of the European Union and Greek National Funds through the Operational Program Central Macedonia 2014-2020 (KMP6-0083632; GRAEGA CHEESE).

Risk factors for navigation ability of laying hens at housing in an aviary system

C. Ciarelli, F. Bordignon, G. Pillan, G. Xiccato and A. Trocino

University of Padova, Department of Agronomy, Food, Natural Resources, Animals and Environment, viale dell'Università 16, 35020, Italy; angela.trocino@unipd.it

To evaluate the risk factors for navigation ability of two genotypes of laying hens at housing in an aviary system, 1,800 pullets, half Lohmann White-LSL and half Hy-line Brown, were randomly allocated at 17 weeks of age in 8 pens of an experimental aviary (3 tiers), according to a bi-factorial arrangement, 2 genotypes (brown vs white hens) × 2 types of pens (enriched or not enriched with additional perches). Data collected by video-recording at 17 and 20 weeks of age were used to assess the number of successful and unsuccessful landings from any part/equipment of the aviary to the floor. Risk factors related to failed landings were evaluated by multivariate logistic regression analysis through a forward stepwise selection using the PROC LOGISTIC of SAS. The regression coefficients were expressed as odds ratio (OR) with 95% confidence interval (CI). Compared to brown hens, white hens performed a significantly higher number of landings per hour in the observation interval (80.7 vs 35.4; $P<0.001$) with a higher success rate (94.8 vs 88.6%; $P<0.01$). Brown hens had higher odds of failed landings compared with white hens (OR: 6.65; 95% CI: 4.36-10.1). The logistic regression analysis showed significantly higher odds (OR: 1.90; $P<0.001$) of experiencing failed landings at 17 weeks compared to 20 weeks. No significant difference in the number or in the rate of success of landings was recorded between enriched and not enriched pens, where the logistic regression analysis only measured a trend (OR: 1.29; $P=0.09$). The odds of failed landings were greatly higher when comparing long with medium flight distance to floor (i.e. hens starting from the third vs the second tiers of the aviary) (OR: 31.1; $P<0.001$) and lower comparing short (i.e. hens starting from the first tiers of the aviary) with medium flight distance (OR: 0.17; $P<0.001$). In conclusion, under the condition of the present study, white hens exhibited higher navigation activity and ability compared to brown hens since the first week after housing; the navigation ability improved four after housing weeks; the enrichment with additional perches played a minor role. Long-term effects on space use should be evaluated over the laying period.

Busy birds – what do turkey hens use dust baths for?K. Skiba¹, M. Kramer¹, P. Niewind², B. Spindler¹ and N. Kemper¹¹University of Veterinary Medicine Hannover, Foundation, Institute for Animal Hygiene, Animal Welfare and Farm Animal Behaviour (ITTN), Bischofsholer Damm 15, 30173 Hannover, Germany, ²Agricultural Chamber of North Rhine-Westphalia, Haus Duesse 2, 59505 Bad Sassendorf, Germany; karolin.skiba@tiho-hannover.de

In this study, six groups of 71 turkey hens were observed for one hour after renewing the dust baths using video cameras. Each group was kept in a 17.5 m² compartment. Next to straw pellets, which were used as bedding material, each compartment included one dust bath (DB, 1 m²). The DB was available at all times during the fattening phase (5th-16th week of life (WL)) and renewed once weekly, using either rock flour, sawdust or sand for two groups each. The occupancy of the DB was analysed via scan sampling every five minutes within one hour after renewing the baths, five times during the fattening phase (6th, 8th, 10th, 12th and 14th WL). Next to counting the animals inside the DB, the behaviour of each animal was recorded. In order to categorise each behaviour correctly, the previous 20 seconds to each scan were watched. Results showed an average number of 2.2 turkey hens per hour and DB throughout the fattening phase. In 8.9% of all samples, the process of dust bathing was identified. The remaining behaviours shown in the DB were exploration (37.6%), rest/inactivity (32.3%), agonistic behaviour (15.0%), and comfort behaviour (6.2%). The peak of bird numbers in the DB was found in the 10th WL (n=2.5), which matched with the peak for dust bathing activity (n=0.4; 15.5%). Over the course of the fattening phase, next to all other behaviours, dust bathing occurred most frequently in rock flour (n=0.3; 12.9%), followed by sand (n=0.2; 9.0%) and then sawdust (n=0.1; 4.8%). In this study, turkey hens used dust baths primarily for exploration and rest. Dust bathing frequencies varied between substrate type and age of the animals and should be investigated further. This work (Model- and Demonstration Project for animal welfare #Pute@Praxis) is financially supported by the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany, granted by the Federal Office for Agriculture and Food (BLE); grant number 'FKZ 2817MDT611'.

Session 23

Theatre 13

Pre-slaughter fasting on stress response and meat quality in rainbow trout (*Oncorhynchus mykiss*)A. De La Llave-Propín¹, A. Martínez Villalba², R. González Garoz², J. De La Fuente², C. Pérez³, E. González De Chavarri², M.T. Díaz², A. Cabezas², M. Villarroel¹ and R. Bermejo-Poza²¹ETSIAAB, Universidad Politécnica de Madrid, Departamento de Producción Agraria, Avenida Complutense 3, 28040, Madrid, Spain, ²Facultad de Veterinaria, Universidad Complutense de Madrid, Departamento de Producción Animal, Universidad Complutense, Avenida Puerta de Hierro s/n, 28040, Madrid, Spain, ³Facultad de Veterinaria, Universidad Complutense de Madrid, Departamento de Fisiología Animal, Universidad Complutense, Avenida Puerta de Hierro s/n, 28040, Madrid, Spain; alvaro.delallave.propin@alumnos.upm.es

The stress response in fish is conditioned by water temperature. The objective of this study was to evaluate the effects of the application of different pre-slaughter fasting on the stress response and meat quality in rainbow trout (*Oncorhynchus mykiss*) in summer. 270 fish (initial biomass = 17±0.10 kg/tank) were subjected to different pre-slaughter fasting in terms of degree days (no fasting -0 °C d-, 3 days fasting -50 °C d- and 6 days fasting -100 °C d-) in summer conditions (water mean temperature = 22 °). After slaughter by ikejime, biometric (slaughter weight, standard length, body condition and hepato-somatic index) and flesh quality parameters (muscle and liver colour, muscle pH, liver glycogen, liver weight and *rigor mortis*) were measured. Fasting at 50 °C d showed intermediate results over the groups of 0 and 100 °C d, with the exception of liver colour, exhibiting lower values than the rest of the groups. Fasting at 100 °C d had a greater effect, decreasing biometric parameters and presenting lower meat quality. Muscle pH, *rigor mortis* and liver glycogen were lower in the fasting groups compared to the non-fasted. In conclusion, it was observed that fasting had a significant effect on the parameters analysed and that the fish subjected to fasting, especially at 100 °C d, showed a worse productive state and meat quality, so a pre-slaughter fasting of less than 50 °C d is recommended in rainbow trout.

Effects of a new cooled cubicle waterbed on cow behaviour and lameness: a randomized control trial

O. Levrard, R. Guatteo, A. Lehébel, L. Bouglé, M. Tourillon, N. Brisseau and A. Relun
 Oniris, INRAE, BIOEPAR, Chantrerie, 44300 Nantes, France; olivier.levrard@oniris-nantes.fr

In Europe, farmers commonly use fans or sprinklers to mitigate heat stress in dairy cows. Innovative strategies are needed to reduce water and energy use. A randomized controlled trial was implemented in summer 2021 to assess the effects of a new cooled waterbed on the behaviour and lameness of dairy cows, assuming that cows on the cooled waterbed would spend less time standing and more time feeding, and therefore develop fewer claw lesions and lameness. At calving, 219 cows were randomly allocated to one of two adjacent barns, with cubicles equipped with either a conventional or a water-cooled cubicle mat (Louisiane vs Aquaclim; Bioret-Agri, France). The temperature-humidity index (THI) was recorded every 15 minutes. Posture and location of cows in the barns were continuously monitored using computer vision (AIherd; France). Cows' feet were trimmed by a hoof trimmer at the beginning and end of the trial. Gait was scored every fortnight. Behavioural response variables and incidence of lameness were analysed by multiple regression (linear and Cox models respectively). At baseline, cows were primarily affected by digital dermatitis, with no difference in lameness score between mats ($P=0.25$). Between 14 June and 30 September, 17 days were slightly hot ($68 \leq \text{THI} < 72$) and 8 days moderately hot ($72 \leq \text{THI} < 79$). 83 cows calved during this period. Cows in the waterbed group spent significantly more time feeding (+ 46 min/d), lying down (+1 h 47 min/d) and less time drinking (-6 min/d), standing in the alley (-63 min/d) and in the stall (-67 min/d), regardless of average daily THI. Consequently, cow comfort and stall use indexes were significantly improved in the waterbed group (74 and 54% respectively vs 63 and 44% in the control group). Of the 58 cows that were sound at their first post-calving assessment 41 developed lameness before 150 DIM (75 and 65% in the control and waterbed groups, $P=0.42$), at a mean of 68 DIM ($P=0.83$). Incidence of lameness did not differ between mats. The water-cooled cubicle mat is an interesting tool to improve cow comfort. Further studies are needed to draw a firm conclusion on its impact on lameness and to find the optimal settings to mitigate heat stress.

Session 23

Poster 15

Evaluation of milk and residual milk production of dairy Gyr cows

R.C. Castanheira¹, M.I. Paiva¹, K.T. De-Sousa¹, M.S.V. Salles¹, E.A. Silva² and L. El Faro¹

¹Animal Science Institute, Beef Cattle Center, Rod Carlos Tonani, km 94, 14174-000 Sertãozinho-SP, Brazil, ²Epamig Oeste – Campo Getúlio Vargas, Dairy Cattle, R. Afonso Rato, 1301, 38060-040, Uberaba, MG, Brazil; lenira.zadra@sp.gov.br

We aimed to evaluate the milk production (MY) and residual milk (RM) of 40 dairy Gyr cows. The cows calved in Uberaba, Minas Gerais, Brazil, in two periods: PC1- October and November/2021, and PC2- December/2021 and January/2022. Milking was performed twice a day, and the calves had access to one teat from their dam during each milking, until 90 days of age. The calves were distributed into two treatments according to the feeding management: conventional ($n=20$) and optimized ($n=20$). For optimized management, the calves receive 4 or 2 l of milk (depending on age) in bottles after milking. MY and RM were recorded at 30, 60, 90 e 120 days-in-milk, in both milkings. To measure the RM, 1 ml of oxytocin was applied right after milking. The variables were analysed using a linear model, with measures repeated over time using the SAS MIXED procedure. The fixed effects were treatment, period of calving (PC=1, 2), parity order (PO, primiparous and multiparous), days-in-milk (DIM), and interactions (Treatment $\times$ PC; Treatment $\times$ PC $\times$ DIM; PO $\times$ DIM). Means estimated by least squares were compared by Tukey's test. For MY, there was an effect ($P<0.05$) of PO (primiparous: 7.9 ± 0.88 kg; multiparous: 10.2 ± 0.83 kg) and DIM (d30: 8.1 ± 0.61 kg; d60: 8.2 ± 0.61 kg; d90: 7.5 ± 0.61 ; d120: 9.3 ± 0.61 kg). There was an effect ($P<0.05$) of the PC and DIM on RM. The least square means for RM in P1 was 1.9 ± 0.17 kg, and in P2 was 1.3 ± 0.21 kg. The estimated RM varied over days-in-milk (d30: 1.3 ± 0.34 kg; d60: 1.2 ± 0.34 kg; d90: 2.0 ± 0.34 ; d120: 2.4 ± 0.34 kg). The lower value of RM in P2 can be explained by the fact that calves in P2 consumed more additional milk and food than the calves in P1 and, possibly sucked smaller amounts of milk from their mothers. Our results showed that residual milk may be related to the amount of feed the calf receives. Based on this, future studies can evaluate strategies for feeding calves, in order to improve milk production and reduce residual milk.

Environmental enrichment and tactile stimulation on the welfare of F1 Holstein × Gir calves

C.O. Miranda¹, A.E. Vercesi Filho¹, M.L.P. Lima¹, F.F. Simili¹, M.S.V. Salles¹, E.G. Ribeiro¹, J.A. Negrão² and L.E.F. Zadra¹

¹Animal Science Institute, Beef Cattle Center, Carlos Tonani, 94, 14.174-000 Sertãozinho São Paulo, Brazil, ²Universidade de São Paulo, FZEA, Duque de Caxias, 225, Campus Fernando Costa, 13635-900, Pirassununga, São Paulo, Brazil; lenira.zadra@sp.gov.br

This study aimed to measure the physiological traits related to the welfare of F1 Gyr × Holstein calves. The experiment was carried out at Instituto de Zootecnia, Ribeirão Preto, SP, Brazil, with 34 calves with 30 days of age, housed for 90 days in collective barns. A 2×2 factorial design, with two environments (with and without environmental enrichment with playful objects, (EE and WE) and two managements (with and without tactile stimulation, TS and WS). During 31 days of experiment (up to 60 days of age), heifers received TS (brushing). Weaning occurred at 60 days of experiment (90 days of age). Serum levels of cortisol, lactate, glucose and oxytocin, as well as the flight distance (FD) were analysed using mixed linear models, with repeated measures over time. The model of analysis for the variables (cortisol, lactate, glucose and oxytocin) included the fixed effects of management group class (enriched environment and/or tactile stimulation and the interaction between them), day of record (1, 30, 55, 60, 65 and 90 days). For FD, the same fixed effects were considered, but the collection days at 10, 20 and 22 days after weaning. There was no interaction between EE and ST for all traits ($P>0.05$). The effect of animal within treatment accounted the repeated records. Both tactile stimulation and EE were important to reduce the animals' stress, but as the TS was only offered for 30 days, the EE effect was more visible throughout the experimental period. Animals that received EE had shorter flight distance (2.19 ± 0.22 vs 3.09 ± 0.22 m), lower serum lactate levels (15.49 ± 0.79 vs 20.06 ± 0.81 mg/dl) and higher oxytocin levels (39.7 ± 0.28 vs 18.8 ± 0.29 uUI/ml) than WE animals. For tactile stimulation management only oxytocin level was significantly different, with higher estimated means for ST (36.84 ± 0.31 uUI/ml) than that WS (20.88 ± 0.27 uUI/ml). The use of EE together with TS promoted important in the improvement of the welfare of the animals.

Session 23

Heat stress indicators in dairy cattle breeding provided by automatic milking systems (AMS)

M.A. Leandro, J. Stock, J. Bennewitz and M.G.G. Chagunda

University of Hohenheim, Garbenstraße 17, 70599, Stuttgart, Germany; miguel.ribeiroleandro@uni-hohenheim.de

Heat stress in dairy cattle represents a major economic loss and animal welfare problem. Apart from direct effects on animals, heat stress has an indirect effect on the increased proliferation of diseases such as mastitis and claw disease. Automatic milking systems (AMS) are becoming common on dairy farms and allow for the non-invasive measuring of many animal parameters without disturbing the cow's normal behaviour. While common for predicting the onset of disease, research on prediction and management of heat stress in dairy cows using AMS is sparse. This review examines the associations of milk- and animal behaviour-based parameters with heat stress. It also examines the availability and accessibility of such parameters in the AMS and infers their potential to be used as indicators of heat stress in dairy cattle breeding. This review also evaluates the potential of these traits to be used in breeding programmes through examination of the heritability values. In terms of animal behaviour-related traits, the literature showed that heat stress manifests through reduced feed intake (up to 10%), higher respiratory rate (panting) and reduced activity. It was also shown that animals reduced number of visits to the AMS, as they spent more time laying down and at water sources. For milk-based indicators, the literature has shown reduced milk yield (up to 21%), correlated with an increase in somatic cells in the milk as well as reduced protein (up to 2.7%) and fat content (up to 9.5%). Milk temperature has also been found to be correlated to body temperature. Furthermore, the AMS also provides information on its interactions with the cows, such as the number of successful milkings per individual, and milking efficiency. From an animal breeding perspective, most of these traits have been reported to have moderate heritability with milk yield=0.27, milk fat content=0.44, milk protein content=0.55, respiratory rate 0.04 and body temperature=0.15-0.3. This review develops a framework examining the potential of generating non-invasively measured indicators of heat stress phenotypes from automatically milked cows.

Impact of floor type and group size on veal calves' behaviour*D. Bastien and V. Lefoul**Institut de l'Elevage, Qualité des Carcasses et des Viandes, 8 route de Monvoisin, 35650 Le Rheu, France; didier.bastien@idele.fr*

Calf housing is at the heart of societal and regulatory issues. In this context, a trial was conducted to study the impact of floor type and group size in veal calf production. 80 male Prim Holstein calves aged 20 days and weighing 52.7 kg were divided into 4 batches: wooden floor with 5 calves per pen (control, W5), wooden floor with 10 calves per pen (W10), rubber floor with 10 calves per pen (R10), and wooden and rubber mixed floor with 10 calves per pen (M10). The calves were individually housed the first 28 days and were fattened for 24 weeks using the same feeding plan and health protocol. Each batch had the same density (1.8 m²/calf). Scan sampling and continuous sampling observations were carried out from 6 am to 8 pm on 3 days (D22, D75 and D145), supplemented by activity measurements from pedometers placed on 5 calves per batch. W10 calves walked more than W5 calves (+20% at mid fattening, NS and +40% at the end of fattening, $P < 0.05$). However, the group size had no effect on lying time (68.2% of the day spent lying for both batches at the beginning of fattening period, 66.9% at mid-fattening and 65.5% at the end of fattening), nor on ruminative or stereotypic activities. It also had no impact on the number of health treatments per calf (W5=3.2 treatments vs W10=3.7 treatments, NS). Total growth rates were also identical (W5=1,244 g/d vs W10=1,236 g/d, NS). The calves preferred the rubber floor for lying: 90% of the lying in M10 was done on the rubber floor. However, the lying time was identical between W10, M10 and R10. We measured more steps for R10 than W10 (334 steps/day vs 288 at the beginning of fattening, 524 vs 427 at mid-fattening and 459 vs 414 at the end of fattening), but these differences are NS (M10 being intermediate). 33% of R10 calves were scored dirty during fattening vs 18% for M10 and 1% for W10. This state of cleanliness had an impact on calf grooming (W10=4.8% of daily activity in mid fattening vs M10=7.1% and R10=5.7%). In terms of zootechnical performances, floor type had no effect on calf growth or carcass weight. Nevertheless, it had an impact on carcass colour (W10=5% of coloured carcasses vs M10= 35% and R10=30%).

Session 24

Theatre 1

Heterogeneity of 3D cameras feed intake heritabilities in Holstein, Jersey and Nordic Red cows*C.I.V. Manzanilla-Pech¹, R.B. Stephansen¹ and J. Lassen^{1,2}**¹Aarhus University, C. F Møllers allé 3, 8000 Aarhus C, Denmark, ²Viking Genetics, Ebeltoftevej 16, Assenstoft, 8960 Randers, Denmark, Denmark; coralia.manzanilla@qgg.au.dk*

Recording sparse phenotypes as feed intake on a large scale is becoming possible with the incorporation of recently developed new technologies, as the use of 3D cameras. With the availability of dry matter intake (DMI) records from such systems, it becomes possible to estimate heritabilities across lactation with complex models as random regression. The objective of this study was to estimate heritabilities for DMI measured by 3D cameras across lactation week in first parity Holstein (HOL), Jersey (JER), and Nordic Red (NR) cows. Data was collected on 18 commercial farms in Denmark (HOL=7, JER=5, NR=6) in the period from 2020 to 2022. A total of 69,971 weekly records in 3,572 first parity cows were analysed (HOL=28,966 records/1,441 cows, JER=23,234 records /1,086 cows, NR= 17,771 records /1,045 cows). In average, 17 to 21 weekly DMI records were available per cow per breed. Fixed effects included herd-year-season, week of lactation (1-44, modelled with 3rd order Legendre polynomial) and age at first calving as covariate. Random effects included genetic and permanent environmental effects, which were modelled using a 2nd order Legendre polynomial. Heterogeneous residual variance was modelled per month of lactation (1-11). Preliminary results indicate estimated heritabilities for DMI ranging from 0.18 to 0.35 for Holstein, from 0.11 to 0.21 in Jersey and from 0.38 to 0.53 in Nordic Red. These heritabilities values are within the range of previously reported in literature for DMI across the lactation measured by traditional methods as feed bins.

Genomic correlations of MIR-predicted and measured feed efficiency traits in Holstein FriesianA. Seidel¹, C. Heuer¹, L.M. Dale², A. Werner², H. Spiekens³ and G. Thaller¹¹Christian-Albrechts-University, Institute of Animal Breeding and Husbandry, Olshausenstr. 40, 24098 Kiel, Germany,²Regional association for performance testing in livestock breeding of Baden-Wuerttemberg, Heinrich-Baumann Str. 1-3, 70190 Stuttgart, Germany, ³Bavarian State Research Centre, Institute for Animal Nutrition and Feed Management, Prof.-Dürrwachter-Platz 3, 85586 Poing, Germany; aseidel@tierzucht.uni-kiel.de

Feed is a major component of variable and environmental costs associated with dairy systems and is therefore a crucial parameter for future breeding programs. However, feed related traits are complex and costly to measure at the population level. Thus, individual estimations based on routinely measured mid-infrared spectroscopy (MIR) data from milking cows could serve as a potential indicator for phenotypic and genetic purposes. Therefore, the aim of this study was to compare predictions for the traits energy balance (EB NEL) energy efficiency (EE NEL) according to GfE (2001) as well as feed efficiency (FE ECM) from the MIR spectra to on-farm measurements. All MIR models were built in R software with the help of 'pls' and 'glmnet' packages with a RPD higher than 2. Pairwise bivariate (one trait, on-farm vs MIR) random regression models were established to estimate SNP based genomic correlations. For the analyses, 13,797 measured as well as MIR predicted observations of 671 Holstein Friesian cows from four German research farms were used. For all animals 50k SNP genotypes were available. In the models, herd-year-season and lactation number (1, 2, 3, 4, ≥5) were considered as fixed effects. Parameters were estimated from lactation days 10 to 300. The additive genetic and the permanent environmental effect were both modelled using the third degree polynomial distribution of lactation day, allowing for heterogeneous variances. SNP based correlations were calculated as the average correlation (20,000 replicates) of posterior breeding values for each lactation day. Average genomic correlations within trait and across days in milk varied between 0.34-0.95. Specifically, for the traits EB NEL, EE NEL and FE ECM, 0.82 to 0.95, 0.34 to 0.51 and 0.52 to 0.55 respectively. The results demonstrate high potential integrating MIR-estimated efficiencies as indicator traits for innovative breeding purposes.

Session 24

Theatre 3

Heritability of dry matter intake in Norwegian Red with measures on feed intake in commercial herdsK.A. Bakke¹ and B. Heringstad^{1,2}¹Geno A.I and Breeding organisation, Storhamargata 44, 2317 Hamar, Norway, ²Norwegian University of Life Sciences, Oluf Thesens vei 6, 1430 Ås, Norway; karoline.bakke@geno.no

An ongoing project for monitoring direct feed-intake in commercial dairy herds enables longitudinal measurements on cows direct feed intake. The aim of the current study was to perform the first genetic analyses of daily dry matter intake in Norwegian Red cows. Equipment for recording of roughage intake has been installed in collaborating dairy herds. Data from 7 of these herds from 2022 was included in the analyses. After editing the data and combining data from concentrate intake, roughage intake, and the monthly feed analyses of roughage a total of 58,370 records of daily total dry matter intake from 484 Norwegian Red cows entered this study. The mean (standard deviation) daily dry matter intake in the period from January to October 2022 were 20.5 (4.3) kg. Variance components for daily dry matter intake were estimated with a linear animal repeatability model. The fixed effects of herd, days in milk and parity were included. For first parity cows, age at calving in months were included. As random effects we modelled herd-test-day, additive genetic effect, and permanent environment effect of animal. The heritability (se) for daily dry matter intake in Norwegian Red was 0.18 (0.05) with a repeatability (se) 0.33 (0.02). Predicted breeding values (BLUP) varied from -3.49 to 3.81 (1.22) for the 484 animals with data. Results are promising for Genos further work on feed efficiency and the amount of data are steadily increasing. The future work will include genetic analyses of energy-corrected feed-intake and its correlation to milk yield and to estimate genomic breeding values for all cows in the 14 herds with equipment for recording feed intake.

Assessing the potential of faecal NIR spectra for the prediction of feed efficiency in dairy cowsS. Ampuero Kragten¹, T. Haak^{2,3}, K.-H. Südekum² and F. Schori³¹Agroscope, Method Development and Analytics, 1725 Posieux, Switzerland, ²University Bonn, Institute of Animal Science, Bonn, Germany, ³Agroscope, Ruminant Nutrition and Emissions, 1725 Posieux, Switzerland; silvia.ampuero@agroscope.admin.ch

Optimizing the feed efficiency (FE) of ruminants might reduce greenhouse gas emissions while limiting production costs. Thereby, reducing the environmental footprint of dairy production. This paper assesses the potential of faecal NIR spectra prediction models to estimate: feed conversion ratio [FCR = dry matter intake (kg DMI/d)/energy corrected milk yield (kg/d)], nitrogen use efficiency [NUE = milk-N yield (g/d)/feed-N intake (g/d)], residual feed, energy and nitrogen intakes [actual – predicted values (RFI: kg DMI/d), (REI: MJ NEL/d), (RNI: g N/d) resp.]. Within the frame of larger projects, FE traits were evaluated for 86 lactating cows (60 Holstein, 16 Swiss Fleckvieh), (grazing and stall-fed), primiparous and multiparous, in mid and late lactation. The n-alkane marker method for grazing cows and weighing consumed rations for stall-fed cows were used for DMI determination together with Swiss feed recommendations for predicted intake, NEL and N values. Freeze-dried faecal samples were scanned in diffuse reflectance mode with a NIRFlex N-500 (Büchi, CH-Flawil), with 3 replicate spectra per sample, 21 scans per replicate, in the range of 4,000 to 10,000 cm⁻¹. 132 samples were a 7-days mass ratio pool of a one-week measurement period; 32 of those were also scanned as 3-days pool (1, 4 and 7 d) and as single-day sample (1 d). NIRS models were developed with PLS algorithms including: snv (normalization standard normal variate), mf (normalization MSC Full) and db1g2 (1st derivative BCAP Gap 2). NIRS models (independent calibration (cal) and validation (val) sets, ~70 and 30% of samples resp.) showed moderate to good predictive potential for FE traits [R² (cal/val): 0.75/0.76, 0.84/0.84, 0.58/0.58, 0.67/0.65 and 0.88/0.82; residual prediction deviation (SD calibration-set/standard error of prediction): 2.2, 2.5, 1.6, 1.9 and 2.8 for FCE, NUE, RFI, REI and RNI resp.], which is interesting, especially for selection of dairy cows. These models should be incremented with samples from diverse origins (breeds, diets, production and environmental conditions) to improve their robustness.

Session 24

Theatre 5

Genetic parameters for potential auxiliary traits for lameness based on data from PLF technologiesK. Schodl^{1,2}, B. Fuerst-Waltl², F. Steininger¹, M. Suntinger¹, H. Schwarzenbacher¹, A. Köck¹, D4dairy Consortium¹ and C. Egger-Danner¹¹ZuchtData EDV-Dienstleistungen GmbH, Dresdner Str. 89, 1200 Vienna, Austria, ²Univ.Nat.Res.Life Sci. Vienna, Gregor-Mendel-Str. 33, 1180 Vienna, Austria; schodl@zuchtdata.at

Lameness in dairy cattle presents a widespread animal welfare and economic issue. Lameness may be associated with changes in milk performance or behaviour. Integrating lameness into routine genetic evaluation is important for improving dairy health and welfare. However, like many other direct health traits large scale phenotyping is challenging. Precision livestock farming (PLF) technologies such as sensor and automatic milking systems (AMS) provide a valuable opportunity for large scale phenotyping. Within the D4Dairy project we investigated the potential of PLF data for deriving auxiliary traits for lameness, which may be used in genetic evaluation. Data from 32 farms equipped with Lely AMS and sensors measuring activity, rumination and feeding time were collected between January 2020 and March 2021. Lameness was assessed by employees of the milk recording organisations during their routine visits and data from 78 farms were included. The lameness assessment scale ranged from 1 (not lame) to 5 (severely lame). Daily mean, median, and standard deviation (SD) were calculated for the sensor parameters and daily milk yields were derived from the AMS. Variables for genetic parameter estimation comprised lameness scores, daily milk yields and sensor parameters on days 0, -5, and -10 to the lameness assessment. Bivariate linear animal models were fitted to 33,977 observations of 4,888 Simmental cows (13,742 observations and 1,993 animals including sensor and AMS data) to estimate heritabilities (h²) and genetic correlations (r_g). The h² was highest for feeding behaviour (0.11-0.44) followed by rumination (0.04-0.30) and activity (0.7-0.18) and lameness (0.12) with low standard errors for all traits. Low r_g were found for mean feeding time (0.07), for rumination SD during days -10 (0.21) and for median activity on day 0 (-0.13). Heritabilities show that sensor parameters have potential for use in breeding. Low correlations to lameness were found for some traits, but the use as proxies for lameness require further work on trait definition.

Breeding for resilience based on rumination time data of Chinese Holstein heifersW. Lou^{1,2}, R. Shi^{1,2}, B. Ducro², A. Van Der Linden², H.A. Mulder², S.J. Oosting² and Y. Wang¹¹China Agricultural University, No.2 Yuanmingyuan West Road, Haidian District, 100193 Beijing, China, P.R., ²Wageningen University & Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; wenqi.lou@wur.nl

Breeding for resilient cows could result in lower impact of stressors and reduce extra costs for labour and antibiotics. Resilience indicators can be derived when it is possible to record perturbations in the cows' rumination. These indicators can be used in farm management and breeding provided these are inherited traits. Therefore, the aims of this study were to define resilience indicators from daily rumination time (DRT) in heifers, and to investigate if they can be used to genetically improve resilience. After quality control and outlier detection, 113,813 records on 2,246 Chinese Holstein heifers were used in this study. The resilience indicators were defined based on deviations from a quantile polynomial regression model on DRT. Genetic parameters for the resilience indicators were estimated using an animal model. Results showed that DRT had a moderate heritability (0.17-0.44) and repeatability (0.21-0.66), while resilience indicators had low to moderate heritability (0.03-0.16). The top 10% heifers with highest estimated breeding value (EBV) for resilience had more often a successful first insemination (57 vs 53%), an easy first calving more often (76 vs 66%), and a lower disease incidence (26 vs 30%) than the 10% heifers with the lowest EBV for resilience. The top 10% sires with the highest EBV for resilience had a higher genomic EBV for feed efficiency (71.92 vs 61.13) and feed saved (79.09 vs -48.83), productive life (1.54 vs 0.78), and body confirmation score (0.15 vs -0.29) than the 10% sires with lowest EBV for resilience. These findings lay a foundation for future work to select more resilient dairy cows based on resilience indicators from rumination time.

Session 24

Theatre 7

Validation of a high-throughput movable 3D device for the acquisition of the whole cattle bodyA. Lebreton¹, C. Allain¹, L. Delattre², J. Loof¹, Y. Do¹ and M. Bruyas³¹Institut de l'Elevage, 149 Rue de Bercy, 75595 Paris, France, ²3D Ouest, 5 Rue Louis de Broglie, 22300 Lannion, France,³Eliance, 149 Rue de Bercy, 75595 Paris, France; adrien.lebreton@idele.fr

In the past ten years, proofs of concept have flourished around the use of three-dimensional imagery to assess cattle morphology, but devices were not adapted for on-farm phenotyping. Indeed, most of them were sensitive to animal movements, sunlight or dust. Our objective was to upscale a 3D image scanner adapted to on-farm phenotyping and movable from one commercial farm to another. The 3D scanner is a dismountable gantry (3×2.5×0.7 m) embedding 10 depth sensors which combine their data acquisition to provide a 3D image of the whole body. Animals are scanned in motion by walking under the device allowing high throughput phenotyping. Embedded algorithms clean the image automatically allowing a direct processing of the image. The scanner was tested in a variety of situations: inside and outside, positioned at the end of a scale or between 2 pens in a fattening barn. To validate the accuracy of the 3D image acquisition, we used the method proposed by Le Cozler *et al.* comparing the values measured on the live animals (REF) to those extracted from the 3D images manually (MAN) and automatically by image processing (PROC). The traits used in the validation process were hip width (HW), heart girth (HG), chest depth (CD), wither height (WH) and sacrum height (SH). REF measures were collected in 2 sessions on 33 animals (crossbreed calves 6-12 mo). Animals were scanned in the different conditions described above. Correlations with REF for both MAN and PROC methods were higher than 0.9 on WH and SH measures, higher than 0.8 for CD and HW measures and higher than 0.7 on HG. RMSEs and coefficients of variation of repeatability were also assessed. The accuracy of this new device allows on farm phenotyping. Automatic processing of the image is already promising and will be further developed into the PHENO3D project that aims to predict body weight and morphological trait scores used in the beef cattle genetic indexes.

MIRS coupled with machine learning for the prediction of cow colostrum immunoglobulins concentrationA. Costa¹, A. Goi² and M. De Marchi²¹University of Bologna, via Tolara di Sopra, Ozzano dell'Emilia 40064, Italy, ²University of Padova, Viale dell'Università, Legnaro 35020, Italy; angela.costa2@unibo.it

The concentration of immunoglobulins G (IgG, g/l) is the key parameter for the quality of colostrum and IgG below 50 g/l indicates insufficient quality due to the concrete risk of failure of passive transfer in calves. Mid-infrared spectroscopy (MIR), routinely used for milk official analyses worldwide, can be exploited for quality screening of colostrum for different purposes on both portable or benchtop devices. In the present study we evaluated how MIR spectra coupled with machine learning perform for the prediction of colostrum quality based on IgG. 531 colostrum samples were harvested within 6 h from calving from 531 Italian Holstein cows in different parities (1 to 8) and farms (n=9) between 2019 and 2020. Cows were not vaccinated before calving. The RID assay was adopted for IgG concentration determination, whereas MIR spectra were collected through a Milkoscan FT7 (FOSS A/S, Hillerød, Denmark). Samples were flagged as 'low quality' if IgG was either below 50 or 70 g/l. The 1,060 spectral wavelengths, in absorbance, were used as predictors of: (1) IgG in regression; (2) and quality level in classification. The 70% of data were adopted to train the model using bootstrapping and testing was carried out on the remaining 30% of data. Regardless of the approach used, MIR coupled with machine learning provided promising prediction accuracy. As regards the classification ability, when the threshold at 70 g/l was considered, the amount of true positive (96.7%) and true negative samples (81.8%) in the testing set were greater compared to the other threshold, i.e. 50 g/l. In training, the out-of-bag errors were 0.05 (50 g/l) and 0.07 (70 g/l). Satisfactory accuracies were observed in regression: the coefficient of determination in training (0.97) and testing (0.74) resulted promising. The ten most important wavenumbers were similar between regression and classification with a slight re-ranking and were located in milk protein absorption region. Based on our findings, it would be possible in future to accurately assess colostrum quality exploiting MIR-based devices.

Extracting video-based phenotypes in a pig breeding programmeC. Coello¹, Ø. Nordbø¹, R. Sagevik¹, F. Cheikh², M. Ullah², K.H. Martinsen¹ and E. Grindflek¹¹Norsvin AS, Storhamargata 44, 2317, Norway, ²NTNU Gjøvik, Department of Computer Science, Teknologivegen 22, 2815 Gjøvik, Norway; christopher.coello@norsvin.no

In breeding and management of pigs there are needs to improve welfare of pigs raised in groups, for example to minimize biting and damage to pen mates, minimize stress and fair of the animal itself, or avoid aggression towards farmers. Behaviour phenotypes are, however, difficult to obtain in an objective, repetitive and cost-effective way for breeding companies. Video cameras, together with analysis pipelines extracting the phenotypes of interest, have been proposed in order to achieve this. One critical aspect of this analysis pipeline is the necessity to identify the animal from which the behaviour is detected. The robustness of this identification is necessary in order to define the genetic component for the behaviour. Pigs' similarity makes this step complex and prone to error. In addition, other factors like animal density in the pen, pig's willingness to lie very close to each other or frequent occlusions occurring due to the top-down acquisition geometry of the video camera. Therefore, additional information needs to be combined to the video feed in order to achieve this identification robustly. The objective of this work is to set up a baseline pipeline to measure activity budget phenotypes like walking distance, time spent lying, etc. To achieve this, we have implemented a state-of-the-art activity budget detection pipeline based on a detection module (Yolov8), a tracking module (StrongSORT) and an identification module (colocalization with feeding station). We have looked at how the identification of the tracks can be successful using additional information like colour eartag information. Manually labelled video tracks were used to validate this automatic phenotype extraction method. Use-case specific validation metrics, like the fraction of the video feed that an animal is correctly identified, were measured in parallel to the more classic detection metrics (e.g. F₁-score=0.965 and mAP@.5=0.976) and tracking metrics (e.g. identity switches). From our initial experiments, robust identification of animals (correct identity>50% of the time) cannot be achieved with the current tracking algorithm by only using colocalization with feeding station as identification procedure.

Impact of the social effect on feeding behaviour in pigsP. Núñez¹, S. Gol², J. Reixach² and N. Ibañez-Escriche¹¹Universitat Politècnica de València, Institute for Animal Science and Technology, Cami de Vera, 46022, Spain, ²Selección Batallé S.A., Riudarenes, 17421, Spain; pnuez@posgrado.upv.es

Automatic feeders allow the measurement of individual feeding behaviour in porcine. Social interactions within a group of growth pigs could influence feeding behaviour. This study aims to estimate the percentage of phenotypic variance explained by the social effect on feed consumption and duration per visit. Data analysed had 843,605 visits from 1,608 purebred Pietrain pigs (Batallé S.A. selection nucleus) housed in groups of 12.7 ± 1.8 pigs with a 1.5 m^2 per pig density. The feed intake and duration were measured with automatic feeders (PPT, Nedap, Netherlands). Bayesian analyses were carried out using a classical animal model $y = Xb + Za + e$, and a 'social model' $y = Xb + Za + Z's + e$, which included the social effect ($Z's$) of the pig that visited the feeder (follower) immediately after the visit under analysis. The analyses were performed with the complete database, as well as for two subgroups classified as competitive visits (time < 60 seconds between visits, $n = 336,914$) and no competitive visits (> 600 seconds, $n = 129,180$). Fixed effects included the contemporary group, the hour of the day, and the age in days. The assumed distributions were $a \sim N(0, A\sigma^2)$ and $s \sim N(0, I\sigma^2)$ for the additive genetic and social effect, respectively. Models' effects and variance components were obtained from the posterior marginal distribution generated with Gibbs1f90. The estimated heritabilities with both models showed similar values for the three databases (from 0.21-0.25 for the duration and 0.15-0.16 for consumption). The social effect explained less than 1% of both traits in the complete database and the 'no competitive' database. However, this percentage increased to 2.3% in the competitive visits. These results are similar to those found in Angarita *et al.*, where the same models were evaluated for duration but with fewer animals. As we expected, the social effect was more important in the competitive visits compared with no competitive visits. However, this effect explained a small portion of the phenotypic variance (2.3%). These results indicate that in these housing conditions and genetic line, the social effect did not have a relevant impact on the duration and feed intake per visit.

Session 24

Theatre 11

Assessing lactating sow behaviour using sensor technology and machine learningG. Dumas¹, L. Maignel², J.-G. Turgeon¹ and P. Gagnon¹¹Centre de développement du porc du Québec, Place de la Cité – Tour Belle Cour 450 – 2590, boulevard Laurier, Québec City, Québec, G1V 4M6, Canada, ²Canadian Centre for Swine Improvement, 960 Carling avenue Building 75, Ottawa, Ontario, K1A 0C6, Canada; laurence@ccsi.ca

Sow behaviour during lactation is a key factor affecting pre-weaning survival. Maternal behaviour is a combination of several complex traits, including sow temperament and nervousness after farrowing. The frequency of postural changes in lactating sows is often used as a predictor of their stress level. Calm sows tend to wean more piglets, however, they have to be alert to raise up quickly to avoid crushing piglets, and stand up to eat and drink enough to cover their high energy requirements during lactation. Frequent standing/laying transitions lead to increased risk of piglet crushing. Vision systems allowing for 24/7 tracking of lactating sows allow for real-time behaviour tracking as potential management tools and provide opportunities to record activity levels as potential selection criteria. Since it might not be possible to install cameras in all farms, a simplified system using a set of infrared sensors was designed by the Centre de développement du porc du Québec (CDPQ) and tested to collect information to identify and quantify basic sow postures over time. Ten farrowing pens were equipped with cameras and sensors at the CDPQ Sow Research and Training Barn (Armagh, Québec) and a total of 59 commercial sows were tracked from entry to weaning. Specific 1-hour video sequences were annotated using standard methods to be used as a training set. The data collected by the sensors was used to predict basic sow postures including standing, sitting and laying down using machine learning approaches such as random decision forests. Preliminary results show that the sensors can classify sow postures and detect sow postural changes, however the prediction accuracy varies across sensors, and the algorithm should be improved before we can use it to compute indicators of interest such as the amount of time spent in each posture and the frequency of postural transitions for each day in lactation. The newly developed sensor system is a promising easy to install, inexpensive, contactless and accurate solution to track sow behaviour during lactation.

Relationships between sow activity over the days after farrowing and litter weight gain

O. Girardie¹, D. Laloë², M. Bonneaur³, Y. Billon⁴, J. Bailly⁴, I. David¹ and L. Canario¹

¹INRAE, GenPhySE, 31320 Auzeville-Tolosane, France, ²INRAE, GABI, 78350 Jouy-en-Josas, France, ³INRAE, ASSET, 97170 Petit-Bourg, Guadeloupe, ⁴INRAE, GenESI, 17700 Surgères, France; oceane.girardie@inrae.fr

Litter growth during the first week of lactation depends on sow maternal ability. The objective of the study was to identify which behaviours of the sow are related to the average daily gain of her litter (ADGL) considering 3 periods after farrowing: D0 to D1, D1 to D3 and D3 to D7. Behaviour of 21 Large White and 22 Meishan primiparous sows, kept in individual pens, was extracted from the analysis of video records. Convolutional Neural Networks were used to obtain sow daily time-budgets for posture activity and standing activity. Sow postures included standing, sitting, lying ventrally, lying laterally with/without udder exposed and the number of posture changes per day (total and those hiding the udder). Sow standing activity included eating, drinking and other (e.g. exploring, rooting). Daily feed intake of each sow was also recorded and grouped with standing activity behaviours. Piglets were individually weighted at D0, D1, D3 and D7. To dissect the temporal evolution of data structure, a special type of PCA, the Partial Triadic Analysis (PTA) was applied to litter ADGL values, and either posture activity or standing activity, considering the 3 periods. Such analysis permits to study the temporal evolution of the association between behaviour and litter growth in comparison to a compromise. Since breeds differed greatly in piglet growth, data was adjusted for the breed effect. On this compromise, ADGL showed a slightly positive correlation with sow feed intake and time spent eating, according to axis 1 which explained 51% of variability. This association was much stronger on the first period (D0-D1) than subsequent periods. The ADGL was positively correlated to number of posture changes and negatively correlated to time spent lying ventrally according to axis 2 (27% of variability explained), markedly at D0-D1 but not at subsequent periods. In conclusion, sows that were eating more and were more restless on D0 had a higher litter weight gain during D0-D1 than other sows. Further explanatory analysis of ADGL according to behavioural data is in progress.

Theatre 13

Multi-camera tracking of turkeys in large groups using instance segmentation

Z. Wang¹, P. Langenhuizen², B. Visser³, H.P. Doekes¹, P. Bijma¹ and P.H.N. De Wit²

¹Wageningen University and Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands, ²Eindhoven University of Technology, Centre for Care & Cure Technology, P.O. Box 513, 5600 MB Eindhoven, the Netherlands, ³Hendrix Genetics Research, Technology & Services B.V., Spoorstraat 69, 5830 AC Boxtmeer, the Netherlands; zhushan.wang@wur.nl

Aggressive feather pecking in poultry can result in poor plumage, skin damage and mortality. Feather pecking is a multidimensional problem, relating to e.g. housing conditions, feed, management and genetics. Although the trait is heritable, breeding against feather pecking is still limited due to a lack of automated phenotyping methods for large groups of birds. To develop an automated phenotyping method, there are two main challenges: (1) detecting pecking events, and (2) identifying the birds involved. Here, we focus on the latter. We set up a system based on computer vision and radio-frequency identification (RFID) to track over 300 turkeys in a pen of 120 m². We installed 35 cameras, such that each part of the pen was covered by two cameras. We equipped each bird with a RFID tag and placed RFID antennas in the feeders for (re-)identification. Between a feather pecking event and re-identification at a RFID antenna, birds need to be tracked through computer vision. For this purpose, we here present a multi-camera tracking algorithm. First, the 35 fields of view were calibrated and transformed to a global coordinate system. Second, a YOLOv7 instance segmentation model was trained to segment the turkeys in each field of view. Third, to track birds across cameras, the overlap of instance segments from neighbouring cameras was calculated. If two segments overlapped more than 60%, they were considered to be the same bird. Fourth, to track birds over time, the overlap of segments between subsequent frames was calculated. Again, if overlap was more than 60%, the segments were considered to be the same bird. Here we present results of the tracking accuracy. The current tracking time is not enough yet to bridge the time gap between a pecking event and re-identification at the feeder. However, we believe that improvement of this model will enable tracking of animals for longer time periods in the near future.

Evaluation of tracking individual broilers using video data

J.E. Doornweerd¹, G. Kootstra², R.F. Veerkamp¹, B. De Klerk³, M. Van Der Sluis¹, A.C. Bouwman¹ and E.D. Ellen¹
¹Wageningen University and Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH, Wageningen, the Netherlands, ²Wageningen University and Research, Farm Technology, P.O. Box 16, 6700 AA, Wageningen, the Netherlands, ³Cobb Europe BV, Koorstraat 2, 5831 GH, Boxmeer, the Netherlands; janerik.doornweerd@wur.nl

Tracking individual broilers on video could provide valuable information on the health, welfare, and performance on many animals with one sensor. These individual broiler tracks would enable breeders to phenotype for novel or indicator traits that aid genetic improvement. However, tracking group-housed individual broilers is a challenge due to the large number of similar looking animals in the barn. The aim of this study was to measure how long broilers could be tracked in terms of time and distance in our experimental pen. The experimental pen (1.80×2.61 m) housed 39 male broilers, of which 35 were non-colour marked. Only data at 18 days of age were used. A YOLOv7 model was trained (n=140), validated (n=30), and tested (n=30) on two-hundred annotated frames to detect broilers within frames. On the test set, YOLOv7 had a precision and recall of 0.99 and an average precision (@0.75 – Intersection over Union threshold) of 0.98, which showed that individual animals were reliably detected within frames. The tracker (SORT) – to link individual detections between frames – was evaluated on human annotated ground-truth tracks of eleven white broilers based on the first frame of every minute (136 frames) over an approximately 2-hour period. Broilers had an average of 10 ID-switches (IDSW) per ground-truth track, with a maximum of 20 IDSW and a minimum of 5 IDSW. Broiler tracklets were on average 12 minutes, with the longest tracklet lasting 51 minutes. The average tracking distance was 1.83 meters per tracklet, with a maximum of 17.07 meters. Shorter tracklet durations and distances seem to coincide with more IDSW, and thus a shorter time to phenotype the animal. Almost all broilers were detected (YOLOv7), but the tracker (SORT) could be improved to reduce the number of IDSW. Overall, tracking group-housed individual broilers on video shows promise in enabling breeders to phenotype for novel or indicator traits to aid genetic improvement.

Poster 15

Genetic variation of new sheep traits measured by dual energy Xray absorptiometry

C.E. Payne¹, B. Paganoni¹, S.F. Walkom², G.E. Gardner³ and D.J. Brown^{2,3}

¹Department of Primary Industries and Regional Development WA, Nash Street, Perth WA, 6000, Australia, ²Animal Genetics & Breeding Unit, University of New England, Armidale NSW, 2351, Australia, ³Advanced Livestock Measurement Technologies, Murdoch University, Murdoch WA, 6150, Australia; claire.payne@dpiird.wa.gov.au

Dual energy Xray absorptiometry (DEXA) is regularly used to measure body composition and bone characteristics in human medicine. Medical grade DEXA can accurately measure the proportion of fat, lean and bone in production animals, as well as bone minerals in lambs. Recently, DEXA modified for lamb carcass scanning at abattoir-chain-speed precisely predicted CT fat and lean % over a range of lamb genotypes. There is opportunity to measure new traits and identify the genetic variation of these traits on live sheep using a medical grade DEXA. Lambs from the Genetic Resource Flock (n=400) are live DEXA scanned at the Katanning Research Station and subsequently DEXA scanned as carcasses at the processing facility. DEXA technology scans an object at two different energy levels. The ratio (R value) between the high and low energy level for each pixel in the image relates to the atomic mass of the tissue. Analysis will include whole body and sub-regional lean and fat %, and bone %. Individual pelvic bones are also analysed on the live DEXA scans to measure pelvic area and bone content. This data will provide the opportunity to identify correlations between live DEXA and carcass DEXA measures of body composition within and across sire types. Furthermore, there is potential to link individual bone analysis to important genetic reproduction traits such as lamb birthweight and lamb survival.

Monitoring within-breed genetic variation at global level

Despite the recognised importance of maintaining genetic variation, the inclusion of related indicators in global monitoring systems has been neglected in recent decades. Especially when considering molecular indicators, there are many challenges related to technological and organisational capacities: Sampling requirements, the choice of the marker sets and methods' properties limit the feasibility of many indicators. A review of demographic, pedigree and genomic parameters that could complement the existing indicators in Domestic Animal Diversity Information System (DAD-IS) shows that the main constraint is the lack of availability of pedigree and molecular data, especially in developing countries. In this context effective population size (N_e) appears to be an appropriate and practical candidate, as it is a direct measure of how well genetic diversity in a population is maintained, and therefore of the genetic risk status of a population. It can be compared across populations and species and is straightforward in terms of interpretation. Moreover, it can be estimated from demographic, pedigree and genomic information sources. Molecular tools provide the opportunity to obtain estimates of N_e that are considerably more accurate compared to demographic indicators and pedigree based measures, especially if pedigree information is of low quality. Given the approximations and potential biases for specific methodologies and data sources, details should be carefully documented in respective information systems, especially for long-term monitoring standardization and comparison.

Theatre 2

Real-time monitoring of genetic diversity in animal populations: the RAGEMO project

C. Danchin¹, I. Palhière², B. Servin² and G. Restoux³

¹IDELE, 149 rue de Bercy, 75012 Paris, France, ²INRAE – GenPhySe, 24 chemin de Borde-Rouge, 31326 Castanet Tolosan, France, ³INRAE – GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France; gwendal.restoux@inrae.fr

Genetic diversity is essential to maintain genetic gain and adaptation abilities for new breeding goals or conditions. However, in selected populations, it is often threatened due to either or both selection on the one hand and genetic drift and inbreeding on the second hand. Thus, a careful and frequent monitoring of the level of variability is necessary. While pedigrees are widely available in France for most breeds, many local breeds have still limited genealogies. Thus, SNP arrays used for genomic selection appear as an affordable solution to estimate the levels of genetic diversity in these cases. Moreover, they allow to estimate additional information about the structure and history of the population like the level of admixture between breeds, the age of the co-ancestry and the presence of deleterious mutations. The RAGEMO project funded by Apis-Gene proposes to develop an automated analysis framework from the deposit of the genotype to the design of a tailor-made report. We worked together with the stakeholders including breed associations (CAPGENES), to select the appropriate indexes and to design the reports depending on the target audience and their uses. The chosen indexes include: (1) within population indexes: (kinship, inbreeding, effective population size, etc.); (2) population structure (PCA, admixture, etc.); and finally (3) the identification of deleterious mutations. The output of these analysis should allow a precise management of breed by making it possible to check the quality of pedigrees, retrieve genealogical relationships, measure the level of diversity and define the limit of the breed (e.g. inclusions of external individuals). As a proof of concept, we first focused on French goats, since they have interesting features including numerous breeds of different population sizes with various status (conservation, selection, with more or less complete pedigrees, etc.). The first results and the analysis pipeline will be presented. The ultimate goal is to extend this monitoring to all French ruminant species by automatically including on the fly all available genotypes.

Evolution of the genomic relationship between a local breed and its mainstream sister breedH. Wilmot^{1,2}, M.P.L. Calus³ and N. Gengler^{1,2}*¹ULiège-GxABT, TERRA Teaching and Research Centre, Passage des Déportés, 2, 5030 Gembloux, Belgium, ²National Fund for Scientific Research (F.R.S.-FNRS), Rue d'Egmont, 5, 1000 Brussels, Belgium, ³Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg, 1, 6700 AH Wageningen, the Netherlands; Helene.Wilmot@uliege.be*

In Benelux countries, there is a genomic continuum of red-pied cattle breeds. Some of them are still rather common, like the Meuse-Rhine-Yssel (MRY), from the Netherlands, while others have the endangered European status like the Red-Pied of Ösling (RPO), from Luxembourg. Survival of a small population like RPO is based on finding a good balance between keeping genetic specificities and collaborating with their sister breeds. We therefore tried to estimate the historical evolution of the genomic relationship between RPO and MRY. For this purpose, we divided the MRY samples into four cohorts depending on the birthdate of animals: before 1990 (cohort 1), between 1990 and 1999 (cohort 2), between 2000 and 2009 (cohort 3) and after 2009 (cohort 4). Results from principal component analysis, F_{st} values and the genomic relationship matrix showed that current RPO animals were on average slightly more related to MRY animals from cohorts 1 and 4 (born before 1990 or after 2009) than to MRY animals from cohorts 2 and 3 (born between 1990 and 2009). These results confirmed the known history of RPO. Breeders in Luxembourg imported MRY animals or semen on a large scale before 1990. After 1990, breeding in Luxembourg was more focused on collaboration with Germany and German dual-purpose red-pied (RDN) cattle were not collaborating a lot with MRY at that time. This changed during the last 20 years and many recent RDN sires have MRY ancestors which could explain increasing relationships with RPO too. Even if this study did not contain RDN animals, it shows the evolution of the complex relationships between some of these sister breeds. Genome assisted mating advice should be used to help breeders in their choice of an appropriate MRY (or other related breed) animal for mating. These animals should be genomically close to the current RPO population which will strengthen the collaboration of these breeds and, finally, support the further across-breed genomic evaluations.

Session 25

Theatre 4

Fine decomposition of inbreeding into the source of the co-ancestriesS. Antonios¹, S.T. Rodríguez-Ramilo¹, J.M. Astruc², L. Varona³ and Z.G. Vitezica¹*¹INRAE, GenPhySE, 24 chemin de Borde Rouge, 31326 Castanet Tolosan, France, ²Institut de l'Élevage, 24 chemin de Borde Rouge, 31321 Castanet Tolosan, France, ³Universidad de Zaragoza, Instituto Agrolimentario de Aragón (IA2), Facultad de Veterinaria, 50013 Zaragoza, Spain; simona.antonios@inrae.fr*

Offspring from related individuals yield to a higher degree of homozygosity across the whole genome, also called inbreeding. Several decompositions of inbreeding have been proposed. For instance, inbreeding can be partitioned into effects attributed to founders by following the pathways back to the origin of the alleles that might be identical by descent in inbred animals. In this study, inbreeding is decomposed into the sources of co-ancestry between the parents of an individual. This decomposition is called the Mendelian decomposition of inbreeding and involves founders and the Mendelian sampling of non-founders. The objective of this work is to decompose inbreeding into the source of the co-ancestries. Real data of three French dairy sheep breeds (Basco-Béarnaise, BB; Manech Tête Noire, MTN; and Manech Tête Rousse, MTR) were used. The pedigree data included 190,276, 166,028 and 633,655 animals in BB, MTN, and MTR, respectively, born between 1985 and 2021. In BB, 41% of the individuals were inbred with an average inbreeding coefficient of 0.013. In MTN, inbreeding affected 24% of the individuals, and the average inbreeding coefficient was 0.007. In MTR, 56% of the individuals were inbred and the average inbreeding coefficient was 0.014. The partial inbreeding coefficients from the Mendelian decomposition of inbreeding were 7,044,811, 1,501,362, and 54,758,519 coefficients generated from 3,268, 2,563, and 11,078 ancestors in the BB, MTN, and MTR breeds, respectively. The average partial inbreeding coefficients ($\pm$ standard deviation) were 5.82×10^{-5} ($\pm 1.04 \times 10^{-3}$) in BB, 1.912×10^{-4} ($\pm 2.06 \times 10^{-3}$) in MTN, 2.33×10^{-5} ($\pm 8.01 \times 10^{-4}$) in MTR. Most of the partial inbreeding coefficients were very low; 99.9 and 96.4%, 99.6 and 92.9%, and 99.9 and 98.7% were lower than 0.01 and 0.001 in the BB, MTN, and MTR breeds, respectively. Our findings contribute to understand the state of inbreeding in those breeds and will be helpful for future studies to predict the inbreeding depression load of any individual in the pedigree.

Predicting homozygosity-by-descent to manage inbreeding and diversity*N.S. Forneris and T. Druet**Unit of Animal Genomics, GIGA-R & Faculty of Veterinary Medicine, University of Liège, Avenue de l'Hôpital 1, 4000, Belgium; nforneris@uliege.be*

Prediction of homozygous-by-descent (HBD) segments in the future offspring of a given mating is a valuable tool for the management of inbreeding and diversity as it provides information on expected inbreeding levels, at both genome-wide and local scales, and has proven to be efficient. Such prediction amounts to identify identical-by-descent (IBD) segments in the parents. Here we took advantage of 98 whole-genome sequenced trios (sire-dam-offspring) of a Holstein pedigree (264 animals, 84 couples) to evaluate different HBD prediction methods that we classified as follows: (1) hidden Markov models (HMM) that model IBD along the four parental chromosomes, with 15, 9 or 3 IBD classes; (2) ruled-based haplotype-matching methods that scan for identity-by-state segments; (3) methods designed to estimate inbreeding within individuals (ZooRoH or the rule-based ROH) applied on pairs of parental haplotypes; (4) SNP-by-SNP measures; and e) pedigree-based. Medium-density (50K) genotypes from the parents were used to predict inbreeding in the offspring. Scenarios with lower marker density data, genotyping-by-sequencing (GBS) data or smaller sample sizes were also investigated. The methods were compared in terms of correlations between predicted and reference genome-wide inbreeding levels or between locus-specific values (HBD probabilities). Reference inbreeding levels were defined with respect to different based populations (recent vs ancient inbreeding). Two HMM approaches (relying respectively on a 15 IBD class model and on ZooRoH) proved accurate, flexible and robust to predict recent inbreeding across the different tested scenarios, both at the genome-wide ($r=0.74-0.75$) and locus-specific levels ($r=0.48-0.49$). An efficient haplotype-matching method proved fast and accurate for genome-wide prediction. Use of GBS (both globally and locally) and lower marker density (at the locus-specific level) data resulted in lower performances than those obtained with the medium density array. Lower sample size did not affect the relative behaviour of the predictors, when results were averaged across subsets. We are currently running simulations, with two demographic scenarios, to further characterize the different methods.

Session 25

Theatre 6

GWAS analyses for dairy traits in Cyprus sheep and goat breeds reveal important protein networks*G. Maimaris, A.N. Georgiou, A.C. Dimitriou and G. Hadjipavlou**Agriculture Research Institute, Animal Production, P.O. Box 22016, 1516, Lefkosia, Cyprus; gmaimaris@ari.moa.gov.cy*

The importance of food securing and hence of investing in the Primary Production Sector was repeatedly highlighted in the past few years because of the climate change impacts, the globally long-lasting economic crisis and the fast-changing geopolitics, especially in Eastern Europe. The island of Cyprus is located in the southeastern part of Europe and due to unfavourable environmental conditions, crop production is limited while at the same time sheep and goat milk demand is constantly increasing. This need is not only attributed to the local growing population but also to the recent registration of halloumi cheese as a product with Protected Designation of Origin. Halloumi cheese consumption is one hundred times more abroad than within the island's borders. Therefore, given the increasing milk demand, the arid climate and the limited size of the country, investing in the genetic improvement of the small ruminant population, is of utmost importance for Cyprus. Towards this direction, the Agriculture Research Institute (ARI) has initiated a four-year project including 15,000 animals from the local Cyprus Chios sheep and Cyprus Damascus goat breeds. Given their constant presence on the island for more than 70 years, these breeds are highly adapted to the local environmental conditions. Therefore, they are ideal candidates for genetically improving commercial-value genetic-traits including milk-, protein- and fat- yield or protein- and fat content, along with weight gain, adaptation and disease resistance, in the context of optimum cost-effective conditions. Using commercially available SNP microarrays (OvineSNP50v3, ICSG_SNP65k_v2), 1000 individuals from each breed have already been genotyped and identified polymorphisms have been incorporated in GWAS analyses. The resulting gene sets and their associated proteins were then incorporated in network and pathway analysis, revealing enrichment in important Biological Processes and Molecular Functions related to the genetic traits of interest.

A severely introgressed South China pig breed in urgent need of purificationL. Cao¹, T. Luan², T.H.E. Meuwissen², P. Berg², J. Yang¹ and Z. Wu¹¹South China Agricultural University, College of Animal Science, Wushan Street 483, Tianhe District, 510642, Guangzhou, China, P.R., ²Norwegian University of Life Sciences, Faculty of Biosciences, P.O. Box 5003, 1432 Ås, Norway; cao.lu@scau.edu.cn

Yuedong Black pig (YDH) only distribute in Guangdong province in China. It is one of the four national indigenous pig breeds that are originated in South China region and currently under conservation status. The breed features of black hair and excellent meat quality make YDH popularly embraced by the local market with over 100 million consumers, leading to a considerably higher price than other pig breeds. In addition, its rough feeding resistance, tameness, good fecundity, long service life of sows, and good performance in crossbreeding draw increasing concern from breeders and producers on its potential for development and utilisation. Therefore, we studied the genetic diversity, phylogeny, and population structure of 360 representative YDH pigs using their SNP chip data, in combination of 782 publicly downloaded genome-wide SNP data from other 42 Eurasian or American breeds and wild boars. The final clean dataset contained 1,142 individuals with 34,579 variants. Our results showed the present inbreeding level, expected and observed heterozygosity, ROH, and LD ($r^2_{0.3}$) of YDH population was respectively <0.254, 0.265~0.370 and 0.266~0.331, 0.09~1.15 Mb, and 1.06~7.44 kb, depending on the subgroups of 360 YDH. These results indicated relatively rich genetic diversity in the existing YDH population possibly due to recent introgression into YDH. Moreover, huge genetic variation within YDH population was observed from scattered clustering in principal component analysis. Neighbour-joining tree constructed by identical-by-state-based genomic distance matrix captured 56 YDH pigs far from the major cluster of YDH population, suggesting some severely admixed YDH pigs. Admixture analysis after excluding 56 severely admixed YDH revealed 19.08~43.96% introgression rate in current YDH population. For further study, advanced optimum contribution selection strategy considering genomic information will be mainly explored to search for the possibility of purifying YDH, with aim to provide insight to YDH conservation program.

Session 25

Theatre 8

Insights into ancient and recent inbreeding patterns in Alpine Grey cattle using ROH analysis

G. Gomez Proto, E. Mancin, B. Tuliozi, C. Sartori and R. Mantovani

UNIPD, DAFNAE, Viale dell'Università 16, 35020, Italy; guido.gomezproto@studenti.unipd.it

The maintenance of genetic diversity is a major concern in livestock populations therefore the study of inbreeding is a determining factor to guarantee this genetic background, especially in local breeds such as the Alpine Grey cattle. The use of runs of homozygosity (ROH) as a method for exploring inbreeding has gained popularity due to its ability to precisely identify genome regions that have undergone recent or ancient inbreeding. This approach allows even knowledge of the inbreeding pattern, as well as to make conservation and breeding decisions. The aim of this study was to evaluate genomic inbreeding using ROH analysis and identify regions of genome with ancient and recent inbreeding patterns, using 1,194 Alpine Grey individuals genotyped with medium-low (33K), and high-density (150K) panels. The ROHs were detected using the sliding-window methodology within the 'detectRUNS' R package. Genes potentially related to disease resistance and fertility were found in BTA6 and BTA7. Additionally, two sets of ROHs were established based on their length: short or ancient ROH (ROHA), and long or recent ROH (ROHR), with a cut-off of 8 Mbp of length. The inbreeding coefficient based on ROH (FROH) was calculated as the ratio between the total length of all ROH and the autosomal genome length. The Alpine Grey showed a higher prevalence of short ROHs than long ROHs, with an average of 35.9 ROHA and 4.3 ROHR per individual, meaning that inbreeding in this breed is mainly ancient. Additionally, the regions containing short ROH had a higher FROH than regions containing long ROH with values of 0.04 and 0.02. The correlation between FROHA and FROHR was weakly positive, with a value of 0.05. The maintenance of genetic diversity in Alpine Grey cattle, as well as its productivity and adaptability, should be the focus on future conservation and selection efforts. Achieving this goal will require the development of strategies that mitigate the negative effects of inbreeding on these selected traits. The study was done within Agritech NRC and received funding from the EU Next-GenerationEU (PNRR – Missione 4 Componente 2, Investimento 1.4–D.D.1032 17/06/2022, CN00000022) and by the Dualbreindg project (CUP J51J18000000005).

Study of Bottleneck effect for conservation of Poonchi chicken from international borders of India aM. Azad¹, D. Chakraborty¹, K. Kour¹, D. Kumar¹ and P. Birwal²¹Sher-E-Kashmir University Of Agricultural Sciences & Technology Of Jammu, Animal Genetics and Breeding, Main Campus, Chatha Jammu, Jammu and Kashmir, 180009, India, ²Punjab Agriculture University, Food Engineering, Ludhiana, 141004, India; mandeepsinghazad@gmail.com

In conservation studies population bottlenecks attributes to the loss of genetic variation in the population in due course of time due to drastic climate changes, predation, limited resources that lead to random fluctuation in the population size. Bottleneck effect within Poonchi chicken of Jammu and Kashmir was evaluated using ten number of microsatellite markers. The microsatellite markers namely ADL0268, MCW026, MCW0081, ADL0278, MCE0069, MCW0111, MCW0222, MCW0016, LEI0094 were analysed in Poonchi chicken. A total of 72 alleles were observed with maximum alleles (9) contributed by locus MCW069, MCW0016 & and the lowest alleles (6) by ADL0268, ADL0278, MCW022. The average observed heterozygosity was 0.8520 with standard deviation of 0.1331, whereas the average expected heterozygosity was 0.8110 with standard deviation of 0.0471. The expected numbers of loci with heterozygosity excess in Poonchi chicken were 5.97 ($P < 0.05$), 5.93 ($P < 0.05$), 5.90 ($P < 0.05$) for Infinite Allele Model (IAM), Two Phase Model of Mutation (TPM) model and Stepwise Mutation Model (SMM), respectively in Sign test. The IAM, TPM and SMM values for one tail for heterozygosity excess in Wilcoxon rank test revealed significant values of ($P < 0.05$) deviation indicated all the loci deviates from mutation-drift equilibrium. The qualitative test for allele frequency showed a slight shift from normal L-shaped curve suggesting the recent bottleneck effect in the population. The presence of genetic bottleneck might have affected the number of alleles and resulted in loss of several effective alleles. Furthermore, loss of several effective alleles suggests urgent need of designing effective breeding policy to conserve this unique native germ plasm of Jammu and Kashmir. This study on native chicken of Poonch region is the first report indicating genetic bottleneck effect.

Session 25

Theatre 10

Up to date results from the ongoing *in situ* genetic management of the local breed Noire de ChallansR. Rouger¹, H. Deloison², M. Teissier³, G. Restoux⁴ and S. Brard-Fudulea¹¹SYSAF, Centre INRAE Val de Loire, UMR BOA, 37380 Nouzilly, France, ²Association pour la sauvegarde et la valorisation de la poule Noire de Challans, 52 Le Broussais, 44460 Saint Nicolas de Redon, France, ³INRAE GenPhySE, 24 chemin de Borde-Rouge – Auzeville Tolosane, 31326 Castanet Tolosan, France, ⁴INRAE GABI, Domaine de Vilvert, 78530 Jouy-en-Josas, France; romuald.rouger@inrae.fr

Poultry local breeds represent a genetic reservoir so large that it is difficult to measure exhaustively. Contrarily to other livestock species, individual identification of local breed animals is uncommon and pedigrees are rarely recorded. As a result, these breeds are at risk of genetic dilution and high level of inbreeding. In this work, we present up to date results about the use of molecular tools to investigate the level of genetic diversity in the French local breed 'Noire de Challans' and reconstruct the pedigree of the animals. One hundred and ninety two SNP markers were tested on a reference population of 54 individuals (generation G0: 15 males and 39 females). After having discarded markers of poor quality, the average minor allele frequency (MAF) of G0 was 0.36. The F_{IS} was significantly positive due to a genetic substructure in G0. A final panel of 96 markers was designated by keeping those with the highest MAF among the markers for which the F_{IS} is comprised between -0.25 and 0.25. The probabilities of identity (1.3×10^{-37}) and exclusion (> 0.9999) of this final panel were compatible with its use for parentage assignment purposes. A simulated annealing algorithm was used to design breeding pens aiming to maximise the genetic distance between sires and dams. Ninety-five individuals from the next generation (G1) were genotyped using the panel of 96 markers. Parentage assignment only permitted to designate unambiguously the parents of 47 G1 individuals because of the use of non-genotyped mother to compensate zootechnical issues in G0. Next generations should permit to validate this proof of concept of an *in situ* management of genetic diversity in a local poultry breed. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N°101000236 (GEroNIMO project). This project is part of EuroFAANG.

An empirical approach to assess increase in homozygosity: the Gochu Asturcelta pigK.D. Arias¹, J.P. Gutiérrez², I. Fernández¹, I. Álvarez¹ and F. Goyache¹¹SERIDA-Deva, Camino de Riosedo 1225, 33394 Gijón, Spain, ²UCM, Dpto. de Producción Animal, 28040 Madrid, Spain; kathyah18@gmail.com

Despite the availability of SNP array data, differentiation between the observed homozygosity and that caused by matings between relatives (autozygosity) has major difficulties. This research investigates the usefulness of two recent estimators of increase in homozygosity to monitor the genetic diversity in small populations. Up to 526 Gochu Asturcelta pig parent-offspring trios (534 individuals; 76 families) were genotyped using the Axiom-PorcineHDv1 (Affymetrix). Pedigree depth varied from 0 (founders) to 4 equivalents to discrete generations (t). Four homozygosity parameters (Runs of Homozygosity, H_{ROH} , Heterozygosity-Rich Regions, H_{HRR} , Li and Horvitz's, H_{LH} , and Yang *et al.*'s, H_{YAN}) were computed for each individual, adjusted for the variability in the Base Population (BP; six individuals) and further jackknifed over autosomes. Individual increase in homozygosity (depending on t) and increase in pairwise homozygosity (i.e. increase on the parents' mean) were computed for each individual; effective population size (N_e) was computed for five different cohorts. Genealogical parameters were used for comparisons. Mean inbreeding was 0.120 ± 0.074 ; mean BP-adjusted homozygosity varied from 0.099 ± 0.081 (H_{LH}) to 0.152 ± 0.075 (H_{YAN}). After jackknifing, mean values were slightly lower. Increase in pairwise homozygosity tended to be two-fold higher than the corresponding individual increase in homozygosity values. When compared with genealogical estimates, N_e estimates based on increase in pairwise homozygosity using both H_{ROH} and H_{HRR} took the lower root-mean-squared errors. Our results suggest that parameters characterizing homozygosity may have difficulties in depicting losses of variability in real small populations in which breeding policy avoids matings between close relatives. Assuming that increase in homozygosity depends only on pedigree depth lead to underestimations in populations with shallow pedigrees. Increase in pairwise homozygosity computed from either H_{ROH} and H_{HRR} can be a promising approach to characterize autozygosity. Project PID2019-103951RB/AEI/10.13039/501100011033. Grant PRE2020-092905.

Preliminary analysis of Nubian goats and their influence on Old English and Anglo-Nubian goatsS.A. Rahmatalla^{1,2}, D. Arends³, G.B. Neumann¹, H. Abdel-Shafy⁴, J. Conington⁵, M. Reissmann¹, M.K. Nassar^{1,4} and G.A. Brockmann¹¹Humboldt-Universität zu Berlin, Albrecht Daniel Thaer-Institute, Invalidenstr. 42, Berlin, Germany, ²University of Khartoum, Faculty of Animal Production, Shambat str., Khartoum, Sudan, ³Northumbria University, Dep. of Applied Sci., Newcastle upon Tyne, NE7 7XA, United Kingdom, ⁴Cairo University, Faculty of Agriculture, Uni. str., Giza, Egypt, ⁵SRUC, W Mains, Rd, Edinburgh, United Kingdom; siham.rahmatalla@hu-berlin.de

Nubian goats found in the countries of Northeastern Africa, such as Sudan and Egypt. They play a crucial role in providing self-sufficiency and food security, due to their ability to provide a rich source of milk and meat. In the latter half of the 19th century, Nubian goats were exported from Africa to Britain and crossed with native Old English goats to create the modern Anglo-Nubian breed. We characterized the genetic diversity of Nubian goats from Sudan ($n=124$) and Egypt ($n=11$) and their relationship to Old English ($n=40$) and Anglo-Nubian ($n=13$) British goats. Animals were genotyped with the Axiom Caprine 60K SNP chip. Nucleotide diversity, observed and expected heterozygosity, and excess of homozygosity were used to assess the genetic diversity. Fixation index (F_{ST}), hierarchical clustering, and principal component analysis (PCA) were used to compare the relationship between populations. The nucleotide diversity in Anglo-Nubian (2.16×10^{-5}) was the lowest compared to the other breeds. Consistently, the highest observed heterozygosity was found in Nubian from Sudan (35.97) and the lowest in Anglo-Nubian goats (24.62). Excess of homozygosity showed the reverse pattern. Four distinct clusters were detected with the hierarchical clustering (Nubian from Sudan, Old English, Anglo-Nubian, and Nubian from Sudan and Egypt), which were confirmed by PCA and F_{ST} analyses. The first two PCs explain 14.3% (PC1) and 6.7% (PC2) of the genetic variation between all individuals. The SNPs that contributed strongly to PC1, and therefore, mostly differentiate Nubian from Old English goats, are located across 16 chromosomes. Candidate genes for adaptation, immune response, reproduction, pigmentation, metabolic process, and goat evolution were found in these regions. Further analysis of these regions will enhance our understanding of breed adaptation.

Towards a flexible definition of core sets based on the haplotype diversity of German sheepJ. Geibel^{1,2}, C. Reimer^{1,2}, A. Weigend², Y. Shakyar³, H. Melbaum⁴, K. Gerdes⁵ and S. Weigend^{1,2}

In recent years, attitudes towards gene banks changed from being a pure backup of a breed for the case of emergency towards being also an active tool in breed conservation. This requires setting scientifically derived demarcations between a ‘core’ collection (to serve as long term backup) and a ‘working’ collection of the gene bank. Usual recommendations thereby suggest the optimization of the core collection to preserve a certain amount of the diversity of a breed of interest. However, common definitions of the diversity of populations do not represent something like a total amount of diversity a population has and of which a certain proportion is available in the gene bank, a number which would be possible to communicate to stakeholders. We use simulations based on deep pedigrees to provide a control of the historic breeding background as well as genotypes of East Friesian Milk Sheep and Bentheimer Landschaf being already part of the German Gene Bank together with selected individuals from the field to evaluate the ability of haplotypes (defined as haploblocks) segregating in the population to serve as proxy of the founder genome content of the animals. This allows for the definition of a ‘proportion of total diversity’ based on the share of all population-wide haploblocks that is present in the collection and by this the derivation of reasonable required sizes of the core collection. This number then allows to be visually communicated to stakeholders. It further enables derivation of conservation decisions independent from the knowledge of potential future relevance of certain genomic variants, as a haploblock should preserve all potential additive and local epistatic effects of single variants.

Use of genomic information for the determination of insemination doses per sire in a gene bankC. Reimer^{1,2}, S. Weigend^{1,2}, T. Pook^{1,3} and J. Geibel^{1,2}

¹University of Goettingen, Center for Integrated Breeding Research, Carl-Sprengel-Weg 1, 37075 Göttingen, Germany, ²Friedrich-Loeffler-Institut, Institute for Farm Animal Genetics, Höltystraße 10, 31535 Neustadt, Germany, ³Wageningen University and Research, Animal Breeding and Genomics, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands; christian.reimer@fli.de

The overarching aim of a gene bank is to cryo-convertible material of breeding animals for a future moment when the in-situ population became inviable. Strategies to restore a breed from semen through a back-crossing scheme exist for long and support the prominent assumption of required 25 sires with 100 insemination doses each. Recently, the role of gene banks has been interpreted in a broader sense. Rather than just ensuring the restoration of an extinct breed, they can be active elements in the breeding program. Individual animals could be re-introduced into the population in time in order to restore genetic diversity and advantageous traits. If the relevant traits cannot be genomically characterized, what we expect to be the normal case, and specifically be introgressed, this consequently means ensuring that the majority of the donor genome is transferred to subsequent generations. We have derived a simple equation to determine how many inseminations are necessary to pass on a certain proportion of the donor genome, taking into account the number of offspring, degree of inbreeding, fertilisation success and the number of chromosomes, and support this by simulating appropriate scenarios on the genomic level. Upon the simplistic estimation, it showed that in cattle, due to the high efficiency of artificial insemination and in pigs, due to the high number of offspring, around ten doses, are needed to transfer 95% of the diploid donor genome. In small ruminants, small litter sizes and low efficiency of artificial insemination coincide, and similar transfer rates as in the aforementioned species require already 35 insemination portions. Autozygosity of an animal can reduce the number of required doses, but only with moderate effect unless it is up to a high degree. In view of the fact that this number is sometimes close to the technical maximum to be collected, there is an urgent need for improvements in efficient reintroduction strategies.

Is it possible to skip the SNP selection step for breed assignment?H. Wilmot^{1,2}, T. Niehoff³, H. Soyeurt¹, N. Gengler^{1,2} and M.P.L. Calus³¹ULiège-GxABT, TERRA Teaching and Research Centre, Passage des Déportés, 2, 5030 Gembloux, Belgium, ²National Fund for Scientific Research (F.R.S.-FNRS), Rue d'Egmont, 5, 1000 Brussels, Belgium, ³Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg, 1, 6700 AH Wageningen, the Netherlands; helene.wilmot@uliege.be

Breed assignment of animals generally relies on three main steps: (1) selection of a SNP panel that allows to distinguish between the breeds of interest; (2) training of a classification algorithm; and (3) validation of this classification on new animals. In recent years, to select the most informative SNPs, more complex methodologies have been developed, e.g. by the combination of several methods. There is no consensus about the protocol to follow to select the best SNPs and many questions stay unanswered. How to select the most informative SNPs? What is the optimal number of SNPs to select? To solve these issues, we proposed to skip the SNP selection step by using a genomic relationship matrix based on all available SNPs to assign animals to their breed of origin. Three new methodologies were developed for three cattle breeds: (1) breed assignment based on the highest mean relatedness of an animal to the reference population of each of the three breeds; (2) breed assignment based on the highest standard deviation (SD) of the relatedness of an animal to the reference population of each of the three breeds; and (3) a methodology that combines the values of mean and SD of the relatedness of each animal in a linear support vector machine model (SVM). These new methodologies were compared with a control methodology: a previously developed model based on a reduced SNP panel. The linear SVM achieved a similar percentage of correct assignment as the control methodology, and was substantially faster to compute. The main advantage of using the new methodology, based on the linear SVM, is to bypass the SNP selection step.

Copy number variation regions differing in segregation patterns spanned different sets of genesK.D. Arias¹, J.P. Gutiérrez², I. Fernández¹, I. Álvarez¹ and F. Goyache¹¹SERIDA-Deva, Camino de Rioseco 1225, 33394 Gijón, Spain, ²UCM, Dpto. de Producción Animal, 28040 Madrid, Spain; kathyah18@gmail.com

Copy Number Variations Regions (CNVR) are genomic alterations influencing performance frequently used as informative markers in association studies for economically important traits in livestock. However, CNVR segregation patterns usually depart from Mendelian rules and there is no consensus on how CNVR mirror useful genomic variation. This research aims to identify the genes spanned in CNVR differing in segregation patterns using a pedigree of the Gochu Asturcelta pig. Up to 478 parent offspring-trios belonging to 61 different families were genotyped using the Axiom_PigHDv1 Array. CNVR were identified following Arias *et al.* and classified as singleton de novo CNVR (sdnCNVR; n=20), recurrent de novo CNVR (rdnCNVR; n=255) and segregating CNVR (sCNVR; n=69). Gene-annotation enrichment and functional annotation analyses were performed using BioMart Software (Ensembl Genes 99 database) and DAVID Bioinformatics Resources 6.8. Previous studies show that sdnCNVR, occurring in one individual only, are probably Allele-Drop-In loci caused by technological issues whereas rdnCNVR are present in various individuals and families and may represent real genomic variation. Enrichment analyses informed that both the rdnCNVR (identified in 5 individuals or more) and sCNVR spanned 1,292 and 970 candidate genes, respectively. As expected, both CNVR classes gathered genes mainly involved in immunity and control of cellular function. Interestingly, sCNVR in the Gochu Asturcelta pig breed spanned genes putatively involved in prolificacy of sows and piglets' survival via the oxygen transport function, whereas rdnCNVR spanned growth-promoting genes. Genomic variation gathered by sCNVR may be of importance at the whole population level whereas that of rdnCNVR may explain differences in individual performance. Project PID2019-103951RB/AEI/10.13039/501100011033. Grant PRE2020-092905.

Genomic characterization as tool in the breed recognition process

C. Danchin and D. Duclos

IDELE, 149 rue de Bercy, 75012 PARIS, France; coralie.danchin@idele.fr

The most prominent French goat breed is the Alpine, which originated in the northern part of the French Alps. For 50 years the breed has been intensively selected for dairy traits. The main selection nuclei are now located in the west and centre of France. Meanwhile, some farmers kept the traditional population in the Alps and claimed to have limited exchange of animals or germ plasm with the rest of the breed. A breeders' association was created 20 years ago to preserve this population which they called 'Savoie'. The breeders' association set up pedigree recording with the help of the French Livestock Institute (IDELE) however the pedigree information remained quite scarce. Finally, from a phenotyping point of view, the Alpine and the Savoie are sharing some colour patterns since the Alpine is not completely standardized with the 'bezoar' colour pattern. The association struggled to achieve an official recognition by the Ministry of Agriculture since it was difficult to prove that the population was significantly different from the Alpine breed. In the mid-2010s, a medium SNP goat chip (by Illumina Inc.) became available in France for a reasonable price (about 40 €/genotype). The breeders' association, in collaboration with IDELE, took this opportunity to sample and genotype about 40 goats to compare it with available Alpine genotypes. The goats were chosen based on pedigree and phenotyping information to maximize the sample diversity. First IDELE performed a principal component analysis based on a kinship genomic matrix that showed that the Savoie breed is indeed a close relative to the Alpine breed, but that the population differs now from it. A second analysis was performed by using the ADMIXTURE software to detect animals that were clearly crossbred recently with the Alpine, leading to their withdrawal from the conservation programme. The results of the genomic analysis were provided to an expert commission and were one of the factors that led to the official recognition of the Savoie breed by the French Ministry of Agriculture in 2020.

Homozygosity by descent in mice divergently selected for environmental birth weight variabilityC. Ojeda-Marín¹, J.P. Gutiérrez¹, N. Formoso-Rafferty² and I. Cervantes¹¹UCM, Producción Animal, Avda Puerta del Hierro, s/n, 28040, Spain, ²UPM, E.T.S.I.A.A.B, Producción Agraria, Avda Puerta del Hierro, s/n, 28040, Spain; candelao@ucm.es

Inbreeding could lead negative effects as inbreeding depression. Purging process produced that deleterious alleles are mostly young and maintain at low frequencies in populations. As a result of divergent selection experiment of birth weight environmental variability in mice two lines, high variability line (H-Line) and low variability line (L-Line), were created. L-Line presented advantages in robustness, animal welfare and production. The aim of this study was to analyse genomic inbreeding in both selected lines and to compare it with pedigree inbreeding (F_{PED}) to ascertain if there were differences between lines. A total of 844 individuals of H-Line and 855 individuals of L-Line belonging to 26 generations of selection were genotyped using a high density genotyping array. Homozygosity by descent segments (HBD) were analysed using a multiple classes Hidden Markov Model with 9 HBD classes (2,4,8,16,32,64,128,256 and 512) and one non HBD class (512). Hence, global HBD inbreeding (F_{HBD}) and specific class HBD inbreeding (F_{HBD2} , F_{HBD4} , F_{HBD8} , F_{HBD16} , F_{HBD32} , F_{HBD64} , F_{HBD128} , F_{HBD256} and F_{HBD512}) were computed. Genomic inbreeding computed using runs of homozygosity (F_{ROH}) and F_{PED} were also computed. Moreover, F_{PED} was decomposed in recent inbreeding (F_N) and old inbreeding (F_O) using as generation thresholds 4, 5, 6, 7 and 8 generations. Correlations between different inbreeding coefficients were computed. The evolution of F_{PED} , F_{HBD} and F_{ROH} were positive across the generations. F_{HBD} and F_{PED} presented greater differences between lines than F_{PED} . High correlations were observed between F_{HBD} , F_{PED} and F_{ROH} . The greatest correlations were found between F_{HBD} - F_{ROH} in both lines. H-Line presented greater contribution of younger HBD classes than L-Line and F_{HBD16} presented higher correlations with F_N and F_O in H-Line. Differences between lines were observed in the contribution of HBD classes to total F_{HBD} that were not observed with other inbreeding coefficients. Further studies should analyse local HBD to clear up if there were genomic differences in homozygosity between lines.

Inbreeding depression is associated with recent HBD segments in Belgian Blue beef cattleM. Naji¹, J.L. Gualdron Duarte², N.S. Forneris¹ and T. Druet¹¹Unit of Animal Genomics, GIGA-R & Faculty of Veterinary Medicine, University of Liège, Avenue de l'Hôpital, 1, 4000 Liège, Belgium, ²Walloon Breeders Association (awe group), Ciney, 5590, Belgium; mnaji@uliege.be

Intensive use of high-merit bulls is common in cattle populations and results in high inbreeding levels that can lead to outbursts of genetic defects or to inbreeding depression (ID). We herein used data from 14,205 Belgian blue beef cattle cows, genotyped at medium marker density (30K SNPs) and phenotyped for eleven linear classification traits, to study ID. We first computed several estimators of the inbreeding coefficient F , relying either on the pedigree information (F_{PED}), on the correlation between the uniting gametes (F_{UNI}), on the diagonal elements from the genomic relationship matrix (F_{GRM}), or on homozygous-by-descent (HBD) segments identified with the RZooRoH package (F_{HBD}). We observed that F_{UNI} and F_{GRM} were highly sensitive to allele frequencies used in their estimation (e.g. founder vs sample allele frequencies), whereas F_{HBD} was more stable. Using a linear mixed model, we detected significant ID for four traits, related to height and length; F_{UNI} and F_{HBD} had the strongest association, confirming that both are efficient estimators of F . The regression coefficient associated with ID was for instance equal to -21 cm for height when using F_{HBD} . RZooRoH classifies HBD segments in different age-based groups (the length of HBD segment being inversely related to the number of generations to the common ancestors). We took advantage of this feature to test whether HBD segments associated with more recent common ancestors were more deleterious than shorter HBD segments associated with more remote ancestors. Recent HBD classes (ancestors present approximately up to 15 generations in the past) presented stronger ID than more ancient HBD classes. Simulations indicated that these observations were not due to lack of variation in more ancient HBD classes. Similar results were obtained with higher-marker density, suggesting that lack of ability of the model to capture shorter HBD segments was not an issue neither. Overall, our results suggest that mutational load decreases with haplotype age, and that mating plans should consider mainly the levels of recent inbreeding.

Session 25

Assessing the intrapopulation structure of Slovak Spotted cattle by genome-wide dataR. Kasarda¹, N. Moravčíková¹, J. Candrák¹, J. Prišťák¹ and I. Pavlík²¹Slovak University of Agriculture in Nitra, Institute of Nutrition and Genomics, Tr. A. Hlinku 2, 94976 Nitra, Slovak Republic, ²Research Institute of Animal Production – NPPC Slovakia, Hlohovecká 2, 95141 Lužianky, Slovak Republic; radovan.kasarda@uniag.sk

Artificial selection, especially the preferential use of particular sire lines and maternal families, simultaneously affects the diversity status and genetic structure of livestock populations across generations. Therefore, this study aimed to assess the intrapopulation genetic structure and diversity of the Slovak Spotted cattle by analysis of genome-wide data. Slovak Spotted cattle gene pool represented 37 sires born in 1972-2011, 50 dams and 89 cows from active populations. The two most commonly accepted diversity parameters, genomic inbreeding (F_{ROH}) and effective population size (N_{eLD}), were used to describe the current genetic status of the breed. The intrapopulation structure was tested by principal component analysis. A total of 9,719 runs of homozygosity (ROHs) with an average length of 8.73 Mbp and 3,5487 ROHs with an average length of 8.96 Mbp were identified in the genome of sires and cows, respectively. The observed level of inbreeding ($F_{ROH<16Mbp}=1.65\pm1.30\%$ and $F_{ROH>16Mbp}=1.43\pm1.27\%$) pointed to a sufficient level of variability in the current population, but there were significant differences among the individuals, as confirmed by the analysis of the individual inbreeding coefficient depending on the sex. The current effective population size of 75.49 individuals indicated that the preferential use of sire lines and a general decline in breeders' interest led to a relatively high intergeneration decline (7.76 individuals). PCA showed that sires and dams created a common genetic cluster, while cows were distributed depending on the sire lines preferred by a particular farmer. The distribution of genetic variability outside the breed nucleus creates the potential for the selection of suitable genotypes of future sires, whose inclusion in breeding can positively impact the development of effective population size. This study was supported by the Slovak Agency for Research and Development (grants no. APVV-17-0060 and APVV-20-0161).

Genomic selection has aided Nordic Jersey to decrease risks of inbreedingS. Tenhunen^{1,2}, J.R. Thomasen¹, L.P. Sørensen¹, P. Berg³ and M. Kargo²¹VikingGenetics, Ebeltoftevej 16, 8960 Randers SØ, Denmark, ²Aarhus University, QGG, C. F. Møllers Allé 3, bld. 1130, 8000 Aarhus, Denmark, ³Norwegian University of Life Sciences, NMBU, Universitetstunet 3, 1433 Ås, Norway; [satene@vikinggenetics.com](mailto:saten@vikinggenetics.com)

Recently, many dairy cattle populations across the world have demonstrated a rapid increase in inbreeding which may lead to inbreeding depression. The main reasons for this have been reported to be the changes in breeding practices due to genomic selection (GS). This research aimed to identify and study past events which have influenced the rate of inbreeding (ΔF) and coancestry (ΔC) in the Nordic Jersey (NJ) population. Retrospective analysis was performed of 99,083 NJ animals with pedigree information and 41,896 SNP imputed genotypes. Animals were divided into two groups: before (2009-2014) and after (2015-2021) GS implementation in the NJ population. Pedigree (PED) was used to calculate yearly ΔF and ΔC and runs of homozygosity (ROH) was used to calculate genomic ΔF where shared segments (SEG) between pairs were used to calculate genomic ΔC . Effective population size (N_e) was calculated from ΔF and ΔC was used to calculate future effective population size (FN_e) for each animal group. The yearly average generation interval (L) decreased from 4.7 to 3.2 after GS. PED ΔF was at the same level before and after GS, but there was a distinct increase in ROH ΔF from 0.0035 to 0.0052. PED ΔC had decreased from 0.0031 to 0.0017 between the periods and no changes in SEG ΔC were seen. N_e PED increased from 32 to 55 and N_e ROH was 30 in both periods. FN_e PED increased significantly after GS implementation from 34 to 91, and FN_e SEG saw a more moderate increase from 41 to 57. Increases in N_e ROH and FN_e SEG were mainly caused by a decrease in L between the periods. From the yearly estimates we could identify a period before GS when ΔC increased rapidly in the NJ. In this period, heavy use of related sires was observed. This may explain the increased ΔC in the population which may have caused the higher ΔF after GS. N_e is currently on the increase in the NJ population and FN_e indicates that this trend will continue in the coming years. In conclusion, GS seems to have been instrumental in decreasing the risk for inbreeding depression now and in the future.

Management of local cattle breed diversity in Croatia: use of molecular and pedigree indicatorsA. Ivanković¹, Z. Ivkić², G. Šubara³, M. Pečina¹, J. Ramljak¹ and M. Konjačić¹¹University of Zagreb Faculty of Agriculture, Svetošimunska cesta 25, 10000, Croatia, ²Croatian agency for agriculture and food, Vinkovačka cesta 63 c, 31000 Osijek, Croatia, ³Agency for Rural Development of Istria, Tugomila Ujčića 1, 52000 Pazin, Croatia; aivankovic@agr.hr

In addition to conventional cattle breeds, three local breeds are also preserved in Croatia. They are classified as endangered breeds and are included in a program for conservation and economic revitalization. Breeding associations carry out breeding programs with the help of public and scientific institutions and optimize breeding and economic measures. There is constant monitoring of breeding activities, optimization of genetic evaluation methods and harmonization of population indicators (*molecular, pedigree, exterior, productivity*). Three local cattle breeds in Croatia were studied under different population situations (*size, distribution and competitiveness*). Molecular characterization using microsatellites is performed continuously, supported by regular pedigree testing. Genotyping of the breed using SNP-s is performed only sporadically and on a smaller number of individuals, mainly for scientific purposes. The indicators of pedigree analysis are used daily in direct selection (*maintenance of lines, preparation of mating plans, etc.*). Experience in implementing the management program shows that pedigree indicators, supported by molecular information, are the basis for efficient management of population diversity. Pedigree and molecular markers synergistically show that the greatest preserved genetic diversity is found in the Buša population, while the Slavonian-Syrmian Podolian population has the highest level of inbreeding or bottleneck. The indicators for the Istrian cattle population are more favourable, and the sustainability of the breed is more likely, especially considering the increasing demand for 'Istrian beef'. The example of local cattle breeds in Croatia illustrates the need for synergistic and continuous use of molecular and pedigree indicators to maintain the diversity of local breeds, as this increases their informative value and applicability. It should be noted that pedigree indicators are easier and more understandable for breeders and can be used in daily herd and population management.

Genomic differences between the domesticated pig breed and its ancestor wild boar

N. Moravčíková¹, R. Kasarda¹, M. Hustinová^{1,2}, E. Krupa³, Z. Krupová³ and E. Žáková³

¹Slovak University of Agriculture in Nitra, Tr. A. Hlinku 2, 94976 Nitra, Slovak Republic, ²Slovak Hunting Chamber, Štefánikova 10, Bratislava 81105, Slovak Republic, ³Institute of Animal Science, Přátelství 815, 104 00 Praha-Uhřetěves, Czech Republic; nina.moravcikova@uniag.sk

This study aimed to identify the genomic differences between the autochthonous Czech pig breed Přestice Black-Pied and wild boar by screening selection signals distribution in the autosomal genome. Analysis of selection signals was based on the assumption that SNPs extremely related to the population structure can be responsible for biological adaptation. We used genomic data from 265 Přestice Black-Pied pigs and 75 wild boars collected in Czechia and Slovakia, respectively. Animals were genotyped by two platforms, Illumina Porcine SNP60 and GGP Porcine 50k. After SNP pruning, the database included 30,704 informative autosomal SNP markers. Selection signals were defined by outlier SNPs resulting from the principal component analysis while accounting for population structure. Above the cut-off value set based on the Bonferroni correction were found 234 outliers. Selection signals were distributed in different areas on autosomes 1, 2, 4, 8, 9, and 14. The strongest signal was found on autosome 1 close to the *CTIF* gene included in pathways resulting in the formation of proteins by the translation of mRNA. In addition, *TMEM161B*, *ZNF697*, *HSD3B1*, *EDNRA* and *CTNNA3* genes involved in pathways controlling the frequency or rate of heart contraction, cardiac muscle cell action potential, reproduction, vasoconstriction, regulation of blood pressure, fertility was identified close to the top of signals on chromosomes 2, 4, 8, and 14. The results of this study can contribute to research related to the explanation of the effect of domestication and livestock breed development on their genome structure compared to wild ancestors. This study was supported by the Slovak Agency for Research and Development (grants no. APVV-17-0060 and APVV-20-0161) and Ministry of Agriculture of the Czech Republic (project no. MZE-RO0723 V02 and QK1910217).

Genetic polymorphism of kappa-casein in Serbian Holstein-Friesian cattle

M. Zorc¹, M. Šaran², L.J. Štrbac², D. Janković², P. Dovč¹ and S. Trivunović²

¹University of Ljubljana, Biotechnical Faculty, Department of Animal Science, Jamnikarjeva 101, 1000 Ljubljana, Slovenia,

²University of Novi Sad, Faculty of Agriculture, Department of Animal Science, Trg Dositeja Obradovića 8, 21000 Novi Sad, Serbia; minja.zorc@bf.uni-lj.si

Milk proteins have been thoroughly studied in cattle. Considerable genetic variation has been identified and characterized in the genes coding milk proteins, mainly due to the effects of milk protein variants on milk composition and cheese-making characteristics. Previous research has determined that kappa-casein polymorphism affects the total milk protein content and cheese yield. In order to examine the polymorphism of kappa-casein, a total of 1,600 Serbian Holstein-Friesian cows were genotyped with a GGP Bovine 100K SNP array. Nine markers from the SNP array targeting the kappa-casein gene (*CSN3*) were examined. Out of the total number of cows, the genotype was successfully determined for 1,591 cows. It was found that the most frequent allele was allele A (63%), followed by allele B (28%) and allele E (9%). Kappa-casein genotype frequencies were: 35.3% AA, 38.0% AB, 17.8% AE, 8.5% BB, and 0.4% EE. Using the chi-square test, it was determined that the population is not in Hardy-Weinberg equilibrium for the studied gene ($P < 0.05$), which may indicate the existence of evolutionary processes or selection in the studied population. The observed heterozygosity (H_o) and expected heterozygosity (H_e) were 0.56 and 0.52, respectively. Constant monitoring of milk protein variation in different breeds of cattle is an essential practice to avoid an increase in the frequency of mutations with unfavourable effects on cheese production. Acknowledgments: This research is funded by Ministry of Science, Technological Development and Innovation of the Republic of Serbia (Contract No. 451-03-47/2023-01/ 200117). The data used in this research were collected during the realization of PROMIS project: 'A Bioinformatics Approach to Dairy Cattle Breeding Using Genomic Selection', No. 6066512, funded by the Science Fund of the Republic of Serbia.

Estimation of recent and ancestral inbreeding for X-chromosome in Old Kladrub horseL. Vostry¹, M. Shihabi², J. Farkas³, G. Kövér³, H. Vostra-Vydrova¹, B. Hofmanova¹, I. Nagy³ and I. Curik²¹CZU Prague, Kamycka 129, 165 00 Prague, Czech Republic, ²University of Zagreb, Faculty of Agriculture, Svetošimunska 25, 10000 Zagreb, Croatia, ³Hungarian University of Agricultural and Life Sciences, Guba S 40, 7400 Kaposvar, Hungary; vostry@af.czu.cz

A number of pedigree inbreeding coefficients (F_{ped}) have been developed to analyse inbreeding depression or its purging, such as the new Kalinowski inbreeding coefficient (F_{new}), the Kalinowski ancestral inbreeding coefficient (F_{a_Kal}), the Ballou ancestral inbreeding coefficient (F_{a_Bal}), and the Ancestral History coefficient (AHc). Estimation of inbreeding coefficients between sex and autosomal genes is different and depends on the order of male and female individuals in their pedigree. Unfortunately, there is no programme to calculate sex-specific inbreeding coefficients (e.g. F_{new} , F_{a_Kal} , and/or F_{a_Bal}) needed for purging analysis. In this study, we estimated and analysed a large number of sex-specific inbreeding coefficients calculated by the algorithm implemented in the GRainX software using a long and complete pedigree of Old Kladrub horses. The ratio of sex-specific to autosomal inbreeding estimates (sex/autosomal) was higher for F_{ped} (1.3), F_{ped} five-generation (1.46), F_{a_kal} (1.4), and F_{new} (1.3). In contrast, a lower ratio (sex/autosomal) was observed for F_{a_Bal} (0.93) and AHc (0.71). At the same time, correlations between autosomal and sex inbreeding coefficients ranged from 0.37 (AHc and AHcX) to 0.65 (F_{ped} and F_{pedX}). Our results showed that sex-specific inbreeding coefficients obtained with GRainX software can be used to estimate inbreeding depression and its purging for sex chromosomal genes. This study was supported by projects QK1910156 and ANAGRAMS-IP-2018-01-8708.

Poster 26

Genetic diversity and population structure of a Peruvian nucleus cattle herd using SNP dataF.-A. Corredor¹, D. Figueroa¹, R. Estrada¹, W. Salazar¹, C. Quilcate¹, H. Vasquez², J. Gonzales³, J. Maicelo², P. Medina¹ and C. Arbizu¹¹Instituto Nacional de Innovación Agraria, Lima, 15024, Peru, ²Universidad Nacional Toribio Rodríguez de Mendoza de Amazonas, Chachapoyas, 01001, Peru, ³Universidad Nacional de Frontera, Piura, 20103, Peru; corredor@alumni.iastate.edu

New-generation sequencing technologies, among them SNP chips for massive genotyping, are useful for the effective management of genetic resources. To date, molecular studies in Peruvian cattle are still scarce. For the first time, the genetic diversity and population structure of a reproductive nucleus cattle herd from a Peruvian institution were determined. Samples from Brahman, Braunvieh, Gyr, Simmental, and creole cattle (AFB) were incorporated. Female individuals were genotyped with the GGPBovine100K and males with the BovineHD. Quality control, and the proportion of polymorphic SNPs (Pn), minor allele frequency (MAF), expected heterozygosity (He), observed heterozygosity (Ho), and inbreeding coefficient (Fis) were estimated for the five breeds. Admixture, principal component analysis (PCA), and discriminant analysis of principal components were performed. Also, a dendrogram was constructed using the Neighbour-Joining clustering algorithm. The genetic diversity indices in all breeds showed a high Pn, varying from 51.42% in Gyr to 97.58% in AFB. Also, Braunvieh possessed the highest Ho (0.43 ± 0.01), while Brahman the lowest (0.37 ± 0.02), indicating that Brahman was less diverse. The pairwise genetic differentiation estimates between breeds showed values that ranged from 0.08 (Braunvieh vs AFB) to 0.37 (Brahman vs Braunvieh). Similarly, pairwise Reynold's distance ranged from 0.09 (Braunvieh vs AFB) to 0.46 (Brahman vs Braunvieh). The dendrogram, similar to the PCA, identified two groups, showing a clear separation between *Bos indicus* (Brahman and Gyr) and *B. taurus* breeds (Braunvieh, Simmental and AFB). Simmental and Braunvieh grouped closely with the AFB cattle. Similar results were obtained for the population structure analysis with K=2. The results from this study would contribute to the appropriate management, avoiding loss of genetic variability in these breeds and for future improvements in this nucleus. Additional work is needed to speed up the breeding process in the Peruvian cattle system.

Within-breed stratification for across-breed reference populationH. Wilmot^{1,2}, T. Druet^{2,3}, I. Hulsegge^{4,5}, N. Gengler^{1,2} and M.P.L. Calus⁵

¹ULiège-GxABT, TERRA Teaching and Research Centre, Passage des Déportés, 2, 5030 Gembloux, Belgium, ²National Fund for Scientific Research (F.R.S.-FNRS), Rue d'Egmont, 5, 1000 Brussels, Belgium, ³ULiège-GIGA-R & Faculty of Veterinary Medicine, Unit of Animal Genomics, Avenue de l'Hôpital, 1, 4000 Liège, Belgium, ⁴Wageningen University & Research, Centre for Genetic Resources, Droevendaalsesteeg, 1, 6700 AH Wageningen, the Netherlands, ⁵Wageningen University & Research, Animal Breeding and Genomics, Droevendaalsesteeg, 1, 6700 AH Wageningen, the Netherlands; nicolas.gengler@uliege.be

In endangered breeds, it is difficult to have large reference populations needed for accurate genomic predictions. To solve this issue, one solution can be to build an across-breed reference population. In that case, candidate animals should however be genetically close enough to the reference population. Therefore, special attention must be paid to the animals from other breeds that are selected to be part of the across-breed reference population. In our study, we explored different measures of genetic diversity, namely principal component analysis (PCA) and ADMIXTURE clustering based on genotypes, to detect stratification within Dutch red-pied cattle breeds with the aim to build an across-breed reference population for two genomically related endangered red-pied cattle breeds from Belgium and Luxembourg. The PCA analysis showed that the Dutch, Belgian and Luxembourgish breeds were part of a genomic continuum. We detected stratification within the Dutch breeds and consequently also genomically related animals to the Belgian and Luxembourgish breeds. Although empirical validation of across-breed genomic prediction is needed to confirm which reference population yields the best predictions, our results do suggest that stratification within breeds should be considered when construction across-breed reference populations.

The livestock sector and research in animal science in FranceX. Fernandez¹, J.F. Hocquette² and S. Ingrand¹

¹INRAE, Animal Physiology and Livestock Systems division (Phase), 37380 Nouzilly, France, ²INRAE, VetAgroSup, INRA Herbivores, UMR1213, 63122 Theix, France; xavier.fernandez@inrae.fr

In 2022, the numbers of farm animals in France were, in million heads, 17.8 for cattle, 13.7 for pigs, 7.2 for sheep, 1.4 for goats and 157.6 for poultry meat. In 2020, 145,000 French farms were devoted to livestock farming, i.e. 37% of all farms (meat, milk, mixed cattle; sheep; pigs; poultry). The consumption of animal products (per capita / year) in France is the following: for pig meat, 31 kg; for poultry, 28 kg; for cheese, 26 kg; for beef, 22 kg; for eggs, 13 kg; for butter, 8 kg. France produces 24 billion litres of cow's milk. This is the 2nd European production with 51 dairy protected designations of origin (PDO). There are also 226 products with the 'label rouge' quality sign in the poultry/egg sector (from <https://agriculture.gouv.fr/infographie-lelevage-francais>). The different animal sectors in France are represented by interprofessional organizations such as INTERBEV for the red meat sector, INAPORC for the pig sector, ANVOL for the poultry sector, CNIEL for the dairy sector and FGE for the genetic sector. According to scientific papers in the Web of Science, France is the 7th country in terms of research in dairy and animal science (after the USA, Canada, Brazil, India, Germany and Australia) with 50.4% of the papers published in open access. INRAE has co-authored 85% of French scientific articles of the Web of Science in dairy and animal science. The main research areas in animal science (genetics, health, physiology, livestock systems) will be described orally. After INRAE, the other main actors of French research in dairy and animal science are universities, 'grandes écoles' for engineers and veterinarians, other research institutes (such as CIRAD) and also technical institutes for herbivores (IDELE), pigs (IFIP) and poultry (ITAVI) production in charge of research transfer to the industry. Coordination between all these actors is achieved through the scientific group of interest 'Avenir Elevage' for research and the French Association for Animal Production (AFZ) for dissemination.

Solutions to achieve healthy and sustainable diets worldwide

H. Guyomard, A. Forslund, A. Tibi, B. Schmitt, P. Debaeke and J.-L. Durand

INRAE, SDAR, La Motte au Vicomte, 35650 Le Rheu, France; herve.guyomard@inrae.fr

World food systems are neither healthy nor sustainable. In that context, numerous studies aim at assessing the ability of world agriculture to feed an increasing world population in a healthy and sustainable way. On the final consumption side, the presentation adopts a normative assumption for diets that would evolve in all world regions towards healthy diets by 2050. We first describe what these healthy regional diets are by 2050 and the required changes relative to current regional diets. In a second part, we use the GlobAgri biomass model to analyse cropland and pastureland induced needs based on complementary assumptions for crop and forage yields, cropping intensities, and livestock feed efficiencies. Yields and maximum cultivated areas are impacted by climate change. In addition, we adopt a second normative assumption by excluding any deforestation since the latter is a key factor of greenhouse gas emissions and biodiversity loss. Simulation results allow us to determine cropland and pastureland needs in the world divided into 21 regions as well as impacts on agri-food trade. Several regions in the world would be constrained by their maximum available cultivated areas. In addition, pastureland needs will be very high in several regions, notably in Sub-Saharan Africa. As a consequence, the last part of the presentation analyses to what extent it would be possible to reduce agricultural land needs by activating supply drivers (sustainable intensification of yields, sustainable improvements in feed efficiencies, reduction of pre-harvest losses, etc.) as well as demand drivers (reduction in post-harvest losses, replacement of red meat by white meat in diets, replacement of animal proteins by plant proteins in diets, etc.). We conclude by implications for public policies.

Session 26**Theatre 3****Moving towards bold food systems resilience**

J. Fanzo

Berman Institute of Bioethics, Nitze School of Advanced International Studies (SAIS), and Bloomberg School of Public Health, Johns Hopkins University, 1717 Massachusetts Ave NW 730, Washington DC 20036, USA; jfanzo1@jhu.edu

With climate change, the COVID-19 pandemic, and ongoing conflicts, food systems are facing increasing fragility. In a turbulent, hot world, threatened resiliency and sustainability of food systems could make it all the more complicated to nourish a population of 9.7 billion by 2050. Climate change is having adverse impacts across food systems with more frequent and intense extreme events that will challenge food production, storage, and transport, potentially imperilling the global population's ability to access and afford healthy diets. At the same time, the way food is grown, processed, packaged, and transported is having adverse impacts on the environment and finite natural resources further accelerating climate change, tropical deforestation, and biodiversity loss. Food system policies and actions can contribute to climate adaptation and mitigation responses and, at the same time, improve human and planetary health, however multi-lateral cooperation, action and investments must be bold. While there is significant urgency in acting, it is also critical to move beyond the political inertia and bridge the separatism of food systems and climate change agendas that currently exists among governments and private sector actors.

A social-ecological agenda for transforming land management toward sustainabilityT. Plieninger^{1,2}¹*Faculty of Organic Agricultural Sciences, University of Kassel, Steinstr. 19, 37213 Witzenhausen, Germany,* ²*Department of Agricultural Economics, University of Göttingen, Platz der Göttinger Sieben 5, 37073 Göttingen, Germany; plieninger@uni-goettingen.de*

Recent high-level reports (for instance, the Global Assessment of the Intergovernmental Panel on Biodiversity and Ecosystem Services, IPBES, and the Global Sustainable Development Report, GSDR) have highlighted that dominant research modes in the agricultural sciences and related research fields are insufficient to guide the transformative change of society that is needed to achieve the Sustainable Development Goals. Accordingly, new approaches toward a transformative land sustainability science are currently on the rise. This keynote presentation takes up a framework of transformative sustainability science to: (1) analyse the systemic interactions in land-management systems that lead to synergies or trade-offs between sustainability outcomes; (2) identify competing values and interests of actors in land management that help or hinder sustainability; and (3) help understand transformations toward sustainable land management in concrete contexts. A social-ecological research agenda will be illustrated with empirical studies from Europe, Asia, and North Africa that focus on multiple innovative agricultural and other land-use practices and systems that are in need of and with potential for sustainable development. The keynote will include cases of agroforestry systems, extensive livestock grazing systems, conservation agriculture, and collaborative agri-environmental governance.

EAAP beyond Europe: establishing and using capacity to feed the world

H. Sölkner

University of Natural Resources and Life Sciences, Vienna, Gregor Mendel Str. 33, 1180 Vienna, Austria

The European Federation of Animal Science (EAAP) provides very strong glue for animal scientists in Europe, helping them thinking outside their narrow disciplinary boxes and doing interdisciplinary research, so valuable for society at large. Over the last two decades, EAAP has evolved a science communication and dissemination platform far beyond its original scope. It is communication partner of virtually all EU funded research projects in the field of animal science. Very recently, EAAP established a partnership program, connecting doctoral students in Europe with doctoral students from around the world. What a great effort! It is my strong belief that animal scientists in Europe can play a crucial role in improving livestock populations and their productivity across the globe, enhancing the livelihoods of many people in developing countries and reducing malnutrition, particularly of infants. The animal breeding research group at BOKU has embarked on this mission around 25 years ago and I have good news to share. Together with local partners as well as the international institutions ICARDA and ILRI, we developed community based breeding programs (CBBP) for small ruminants, cattle and New World camelids in Africa and Latin America. Open nucleus breeding programs, establishing and multiplying breeding stock on station and distributing male breeding animals to farmers used to be the way to go in many developing countries. This approach almost invariably failed, due to many reasons, including the animals not fitting the smallholder system or the type of animal not being accepted by farmers. Establishment of CBBP starts with finding the breeding objectives of farmers with participatory tools and agreeing on simple on farm recording of traits of farmer interest. During the first generations of CBBP implementation, young male animals ready for breeding are ranked based on breeding objectives and corresponding records and farmer committees choose among the candidates. Ways of using breeding animals are agreed on and associations are formed, providing by-laws for that. The most impressive use case of CBBP is that of small ruminants in Ethiopia, where this system was decreed the breeding method of choice by the national government. The key to this success has been the capacity and commitment of a few persons leading the programs. This is very similar to the farmer-led cattle and pig breeding programs in Austria, where technically sophisticated and well trained staff of breeding associations play that role. International collaboration, including its North-South and South-South variants, has very many facets, joint supervision of doctoral students is one of them. The EAAP international student partnerships are a new device of that collaboration. May that work well and may the student partners take their respective supervisors on their journey. Good luck to all of you!

Effect of genomic selection on allele frequencies of QTL associated to number of teats in pigsC.A. Sevillano¹, B. Harlizius¹, M.S. Lopes^{1,2}, M. Van Son³ and E.F. Knol¹¹Topigs Norsvin Research Center, P.O. Box 43, 6640 AA Beuningen, the Netherlands, ²Topigs Norsvin, Visconde do Rio Branco 1310, 80.420-210 Curitiba, Brazil, ³Norsvin, Storhamargata 44, 2317 Hamar, Norway; claudia.sevillanodelaguila@topignorsvin.com

Number of teats (NTE) is an important trait for pig welfare because it influences directly the milk production of the sow and indirectly the survival and weight gain of piglets. NTE is a heritable trait and shows considerable variation between and within breeds. NTE have been included in the breeding goal of Topigs Norsvin maternal lines in the last decades, while genomic selection (GS) was adopted in 2012. It is known that GS has increased the rate of genetic gain in the short term but its impact on allelic diversity is not known. In this study we aimed to better understand the impact of GS on NTE by following the changes in allele frequency across generations on different QTL regions affecting NTE in two maternal lines. NTE was recorded at birth on 187,867 L (Landrace) and 173,288 LW (Large-White) animals from both sexes born between 2011 and 2022. All animals were genotyped on Illumina GeneSeek custom SNP chips (25K, 50K or 80K) or Axiom porcine 660K array from Affymetrix and imputed within population to 660K SNPs. The mean value for NTE is around 1 teat higher in the L compared to LW (16.89 vs 15.96). L line has gained 1.8 extra teat in the last 11 years, while the LW line has only gained 0.7. Heritability was 0.39 for L and 0.34 for LW. Results from a single-SNP GWAS performed within population clearly show the *VRTN* promoter SNP (*VRTN_RS709317845*) located on chromosome 7 as the most significant SNP in both lines. In addition, 2 QTL regions overlap between the two populations on chromosomes 10 and 12. The frequency of the allele C of the *VRTN* promoter SNP increasing NTE is almost five times higher in the L line compared to LW (0.79 vs 0.17). Allele frequency trend across the last 11 years shows that the frequency has been increased in L line, whereas this favourable allele is decreasing in LW line. These results show that although the breeding objective of increasing NTE has been achieved, the selection pressure on the *VRTN* promoter is different in both lines. The reasons for this difference, such as unfavourable correlations with other traits, needs to be further evaluated.

Session 27

Theatre 2

Management of genetic defects in breeding programsS.T. Rodríguez-Ramilo¹, I. Palhière¹, J. Raoul^{1,2} and J. Fernández³¹GenPhySE, Université de Toulouse, INRAE, ENVT, Castanet-Tolosan, 31326, France, ²IDELE, Castanet-Tolosan, 31326, France, ³Departamento de Mejora Genética Animal, INIA – CSIC, Madrid, 28040, Spain; jmj@inia.csic.es

Allele frequencies of genetic defects can increase in selected populations mainly due to a couple of reasons. Firstly, hitchhiking effect linked to genes controlling traits included in the selection objective. Secondly, genetic drift caused by the reduced number of candidates selected as parents of the next generation. Breeding programs for populations with individuals carrying genetic defects need considering the reduction of their allele frequencies, besides the typical aims of maximisation of genetic gain, and minimisation of genetic diversity loss. The objective of this study was to evaluate the evolution of allele frequencies of genetic defects, the genetic gain and diversity when managing genetic defects through a selection index combining the GEBVs with the individual weighted gene content. Stochastic simulations were used to generate a population with reasonable levels of linkage disequilibrium and expected heterozygosity using a mutation-drift equilibrium approach. Around 50,000 biallelic loci were assumed to be SNPs for management purposes and another 50,000 non-genotyped loci to determine the effect on the rest of the genome. An additive quantitative trait with a heritability of 0.4 was defined. One, 3 or 10 loci (with initial allele frequencies between 0.1-0.2) controlled the expression of a monogenic genetic defect each. One hundred individuals were randomly sampled from the population at equilibrium constituting the founders of the breeding program. Truncation selection on the index values was performed for ten non-overlapping generations. Averaged results for one hundred replicates shows that both the genetic gain and genetic diversity were affected by the number of genetic defects and the weight given for each of them. Removal of the genetic defects from the population was fast with high weights on the genetic defects. However, mean breeding values were lower when weights were higher and a high number of genetic defects were considered. Genetic diversity remained relatively stable across simulated scenarios. Extension of this study will involve the management of these genetic defects in an optimum contribution selection strategy.

Genetic management of cryptorchidism and horn mutations in Manech tête Rousse dairy sheep breedJ. Raoul^{1,2}, F. Fidelle³, C. André³, M. Ben Braiek², S. Fabre², A. Gouzenes², D. Buisson¹ and I. Palhière²¹Idele, CS 52637, 31321 Castanet-Tolosan, France, ²GenPhySE, Université de Toulouse, INRAE, ENVT, 31326 Castanet-Tolosan, France, ³CDEO, 140 Route Ahetzia, 64130 Ordiarp, France; jerome.raoul@inrae.fr

Since the 90s, the 'horned' phenotype has been counter-selected in the Manech tête Rousse (MTR) dairy sheep breed. Among the elite dams, around 30% are horned and thus excluded from matings that produce candidate males for artificial insemination. In the meantime, breeding society managers have observed an increase in the number of cryptorchid young males among the candidates to selection. Recent work has highlighted the genetic determinism of these two traits and their interrelationship in the MTR breed. This determinism can be formalized by the segregation of three haplotypes: the allele for horns (H), the allele for being polled and non-cryptorchid (Pn) and the allele for being polled and cryptorchid (Pc). Only [HH] females are horned while all [HH] males and part of [HPn] males are horned (incomplete penetrance). [HPc] and [PcPc] males are polled, and only [PcPc] males are cryptorchids. Using stochastic simulations that mimics the current breeding program, we evaluated strategies combining: (1) selection of young AI males (that are genotyped for genomic selection) based on genotypes for the 'horn-cryptorchid' haplotype; and (2) the selection based on 'horned/polled' phenotype for other categories: young male candidates to be genotyped, elite dams, and ewe lambs. Strategies were compared over a 15-year period for both the genetic gain for milk yield and the changes in allelic and genotypic frequencies of the 'horn-cryptorchid' haplotype of ewe lambs. Selection based on genotype of AI males was the most efficient for the increase of the Pn allele frequency ($f(H)=0.12$; $f(Pn)=0.85$; $f(Pc)=0.03$) and the control of genotypes associated with horned or cryptorchid phenotypes ($f(HH)=0.01$; $f(HPn)=0.22$; $f(HPc)=0.01$; $f(PnPn)=0.71$; $f(PnPc)=0.05$; $f(PcPc)=0.00$). This strategy is associated with a loss of genetic gain, -14%, compared to the reference strategy where horn phenotype is not considered. Combined strategies, as the selection based on genotype of young males and the exclusion of horned elite dams, limited the loss of gain (12%) whereas some other strategies induced higher losses (-22%).

Session 27

Theatre 4

Strategies to improve selection compared to selection based on estimated breeding values

T. Pook, T. Niehoff, Y. Wientjes, L. Zetouni, M. Schrauf and M. Calus

Wageningen University & Research, Animal Sciences, Droevendaalsesteeg 1, 6700 AH Wageningen, the Netherlands; torsten.pook@wur.nl

Selecting animals based on estimated breeding values based on additive effects is shown to maximize short-term response to selection when using random mating. As rare beneficial alleles are oftentimes difficult to identify, have small estimated effects, and are in linkage with unfavourable alleles, this can lead to the loss of those alleles by drift and hitchhiking. To offset this, there are various strategies to reduce inbreeding, increase genetic diversity and thus allow for higher long-term genetic gains at the cost of slightly lower short-term genetic gain. We compared several of these strategies in a simulation study, using the software MoBPS. Applying a weighting factor to loci based on the frequency of the beneficial allele when calculating the estimated breeding value reduced the short-term genetic gain by -0.14 genetic standard deviations (gSD) while resulting in an increase of the long-term genetic gain of 2.02 gSD after 50 generations and reducing inbreeding rates by 22% compared to selection according to traditional estimated breeding values. Secondly, we considered including an additional trait in the selection index that represents the uniqueness of a given individual for the breeding program. As uniqueness criteria, we considered the number of estimated beneficial rare alleles, the total number of rare alleles, the average kinship to other animals, inbreeding rates, and the position in a principal component analysis. Putting 5% of the index weight on the average kinship to top animals led to virtually no short-term losses (-0.01 gSD) while reducing inbreeding rates by 6% and yielding 0.61 gSD more long-term genetic gain. The presented results probably represent a conservative estimate as the simulations did not include any deleterious variants and / or inbreeding depression. All considered strategies do not result in additional costs or extensive computations and thus implementation into practical breeding programs should be very straightforward and come with virtually no downsides. Considered strategies could also be combined with each other, with methods for optimum contribution selection, or with approaches to account for mendelian sampling variance.

The validity of breeding goals*R. Wellmann**University of Hohenheim, Department of Animal Genetics and Breeding, Garbenstraße 17, 70599, Germany; r.wellmann@uni-hohenheim.de*

Breeding goals of livestock breeds are commonly derived from profit calculations, while breeding goals of companion breeds are defined by expert assessments. In both cases, the question arises whether the obtained breeding goals are valid. This study characterizes the validity of breeding goals and proposes a method for optimising them. A breeding goal can be called valid if there exists a group of owners who would prefer the improved breed over other breeds, and if this group of owners remains sufficiently large for the long-term survival of the breed. The environments that are provided by this group of owners can be called the breed's niche. A breeding goal can thus be called valid if there would exist a niche for the improved breed that is sufficiently large for the long-term survival of the breed. As a small population of the breed that would be placed into that niche would increase in size, this definition of a niche extends the definition of an ecological niche towards domestic animal breeds. The definition of the validity of a breeding goal allows to evaluate the breeding goals of arbitrary domestic breeds. Furthermore, it provides a sound base for the optimisation of breeding goals. The proposed optimisation method consists of defining an envisaged niche for the breed and of determining the conformation, performance and behaviour that maximises the adaptation of the breed to its envisaged niche. The general framework for the optimisation of breeding goals can be applied to both, livestock breeds and companion breeds. For example, the breed standards of many dog breeds changed only very little over long periods of time, even though their population sizes are decreasing, and their historical uses have changed. This observation suggests that the validity of their breeding goals is questionable. The same could apply to some endangered livestock breeds. Their breeding goals should be evaluated and adjusted not only with regard to animal welfare aspects, but also with regard to their validity.

Session 27

Theatre 6

Beyond scenarios-optimization of breeding program design using evolutionary algorithms (MoBPSopti)*A. Hassanpour¹, J. Geibel^{1,2} and T. Pook^{1,3}**¹University of Goettingen, Center for Integrated Breeding Research, Animal Breeding and Genetics Group, Albrecht-Thaer-Weg 3, 37075, Goettingen, Germany, ²Friedrich-Loeffler-Institut, Institute of Farm Animal Genetics, Höltzstraße 10, 31535 Neustadt, Germany, ³Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 388, 6700 AH Wageningen, the Netherlands; azadeh.hassanpour@uni-goettingen.de*

Optimization of breeding program design requires accounting for multiple objectives along with many interdependent factors. Improving resource allocation facilitates breeders' decisions on what combinations and to what extent different breeding objectives are attainable. In a previous study, we used stochastic simulations and a kernel regression model to optimize the allocation of resources in a dairy cattle scheme. Our goal was to balance gain and inbreeding within a specified budget. Although kernel regression has aided in testing a broad range of potential breeding programs, the large number of needed simulations ultimately weakens its usability. This study aims to decrease the number of required simulations till convergence for the same problem via an evolutionary algorithm model. To achieve this, initial simulations were carried out with randomly generated parameter settings, and their fulfilment of the target criteria was evaluated. The most promising parameters will be selected as parents for the next iteration. Offspring parameterizations are generated through linear combination (recombination) and with minor changes to individual parameters (mutations) to explore different combinations of parameters in the search space. Our iterative process has an initial search phase with higher mutation rates to identify promising parameter combinations, followed by a refinement phase with a lower mutation rate to reduce parameter variations and thus narrow down the actual optima even further. We utilized Snakemake to automate all steps for efficient execution. The method proved robust by converging faster and stabilizing more quickly than kernel smoothing.

Ecobreed – what is the economically optimal longevity of a cow?

S. Schlebusch

Agroscope, Dürntenstrasse 9, 8340, Switzerland; simon.schlebusch@agroscope.admin.ch

The question when to cull a dairy cow is frequently asked by farmers as well as by the scientific community. In Switzerland, there is the general opinion that cows should be kept longer to reach the economical optimum, though in reality this is almost never realized. Hence, are longer living cows really more profitable or are the farmers culling decisions sub optimal due to lack of complete economic information. The goal of the project Ecobreed is to provide to the farmers complete economic information about their culling decisions. This is done with a model that calculates the expected monetary value of a cow in the future. The first part of the model consists of a Markov chain simulation based on herd data from 2010 to 2018. In this simulation the life of a cow is split up in 4 different states, lactation, month in milk, month pregnant and the culled state. The model then calculates with which probability a cow moves from one state to another until the cow reaches the culled state. The time between birth and the cow reaching the culled state corresponds to the expected lifetime of the cow. This life expectancy is then combined with a monthly profit equation of the cow's revenue and cost, such as milk yield and price, feed cost, veterinarian cost, etc. The profit equation combined with the life expectancy results then in the cow own worth. In the simulation based on the previously described model the optimal length of life of a cow is calculated. This is done for different farm types based on typical farms in Switzerland. In Switzerland there is a vivid debate about implementing direct payments to farmers for cows with a certain minimum number of lactations. Therefore, the goal of the project is also to find the effects of such a payment on the economically optimal longevity of a dairy cow. The results of this project are meant to be implemented in an online tool that can be given to farmers. This tool should be able to help the farmers to make informed culling decisions.

Differences in breast milk composition in rabbit lines divergently selected for intramuscular fat

P. Hernández, N. Ibáñez, I. Heddi, M. Martínez-Álvaro and A. Zubiri-Gaitán

Institute for Animal Science and Technology. Universitat Politècnica de València, Camino de Vera s/n, 46022 Valencia, Spain; phernan@dca.upv.es

An experiment of divergent selection for intramuscular fat (IMF) in Longissimus thoracic and lumborum (LTL) muscle was performed in rabbits over ten generations. The aim of the study is to estimate the correlated response to selection for IMF of LTL muscle on does' milk composition since previous studies have pointed out the importance of maternal effects for IMF. Milk samples were collected on day 15 of lactation from 38 does from the high-IMF (H) line and 34 from the low-IMF (L) line, and its composition and fatty acid profile were analysed. A linear model was fitted to estimate the differences in milk composition between the H and L lines, solved using Bayesian inference. The model included the line, sampling date (month), and parity order as fixed effects, and the number of lactating kits (LK) as a covariate. The marginal posterior distribution of the difference between lines was obtained using the Rabbit program (<https://github.com/VLabUPV/runRabbit>). The median (DH-L) of the marginal posterior distribution of the difference between lines and its probability of differing from 0 (P0) were calculated. The milk of the H-line showed greater fat content (P0=0.98) than the L-line with DH-L of 0.9%. In contrast, L-line milk had a higher percentage of lactose than H-line, with DH-L of 0.2% (P0=1). No difference was found in urea (DH-L=11.6, P0=0.62) and protein (DH-L=-0.05, P0=0.63) content. In general, H-line milk showed greater saturated fatty acid (SFA) and lower polyunsaturated fatty acid (PUFA) percentage than L-line, with no differences in monounsaturated fatty acids (MUFA). Among the SFA, the H line had a higher percentage of C10:0, C12:0, and C16:0 and a lower percentage of C8:0, C15:0, and C17:0 than the L line. The C18:3n6 and CLA9t11t were present in higher percentages in the H line. As for PUFA percentage, C18:2n6, C18:3n3, and C20:3n3 percentage was lower in the H line. The two lines divergently selected for IMF content presented substantial differences in breast milk composition confirming a correlated response to selection for IMF, suggesting that the milk composition is one of the factors explaining the maternal effects for IMF.

Combined genomic evaluation of Australian Merino and Dohne Merino sheep populationsM. Wicki^{1,2}, D.J. Brown³, P.M. Gurman³, J. Raoul^{1,2}, A. Legarra^{1,4} and A.A. Swan³¹INRAE, INP, UMR 1388 GenPhySE, Animal Genetics, 24 Chemin de Borde Rouge, 31320 Castanet-Tolosan, France, ²Institut de l'Elevage, Animal Genetics, 24 Chemin de Borde Rouge, 31320 Castanet-Tolosan, France, ³AGBU, a joint venture of NSW Department of Primary Industries and University of New England, AGBU Building, 2350 Armidale, Australia, ⁴Current address: Council on Dairy Cattle Breeding, 4201 Northview Dr, Bowie, 20716 MD, USA; marine.wicki@inrae.fr

Historically, the Merino has been the dominant sheep breed in Australia having first been imported to the country over 200 years ago. In addition, starting in the late 1990s, sheep producers began importing Dohne Merino embryos from South Africa to improve on attributes such as reproduction and carcass composition. Since then, this breed has continued to expand in Australia but the number of genotyped and phenotyped purebred individuals remains low, calling into question the feasibility of genomic selection in this breed. The Australian Merino on the other hand has a very large reference population in a separate genomic evaluation. Many studies have shown that combined genomic evaluation of several populations can be advantageous in terms of accuracy when it involves genetically close populations. In particular, combined evaluations can be very advantageous for small breeds that can benefit from the large reference population of another breed. This study was based on 27,632 Australian Merino (M), Dohne Merino (D) and crossbred (C) genotyped individuals and a pedigree of more than 4 million animals and more than 5.2 million phenotypes for two wool traits (fibre diameter and greasy fleece weight) and one weight trait (yearling liveweight). The first objective of this study was to characterize the genomic structure and relationships between these populations. A Principal Component Analysis of the genomic relationship matrix as well as computations of Hudson's fixation index (Fst), that were below 0.08, revealed a low genetic differentiation between M, D and C populations. This suggests that crossbred or combined predictions may be feasible. In the following step of this work, we will investigate the accuracy of genomic evaluation in a Dohne validation population based on purebred D, purebred M, crossbred C or the combination of these three reference populations.

Effect of germplasm exchange strategies on genetic gain and diversity in dairy stud populationsE.A. Lozada-Soto¹, F. Tiezzi², J. Jiang¹, J.B. Cole³, P.M. Vanraden⁴, S. Toghiani⁴ and C. Maltecca¹¹North Carolina State University, Department of Animal Science, Raleigh, NC, 27607, USA, ²University of Florence, Department of Agriculture, Food, Environment and Forestry (DAGRI), Florence, 50144, Italy, ³URUS Group LP, Madison, WI, 53718, USA, ⁴USDA, Animal Genomics and Improvement Laboratory, Beltsville, MD, 20705, USA; cmaltecca@ncsu.edu

This study aimed to determine the effect of different germplasm exchange strategies on long-term genetic gain, homozygosity, and inbreeding. Genotypes from U.S. Holstein cattle born between 2010 and 2020 and belonging to 3 distinct stud populations were used as a basis for a simulated breeding program. Ten generations of selection were simulated (using the R AlphaSimR package) within each population by mating 200 bulls with 5,000 cows. Three traits were simulated (one for each population) with the same underlying genetic architecture (either 10 or 100 QTL/per chromosome) and an additive genetic correlation between traits that varied according to a parameter ϵ ($\epsilon=0.10, 0.50$, or 0.90). Animals within a given population were selected either randomly, using true breeding value (TBV), estimated breeding value (EBV), or an estimated breeding value penalized for kinship (pEBV) with females. To evaluate the effect of germplasm exchange between populations, we simulated scenarios where sires (25 or 100) from the other two populations were used for mating instead of a portion of within-population sires. These sires were chosen either randomly, using pEBV, or using genomic future inbreeding (GFI). The study monitored genetic progress, homozygosity, and inbreeding. The simulation was replicated ten times. A mixed-linear model was fitted using the fixed effects of within- and across-population selection scenarios, population, number of QTL, ϵ parameter, all the two-order interactions, and the random effect of replicate. Least-squares means were obtained for each level of the main effects. Using sires from other populations (specifically the pEBV and GFI scenarios) provided higher long-term genetic gain (pEBV_100 = 2.30 genetic SD vs no exchange = 1.77 genetic SD), a decrease in homozygosity (GFI_100 = -1.16% vs no exchange = 0.28%), and a lower average inbreeding increase (pEBV_100 = 0.26% vs no exchange = 0.38%).

Local livestock breeds in Flanders are confirmed to be ‘at risk’!

S. Janssens, L. Chapard, R. Meyermans, W. Gorssen and N. Buys

Center for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, Box 2472, 3001 Leuven, Belgium; steven.janssens@kuleuven.be

Within the EU, member states can support their local breeds if they are classified with a status ‘at risk’. Granting such a status should be supported by advice, which is issued by an experienced body. Here, we report the assessment of the status of 17 breeds of cattle (4), sheep (8), goat (3) and pigs (2) in Flanders which was requested by the Flemish government, Department Agriculture and Fisheries. We investigated demographic and genealogic information, as well as genomic information for 8 breeds. The primary source of information was pedigree data, containing id’s (animal, sire and dam), birth year, the owner of the animal. The cattle pedigree was preselected and contained the active animals for the years 2017-2022 and all ancestors of these animals. Sheep, goat and pig pedigrees were obtained ‘unselected’ from the responsible organizations and from these, the cohorts of animals born and registered in 2017-2022 and all their known ancestors were selected. Active breeding females and males (at least one offspring in a particular year) were counted per year. The number of active females and its trend over time were retained as separate criteria and converted in scores (0=no problem; 5=high risk) based on FAO guidelines. All pedigree files were cleaned and were used to infer effective sizes (N_e) following the decision tree implemented in POPREPORT. Genotypic data was available for 4 breeds of cattle and 4 sheep breeds and was used to compute genomic inbreeding and N_e . N_e estimates were converted in scores from 0 to 5, 5 corresponding to $N_e < 45$. N_e was retained as the third criterion. A score of 4 or 5 for any of the 3 criteria was considered sufficient to classify a breed as endangered. Following this rule, all 17 breeds in the study were categorized as being at risk. Most breeds fall short on more than one criterion and their risk status is often aggravated by low and decreasing numbers of active breeders (2017-2022). Our across-species approach, applying formal criteria helps stakeholders to better monitor the local breeds in Flanders and calls for urgent action in the field.

Session 27

Theatre 12

Probabilistic breeder’s equation used for retrospective and prospective analysesD. López-Carbonell¹, I. Pocrnic², G. Gorjanc² and L. Varona¹*¹Instituto Agroalimentario de Aragón (IA2), Universidad de Zaragoza, Departamento de Anatomía, Embriología y Genética Animal, Calle Miguel Servet, 177, 50013, Zaragoza, Spain, ²The Roslin Institute and Royal (Dick) School of Veterinary Studies, The University of Edinburgh, Easter Bush Campus, EH25 9RG, Edinburgh, United Kingdom; davidlc@unizar.es*

The breeder’s equation (BE) is the most important equation in breeding and also key in quantitative genetics. It is traditionally used to predict the response to selection in a population. This prediction is based on the intensity of selection, the accuracy of selection criteria, and the additive genetic standard deviation. However, in non-experimental populations, the genetic contributions, accuracies and genetic variances are unknown variables inferred from the data. This entails uncertainty in predictions with the BE, which is commonly ignored. While the BE is mainly used for a prospective analysis/prediction, it also has application in retrospective analysis. To this end, García-Cortés *et al.* developed a method to analyse past genetic trends by partitioning breeding values of individuals into parent contribution terms and Mendelian sampling and allocating these terms to different paths of selection. Here we combine the principles of the BE and the partitioning method for probabilistic retrospective analyses. By doing this, the posterior distribution of the elements of the BE for user-defined paths of selection is obtained. These results provide an understanding of the past genetic changes due to selection within and between different paths of selection and how each of these paths contributed to the overall change. To test the method, we first simulated 5 generations of selection on true breeding values with variable male and female contributions. The results showed that genetic changes are proportional to the genetic contribution of male and female paths and their respective selection intensities following the BE. Second, we simulated selection on breeding values estimated from the data with uncertainty. We used the developed method to obtain the posterior distribution of selection intensity, accuracy, and genetic variance in each generation. This work will give further insight into past genetic changes in breeding programmes and provide probabilistic predictions.

Re-organising the Danish dairy cattle sector with alternative breeding goals and crossbreedingJ.B. Clasen^{1,2}, R.D. Kring¹, J.R. Thomassen³ and S. Østergaard^{1,2}¹SimHerd A/S, Niels Pedersens Allé 2, 8830 Tjele, Denmark, ²Aarhus University, Animal and Veterinary Science, Blichers Allé 20, 8830 Tjele, Denmark, ³VikingGenetics, Ebeltoftevej 16, 8960 Randers SØ, Denmark; julie.clasen@anivet.au.dk

In this simulation study, we analysed the economic impact of re-organising the Danish dairy cattle sector inspired by the pig sector. The system involves herds with purebred animals acting as multipliers for production herds with crossbred animals. Hereby, utilising the strengths of the major dairy breeds in Denmark in a terminal crossbreeding system, potentially increasing the overall profitability of the sector. The selection of female breeding candidates will be intensified by only using embryo technologies. The proportions of cows in multiplier and production herds were calibrated to meet the minimum number of breeding animals for the highest genetic gain with a reasonable inbreeding rate. It resulted in 7% of the cows being purebreds in multiplier herds, and 93% of the cows being crossbreds in production herds. A scenario illustrating the current dairy sector was simulated for economic comparison. In the economic analyses we assumed same market prices and costs associated with breeding in the current and re-organised sector. We also assumed a zero-profit of production of crossbred heifers in the multiplier herds. The preliminary results show, that multiplier herds in will gain a 3% higher contribution margin than an average herd in the current sector, while production herds will gain 19%. The additional contribution margins are expected to cover the cost of producing crossbreds by using embryo technologies in the breeding programme of the re-organised sector. Furthermore, the preliminary results show that the re-organised sector is able to deliver the same amount of milk as the current sector, but with a 5% larger cow population. On the other hand, the number of young stock for replacement (both purebred and crossbred) will be reduced by 35%. We expect that including genetic gains will increase the economic potential of crossbreeding the re-organised dairy sector. Furthermore, the economic potential of having alternative breeding goals aimed to specialise the breeds used in the crossbreeding system will be analysed.

Session 28

Theatre 1

How to balance selection for litter size in pigs with survival, health and welfareP.W. Knap¹, A. Huismans², C. Sørensen³ and E.F. Knol⁴¹Genus-PIC, Ratsteich 31, 24837 Schleswig, Germany, ²Hendrix Genetics, P.O. Box 30, 5830 AA Boxmeer, the Netherlands,³Danish Agriculture & Food Council, Agro Food Park 15, 8200 Aarhus N, Denmark, ⁴Topigs Norsvin Research Center, Schoenaker 6, 6641 SZ Beuningen, the Netherlands; pieter.knap@genusplc.com

Animal populations adapt to their environments in order to survive. Adaptation to farming conditions can take place by natural selection (when the best-adapted individuals produce more offspring), but targeted genetic selection results in larger changes. To steer genetic change in the desired direction, livestock genetic programs need to record many characteristics on individual animals, ideally this should be done under the farming conditions of the future. In the EU, societal discussions will soon lead to clearer definition of those conditions, e.g. free farrowing for sows. Another EU- and worldwide development is the increasing shortage of labour, especially on (pig) farms. Both these issues require an increased self-sufficiency of sows and piglets. Breeding goals that emphasize pig meat production efficiency lead to a genetic increase in litter size. Litter size has negative (unfavourable) genetic correlations to piglet survival, mediated by changes in weight and physiological maturity at birth, gestation length, and farrowing duration. Such unfavourable correlations can be neutralized by balanced index selection based on a proper understanding of the underlying biology; this leads to favourable trends in litter size and piglet survival at the same time. This involves appropriate recording of piglet survival itself (at farrowing and during lactation), birth weight and its within-litter variation, teat number, weaning weight, gestation length, farrowing duration (relevant for colostrum intake), and/or the various types of maternal behaviour and mothering ability. We present: (1) realized phenotypic and genetic trends of various reproduction traits and the way they relate to each other; (2) past and future breeding goals; and (3) developments in data recording, of four leading pig breeding organizations. We show that it is possible to balance selection for litter size in pigs with survival, health, and welfare. And by doing so improve both animal welfare and efficiency within the pork value chain.

Selection for robustness and welfare in Iberian pig through birth weight uniformity as criterion

J.P. Gutiérrez¹, N. Formoso-Rafferty², F. Sánchez-Esquileche³, M. Muñoz⁴, J.M. García-Casco^{4,5} and I. Cervantes¹
¹Dpto. Producción Animal. Facultad de Veterinaria, UCM, 28040 Madrid, Spain, ²Dpto. Producción Agraria. E.T.S.I.A.A.B, UPM, 28040 Madrid, Spain, ³Dpto. Agropecuaria, Sánchez Romero Carvajal-Jabugo, 21290 Jabugo, Huelva, Spain, ⁴Dpto. After the genetic selection for increased litter size (LS), the pig industry has noticed an increase in birth weight (BW) variability within litter. Within-litter variation of BW has a high importance in breeding practice for animal survival and from an economic perspective. The objective of this study was to analyse the data from a selection experiment for BW variability in Iberian pigs (Sánchez Romero Carvajal population). Two replicates of the generation 0 have been performed during 2022. A total of 243 litters belonging to nulliparous sows (345-458 days of age) and 28 boars were used, totalling 1,544 BW piglets. A heteroscedastic model was used to select animals, including mother age, piglet sex, LS at birth and replicate as systematic effects. Genetic effects (mean and variability) were assigned to the mother. The pedigree contained 1,026 animals. Weight at 21 days (W21), average daily gain to 21 days (ADG) and survival (at birth and at 21 days) were also studied to evaluate the impact of selection. The genetic variance for the BW variability was 0.39 (genetic variation coefficient of 0.62) with a genetic correlation of -0.20 between BW and its variability, although not significant. The mean BW was 1.17 kg and 1.18 kg for the selected and the total sows. LS was 7.3 averaging the number of individuals per litter in which each piglet was born, being 7.8 in the selected sows for uniformity. The intermediate LS values were less variable than the extremes. The correlation between the mean trait and its variability was close to 0 for W21 and ADG. Correlations between BW variability and other traits were favourable for BW, W21 variability, ADG variability, survival at birth and at 21 days. However, they were slightly unfavourable for W21 and ADG. A reduction of 16% in the present BW variability could be achieved without negatively modifying the BW neither LS.

Session 28

Theatre 3

Resilience parameters in fattening pigs are heritable and associated with tail biting and mortality

W. Gorssen¹, C. Winters², R. Meyermans¹, L. Chapard¹, K. Hooyberghs¹, J. Depuydt³, S. Janssens¹, H. Mulder⁴ and N. Buys¹

¹KU Leuven, Center for Animal Breeding and Genetics, Kasteelpark Arenberg 30, bus 2472, 3001, Belgium, ²KU Leuven, Laboratory for Biological Psychology, Tiensestraat 102, 3000 Leuven, Belgium, ³Vlaamse Piétrain Fokkerij vzw, Aardenburgkalseide 254, 9990 Maldegem, Belgium, ⁴Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH, Wageningen, the Netherlands; wim.gorssen@kuleuven.be

Previous research in pigs showed that body weight deviations in longitudinal data are heritable and can be used as a proxy for pigs' general resilience. However, only a few studies investigated their relationship with specific resilience-related traits, such as lameness, bite wounds and mortality. Moreover, most studies focused on purebred pigs, which are often less exposed to challenges than commercial pigs. In this study, 1,865 fattening pigs with known pedigree (135 Piétrain sires and 266 crossbred dams) were weighed every 2 weeks (~8 recordings per pig). During weighing, pigs were also scored for physical abnormalities, such as ear swellings, umbilical hernia, lameness and ear and tail biting wounds. Recordings took place in the same stable between July 2020 and July 2021. The resilience trait *Invar* was calculated as the natural logarithm of the variance of deviations of predicted vs observed weights after Gompertz modelling. Heritabilities, and phenotypic and genetic correlations between *Invar*, physical abnormalities and mortality were estimated using *remlf90* (BLUPF90 software). The resilience trait *Invar* was moderately heritable ($h^2=31.4\%$). Moreover, *Invar* was phenotypically and genetically correlated with tail biting wounds ($r_p=0.22$; $r_g=0.39\pm0.25$), lameness ($r_p=0.21$; $r_g=0.44\pm0.05$) and mortality ($r_p=0.27$; $r_g=0.43\pm0.07$). Low correlations were found between *Invar* and umbilical hernia ($r_p=-0.01$; $r_g=-0.02\pm0.81$), ear biting wounds ($r_p=0.02$; $r_g=-0.02\pm0.26$) and hematomas ($r_p=-0.02$; $r_g=-0.22\pm0.21$). Our findings show that deviations in longitudinal weight data are heritable and positively associated with tail biting wounds, lameness and mortality. These findings are valuable for pig breeders, as they offer evidence that these deviations are an indication of animals' general health and resilience.

The impact of phenotyping, genotyping, and the boar's origin on the genetic gain of organic pigsR.M. Zaalberg¹, J.B. Clasen^{2,3}, T.M. Villumsen¹, J. Jensen¹ and T.T. Chu¹¹Aarhus University, Center for Quantitative Genetics and Genomics, C. F. Møllers Allé 3, 8000 Aarhus, Denmark, ²Aarhus University, Department of Animal and Veterinary Sciences, Blichers Alle 20, 8830 Tjele, Denmark, ³SimHerd Inc., Niels Pedersens Alle 2, 8830 Tjele, Denmark; roos.zaalberg@qgg.au.dk

Pig welfare and organically produced pork are popular among consumers. Yet, for organic pigs, there are no breeding programs that aim specifically at improving organic pigs according to the organic principles. Instead, organic pig breeding programs depend on genetic material from conventional boars. Little is known about how organic pig breeding programs could be optimized. This study investigated how genetic gain in an organic pig population is impacted by phenotyping and genotyping of different types of pigs in the pig production chain. Furthermore, we considered the biology of traits and the origin of the boars. We simulated breeding schemes that included three types of pigs, namely nucleus pigs (L), crossbred pigs (YL), and finisher pigs (DYL). The scenarios used four factors: phenotyping of DYL, genotyping of the three types of pigs, the origin of the L-sire, and the genetic correlation between the purebred- and crossbred performance. The results show that using boars from an external breeding program stagnated the genetic gain of both L- and DYL-pigs. On the other hand, using organic boars resulted in a significantly higher and positive genetic gain in both L- and DYL-pigs. Genotyping of L-pigs increased genetic gain in both the L- and DYL-pigs, whereas genotyping of YL- and DYL-pigs made no difference. Phenotyping of DYL-pigs had a positive impact on the genetic gain in DYL, but only when the correlation between the purebred and crossbred performance was strong. In conclusion, to genetically improve the organic pig population, different factors should be considered. Organic boars should be used instead of external boars, and genotyping should only be done for the L-pigs. Phenotyping DYL may also be considered, under the condition that the correlation between the purebred and crossbred performance is strong.

Session 28

Theatre 5

Genetic correlations between ostrich behavioural traits and slaughter traitsP.T. Muvhali^{1,2}, M. Bonato², A. Engelbrecht¹, I.A. Malecki^{2,3} and S.W.P. Cloete^{1,2}¹Western Cape Government, Directorate Animal Sciences, Private Bag X1, 7607, Elsenburg, South Africa, ²University of Stellenbosch, Department of Animal Sciences, Private Bag X1, 7602, Matieland, South Africa, ³The University of Western Australia, School of Agriculture and Environment, 35 Stirling Highway, WA 6009, Crawley, Australia; pfunzo.muvhali@westerncape.gov.za

Behavioural responses of animals towards humans in livestock industries are vital to improve animal welfare, productivity and occupational health and safety. In the ostrich industry, it is unknown if selection of less temperamental animals that are willing to associate with humans, influence productivity and other traits of economic importance on a genetic level. The aim of this study was to estimate genetic correlations, first among behavioural response traits of juvenile ostriches towards humans and then of juvenile ostrich behavioural traits with bird slaughter weight and skin traits (i.e. skin size, nodule size, nodule shape, presence of hair follicles). Behavioural traits, namely willingness of birds to approach a human, keeping a distance away from the human, allowing touch interactions with a human, excessive pecking, beak clapping and wing flapping were recorded for 1,092 juvenile ostriches. The results of this study revealed moderate to high heritability estimates ranging from 0.12 for excessive pecking to 0.48 for willingness to approach and keeping a distance from the human. Willingness to approach, keeping a distance and allowing touch interactions were all highly correlated genetically with each other at respectively -0.99, 0.87 and -0.87. No unfavourable genetic correlations between behavioural traits and slaughter traits were recorded for slaughter weight, skin size, nodule size score and nodule shape score. There were unfavourable genetic correlations approaching an absolute value of 0.50 of approach, keeping a distance and allowing touch interactions with the prevalence of hair follicles, though the underlying biology of these unfavourable correlations is unknown at present. In conclusion, our results suggested that temperament of ostriches could be improved by selecting birds that demonstrate willingness to associate with humans. Such selection is unlikely to compromise slaughter weight and most skin traits.

Genome-wide copy number variants associated with calving ease and retained placenta in Holstein cows

I.C. Hermisdorff¹, H.R. Oliveira^{1,2}, G.A. Oliveira Júnior¹, T.C.S. Chud¹, S.G. Narayana¹, C.M. Rochus¹, A.M. Butty³, F. Malchiodi^{1,4}, P. Stothard⁵, F. Miglior^{1,6}, C.F. Baes^{1,7} and F.S. Schenkel¹

¹Department of Animal Biosciences, University of Guelph, Guelph, ON, N1G2W1, Canada, ²Department of Animal Sciences, Purdue University, West Lafayette, IN, 47907, USA, ³Qualitas AG, Zug, 6300, Switzerland, ⁴Semex, Guelph, ON, N1H6J2, Canada, ⁵University of Alberta, Edmonton, AB, T6G2R3, Canada, ⁶Lactanet, Guelph, ON, N1K1E5, Canada, ⁷Institute of Genetics, Vetsuisse Faculty, University of Bern, Bern, 3012, Switzerland; idacosta@uoguelph.ca

Calving difficulty and retained placenta (RP) can lead to significant economic losses for dairy producers due to increased veterinary costs, reduced milk production, and increased risk of culling. Copy number variants (CNVs) have the potential to explain part of the phenotypic variation of quantitative traits not explained by other genetic markers. However, despite their potential importance, there is a lack of studies in the literature investigating the impact of CNVs on RP and calving ease (CE). Here, genome-wide association studies using CNVs and de-regressed breeding values for RP and CE were performed using data from 2,465 Canadian Holsteins. A total of four genomic regions containing CNVs (CNVR) were found to be significantly associated ($FDR < 0.05$) with RP (located on BTA4, BTA5, BTA6 and BTA23), while one CNVR was found to be significantly associated with CE (BTA7). The CNVR detected on BTA7, BTA23 and BTA4 had deletions in 36.3, 16.3 and 1.2% of the evaluated animals, respectively. On the other hand, the CNVR detected on BTA5 and BTA6 had duplications in 2.2 and 1.2% of the animals, respectively. A total of 50 (RP) and 93 (CE) positional candidate genes were retrieved from the significant CNVR identified. Among them, two important candidate genes found for CE (*CCDC105* and *SLC1A6*) have been previously associated with fertility traits in dairy cattle. Additionally, the gene *MCM3*, found for RP in a CNVR located on BTA23, plays an important role in cell cycle pathway and is a functional candidate gene for the regulation of follicular maturation. Our findings provide new insights into the genetic architecture of RP and CE in Holstein cattle and may help reveal new strategies for future genetic improvement for these traits.

Indirect effects in infection transmission enhance genetic selection and other interventions

A.D. Hulst^{1,2}, P. Bijma¹ and M.C.M. De Jong²

¹Wageningen University & Research, Animal Breeding and Genomics, P.O. Box 338, 6700 AH Wageningen, the Netherlands,

²Wageningen University & Research, Quantitative Veterinary Epidemiology, P.O. Box 338, 6700 AH Wageningen, the Netherlands; dries.hulst@wur.nl

Genetic selection of livestock to lower the prevalence of infectious diseases has long attracted interest as an addition or alternative to other interventions, but its potential has been seen as limited because of the low heritability of binary disease status. The usual quantitative genetic methods used to estimate this heritability, however, treat disease status simply as an individual trait and thereby ignore the transmission dynamics of infectious diseases. Here we show that the effect of transmission dynamics on the results of genetic selection are considerable. We use simulations of an established epidemiological model (SIS) with genetic variation in individual susceptibility. Feedback effects in the transmission process rapidly lead to a certain degree of herd immunity, which might eventually result in eradication of the infection. Feedback in transmission occurs because individuals that have a low susceptibility are not only less likely to get infected themselves, but thereby also contribute to a lower number of infectious individuals in the population. This leads to indirect (genetic) effects, the effects of the genes of an individual on the infection status of its herd mates. Calculations show that these indirect effects result in a total effect of selection that is a factor of the inverse of the prevalence larger than the direct genetic effect (the breeding value for individual disease status). Thus, the total effect increases strongly with decreasing prevalence, implying that genetic selection will become more and more effective as prevalence goes down. This effect is not limited to genetic selection. If other interventions are applied that reduce prevalence, genetic selection will become more effective as well. Consequently, it can be very beneficial to combine genetic selection with other interventions, and not do only one or the other. One should, for example, not reduce hygienic measures once genetically resistant animals enter the herd, nor should breeding for increased resistance be rejected because hygienic measures are already applied.

Optimizing dairy cattle breeding goals to improve production and udder health of crossbred cowsA. Bouquet¹, H.M. Nielsen¹, V. Milkevych¹, M. Kargo¹, J.R. Thomasen² and M. Slagboom¹¹Aarhus University, Center for Quantitative Genetics and Genomics, C.F. Møllers Allé 3, 8000 Aarhus C, Denmark,²VikingGenetics, Ebeltoftevej 16, 8960 Randers SØ, Denmark; alban.bouquet@qgg.au.dk

Crossbreeding is known to increase economic profitability by benefiting from heterosis and breed complementarity. Breeding goals (BG) used to select dairy cattle breeds have so far been aimed at improving purebred performance which may be sub-optimal when the goal is crossbred performance. The aim of this study is to compare various purebred BGs in a two-way terminal crossbreeding system for dairy cattle over several generations of crossbreeding. We postulated that differentiating BGs in purebred parental lines could be more efficient to increase crossbred performance. Breeding schemes of Danish Jersey (DJ) and Nordic Holstein (NH) cattle were simulated using real haplotypes of 200 founders sampled from each breed. We simulated a founder population where NH had a higher breeding value for milk production and a lower breeding value for udder health compared to DJ. First, genomic reference populations were constituted for 20 years to predict genomic breeding values with appropriate reliabilities. In year 21-30, a genomic selection scheme for NH and DJ aimed at crossbred performance was simulated. Each year, 2,000 young bulls and 2,000 heifers were genotyped. Out of the young bulls, 50 were selected as sires. Three scenarios were set up to test the hypothesis: (1) a reference scenario resembling the economic values in the present Nordic total merit index for DJ and NH; (2) the same BG in NH as in 1, but a higher value on health in the BG of DJ; and (3) BGs only weighing production in NH and only health in DJ. In year 25-30, a population of crossbred cows was simulated alongside the two pure breeding schemes by mating Jersey cows with Holstein bulls. Purebreds in both nuclei were evaluated both for purebred and crossbred performance. For evaluation of crossbred performance, SNP-BLUP breeding values were estimated by using allele frequencies of the purebred population that an animal was bred to, whereas GBLUP was used for purebred evaluation. Outcomes of this study will be useful to assess the importance of updating BGs in purebred breeding schemes to optimize crossbred performance.

Theatre 9

Genes and variants involved in resistance to paratuberculosis in Holstein and Normande cattleV. Sorin¹, A. Boulling¹, A. Delafosse², M. Boussaha¹, C. Hozé³, R. Guatteo⁴, C. Fourichon⁴, S. Fritz³, D. Boichard¹ and M.P. Sanchez¹¹Université Paris Saclay, INRAE, AgroParisTech, GABI, 78350 Jouy-en-Josas, France, ²GDS Orne, 61000 Alençon, France,³Eliance, 75012 Paris, France, ⁴Oniris, INRAE, BIOEPAR, 44300 Nantes, France; marie-pierre.sanchez@inrae.fr

Bovine paratuberculosis, or Johne's disease, is a contagious and incurable disease, caused by *Mycobacterium avium* subsp. *paratuberculosis* (MAP), with adverse effects on animal welfare and serious economic consequences. The recent implementation of genomic evaluation for paratuberculosis resistance in France, effective in Holstein and ongoing in Normande, provides access to a large database of cows with disease status estimated from blood serological data, i.e. likely to be infected (with or without clinical signs), or not to be infected. Using a subset of 4,677 Holstein and 4,845 Normande cows with chip genotyping data, we performed sequence-based genome-wide association studies (GWAS) to identify genes and variants influencing resistance to paratuberculosis. Genotypes from the whole genome sequence were imputed using a multibreed reference population from the 9th run of the 1kBG consortium and in-house data comprising 1,414 Holstein and 160 Normande animals. The GWAS was carried out with a mixed linear model, testing the individual effect of ~14M variants after filtering for low imputation accuracy ($R^2 < 0.2$) or frequency ($MAF < 0.005$), and accounting for the population structure through polygenic effects estimated from a 50k-based genomic relationship matrix. A total of 3,026 and 5,063 variants had significant effects ($7.3 \leq -\log(P) \leq 22$) on resistance to MAP infection in Holstein and Normande, respectively. They were located on chromosomes 12, 13, 18, and 23 in Holstein and on chromosomes 3, 6, 12, and 23 in Normande. The genomic region with the most significant effect was located on chromosome 13 in Holstein (~63 Mb) and on chromosome 23 in Normande (~23 Mb). Based on their position, we identified *PEAR1*, *ELOVL5*, *HS6ST3*, *SNTA1*, and *BOLA-DRA* as the most plausible candidate genes. This study confirms the genomic regions initially identified in Holstein for resistance to MAP infection and reveals novel regions, candidate genes and variants in both Holstein and Normande breeds.

A genome-wide association study for clinical mastitis in Italian Holstein

F. Galluzzo^{1,2}, G. Visentin¹, G. Mészáros³, J.B.C.H.M. Van Kaam², R. Finocchiaro², M. Marusi² and M. Cassandro^{2,4}
¹University of Bologna, DIMEVET, via Tolara di Sopra 50, 40064 Ozzano dell'Emilia, Italy, ²Associazione Nazionale Allevatori della Razza Frisona, Bruna e Jersey Italiana, Via Bergamo 292, 26100 Cremona, Italy, ³University of natural resources and life sciences, NUWI, Gregor-Mendel-Straße 33/II, 1180 Wien, Austria, ⁴University of Padova, DAFNAE, Viale dell'università, 16, 35020, Legnaro, Italy; ferdinandogalluzzo@anafi.it

Clinical mastitis (CM) has a huge detrimental impact on animal welfare, farms' net profit and antimicrobial resistance. Nowadays, on-farm CM diagnoses are available in Italy from the Livestock Environment Opendata (LEO) project of the Italian Breeders Association (AIA). The aim of this study was to identify the SNPs associated to CM resistance and investigate its genetic background performing a genome-wide association study (GWAS). CM was considered a binary trait. Data came from 4 North-Italian regions (Lombardia, Emilia-Romagna, Veneto and Piemonte), recorded from 2014 to 2020: only first records per lactation, from 1 to 305 days in milk, were included. The maximum parity considered was 5. Lower and upper bounds of incidence per herd per year were set to 0.15 and 0.75 respectively. Herd-year-season of calving groups with less than 10 animals were discarded. The edited dataset had 113,289 records; the prevalence was 0.32. The 4 generations pedigree was composed of 140,385 animals. Heritability was previously calculated with a single-trait repeatability threshold animal model: (co)variances were converted to the observed scale in order to fit the trait as linear. Heritability on the observed scale was 0.04. GWAS analysis was performed and, in the intersection of the highest thousand SNPs for explained variance and the thousand most significant SNPs, we identified 32 SNPs. There were 47 genes in their vicinity considering windows of 200 kb, mostly located on chromosomes 5, 7, 25 and 27. Among others, PLXNC1, associated with mastitis resistance in sheep, SEMA7A, associated with immune response in humans and CEP83, associated with paratuberculosis pathological outcomes in Holstein cattle. Results confirmed the complexity of the trait and its highly polygenic nature and provide a better understanding of CM resistance in Italian Holstein.

Session 28

Theatre 11

About the genetic connection between milk and health traits in dairy cows within functional regions

H. Schneider¹, J. Heise², A.-M. Krizanac³, C. Falker-Gieske³, J. Tetens³, G. Thaller⁴ and J. Bennewitz¹

¹Institute of Animal Science, University of Hohenheim, Garbenstr. 17, 70599 Stuttgart, Germany, ²Vereinigte Informationssysteme Tierhaltung w.V., Heinrich-Schröder-Weg 2, 27298 Verden (Aller), Germany, ³Georg-August-University Göttingen, Division of Functional Breeding, Department of Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany, ⁴Institute of Animal Breeding and Husbandry, Christian-Albrechts University of Kiel, Olshausenstr. 40, 24098 Kiel, Germany; helen.schneider@uni-hohenheim.de

Many genomic mutations, all having a small impact, shape most complex traits in mammals. Intensive attempts were made to detect the underlying causal mutations, not only to scrutinize the biological mechanisms underlying these traits but also to enhance genomic selection. Unfortunately, difficulties arise because of linkage between variants and their usually small effect sizes. However, implementing functional and evolutionary information in genomic analyses enhances the detection of potential causal mutations. Thus, the intention of this study was to investigate the contribution of 27 functional and evolutionary genome partitionings to the connection between milk production and health status in dairy cows. De-regressed proofs for ~30,000 German Holstein cows with ~17 million imputed variants were available. Next to milk yield, the observed traits were mastitis, interdigital hyperplasia, digital dermatitis, claw ulcers, retained placenta, metritis and cystic ovaries. We performed a bivariate analysis to obtain genetic correlations between milk yield and the eight health traits on the other side. Each of the eight trait combinations was analysed within each of the 27 partitionings. Thereby, two relationship matrices were included in the model, one consisting of variants on the 50K array and the other one consisting of the respective partitioning. Our results indicate a significant negative connection between milk yield and health traits, which can be assigned to the noncoding part of the genome. This agrees with recent studies observing pleiotropy of causal variants. Our results confirm that variants altering gene expression play an important role for the variation of complex traits and reveal that this holds true also for the trait's genetic correlation.

Frequency of genetic disorders in genomically tested females in the NetherlandsC. Schrooten¹ and E. Mullaart²¹CRV Cooperative, Animal Evaluation Unit, P.O. Box 454, 6800 AL Arnhem, the Netherlands, ²CRV B.V., Global Genetics, P.O. Box 454, 6800 AL Arnhem, the Netherlands; chris.schrooten@crv4all.com

In 2007, CRV started to use genomic chips to obtain genotypes of a large number of SNPs. The chips that have been used since 2014 contained SNP for the most relevant genetic disorders, with a few disorders added on later versions of the chip. Some of the disorders are lethal when animals carry both recessive alleles (for example BLAD, Bovine Leucocyte Adhesion Deficiency), whereas others are less detrimental. In this research, the development of the frequency of the disorders among genomically tested females in the Netherlands was analysed, for female animals born from 2008 onwards. Frequencies were based on real genotypes, imputed genotypes were not taken into account. Number of genotypes used in the analyses ranged from 79,000 (CVM, patent expired end of 2021) to around 500,000 for the disorders that were present on the chip since 2014. For the lethal haplotypes, HH1 and HH3-HH7, highest frequency of carriers was found for HH3 in 2012 (8.2%), HH4 in 2009 (8.3%), and HH5 in 2016 (4.8%). Frequency of carriers decreased for all HH-haplotypes, highest frequency for animals born in 2023 was observed for HH3 (2.6%). The frequency of BLAD carriers gradually decreased from 1.8% in 2006 down to 0.10% in 2022. For cholesterol deficiency haplotype (CDH), which was discovered more recently, carrier frequency decreased from 6.6% in 2015 to 1.9% in 2022. Highest carrier frequency for CVM was for animals born in 2013 (4.2%), carrier frequency for CVM in recent years was less than 1%. For other disorders, like mulefoot, citrullinemia and dumps, carrier frequencies were always lower than 0.4%. The development in frequency of carriers was favourable for all disorders studied, resulting in better health and viability, due to actively selecting against these disorders by AI organizations worldwide.

Genome regions and metabolic processes associated with tick resistance in beef cattleP. Martin¹, T. Hüe², J. Mante³, A. Lescane⁴, D. Boichard¹ and M. Naves⁵¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, Domaine de Vilvert, 78350 Jouy-en-Josas, France, ²Institut Agronomique néo-Calédonien, ARBOREAL, Port Laguerre, 98890 Païta, New Caledonia, ³France Limousin Sélection, Pôle de Lanaud, 87220 Boisseuil, France, ⁴Unité Néo-Calédonienne de sélection et de promotion des races bovines, Port Laguerre, 98890 Païta, New Caledonia, ⁵INRAE, ASSET, Domaine Duclos, 97170 Petit-Bourg, French West Indies, France; pauline.martin@inrae.fr

Ticks cause significant production losses in cattle and consequences of infestation can go up to the animal death. The geographical areas of the parasite keep expanding due to climate change. For these reasons, a better understanding of the genetic control and the metabolic processes involved in host resistance appears of primary importance. To address this question, regular phenotyping have been implemented in 11 commercial farms of French New Caledonia from 2014 to 2021. Six different traits were considered: score of adult female ticks, score of juvenile ticks, total score, and the logarithm of the three previous traits. A total of 556 Limousin animals and 302 Charolais animals were phenotyped, with 1 to 8 visits per animal for the Limousin breed (mean=2.3, s.d.=1.6, total=1,273), and 1 to 12 visits for the Charolais breed (mean=4.2, s.d.=2.8, total=1,281). All the animals were genotyped with the 50K EuroGMD SNPchip. First, a generalized linear model was used to correct performances by the effects of sex, age, herd, technician and period. Then, genome-wide association studies were performed with the GCTA software using an average corrected performance per animal. Five genomic regions in Charolais and 13 regions in Limousin were found to be associated to at least one trait, with two regions in Limousin being highly significant ($P < 10^{-11}$) and shared between traits. Finally, all the significant regions have been included in a Gene Ontology analysis, using the Cytoscape software. Results shows that 37 terms from 9 functional groups are overrepresented, with the three most overrepresented group being the linoleic acid metabolic process, the negative regulation of insulin secretion and the excitatory extracellular ligand-gated ion channel activity. These processes appears as a promising candidate that requires deeper investigation.

Innovative strategy using phenotypes and genetics to optimize partial sampling applied to boar taintA. Markey¹, J. Wavreille², P. Mayeres³, A.C. Huet⁴, D. Duarte^{1,3} and N. Gengler¹¹ULiège – GxABT, Passage des Déportés 2, 5030 Gemboux, Belgium, ²Walloon Agricultural Research Centre, Rue du Liroux 8, 5030 Gemboux, Belgium, ³Elevéo, Rue des Champs Elysées 4, 5590 Ciney, Belgium, ⁴CER Groupe, Rue de la Science 8, 6900 Aye, Belgium; alice.markey@uliege.be

Avoiding castration of male piglets improves their welfare but creates the risk of boar tainted meat. Detecting and reducing boar taint is an important issue in the context of entire male fattening. The incidence of boar taint corresponds to 3-10% of declared carcasses by the human nose method at abattoir as carrying this defect. This detection is however controversial in relation to its reliability. A more reliable detection alternative, but costly and slow, therefore unfeasible in the slaughterhouse, is chemical analyses of compounds known as skatole and androstenone. Reliable genetic and genomic evaluation of boar taint risk needs the most complete phenotyping. However, extending chemical analyses to the whole population is not economical sustainable. An innovative strategy to optimize partial sampling was developed to select samples for chemical analyses after culling. The goal was to obtain a sampling that would be considered 50% tainted and 50% untainted originating from all the tested sire boar lines. A genetic boar taint risk ranking of Pietrain × Landrace crossbred boars based on available phenotypes (792 human noses (one from the abattoir and one from the lab) of which 213 had chemical analyses) in 16 contemporary groups and adjusted for their metabolic weight was computed through a multi-trait model considering a 4-generation pedigree. For the 6 posteriors contemporary groups (i.e. not yet analysed) 15% of samples from animals that were at the top of the list (i.e. most also detected by human nose) or at its bottom were chosen. Diversity of half-sire sib families were guaranteed by avoiding repeating boars from the same family. After chemical analyses allowing to compare observed vs expected status, 15% of errors were found, leading to 57% of tainted and 43% of untainted selected samples. Even if this strategy needs to be improved, it could be used to identify relevant samples to complete human nose phenotyping.

Genetic susceptibility determined by SNP2 in piglets challenged with F4-Enterotoxigenic *E. coli*A. Middelkoop¹, H. Kettunen², X. Guan¹, J. Vuorenmaa², R. Tichelaar¹, M. Gambino³, M.P. Rydal³ and F. Molist¹¹Schothorst Feed Research, Meerkoetenweg 26, 8218 NA Lelystad, the Netherlands, ²Hankkija Oy, Peltokuumolantie 4, PL 390, 05800 Hyvinkää, Finland, ³University of Copenhagen, Grønnegårdsvej 1, 1870 Frederiksberg C, Denmark; amiddelkoop@schothorst.nl

In pig production, post-weaning diarrhoea (PWD) is a frequent gastro-intestinal problem for weaned piglets, commonly associated with Enterotoxigenic *E. coli* (ETEC) as pathogen. Reducing PWD caused by ETEC and associated antimicrobial usage is crucial to improve piglet welfare and to restrict antimicrobial resistance spread among ETEC isolates. Genome-wide association studies have suggested an important role of SNP2 (ASGA0091537), positioned between the genes HEG homolog 1 and mucin 13, in ETEC adherence to intestinal cells. However, the effect of SNP2 on F4-ETEC susceptibility has not been tested yet. The aim of this study was therefore to investigate genetic susceptibility determined by SNP2 in piglets challenged with F4-ETEC. A DNA marker test targeting SNP2 identified 75 suckling piglets (Tempo × TN-70) as susceptible (heterozygous) or resistant (homozygous) to developing F4-ETEC. A total of 50 piglets, half SNP2+ and half SNP2-, were selected and weaned at 30 days of age (7.8 kg, mixed gender). The trial consisted of 10 pens with 5 piglets/pen. At day 10 post-weaning, all piglets were orally infected with F4-ETEC. Fresh faecal samples were collected from individual pigs to determine faecal consistency and the faecal concentration of F4-ETEC using quantitative PCR targeting the inoculated F4-ETEC strain. In addition, the body weight of the piglets was monitored until the end of the study, i.e. day 22 post-weaning. The concentration level of faecal F4-ETEC shedding, the percentage of pigs that developed F4-ETEC diarrhoea (72 vs 32%, $P<0.01$) as well as diarrhoea duration (2.6 vs 0.8 days, $P<0.001$) following infection were higher in SNP2+ compared to SNP2- piglets. SNP2+ piglets also had a reduced growth performance compared to SNP2- piglets (302 vs 399 g/d, $P=0.03$). To conclude, the reported association between SNP2 and ETEC F4ac susceptibility suggests that SNP2 can be a suitable marker for screening piglets to determine F4ac susceptibility for experimental and potential breeding purposes.

Reference genes selection for RT-qPCR in chickens after *in ovo* synbiotic and choline administrationE. Grochowska¹, P. Guz¹, K. Stadnicka² and M. Bednarczyk¹¹Bydgoszcz University of Science and Technology, Department of Animal Biotechnology and Genetics, Mazowiecka 28, 85-084, Poland, ²Collegium Medicum Nicolaus Copernicus University, Faculty of Health Sciences, Łukasiewicza 1, 85-821, Poland; grochowska@pbs.edu.pl

Synbiotics are bioactive substances, which can have positive effect on animal health and performance. Synbiotics and choline are considered potential epigenetic factors. They can modulate gene expression in different organs and tissues. Gene expression can be measured using RT-qPCR. One of the most important steps in RT-qPCR experiments is the selection of optimal reference genes. This study aimed to select the two most stable reference genes, which can be used for gene expression determination in five specific chicken tissues after *in ovo* synbiotic and choline administration. The experiment was conducted on Green-legged Partridge-like chickens. Synbiotic PoultryStar® (Biomim) and choline were injected *in ovo* on the 12th day of egg incubation. Three groups were established: (1) control (C); (2) synbiotic (S); and (3) combined synbiotic and choline (SCH). Jejunum, spleen, cecum, cecal tonsils and liver were sampled from 21-week-old birds. The expression of 11 commonly used reference genes (*ACTB*, *GAPDH*, *YWHAZ*, *SDHA*, *B2M*, *RPL13*, *RPL30*, *G6PDH*, *HPRT1*, *PPIA*, *TBP*) was determined by RT-qPCR. The stability of the genes was evaluated by RefFinder, which integrates geNorm, Normfinder, BestKeeper, and the comparative Δ -Ct method. The comprehensive analysis in RefFinder showed two most stable genes for each specific tissue: *GAPDH* and *YWHAZ* for jejunum, *B2M* and *RPL13* for cecal tonsils, *ACTB* and *HPRT1* for spleen, *TBP* and *YWHAZ* for liver, *ACTB* and *YWHAZ* for cecum. The *ACTB* and *YWHAZ* genes were ranked by the comprehensive analysis method in RefFinder as the two most suitable reference genes for all five tissues. In conclusion, different reference genes are recommended for normalization of gene expression results in specific chicken tissues after *in ovo* administration of synbiotic and choline. *ACTB* and *YWHAZ* are the most suitable reference genes for the gene expression normalization across all 5 tissues in the experiment. This research was supported by National Science Centre, Poland (grant no. 2020/37/B/NZ9/00497).

Genetic parameters of coronet scores related to hoof disorders in Japanese dairy cattleY. Saito^{1,2}, A. Nishiura², T. Yamazaki³, S. Yamaguchi⁴, O. Sasaki² and M. Satoh¹¹Tohoku University, Graduate School of Agricultural Science, Sendai, Miyagi, 980-8572, Japan, ²NARO, Institute of Livestock and Grassland Science, Tsukuba, Ibaraki, 305-0901, Japan, ³NARO, Hokkaido Agricultural Research Center, Sapporo, Hokkaido, 062-8555, Japan, ⁴Livestock Improvement Association of Japan, Koto, Tokyo, 135-0041, Japan; saito865@affrc.go.jp

Hoof disorders are one of the factors that lead to the culling of dairy cattle. They cause serious economic losses and are also an animal welfare problem as they are difficult to detect until they have become severe. The coronet score is used as an indicator of the hoof health of cattle in the Dairy Herd Improvement Program of Japan. It is determined on a scale of 1 (normal) to 5 (severe) based on the degree of redness and swelling around the coronary band, dew claw, and heel bulb. The objective is to investigate the genetic characteristics of the scores to genetically improve the hoof health of cattle. The data used for the analysis were the monthly test-day records of Holstein cows collected by the Livestock Improvement Association of Japan in 2014-2021. The numbers of records used for the analysis of the coronet scores were 606,417, 491,283, and 336,461 on first, second, and third lactation, respectively. Genetic parameters were estimated from a repeatability model of first to third lactation and a multi-trait model by assuming different traits at each lactation time. Herd year, lactation age group, test month, and lactation stage were considered as fixed effects. Additive genetic and permanent environmental effects were included as random effects. Estimated heritabilities were 0.02 for all parities, 0.007 for first and second lactation, and 0.01 for third lactation. Compared to previously reported estimates for the other traits associated with hoof disorders, e.g. locomotion scores, the heritability of the coronet score was estimated to be similar or slightly lower. Genetic correlations between first and second lactation and first and third lactation were 0.78 and 0.70, respectively. In contrast, those in the second and third lactation were 0.92. This suggests that the expression of genotype effects for coronet scores differs between the first and later lactations.

Selection for a lower growth rate to avoid reaching bone apposition limits in chickens*C. Leterrier**CNRS, IFCE, INRAE, Université de Tours, PRC, 37380 Nouzilly, France; christine.leterrier@inrae.fr*

Broiler chickens have been selected for high growth rate. This selection was accompanied by an increase in non-infectious leg troubles. These disorders are related with low bone stiffness due to high porosity of the diaphysis cortex. Comparisons of chickens from genetic strains or crossbreeds with different growth rates were used to understand the pathogenesis of this bone porosity. The results of the histological and biomechanical studies show that the growth of the external diameter of tibiotarsi is linked to the allometric rules. Thus, at the same age, the chickens from the fast-growing animal strains had a tibial diameter greater than the slow-growing chickens. This increase in tibial diameter induces an increase in the external area of the bone, where the osteons are located, and an increase in the diameter of these osteons. The osteoblasts completely covered the internal surface of these osteons and the mineral apposition rate was very high, indicating that the osteon infilling is maximum. These observations have shown that bone apposition in the centre of the osteons reaches the physiological limits, and that the porosity of the bone tissue observed is related to the increase in the size of the osteons imposed by the external growth of the diaphysis, itself imposed by the increase in body weight of fast growing chickens. This work on bone tissue indicates that the selection of high growth rate has led to a growth unbalance: diaphysis cannot get less porous since its strengthening cannot be achieved at the same rate as its external growth. Such limitations are also observed in terms of muscle fibre growth, which indicates that the use of crossbreeds with a lower growth rates is the only way to keep an healthy locomotor apparatus in meat-type chickens of broilers healthy and to preserve their welfare. The importance of genetic factors in determining the diaphyseal growth rate was reinforced by the identification of many QTL related to different parameters describing the diaphysis structure in the chicken.

Session 28

Poster 19

Daily milk yield, variance and skewness of milk deviations in cows' resilience*L. Zavadilová, E. Kašná, J. Vařeka and Z. Krupová**Institute of Animal Science, Genetics and Breeding of Farm Animals, Přátelství 815, 10400, Czech Republic; zavadilova.ludmila@vuzv.cz*

Daily milk yield observations (DMY) were analysed from 484 lactations of 300 Holstein and 84 lactations of 61 Czech Fleckvieh cows monitored via Affimilk software from 1994 to 2017. The database included 167,112 DMY observations between 1 and the maximum ranging from 242 to 305 days in milk. The highest completed lactation was the eighth. Using a linear model with sixth-order Legendre polynomials, the lactation curve predicted a cow's expected milk yield on each lactation day. The deviations of DMY from the predicted milk yield, their variance and skewness (Skew) were determined. The variance of deviations was log-transformed (LnVar) to achieve their normal distribution. There were estimated least square means for DMY, deviations, LnVar and Skew, and the significance of fixed effects and correlations between traits analysed by statistical programme SAS 9.4® using proc GLM and proc CORR. DMY ranged between 5.1 and 54.9 kg, with a mean of 31.3 kg of milk per cow and day. DMY were higher in the Holstein breed than in the Fleckvieh breed and increased with parity. In both breeds, the deviations were significantly influenced by year and calving season and increased with parity. While differences between breeds were found for both LNVar and Skew, LnVar was mainly influenced by parity and Skew by calving year and calving season. The total number of recorded cases of clinical mastitis was 1,253. Lactation incidence for the whole lactation was 95%, in early and middle lactation 50% and in late lactation 34%. The lactation occurrence of clinical mastitis was high. Nevertheless, we could not find the effect of mastitis on the increase of deviations in any breed. The significant effect of mastitis occurred on Skew for Holstein. For LnVar, the effect of mastitis was found in the early lactation of Fleckvieh cows. The correlation between Skew and LnVar was 0.15 ($P < 0.001$) for Holstein cows. Supported by the Ministry of Agriculture of the Czech Republic, institutional support MZE-RO0723 and by the project QK22020280.

Lameness scoring and its use in genetic selection to improve claw health in Austrian Fleckvieh cows

A. Köck¹, C. Fuerst¹, B. Fuerst-Waltl², M. Suntinger¹, K. Linke¹, J. Kofler³, K. Schodl¹, F.J. Auer⁴ and C. Egger-Danner¹

¹ZuchtData EDV-Dienstleistungen GmbH, Dresdner Str. 89, 1200 Vienna, Austria, ²University of Natural Resources and Life Sciences, Vienna, Institute of Livestock Sciences, Gregor-Mendel-Straße 33/II, 1180 Vienna, Austria, ³University of Veterinary Medicine, Vienna, Veterinärplatz 1, 1210 Vienna, Austria, ⁴LKV-Austria, Dresdner Str. 89, 1200 Vienna, Austria; koeck@zuchtdata.at

This study was part of the D4Dairy project. This project aimed, amongst others, to investigate the potential of sensor data and other farm and cow-specific data for disease prediction and genetic improvement of metabolic, udder and claw health. The specific objective of this study was to estimate genetic parameters for lameness and to investigate relationships with claw diseases and culling reasons. A total of 53,490 data records from 6,383 Fleckvieh cows from 91 farms were available from September 2019 to June 2021. Data collection was performed by the regional milk recording organizations. Lameness was scored for each animal at each milk recording using the scoring system of Sprecher *et al.* with 1 = normal, 2 = slightly lame, 3 = moderately lame, 4 = lame, and 5 = severely lame. For genetic analyses, a linear animal model was fitted with fixed effects of herd, lactation, and calving year-month and random effects of animal and permanent environment. The frequency of lame cows was 15.1% (lameness score ≥ 3). Lameness frequency was lowest in first lactation cows (8%) and increased with lactation number (25.4% in fifth and higher lactations). The estimated heritabilities for lameness ranged from 0.06 to 0.09 depending on the trait definition. Relationships between lameness and claw diseases and culling reasons were investigated. The results confirmed the usefulness of lameness scoring to improve claw health.

Association between udder health genomic breeding values and dairy and health traits in French cows

R. Lefebvre¹, S. Barbey², F. Launay², M. Gaborit², L. Delaby³, P. Martin¹ and D. Boichard¹

¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, 78350, Jouy-en-Josas, France, ²INRAE UE326, Domaine Expérimental du Pin, 61310 Gouffern en Auge, France, ³PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France; rachel.lefebvre@inrae.fr

Mastitis is a major issue in dairy cows. Although environmental effects are preponderant, the genetic variability of mastitis resistance is important. A divergent genetic selection experiment on mastitis resistance was carried out at INRAE Le Pin experimental unit in Holstein and Normande breeds, yielding females of resistant and control lines, based on their sire breeding values. The aim of this study was to estimate the impact of udder health genomic breeding values on dairy and health traits throughout the lactation. This study involved 584 Holstein and 343 Normande cows from the experimental facility. Cows were genotyped and characterized by their direct genomic value (DGV) for all traits routinely evaluated in France, including somatic cell score (SCS) and clinical mastitis (CM) summarized in a udder health genomic breeding values (UHg). Own performances were not included in the genomic evaluation. Milk yield (MY) and composition were recorded daily and twice a week respectively, all along their lactation, and all health events were recorded. CM and metritis data were pooled by 2 weeks-period and limited to the first 6 months of lactation for CM and 2 months of lactation for metritis. The model included the date as a fixed effect, the DGV for the analysed trait as a covariate, a within-parity Wilmink model of lactation curve and a regression, function of UHg and the standardized stage of lactation. Trajectories of all traits were found to be dependent on UHg in both breeds. In the beginning of lactation, animals with high UHg (i.e. genetically more resistant) showed lower MY and SCS (-1.5 kg and -0.7 point per UHg genetic standard deviation, respectively), higher fat and protein contents (+1.2 and +0.4 g/kg, respectively) and less frequent CM and metritis. The effect of UHg was constant all along lactation for SCS, whereas it varies with days in milk for other traits. Some of these effects were unexpected and need further investigations.

Validating resilience indicators derived from longitudinal performance measurements

M. Ghaderi Zefreh, R. Pong-Wong and A. Doeschl-Wilson

University of Edinburgh, The Roslin Institute and R(D)SVS, Midlothian, EH259RG, United Kingdom; mghaderi@ed.ac.uk

Resilience is defined as the ability of an animal to be minimally affected or quickly recover from a disturbance. Thanks to an increasing abundance in automated on-farm monitoring systems, longitudinal performance measures of individual animals become more routinely available. Several studies have proposed that statistical measurements of the deviation of an animal from its target trajectory (i.e. performance in ideal condition) provide useful resilience indicators (RI) and may be suitable for genetic selection. The aim of this study was to assess the ability of these RI to discriminate between different response types, and their dependence on the quality of available data. The RI considered in this study were skewness, autocorrelation, integral, mean of squares and log variance of performance deviations. Performance trajectories of three broad response types with respect to a short-term challenge were simulated which were, *Fully Resilient* (not affected by the challenge), *Partially Resilient* (affected but recovered after a period), and *Non-Resilient* (permanently affected by the challenge). The simulations included individual variation within response types. The ability of the RI to discriminate correctly between the response types was assessed assuming that target trajectories were unknown and using different methods to estimate these. Across all simulated scenarios, it was found that all RI could correctly distinguish *Fully Resilient* from *Partially* or *Non-Resilient* animals. However, only log variance, integral and mean of squares correctly identified the *Partially Resilient* response type as more resilient than the *Non-Resilient* type, and this required data both within and outside the perturbation period. The results of this study highlight the potential risk of misclassifying animals based on the diverse RI, and method and data requirements to overcome these. Furthermore, response to selection for the diverse RI on actual disease resilience of animals is currently evaluated using an existing mechanistic host-pathogen interaction model for gastro-intestinal nematode infections in lambs. This study has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement No 772787 (SMARTER).

Session 28

Poster 23

Approaching the genetic evaluation models for clinical mastitis in Spanish dairy cowsM.A. Pérez-Cabal¹, I. Cervantes¹, J.P. Gutiérrez¹, J. López-Paredes² and N. Charfeddine²¹Faculty of Veterinary Science, Complutense University of Madrid, Avda. Puerta de Hierro, 28040 Madrid, Spain, ²Spanish Holstein Association (CONAFE), Valdemoro, 28340 Valdemoro, Spain; mapcabal@vet.ucm.es

Clinical mastitis (CM) is one of the most important health problems on dairy farms due to the costs it causes and the decrease in animal welfare. In the last years, breeding programs are focused on selecting animals less susceptible to udder health problems, among others. The objective of this work was to determine the best model for estimating genetic parameters of CM traits in Spanish Holstein population following the recommendations of the Eurogenomics Golden Standard. We studied six CM traits after differentiating among lactations and periods. Clinical mastitis data collected by CONAFE in first lactation (L1), second lactation (L2) and third or more lactations (L3) have been considered. Each lactation was split into two periods: up to day 68 postpartum (P1) and from day 69 up to 305 days in milk (P2). The final dataset comprised 89,225 records from 57,857 cows calved from 2013 to 2022. Traits were transformed to a normal distribution using the Snell transformation by herd-year strata. The models always included lactation-age (as fixed effect with up to 44 levels), calving month (as fixed effect, 12 levels), and animal and permanent environmental effect (only for L3) as random effects. The tested effects were ratio of days at risk in each period or standardized ratio by herd (as a covariate), herd-year (as fixed effect with up to 481 levels, or as random). The pedigree contained a total of 156,961 individuals. Genetic parameters were estimated using ASReml v.4. and model election was based on Bayesian Information Criterion (BIC). The prevalence of CM in P1 ranged from 8.9 to 16.0%, and in P2 from 17.8 to 34.9%. Regardless lactation and period, the best model should include the standardized ratio. However, in P1 the model should consider herd-year as random while in P2 should be included as fixed. The univariate analyses led to estimated heritabilities in P1 of 0.01, 0.02 and 0.01, for L1, L2 and L3 (in P2 were 0.07, 0.04 and 0.03, respectively). The estimated repeatability for L3 was 0.22 and 0.47 (for P1 and P2, respectively). Further studies should approach bivariate analyses among CM traits.

Milk somatic cell counts in winter and summer are genetically different traits in Norwegian goats*H.B. Olsen, J. Jakobsen and T. Blichfeldt**The Norwegian Association of Sheep and Goat Farmers, Breeding and genetics, Box 104, 1431 Ås, Norway; hbo@nsg.no*

High milk somatic cell count (SCC) is associated with mastitis infections and poor milk quality, but compared to dairy cows, the dairy goats are more prone to elevated SCC due to environmental factors. A recent study using data from Norwegian Dairy Goats (NDG) found an effect of calendar month on SCC with the highest values in summer on pasture. The aim of the present study was to determine if SCC recorded during winter and summer is genetically the same trait. We extracted individual SCC records obtained in 2018-2022 from 5,357 one year old goats from the goat recording system. The goats started lactating between mid-December and through March and belonged to 32 herds. Test day was used to determine if the SCC records should belong to winter (SCC1) or summer (SCC2). Winter was defined as January through March, and summer as June and July. For goats having more than one record within season, the first record was kept for winter and the record closest to July 1st was kept for summer. Individual daily milk yield (DMY) observations obtained the same test date as the SCC1 (DMY1) and SCC2 (DMY2) were included in the analysis with SCC traits. Pedigree was traced as far back as possible on animals with data. We used a multivariate linear animal model to estimate genetic correlations between SCC1, SCC2, DMY1 and DMY2 with year and stage of lactation as fixed effects, and herd-testday, additive genetic effect of animal and residual as random effects. The genetic correlation between SCC1 and SCC2 was 0.49 (0.12) and the genetic correlation between DMY1 and DMY2 was 0.83 (0.05), indicating that SCC during winter and summer are different traits genetically, while milk yield during winter and summer to a large extent are determined by the same genes. Due to seasonal kidding, the winter trait is recorded earlier in the lactation than the summer trait, which makes it difficult to separate lactation stage and lactation season. Nevertheless, somatic cell count recorded in winter and summer is not the same trait in Norwegian goats.

Session 28

Poster 25

Effects of two different traditional sire breeds on performance and behaviour of rearing pigs*A. Lange¹, M. Wutke^{1,2}, S. Ammer³, A.K. Appel⁴, H. Henne⁴, A. Deermann⁵ and I. Traulsen¹*

¹Georg-August-University, Livestock Systems, Albrecht-Thaer-Weg 3, 37075 Göttingen, Germany, ²Georg-August-University, Breeding Informatics Group, Margarethe von Wrangell-Weg 7, 37075 Göttingen, Germany, ³Bavarian State Research Center for Agriculture, Prof.-Dürnwächter-Platz 2, 85586 Poing, Germany, ⁴BHZP GmbH, An der Wassermühle 8, 21368 Dahlenburg-Ellringen, Germany, ⁵ASB GmbH, Boschstraße 9, 49770 Herzlake, Germany; martin.wutke@uni-goettingen.de

As the breeding of fast-growing, lean-meat-producing hybrid pigs and at the same time the frequency of tail-biting has been increasing since the 1950s, this study investigated the effects of different local, traditional sire breeds on the behaviour and performance of rearing pigs. In total, 1,561 piglets were weaned from hybrid sows (Landrace × Large White) that were paired with either Swabian-Hall (SH), Bentheim Black Pied (BB) or Piétrain (Pi) boars. Tails of the piglets were left intact (43.5%) or docked (56.5%), and male piglets were castrated. Piglets were conventionally reared on fully slatted plastic flooring in mixed-sex groups. Starting one day after weaning, skin lesions were scored once per pig, and tail lesions and losses were scored weekly until the end of rearing. The average daily gain was documented for the suckling and rearing period. The activity behaviour of eight focal pens was analysed using video recordings. Differences between modern and traditional breeds were found in this study for skin and tail lesions and tail losses. Significantly fewer BB pigs had severe skin lesions on the front body than SH or Pi pigs ($P < 0.05$). In the first half of the rearing period, significantly more BB pigs were assessed without tail lesions and tail losses than SH and Pi pigs ($P < 0.01$). However, these differences disappeared in the second half of rearing. Either docked or undocked Pi pigs had significantly higher average daily gains than SH and BB pigs ($P < 0.05$). The activity of the focal pens was not influenced by the sire breed or tail lesion class. To conclude, the use of the traditional sire breed BB showed the genetic potential to reduce injurious behaviour in the offspring. Selective breeding for suitable behaviour traits of performance-orientated lines might be promising to further reduce the incidences of tail lesions and losses.

Evaluation of milk parameters and mastitis predisposition in Cyprus Chios sheep

S. Panayidou, T. Christofi, A.N. Georgiou and G. Hadjipavlou

Agricultural Research Institute, Animal Production, P.O. Box 22016, 1516, Lefkosia, Cyprus; spanayidou@ari.moa.gov.cy

Sheep is one of the most important livestock species around the world and different breeds have a significant variation in diverse phenotypic traits. The Cyprus Chios breed is a productive and prolific dual-purpose sheep breed and is the main commercial breed of Cyprus, imported into the country and genetically improved under local conditions for more than 60 years. As part of extensive research activity at the Agricultural Research Institute, data on individual daily milk yield, monthly milk quality traits, and other milk parameters such as individual milk sample electrical conductivity, pH, and somatic cell count have been collected on average for 500 ewes per year, for more than ten years. We also have complete pedigree information for all animals and genomic data on about 1,200 ewes from 2020 onward, based on a 50K single-nucleotide polymorphism (SNP) genotyping array. The aim of this study is to identify genetic factors that affect milk yield, milk quality traits (fat, protein, lactose, total solids), and susceptibility to mastitis for the Cyprus Chios breed, as well as the genetic correlation between traits. Our hypothesis is that milk yield, electrical conductivity, pH, and somatic cells of milk can be predictive of milk composition and indicators for the health status of the mammary gland. Genetic effects and correlations between genetic and phenotypic data for these factors are estimated across all animals, and the genetic difference is examined separately for high- and low-yielding groups of animals for different lactation periods. Estimation of genomic breeding values for mastitis susceptibility indicators shall be incorporated within the existing genetic improvement program of the Chios breed, with the use of more phenotypic and genomic information from about 40 private Chios sheep farms, taking part in a recently initiated research project within an Aid Scheme of the Cyprus Resilience and Recovery Plan, funded by the European Commission.

Poster 27

Influence of early rearing system on later performance of commercial laying hensQ. Berger¹, N. Bédère², P. Le-Roy², S. Lagarrigue², T. Burlot³ and T. Zerjal¹¹Université Paris-Saclay, INRAE, AgroParisTech, GABI, 78350, Jouy-en-Josas, France, ²PEGASE, INRAE, Institut Agro, 35590, Saint-Gilles, France, ³NOVOGEN, 5 rue des Compagnons, 22960 Plédran, France; tatiana.zerjal@inrae.fr

Poultry production is undergoing rapid changes from cage systems to cage-free environments such as floor housing systems. In this study, we examined the effects of early life rearing environment on late performance (from 70 to 93 weeks of age). We used data from 1,024 purebred hens from the nucleus of Novogen, reared in either a floor housing system (120 hens) or in collective cages (904 hens) during the first laying period (FLP) from 18 to 55 wks of age, and then transferred to individual cages for the late laying period (LLP) from 56 to 93 wks of age. More specifically, we recorded daily egg production throughout the measurement period and measured individual feed intake twice a week for three weeks, starting at 70, 80, and 90 wks of age, as well as body weight at the beginning and end of each feed intake recording period. Egg quality was assessed at 70 and 90 wks and body organ weight at slaughter. Random regressions models were used to study trait variation on a trajectory of time and genotype by time interactions. To study the impact of the rearing system of the first laying period on the performance of the late laying period, a fixed effect was included in the model, with two levels: floor or collective cage. The results showed that the rearing environment of the FLP did not affect body weight, feed conversion ratio, weight gain, yolk percentage, or abdominal fat content recorded in the LLP. Instead it affected daily feed intake, egg weight, laying rate, egg mass, Haugh unit, and residual feed intake. Specifically, floor hens had a 9.4% higher daily feed intake, 4% higher egg weight, 3.8% higher laying rate, 7.3% higher egg mass, 6.8% higher Haugh unit, and 133% higher residual feed intake compared to those reared on collective cages in the FLP. They also presented increased liver (+ 15%) and breast muscle (+9%) weight proportion. Although more data are needed to confirm this observation, our results suggest that floor rearing in the first laying period may have an impact on performance at later laying stages, perhaps reflecting a change in the animals' energy allocation.

Differentially expressed genes in tissues of Pietrain sired pigs challenged with high fiber/fat diet

E.U. Nwosu¹, B. Chakkingal Bhaskaran¹, E. Kowalski^{2,3}, W. Gorssen¹, R. Meyermans¹, S. Janssens¹, S. Millet², M. Aluwé², S. De Smet³ and N. Buys¹

¹Centre for Animal Breeding and Genetics, KU Leuven, Department of Biosystems, Kasteelpark Arenberg 30, Box 2472, 3001 Leuven, Belgium, ²ILVO, Scheldeweg 68, 9090 Melle, Belgium, ³Laboratory for Animal Nutrition and Animal Product Quality, Ghent University, Coupure Links 653, Block F, 9000 Ghent, Belgium; emmanuelauchenna.nwosu@kuleuven.be

The use of more by-products in animal feeding is one possibility to close nutrient cycles. They are often higher in fibre and/or fat content and lower in starch and monosaccharides than regular feed ingredients, and may be more variable in nutrient digestibility and composition. In this study, Quantseq was used to identify transcriptomes in liver, duodenum and pancreas, in order to determine the differential expression of genes between a control vs a high fibre feed group in Pietrain crossbred progeny. Thirty two animals were included in a 2×2×2 experiment with diet (based on soybean-cereals vs based on byproducts), sex (castrated male vs female), and genetic background (high vs low estimated breeding value for feed intake) as factors. Compared to the standard diet, the challenge diet was lower in starch and higher in fibre and fat. Pigs were reared for 15 weeks and until 14 weeks all the pigs received the first feeding phase which was similar to the control diet and at 14 week half of the pens received the challenge diet. One pig per pen was euthanised at a liveweight of approx. 50 kg. Tissues were snap frozen in liquid nitrogen, thereafter stored at -80 °C until total RNA extraction and subsequent Quantseq analysis. Total RNA was extracted from liver, duodenum and pancreas using the RNeasy Mini kit. The RNA quality was quantified using Nanodrop and Agilent Bioanalyser. Quantseq was performed on 96 RNA samples and differential expression of genes were tested between the 3 main factors: comparison of high and low EBV for feed intake, comparison of control and challenge feed, and comparison of barrow and gilt using R package DESeq2. The result of the comparisons showed that several genes were expressed differentially. These data will allow a better understanding of the gene functions regulating metabolism of high fibre and fat feeds.

GWAS based on imputed sequence-level genotypes in a huge cow data set: many roles for the GC gene

A.M. Krizanac¹, C. Falker-Gieske¹, C. Reimer², J. Heise³, Z. Liu³, J. Pryce⁴, J. Bennewitz⁵, G. Thaller⁶ and J. Tetens¹

¹Göttingen University, Burckhardtweg 2, 37077 Göttingen, Germany, ²Friedrich-Loeffler-Institut, Höltystr. 10, 31535 Neustadt, Germany, ³Vereinigte Informationssysteme Tierhaltung w.V. (VIT), Heideweg 1, 27283 Verden, Germany, ⁴Agriculture Victoria Research, Bundoora, Victoria 3083, Australia, ⁵Hohenheim University, Garbenstr. 17, 70599 Stuttgart, Germany, ⁶Kiel University, Hermann-Rodewald-Str. 6, 24118 Kiel, Germany; jens.tetens@uni-goettingen.de

GWAS for 57 milk, health, fertility, and conformation traits was performed in a dataset of 252,285 chip genotyped cows imputed to WGS level (presented in another contribution). Such huge data set allows for the identification of highly significant lead variants even for lowly heritable traits. In order to identify genes and variants affecting metabolic stability, we analysed clinical ketosis (KET) and body condition score (BCS) as a potentially correlated trait using deregressed proofs as phenotypes. Initially, we analysed SNP-based heritability and genomic correlation of the two traits based on medium density chip data. The chip heritability for KET and BCS were estimated as 0.07±0.004 and 0.29±0.007, respectively. The genomic correlation was 0.24±0.03. In the GWAS for BCS, 32,309 variants showed genome-wide significance after Bonferroni correction; for KET we obtained 3,940 significant variants. For both traits, the most significant variants were located in a major QTL on BTA 6 containing 14,008 and 3,504 of the significant SNPs, respectively. Next, we partitioned the genomic correlation into a component stemming from BTA 6 and the rest of the genome in a bivariate GREML-run and found that a major part of the correlation stems from this chromosome ($r_{G_{BTA6}} = 0.73 \pm 0.25$, $r_{G_{Rest}} = 0.14 \pm 0.09$). The top variants on BTA6 for both traits as well as for milk performance traits and from a multi-trait GWAS were around the GC gene, which encodes the Vitamin D binding protein. This gene has previously been implicated in milk fever, mastitis and milk traits. Here, we demonstrate its major association with traits related to metabolic stability and thus animal health in early lactation.

GWAS for clinical metritis in Polish HF cows

P. Topolski¹, T. Suchocki^{1,2} and A. Żarnecki¹

¹National Research Institute of Animal Production, Department of Cattle Genetics and Breeding, Krakowska 1, 32-083 Balice, Poland, ²Wrocław University of Environmental and Life Sciences, Department of Genetics, Kozuchowska 7, 51-631 Wrocław, Poland; piotr.topolski@iz.edu.pl

Metritis is one of the most common causes of declining fertility of cows in dairy farming, associated with a significant economic implications and animal welfare. The low heritability of the trait causes that selection for resistance to metritis is possible however, genetic response to traditional selection is small. Consequently, new genomic methods are being used to help a better understand the genetic variability underlying metritis and present options for direct selection of such traits. In our study, we performed a genome-wide association study (GWAS) to identify genetic loci associated with clinical metritis in Polish HF cows. Data for the study were drawn from the data base PLOWET used for veterinary-recording health traits in 4 experimental dairy farms of the National Research Institute of Animal Production and including a total of 1,812 cow genotypes; the incidence of clinical metritis has been recorded in 517 cows. Each cow was genotyped or imputed to Illumina BovineSNP50K beadchip in version 2. As a final dataset we used 53,557 SNPs with $MAF \geq 1\%$ and minimal quality of genotyping $\geq 99\%$. The GWAS data were analysed using single SNP mixed model. We used FDR multiple testing correction. Finally, we found 3 statistical significant SNPs that may be associated with clinical metritis located on 3 chromosomes: 18, 8 and 22. These SNPs were surveyed to their corresponding genes within a distance of 100 kbp. The pathway analysis showed that part of these SNPs were located in or very near genes associated with immune system.

Session 28

Poster 31

Genetic relationships between mastitis, milk yield traits and somatic cell count in Polish HF cows

P. Topolski¹ and W. Jagusiak^{1,2}

¹National Research Institute of Animal Production, Department of Cattle Genetics and Breeding, ul. Krakowska 1, 32-083 Balice near Krakow, Poland, ²University of Agriculture in Krakow, Department of Genetics, Animal Breeding and Ethology, Al. Mickiewicza 24/28, 30-059 Krakow, Poland; piotr.topolski@iz.edu.pl

Genetic correlations between Mastitis (MA), Milk Yield Traits and Somatic Cell Count (SCC) at the first lactation in the population of Polish Holstein-Friesian (PHF) cows were estimated. The dataset for health traits (e.g. MA) was created on the basis of PLOWET database developed by the National Research Institute of Animal Production and included phenotypic data collected in 4 experimental dairy farms. The dataset for Milk Yield Traits and SCC trait was created on the basis of SYMLEK database belonging to the Polish Federation of Cattle Breeders and Dairy Farmers. Phenotypic evaluation of health traits of the cows was carried out between 2016 and 2022 and was based on veterinary registration. The dataset used in our study comprised 6,049 records of cows. Gibbs sampling algorithm implemented in the BLUPF90 package was used for the computations. The linear observation models included additive random effects of animal, fixed effects of herd-year-season of calving subclass (HYS) and lactation stage, fixed regressions on cow age at calving and fixed regressions on cow age at the time the disease was diagnosed. Cow and bull pedigrees contained two generations of ancestors i.e. parents and grandparents. Genetic correlation coefficients were ranged from -0.11 ± 0.019 [MA vs Milk yield (kg)] and -0.12 ± 0.086 [MA vs Protein(%)] to -0.39 ± 0.012 [MA vs Fat(kg)] and 0.47 ± 0.016 [MA vs SCC]. The magnitude of the obtained coefficients of genetic correlation are in the range of coefficients published in the papers of other authors and indicate the possibility of including these results in the national cattle improvement program e.g. to optimize selection indexes.

A New Zealand perspective of the role of genetics in underpinning future sheep production systems

P. Johnson¹, D. Scobie², S.-A. Newman¹, S.J. Rowe¹, S.M. Clarke¹ and K.M. McRae¹

¹AgResearch Invermay, Animal Genomics, Puddle Alley, Mosgiel, 9053, New Zealand, ²Lincoln University, 85084 Ellesmere Junction Road, Lincoln 7647, New Zealand; tricia.johnson@agresearch.co.nz

New Zealand (NZ) has a world-leading sheep genetics improvement programme, underpinned by research. Traditionally, genetic improvement in the NZ sheep industry focussed on production traits, maximising the amount of product produced, but sheep farming operations in NZ (and worldwide) are facing an increasing number of economic, environmental, cultural and social challenges. These challenges include the need for adaptation to overcome the impact of climate change on production systems, a need to contribute towards mitigation of greenhouse gases which contribute towards climate change, together with consumer expectations about their food quality and the systems in which it is produced e.g. animal welfare. As a result, future production systems need to evolve to tackle these challenges. Genetic improvement is a proven method to optimise production systems provided genetic variation in the required traits exists. This has led to numerous research programmes identifying traits that will allow the NZ sheep industry to overcome these challenges and work is underway investigating their genetic control and relationships between these novel traits and other traditional traits. Examples, which will be discussed, include those associated with climate mitigation (methane), climate adaptation (disease traits, heat tolerance and feed efficiency), meat quality (intramuscular fat) and animal welfare (disease traits, tail length and wool cover). For traits where genetic control is being identified, genomic selection is being implemented to increase rates of genetic gain. In addition to traditional host DNA, novel sources of variation that may influence the identified traits, including the rumen microbiome and host genome methylation profiles, are also being explored as additional targets for selection. Cumulatively these research programmes are seeking to provide solutions to ensure that products produced from NZ sheep production systems address the challenges confronting the NZ sheep industry and as such match the expectations consumers and society are increasingly placing on such production systems.

Blockchain technology in the beef breeding sector

B. Jornet and I. Achour

Label Food Chain, 23 Rue Jacques Cottin, 93500 Pantin, France; benjamin.jornet@gmail.com

The initial observation is that there is a loss of information, mainly due to insufficient collaboration between professionals of the beef industry, who only partially communicate traceability information amongst themselves. The result is a loss of information at each stage of the chain, and therefore a loss of added value for the product vis-à-vis the final consumer. This insufficient transparency does not create the conditions necessary to establish a relationship of trust with the final consumer who is obliged to 'believe' the partial information communicated by the actor at the end of the chain (i.e. the distributor in most cases); This article describes how blockchain technology can respond to this problematic. The principle is to establish a decentralized architecture associated with blockchain technology. Indeed, loss or falsification of information is technically impossible in a blockchain system with a satisfying level of decentralization. In practice, multiple entry points and an electronic signature system allow each actor of the chain to provide and certify information that he/she disposes of. The system allows actors to better guarantee the integrity of the data and their origin and thus to self-regulate. For example, a processor could directly access information coming from the farm, without having to go through an intermediate party such as the slaughterhouse. In addition, the blockchain makes it possible to move from a 'declarative' system of information to a system of information 'certified' by each link in the chain. At the end of the chain, the consumer can, thanks to a QR code, access different sources of complete and certified information provided directly by each of the actors of the chain, from the breeder to the final distributor via the slaughterhouse and the processor. Link: <https://www.viandesetproduitscarnes.fr/index.php/fr/1135-la-blockchain-dans-le-secteur-elevage-viande>.

Using science to optimise production systems to produce a premium product – the Lumina™ Lamb StoryP.L. Johnson¹, S. Saunders² and A. McDermott³¹AgResearch Invermay, Puddle Alley, Mosgiel, 9092, New Zealand, ²Stag Valley Station, RD2, Lumsden, 9792, New Zealand, ³AgriFood Strategy, P.O. Box 59, Collingwood, 7054, New Zealand; tricia.johnson@agresearch.co.nz

Science has underpinned the development of a premium meat product in New Zealand, Lumina™ lamb. The journey, that resulted in the Lumina product, started with the establishment of a novel breeding programme to breed sheep of composite genetics suited to the hard-hill country of New Zealand's South Island (Headwaters) with an emphasis on standard productivity traits. With the additional aim to identify, through research, a point of difference under genetic control that could be selected for, to produce a marketable differentiated premium lamb product. The research identified intramuscular fat and omega-3 fats as traits that could be improved through genetic improvement which could lead to a differentiated premium lamb product. It was, however, recognised that genetics was only one part of the equation towards a premium product, and commercial production systems that could complement the breeding programme were also required. This part of the research investigated aspects of the commercial production system including the sex of the lamb, different types of finishing forages and the length of time the lambs required on the finishing forage identified to produce a consistent, differentiated premium product. The resulting integrated value chain for Lumina lamb involves stud breeders producing genetically superior rams which are used on commercial farms where the lambs produced are finished on a chicory/clover diet for a minimum of 35 days, which further increases levels of omega-3 in the final product. All commercial male lambs are castrated to reduce potential pH issues, that can occur at certain times of the year in ram lambs. The resulting combination has been demonstrated in independent research to generate a product identified as most preferred by New Zealand and Chinese consumers when compared with lamb from other standard New Zealand production systems. The programme has also jointly invested in the development of in-line hyperspectral imaging technologies to estimate the levels of intramuscular fat in lamb meat for use within the breeding programme and ultimately for commercial assessment of the product.

Theatre 4

Factors influencing willingness to pay for red meat with potential to improve consumer wellnessR. Zhang¹, Z. Kallas^{2,3}, M.P.F. Loeffen⁴, M. Lee⁵, L. Day¹, M.M. Farouk¹ and C.E. Realini¹¹AgResearch Ltd, Te Ohu Rangahau Kai, Cnr Riddet Rd & University Ave, Massey University Manawatu, 4474, New Zealand, ²DEAB, Department of Agrifood Engineering and Biotechnology, Baix Llobregat Campus, Building D4 (Campus Baix Llobregat), C. Esteve Terradas, 8, 08860, Spain, ³CREDA-UPC-IRTA, Centre for Agro-food Economy & Development, Parc Mediterrani de la Tecnologia Edifici ESAB Esteve Terradas 8, 08860, Spain, ⁴Delytics Ltd, Waikato Innovation Park, 1 Melody Lane, Hamilton, 3216, New Zealand, ⁵Meat & Livestock Australia Donor Company, Coca-Cola Place, 1/40 Mount St, North Sydney, 2060, Australia; carolina.realini@agresearch.co.nz

Consumers are shifting towards a more holistic view of health and well-being and are not only interested in food consumption for physical fitness but also mental wellness. This study investigated consumers' attitudes towards physical and mental wellness improvements through red meat consumption and their willingness to pay (WTP) premium price for the meat. Online surveys were conducted in the US (n=1,000) and Australia (n=523) using commercial platforms. Results showed that over 90% of respondents indicated their interest in purchasing red meat that would improve their wellness status. Respondents from the two countries indicated different interests in the aspects of wellness that they would like to improve through food consumption. Additionally, about 85% indicated their WTP for red meat with potential to provide wellness benefits, with stronger interest by American than Australian respondents. The strong interest consumers showed about eating red meat for improved physical and mental wellness was the key factor contributing to consumers' WTP a price premium. Other favourable factors for increasing WTP were also observed, such as higher frequency of meat consumption, more exercise, good sleep quality and better economic position. Positive consumer responses obtained in this study, could provide the meat industry with a unique opportunity to position meat outlining qualities that support improved health and mental well-being. Providing science-based evidence that meat consumption can result in immediate and/or longer-term wellness benefits, would represent a major opportunity to create and capture more values for the red meat industry.

Perception of the use of rangeland and roughage by actors of the organic pig and layer hen sectors

L. Montagne¹, M. Goujon² and F. Marie³

¹PEGASE, INRAE, Institut Agro, Saint-Gilles, 35590, France, ²CAPL, Angers, 49105, France, ³IBB, Rennes, 35700, France; lucile.montagne@institut-agro.fr

Organic specification imply to add roughage to the ration of monogastric animals. This can be done through access to rangeland, compulsory for laying hens, or the distribution of roughage. This study aimed to cross the points of view of farmers and others stakeholders on the use of rangeland and roughage in organic laying hens and pigs. Farmers in Bretagne or Pays de la Loire (136 for hens, 87 for pigs) and 18 French stakeholders (from research to marketing) participated to a semi-structured interview. This allowed identifying 326 motivations, 266 barriers and 108 levers to the use of rangeland or roughage. The topics included aspects related to technic, animal health and welfare, economy, environment, nutrition, regulation, work, and social dimensions. Barriers and levers were cited in equivalent numbers for both sectors. More motivations (215/326) were cited by actors of the egg sector. The farmers described more motivations (218/326) and levers (66/108) than other stakeholders that reported more brakes (169/266). The main motivation was the improvement of animal welfare: expression of natural and reduction of deleterious behaviours (116/326). All the actors of both sectors shared this point of view that answer to consumer expectations. The barriers mostly evoked were technical aspects (84): maintenance of vegetation cover in rangelands, difficulty for fodders distribution), animal health (44): increased risk of parasitism and infectious diseases, and degradation of working conditions (28/266). Stakeholders also evoked a lack of knowledge (26) in particular in animal nutrition (23). The topic economy included brakes (25/266, cost of fence and equipment) but also motivations (22/326) especially for the pork sector as access to rangeland would be a marketing argument. Levers concerned mainly technic (59/108, rangeland management) and the feed value of forages (23/108). This study highlighted shared elements but also differences of perception of the use of rangeland and roughage between actors and sectors. It has been a prerequisite to research projects aiming to furnish references on the nutritive values of roughage and on rangeland management.

Session 29

Theatre 6

Role of dairy foods in human nutrition

C.M. Weaver

San Diego State University, 5500 Campanile Drive, 92182-7251, USA; cmweaver@sdsu.edu

Consumer demand for milk and milk products is driven by nutrition as well as taste, affordability, and sustainability. Adequate dairy intake is promoted by most countries throughout the lifespan, primarily for bone health. Most countries recommend 2 to 3 servings daily for most age groups. This recommendation is because of the huge contribution of dairy to intake of essential nutrients. On a global scale, milk consumption is ranked very high compared to other food sources for bone building nutrients i.e. first for calcium, second for phosphorus and potassium, third for protein, and fourth for magnesium. Milk also ranked among the top three foods contributing to the global intake of essential amino acids such as lysine, threonine, methionine, and tryptophan. The dairy matrix includes the complex organizational structure of these essential nutrients and other constituents. The dairy matrix may promote health and lower the risk of many chronic diseases beyond the contribution of essential nutrients. Modelling shows that replacing dairy foods with non-dairy foods to meet nutrient intakes is not feasible. Dairy foods are sustainable as well as nutrient dense and are more affordable than plant-based beverage alternatives to milk.

Organoleptic properties of fast-growing and slow-growing chicken meat

R. Berrocal^{1,2}, L. Mur^{1,2}, J.L. Olleta², V. Resconi², M. Barahona², J. Romero² and M.M. Campo²

¹UVESA, Nutrición animal, Polígono Montes del Cierzo A68, Km86, 31500 Tudela, Spain, ²Instituto Agroalimentario IA2, Universidad de Zaragoza-CITA, Producción animal, Calle de Miguel Servet, 177, 50013 Zaragoza, Spain; rberrocal@uvesa.es

The use of intermediate-growing strains appears in the market as an alternative production to reduce fast-growing welfare consequences. It also responds to the new trends in European countries towards longer lifecycles and improved farm conditions. But it is necessary to know the characteristics of the final product and the consumers' opinion. Breast organoleptic characteristics were compared between one of these alternative genetics and a conventional fast-growing broiler through a 7-member trained taste panel. Genetics (Ross 308 vs Ranger Classic) and sex (males vs females) were compared at two ages associated to two commercial fast-growing (44 d) and slow-growing (56 d) nutritional programs at the same experimental farm. Twelve carcasses from each treatment were dissected 24 hours after each slaughter age and the breasts were vacuum packaged and kept frozen until analyses were performed. Meat was grilled until the internal temperature reached 70 °C and attributes were assessed on a 0-10 cm lineal scale from no intense to extreme intense. Genetics, sex, age and their interactions were analysed with a General Lineal Model (SPSS 26.0). Ross breast was more fibrous, firmer and juicier than Ranger breast (6.61 vs 6.17, $P \leq 0.001$; 6.85 vs 6.27, $P \leq 0.001$; 6.99 vs 6.61, $P \leq 0.05$; respectively) and had more intense chicken odour (7.98 vs 7.82; $P \leq 0.05$) and flavour (7.69 vs 7.21; $P \leq 0.001$). Nevertheless, Ranger breast was more tender (7.93 vs 7.47; $P \leq 0.001$) and had a greater metallic taste intensity (4.65 vs 4.35; $P \leq 0.05$). Sex did not have a significant effect in the studied assessors, although meat from males tended to be firmer than from females (6.69 vs 6.64, $P < 0.1$). Meat from younger animals showed more tenderness (7.94 vs 7.46, $P \leq 0.05$) and chewiness (6.76 vs 6.63, $P \leq 0.05$) than older ones which had more fibrousness (6.51 vs 6.28, $P \leq 0.05$) and firmness (6.77 vs 6.35, $P \leq 0.05$). Although all scores were high, it is important to continue with an improving genetics to equal current meat characteristics ensuring consumer preferences.

Session 29

Theatre 8

Implementation of sustainable livestock farming principles for generating innovative animal products

M. Cohen-Zinder, E. Shor-Shimoni, H. Omri, F. Garcia Solares, S. Kaakoosh and A. Shabtay

Sustainable Ruminant Production Lab; Model Farm for Sustainable Agriculture, Neve Ya'ar Research Center, Agricultural Research Organization, P.O.B 1021, Ramat Yishay 30095, Israel; mirico@volcani.agri.gov.il

It is well evident that intensive livestock farming imposes undesired impacts on the environment, animal welfare and public health. These trends have initiated a growing consumer demand for sustainable, environmentally friendly, economically viable for farmers, socially acceptable livestock systems, that are considerate of animal welfare and offer high quality animal food products, as an outcome of transparent and traceable practices along the food chain. To this end, we study and implement new practices of sustainable ruminant production, in order to produce innovative animal-based food products, some of which will be highlighted herein. In a Farm to Table approach, we: (1) demonstrate superiority of the local Holstein cattle by means of meat quality (e.g. tenderness, IMF% and fatty acid profile) over imported beef animals; (2) select towards a new cattle breed (Simmental × Baladi; *SimBal*), adapted among others to climate change and meagre feeds, with unique organoleptic signature; (3) grow a novel crop (*Moringa oleifera*) to be used as animal feed, to improve their production performance and meat quality characteristics. Specifically, our findings highlight the potential of *Moringa* provided as food additive to increase the accumulation of health promoting compounds in animal food products, and to prolong its shelf life. These innovative sustainable livestock farming practices may promote future production of animal products with longer shelf life, as well as improved edible properties and health advantages for livestock and humans.

Recent changes and future expectations about meat consumption

F. Montossi¹, G. Ares², L. Antúnez², G. Brito¹, M. Del Campo¹, C. Saunders³, M. Farouk⁴ and C.E. Realini⁴

¹INIA URUGUAY, Brigadier Gral. Fructuoso Rivera Km 386, 45000, Uruguay, ²UDELAR, By Pass de Rutas 8 y 101, Pando, Uruguay, ³Lincoln University, 85084 Ellesmere Junction Road, Lincoln 7647, Canterbury, New Zealand, ⁴AgResearch Limited, Te Ohu Rangahau Kai, Massey University Campus, Grasslands, Tennent Drive, 4474 Palmerston North, New Zealand; fmontossi@inia.org.uy

A telephone survey was carried out in Uruguay in 2021 with 601 participants over 18 years of age. Participants answered a series of questions about the frequency of recent changes and future expectations in meat consumption. Responses were analysed according to gender, age, place of residence, and educational and socioeconomic level. The percentage of participants who increased (6%), maintained (50%), decreased (35%), and did not consume (9%) meat consumption was not affected by the sociodemographic variables studied ($P>0.05$). In the future, 65% of participants do not intend to alter their meat consumption, while 24% intended to reduce it, mostly women and people with a higher educational level ($P<0.01$). Thirty-three percent of the interviewees were willing to substitute meat for proteins of vegetable origin, mainly women and people with a higher educational level ($P<0.01$). Only 17% of respondents would be willing to try meat analogues produced in laboratories or factories, mainly young people (under 30 years old) and those with higher education level. The proportion of people willing to pay more for meats that have labels/brands and are certified for animal welfare, grass-fed, organic, sustainable, traceable, without the use of antibiotics and growth promoters, and grain-fed were 65, 61, 60, 55, 50, 45, 43, and 18%, respectively. The attributes of organic production, care for animal welfare, and the non-use of antibiotics and growth promoters during production were particularly relevant for participants under 30 years old and those with a higher educational and socioeconomic level ($P<0.05$). Sustainable production is more relevant for older participants ($P<0.05$). Recent and future changes in meat consumption are differentially influenced by sociodemographic variables, and their better understanding can be used in designing public information strategies and promotion campaigns to promote meat consumption.

Session 29

Theatre 10

Sustainability in the beef sector: aligning consumer and farmer perspectives

M. Henchion¹ and V.C. Resconi²

¹Teagasc, Agrifood Business and Spatial Analysis, Ashtown, D15 KN3K, Ireland, ²University of Zaragoza, Department of Animal Production and Food Sciences, C. Miguel Servet 177, 50013 Zaragoza, Spain; maeve.henchion@teagasc.ie

Consumer demands from meat products, and associated production systems, can be complex and conflicting, particularly when seeking to address different elements of sustainability. Following a very brief overview of currents trends in meat production in Europe, this presentation will draw on the results of a pan-European consumer survey to identify some key motivations and factors influencing consumer demands with regards to beef. It will complement this perspective with knowledge gathered within an EU network that was established to address sustainability issues within the beef sector. Specifically, it will identify farmers' concerns relating to sustainability and provide an overview of some of the solutions farmers across Europe are putting into practice, as well as other solutions from research that have yet to be put into practice. It will conclude with some observations about the challenges and opportunities in aligning within and across these different perspectives in order to achieve more sustainable production systems.

FT-MIR spectroscopy to discriminate intramuscular fat of beef fed conventional vs sustainable diets

S. León-Ecay¹, I. Goenaga^{1,2}, A. López-Maestresalas¹, A. Gobeti Barro^{3,4}, M.P. Ellies-Oury^{4,5}, M. Beruete¹ and K. Insausti¹

¹Universidad Pública de Navarra, Arrosadia, 31006 Pamplona, Spain, ²TRASA, Milagro, 31320 Milagro, Spain, ³Londrina State University, Highway Celso Garcia Cid, 86057970 Londrina, Brazil, ⁴INRAE, Vetagro Sup, UMR1213, Theix, France, 63122 Theix, France, ⁵Bordeaux Sciences Agro, CS 40201, 33175 Gradignan, France; kizkitza.insausti@unavarra.es

Large amounts of vegetable by-products are generated by the agri-food industry every day. Giving them a second life can be positive for food and beef companies, because while improving their sustainability indicators they can add value to their products. Besides, the meat industry requires non-destructive, sustainable, and rapid methods that can provide objective and accurate quality assessment with little human intervention. In this context, the objective of this research was to study the usefulness of FT-MIR technology to discriminate the intramuscular fat (IMF) of beef fed a sustainable diet vs a conventional diet. To do so, a total of 23 samples of IMF (Soxhlet extraction) were analysed. 11 came from beef fed vegetable by-products, and 12 from beef fed concentrate and straw. To obtain their infrared spectra, a Fourier-transform infrared (FTIR) Vertex 80v spectrometer with an A225/Q Platinum Attenuated Total Reflectance (ATR) accessory was used. 10 replicates per sample were taken from 32 scans in the 4,000-400 cm⁻¹ spectral range, with a resolution of 4 cm⁻¹, carrying out a calibration before each experiment. To understand the behaviour and find patterns between diets, a decomposition by Principal Component Analysis (PCA) with the software PLSToolbox under MATLAB® R2020a was done. The best resolution was obtained using the pretreatment Standard Normal Variate with 9 Principal Components, recording a RMSEC of 0.01 and a RMSECV of 0.03. The errors were very low and manageable, and for computational issues it shows fast processing. Thus, the potential of FTIR-MIR as a non-destructive and easy to handle methodology to discriminate among the IMF of beef fed on different diets was demonstrated. This research was supported by Government of Navarra, project 0011-1365-2020-000288 'BEEF+: Carne saludable a través de la economía circular'.

Session 29

Study of the genetic parameters of the destructured meat defect of ham on 3 male lines

A. Le Dreau¹, C. Garcia Baccino¹, D. Penndu², A. Buchet², P. Doussal² and B. Ligonésche¹

¹NUCLEUS, 7 rue des orchidées, 35650 Le Rheu, France, ²Cooperl Innovation, 1 rue de la gare, 22640 Plestan, France; a.ledreau@nucleus-sa.com

The destructured meat defect (also called PSE-like defect) occurs during the transformation procedure into cooked ham, which leads to loss of yield and therefore to an economic loss. This defect is quantified using a visual scoring grid that requires deboning the ham. The genetic origin of this defect has not been extensively studied, and the few studies on the subject have always focused on crossbred animals. A study was therefore set up by Cooperl and Nucléus to study the genetic determinism of the PSE-like defect on its purebred populations Pietrain, Duroc and the synthetic line Kador. More than 5,000 hams from animals coming from 3 selection farms have been noted. The scoring consists of assigning a score during the deboning of the ham by a unique trained operator. At the slaughterhouse, meat quality measurements were carried out, namely the measurement of the ultimate pH and the rate of exudate in the loin. Piece weight predictions were also obtained using information from an ultrasonic scanner, the Autofom III™. The traits of interest were measured on these 5,000 animals and their contemporaries. These data involved information about the growth (age standardized at 100 kg), the conformation (back fat thickness and muscle thickness, both standardized at 100 kg) and for some animals, their individual food consumption (to calculate the feed conversion ratio). Due to the fact that the 'destructured' notation is categorical, a part of the study consisted in fitting an adequate model to these data. The pedigree information consisted on 10 generations for each breed and the analysis was carried out using AIREMLF90 software. The first results on Pietrain show a significant heritability of 0.19, with favourable genetic correlations with other meat quality traits. Consequently, selection against the PSE-like defect is possible, and is already made indirectly by selection for the meat quality traits considered in the selection objective. The same analysis on Duroc and Kador will permit to confirm and compare these results.

Consumers' perception towards using seaweed as an alternative to antibiotics in rabbits in SpainS. Al-Soufi¹, J. García², E. Cegarra³, A. Muñños⁴, M. Miranda⁵ and M. López-Alonso¹¹University of Santiago de Compostela, Animal Pathology, Veterinary Faculty, 27002, Spain, ²Polytechnic University of Madrid, Dept Producción Agraria, 28040 Madrid, Spain, ³DeHeus España, Plaza de Mina 1, 15004 A Coruña, Spain,⁴Porto Muñños SL, Cereda, 15185 A Coruña, Spain, ⁵University of Santiago de Compostela, Anatomy, Animal Production and Veterinary Clinical Sciences, Veterinary Faculty, 27002, Spain; sabelaalsoufi.novo@usc.es

The rabbit meat industry has faced critical challenges in the last few years, during which the ban on the prophylactic use of antibiotics in animal feed has added to the weakness of the production system and a decrease in consumption of rabbit meat, mainly within the younger population, due to the lack of rabbit processed products that fit modern types of consumption and to the perception of rabbit as a pet. Seaweed have demonstrated to be a good alternative to antibiotics in animal nutrition by improving the gut health; moreover, some seaweed species enhance the fat quality of the meat. Within the project TIRAC, that aims to reduce the use of antibiotics in growing rabbit farming in Spain by using seaweed, this study seeks to obtain data about the consumers' perception of and attitudes towards consuming rabbit meat if seaweed were included in the feed to reduce the use of antibiotics. A semi-structured questionnaire was carried out using a computer-assisted web interviewing (CAWI) in the city of Lugo (NW Spain). Responders (n=383) were selected with a non-probabilistic sampling by quota based on their gender and age. Most responders declared to be interested in a meat produced using seaweed in the diet of the animals to reduce the use of antibiotics, the positive attitude being related not only to their own health, but also to animal welfare and the environment. Our results indicate that the inclusion of marine algae in rabbit food could potentially become a commercial marketing strategy to attract new consumers concerned about environmental sustainability and who are looking for different, high-quality foods. The project TIRAC was co-financed by the European Agricultural Fund for Rural Development (EAFRD) of the European Union (80%) and the Ministry of Agriculture, Fisheries and Food (20%), within the framework of the National Rural Development Program 2014-2020.

Session 29

Poster 14

Perceptions of viticulture-livestock complementarity in Burgundy: first insightsR. Ibidhi¹, O. Aguirre-Saavedra², S. Ambrosino², G. Houndafoche², M. Seignon², Y. Tanguy-Roump² and C. Philippeau²¹Agroécologie, INRAE, Institut Agro, Univ. Bourgogne, Univ. Bourgogne Franche-Comté, 17 rue Sully, Dijon, 21000, France, ²L'Institut Agro Dijon, 26, bd Docteur Petitjean, BP87999, 21079 Dijon cedex, France; ridha.ibidhi@agrosupdijon.fr

Unlike over specialized farming systems, the integration of crop and livestock systems has been recognized for its potential to improve ecosystem services. The integration of livestock in viticulture production is described as a promising example of an agroecological integrated crop-livestock system. While some studies of the integration of livestock especially sheep into vineyards are already available for other French areas, there is still scarce research on its implementation in Burgundy viticulture systems, a wine region that produces prestigious wines. This study aimed to explore winegrowers and agricultural stakeholders' perceptions on viticulture and livestock synergy and identify potential initiatives implemented in Burgundy. Semi-structured interviews were conducted within 5 winegrowers, 2 winegrowers who use animals in their vineyards and 2 viticulture stakeholders. We find that seasonal integration of sheep in the period of vine dormancy is the most common form of synergy. Indeed, sheep grazing is important for winegrowers to manage cover crop growth. Overall, winegrowers perceive significantly more benefits than challenges with the integration of sheep into vineyards, particularly reduce mowing, improve soil health and organic matter from sheep faeces and reduce chemical costs for weed control. In addition, grazing in vineyards offers an additional supply of forage for sheep. Some practitioners reported an image enhancement for the winegrowers with new marketing options. However, some of the interviewees mentioned that this form of synergy is a labour cost practice and they can also cause compaction in waterlogged soils. Finally, this study suggests a wide-scale adoption of seasonal integration of sheep into vineyards in Burgundy. Where, the integration of livestock into vineyard may contribute to ecological benefits. However, this practice is not yet been sufficiently scientifically validated.

Feeding seaweed as an alternative to antibiotics in growing rabbits improves the meat fat profileS. Al-Soufi¹, J.M. Lorenzo², J. García³, E. Cegarra⁴, A. Muiños⁵, M. Miranda⁶ and M. López-Alonso¹¹University of Santiago de Compostela, Animal Pathology, Veterinary Faculty, 27002 Lugo, Spain, ²CETECA, San Cibrao das Viñas, 32900 Ourense, Spain, ³Polytechnic University of Madrid, Dept Producción Agraria, 28040 Madrid, Spain, ⁴DeHeus España, Plaza de Mina, 1, 15004 A Coruña, Spain, ⁵Porto Muiños SL, Cereda, 15185 A Coruña, Spain, ⁶University of Santiago de Compostela, Anatomy, Animal Production and Veterinary Clinical Sciences, Veterinary Faculty, 27002 Lugo, Spain; marta.lopez.alonso@usc.es

The rabbit meat industry has faced critical challenges in the last few years, during which the ban on the prophylactic use of antibiotics in animal feed has added to the weakness of the production system and a decrease in consumption of rabbit meat. Seaweed are a good alternative to antibiotics in animal nutrition by improving the gut health and enhancing the meat stability, the antioxidant capacity as well as the fatty acid profile by increasing the polyunsaturated and reducing the saturated fatty acids concentrations in the main livestock species; however information in rabbits is very sparse. Within the project TIRAC, that aims to reduce the use of antibiotics in growing rabbit farming in Spain by using seaweed to improve the gut health, this study evaluates the effect of different seaweed supplements (whole *Saccharina latissima*; aqueous extract of *S. latissima*, *Ulva lactuca*, *Himanthalia elongata*, given at 1%) on the proximate composition, antioxidant capacity and the fatty acid profile on the meat. The supplementation with *U. lactuca* showed a statistically significant effect on the fatty acid profile compared to the control group by increasing the concentration of mono-unsaturated, polyunsaturated, n-3 fatty acids and n-6 fatty acids. The potential of seaweed to enhance the fatty acid profile of the meat of rabbits could become a commercial marketing strategy to attract new consumers concerned about environmental sustainability and looking for high quality foods. The project TIRAC was co-financed by the European Agricultural Fund for Rural Development (EAFRD) of the European Union (80%) and the Ministry of Agriculture, Fisheries and Food (20%), within the framework of the National Rural Development Program 2014-2020.

Session 29

Poster 16

Effects of lamb genotype, primal cuts, and vegetables on baby soups' sensory acceptabilityM.R. Marques¹, M. Pimpão¹, C. Oliveira¹ and J.M. Almeida^{1,2,3}¹INIAV – National Institute for Agricultural and Veterinary Research, Rua Prof Vaz Portugal, 2005-424 Vale de Santarém, Portugal, ²AL4Animals – Associate Laboratory for Animal and Veterinary Sciences, FMV-UL, Lisboa, Portugal, ³CIISA – Centre for Interdisciplinary Research in Animal Health, FMV-UL, Av Universidade Técnica, 1300-477 Lisboa, Portugal; joaoalmeida@iniav.pt

Due to the lambs' diet based on sheep's milk, this red meat has a high nutritional quality. Thus, it's one of the first types of animal protein recommended being incorporated into a baby's diet. However, the consumption of this meat, due to its characteristic flavour, is not spontaneous among the new generations of consumers. This study aimed to evaluate the sensory properties of carrot and pea soups with 10% of lamb meat from two Portuguese pure breeds, Saloia (S), Merino Branco (MB) and Ile France × Merino Branco (IF×M) crossbreed. Lambs received the same farm management and were slaughtered at four months of age, which provided carcasses with an average weight of Saloia 10 kg; MB 12.5 kg; IF×M 13.5 kg. It was only used meat from less valued retail cuts, and each soup formula had a lean meat content of 10% (P/P), which ranged from 40 to 50% and 60% of shoulders (S) and breast+neck (BN) in equal parts (40S/60BN; 50S/50BN; 60S/40BN). A Thermomix Vorwerk and standard formula vegetables were used to make 48 soups, which were then evaluated by a panel of experts. Lambs' genetics influenced all sensory parameters ($P < 0.001$), with more intense meat odour and flavour and globally less acceptable from the Saloia meat breed. Conversely, lamb meat from the M and IL×M breeds has given rise to soups with less aromatic intensity, less meaty flavour, and less lamb flavour, which were overall more acceptable. The intensity of lamb flavour was the only characteristic influenced ($P < 0.001$) by the meat proportion from the various primal cuts (S or BN). The base vegetable used significantly influenced global acceptance, with panel preference for peas that originated soups with less intense lamb and meat flavour and higher acceptability. Less valued retail lamb cuts can give highly appreciated baby soups with reduced lamb and meat taste and flavour. Funding: Project: ALGAVALOR: POCI-01-0247-FEDER-035234; LISBOA-01-0247-FEDER-035234; ALG-01-0247-FEDER-035234.

Lipid fraction composition of the longissimus thoracis of Lidia beef breedM.M. Campo¹, M. Barahona¹, V.C. Resconi¹, J.V. Romero¹, S. Romero², S. Zabala², J. Villalon³ and J.L. Olleta¹¹Instituto Agroalimentario IA2, Universidad de Zaragoza-CITA, 50013 Zaragoza, Spain, ²IMIDRA, 28070 Madrid, Spain, ³RUCTL, 28010 Madrid, Spain; marimar@unizar.es

Lidia breed is reared to achieve certain characteristics and behaviour in the bullring. Meat production is not the main aim for farmers, but it has commercial interest. The husbandry system is clearly extensive, reared under natural environments such as dehesa meadows, which results in particular characteristics of the meat in comparison with fattening units. This work aimed to differentiate meat from different commercial products from Lidia breed. At the processing plant, the loin of 20 bulls coming from the bullring (5.4 years old), 10 heifers (2.6 yo) and 6 cows (15.2 yo) were obtained 24-48h after slaughtering. At 7 days of ageing under vacuum conditions at 4 °C, a slice of *longissimus thoracis* was obtained, vacuum packaged and kept at -18 °C until lipid content (ISO 1443:1973) and fatty acid composition (extraction with chloroform:methanol and methylation with KOH) were assessed. Data were analysed with SPSS 26.0 with a GLM procedure, and Tukey test was used to differentiate mean values. Fat content of the cows (4.99%) almost doubled that of the heifers (2.59%) and three-folded that of the bulls (1.57%; $P<0.001$). The older the animal, the fatter the muscle becomes, but in this breed males are very lean, even at 5 years of age. The saturated fatty acid (SFA) profile from bulls was less saturated than that from females ($P<0.001$). No significant differences were found in the monounsaturated profile, but the percentage of linoleic and arachidonic *n*-6 polyunsaturated fatty acids (PUFA) was significantly higher in bulls than in females, especially in cows; whereas heifers showed the highest α -linolenic acid percentage and bulls the smallest. These data make the ratio PUFA/SFA very favourable (0.44; $P<0.001$) but the *n*-6/*n*-3 PUFA very unfavourable (18.9; $P<0.001$) for the bulls. This reflects the nutrition pattern during the last rearing period. Even while suffering a drought that reduces the availability of pastures, heifers are not supplemented. However, a more valuable animal such as the bull receives concentrates with cereals that modifies the fatty acid profile. These differences support the differentiation of products at retail.

Innovation in the production and marketing of local breed products, path to long-term sustainabilityA. Ivanković¹, G. Šubara², E. Šuran², M. Cerjak¹, J. Ramljak¹ and M. Konjačić¹¹University of Zagreb Faculty of Agriculture, Svetošimunska 25, 10000 Zagreb, Croatia, ²Agency for Rural Development of Istria, Tugomila Ujčića 1, 52000 Pazin, Croatia; aivankovic@agr.hr

The development of society (community) is also reflected in the changes in consumption habits. Depending on the development of the society and the region, there is a stratification of consumers in terms of willingness to pay for animal products with nutritional and gastronomic added value. Local breeds are suitable for the design of innovative animal products, as they can highlight the uniqueness of the breed, the territory, the production technology and the innovative approach to the preparation of animal products. The effect (potential) of introducing innovations into the gastronomic offer, i.e. the production of donkey milk, was studied using the example of products made from Istrian beef and milk from Istrian donkeys. An insight into the connection of stakeholders in the 'short supply chains' of Istrian beef (farmer – butcher – chef – consumer) showed a significant influence of gastronomic innovation, which unites the 'terroir' of beef in the original territory and maintains the interest of consumers. Gastronomic innovation makes the breeding of Istrian cattle more profitable and sustainable. It has been estimated that all stakeholders in the path of animal products (from farmer to consumer) achieve a higher income of 15-25% and the region has recognizable local products. The introduction of innovations in the production and processing of Istrian donkey milk has significantly increased consumer interest, diversified the local food offer and created 'short supply chains' that ensure the sustainability of Istrian donkey households. The introduction of innovations in the production and supply of animal products from Istrian cattle and Istrian donkeys highlights the 'terroir' of animal products, arouses consumer interest and significantly increases the economic viability of local endangered breeds.

The ability of the Distell fatmeter to predict intramuscular fat in Yellowtail KingfishD. Milotic¹, F. Anderson¹, G. Partridge², A. Lymbery¹ and G. Gardner¹¹Murdoch University, Agriculture, 90 South St, Murdoch WA, 6150, Australia, ²Harvest Road, Harvest Road Oceans, P.O. Box 3155, Broadway Nedlands, 6009, Australia; dino.milotic@murdoch.edu.au

The aquaculture of Yellowtail Kingfish (YTK) is rapidly developing in Australia. This fast-growing species reaches market size in 12 to 18 months and is not demanding to maintain. Additionally, the YTK can target premium sashimi markets internationally if it contains an optimal amount of intramuscular fat (IMF). Early detection of IMF would inform breeding programs, optimise the grow-out period and thus reduce production costs and enable better market allocation of fish based on quality. A non-invasive measurement of IMF can be acquired using the Distell fatmeter which is a microwave-based technology that estimates crude lipid content within tissues based on the inverse relationship between moisture and lipids. This device was used to scan 240 fish ranging in weights from 300 to 1,500 g. Fish were scanned whole and alive, then after evisceration with head removed (bulleted), and again after skin-off fillets were produced. Scans were captured at four locations (2 scans on each side, above the lateral line), and larger fish were scanned six times (3 per side). Scan locations of right skin-off fillets were matched to previous scans. Chemical analysis consisted of freeze drying the entire right skin-off fillet, homogenizing it using a blender, and extracting crude fat using a chloroform Soxhlet method. Fatmeter values were then associated with chemically extracted lipid %. Distell fatmeter values of whole fish had a moderate association with chemically extracted fillet fat %, with $R^2=0.39$, RMSE=41.1. For skin-off fillet this association was stronger, with $R^2=0.49$, and RMSE=36.6. These results demonstrate that the Distell fatmeter has some capacity to predict fillet IMF. The skin-on results suggest that it could be used *in vivo* on YTK to identify breeding stock or finishing condition prior to slaughter.

Effect of game species on fatty acids, meat quality and shelf lifeM.N. Hlohlongoane¹, U. Marume², O.C. Chikwanha³ and C. Mapiye⁴¹North West University, Mafikeng Campus, Animal Science, Corner of Albert Luthuli and University Drive, Mmabatho, 2745, South Africa, ²North West University, Mafikeng Campus, Animal Science, Corner of Albert Luthuli and University Drive, Mmabatho, 2745, South Africa, ³Stellenbosch University, Animal Science, Mike de Vries Building, Merriman Avenue, 7600, South Africa, ⁴Stellenbosch University, Animal Science, Mike de Vries Building, Merriman Avenue, 7600, South Africa; matsheponthabeleng@gmail.com

The study determined the effect of species on fatty acids, meat quality, and shelf life of impala (*Aepyceros melampus*), mountain reedbuck (*Reduncula fulvorufula*), and springbok (*Antidorcas marsupialis*). Eighteen, 12-14 months old impala, mountain reedbuck, and springboks (n=6) were culled from a game estate. They were then transported to the slaughterhouse on the farm. After 24 hours of chilling (4 °C), the Longissimus thoracis et lumborum was removed for meat fatty acid, meat quality, and shelf life analysis. All data were analysed using generalised linear model procedure of SAS v 9.4. Total saturated fatty acids was affected by species with mountain reedbuck and springbok having higher ($P\leq 0.05$) proportions than impala. Impala and springbok had higher ($P\leq 0.05$) proportions of total monounsaturated fatty acids than mountain reedbuck. Overall, polyunsaturated fatty acids was higher ($P\leq 0.05$) for impala and mountain reedbuck than springbok. Impala and springbok carcasses had higher ($P\leq 0.05$) ultimate pH values than the mountain reedbuck. Meat colour was affected by species ($P>0.05$). Cooking loss and tenderness were influenced by species ($P\leq 0.05$). Impala and springbok meats had higher ($P\leq 0.05$) cooking loss than the mountain reedbuck. Springbok species had more tender ($P\leq 0.05$) meat than the impala and mountain reedbuck. Both lipid and protein oxidation had species $\times$ day interactive effects ($P\leq 0.05$). Overall, it was observed that species affected the total proportions of fatty acids with regard to game meat. As an outcome of this study, meat from impala, mountain reedbuck, and springbok shows desired physical meat quality traits and fatty acids. The findings may be valuable in increasing the marketing of these three game species as a source of meat.

Selection for A2 β -casein genotype in Holstein bulls

L. Jiménez-Montenegro, L. Alfonso, J.A. Mendizabal and O. Urrutia

Public University of Navarre, Department of Agronomy, Biotechnology and Food, Campus de Arrosadia 31006 Pamplona, Navarre, 31006, Spain; lucia.jimenez@unavarra.es

In the last few years, an increasing interest in the use of A2A2 semen bulls has been experienced. This specific genotype belongs to the protein β -casein (β -CN) which is encoded by a single gene located on chromosome 6 called CSN2. From the several alleles that are codified from this gene, the A1 and the A2 are the most common. The A1 β -CN has been related to risk factor in aetiology of some human disorders such as digestive discomfort, but not A2 β -CN. This reason, together with the increase in both the consumption of plant-based substitutes and the milk production costs, has made that some dairy producers moved towards new products development with higher added value such as the A1 β -CN free milk, which only contains A2 β -CN protein. However, it is needed to know if the genetic selection of cows and bulls for A2A2 genotype to produce this type of milk could lead to possible future genetic implications in dairy herds. Thus, the aim of this work was to study the possible association between the genomic selection for A2A2 and estimated breeding values for milk performance traits. Six bovine semen companies were selected for the analysis and statistical analysis using ANOVA was carried out. The results showed a high frequency of the A2 allele, and that the general strategy of the analysed companies seems to be the increase in the number of bulls with the A2A2 genotype. The associations between β -casein genotypes and breeding values for milk production and composition traits varied among companies and there was not a clear common pattern that suggests there is some physiological mechanism that can explain them. Finally, breeding values for milk performance traits for bulls with A2A2 and A1A2 genotypes compared to A1A1 were generally either better or similar, but not worse. This suggest that genetic selection for A2A2 genotype would not have future negative implications in dairy herds in the analysed traits.

Session 30

Theatre 1

Consumer perception of the challenges facing livestock production and meat consumption

J.J. Liu¹, S. Chriki^{2,3}, M. Kombolo³, M. Santinello⁴, S. Pflanzner⁵, É. Hocquette², M.P. Ellies-Oury^{3,6} and J.F. Hocquette³

¹Teagasc Ashtown Food Research Centre, Department of Food Quality and Sensory Science, Scribbletown, Dublin 15, D15 KN3K, Ireland, ²Isara, 23 rue Jean Baldassini cedex 07, 69364 Lyon, France, ³INRAE, UMR1213, Saint-Genès-Champanelle, 63122, France, ⁴University of Padova, Department of Agronomy, Food, Natural Resources, Animals and Environment, VEN, 35020 Legnaro, Italy, ⁵University of Campinas, Department of Food Engineering and Technology, Rua Monteiro Lobato, Campinas 13083-862, SP, Brazil, ⁶Bordeaux Sciences Agro, 1 cours du Général de Gaulle, CS 40201, 33175 Gradignan, France; liujingjing1003@126.com

With the global meat market growing and intensive livestock farming systems increasing, the impacts of livestock are a growing concern among consumers, further influencing their meat consumption. Therefore, it is essential to understand consumer perception of livestock production. This study was conducted with 16,803 respondents in China, France, Brazil, Cameroon and South Africa to investigate the different perceptions of the ethical and environmental impacts of livestock among consumer segments depending on their sociodemographic characteristics. On average, the current respondents in China and Brazil and/or who are females, work outside the meat sector, low meat eaters and/or more educated, were more likely to believe that livestock meat production causes serious ethical and environmental problems; while those who from China, France and Cameroon and/or who are women, younger, outside the meat sector, low meat eaters and/or more educated, agree more that reducing meat consumption could be a good solution to these problems. Additionally, an affordable price and sensorial quality are main drivers of food purchase for the current respondents. In conclusion, sociodemographic factors have significant effects on consumer perception of livestock meat production and meat consumption habits. Perceptions of challenges facing livestock meat production differ between countries from different geographical regions depending on social, economic, cultural contexts and dietary habits.

Sustainable development of China's beef industry driven by a successful triangle beef cooperation

Q. Meng

China Agricultural University, The Center for Sino-French Beef Research & Development, College of Animal Science and Technology, Yuanmingyuan Ws. Rd., Haidian District, Beijing 100193, China, 100193, China, P.R.; qxmeng@cau.edu.cn

China's beef cattle industry has developed rapidly in recent years, which is inseparable from a successful international beef cooperation between China, France, Australia and other countries. By the end of 2021, China had 98.17 million inventory cattle population, of which 82.54 million were beef cattle. The total beef output was 6.98 million tons, the beef imports were 2.33 million tons, and the per capita beef consumption was 6.58kg. China's beef cattle inventory and beef output have jumped to the third place in the world, and its annual beef import has ranked the first place in the world, indicating that China has developed into a major beef producer and consumption country in the world. The international cooperation in China's beef industry has experienced three stages: the early stage from 1949 to 1979, the steady development stage from 1980 to 2000, and the comprehensive development stage from 2001 up to now. Among them, the establishment of the Center for Sino-French Beef Research and Development and the successful Triangle beef cooperation between China, France and Australia are the most remarkable, which have become an important supporting force to promote the right development of China's beef industry. In the future, China's beef industry will develop towards the large-scale, health and sustainability.

Session 30

Theatre 3

The production and quality improvement of mutton in China

H.L. Luo

China Agricultural University, College of Animal Science and Technology, 2 Yuan Mingyuan Xilu, Haidian District, Beijing, 100193, China, P.R.; luohailing@cau.edu.cn

China has been the world's largest producer in mutton from 4.08 million ton in 2013 to 5.14 million ton in 2021, meanwhile the quality has been improved. In China, there are three kinds of feeding methods for mutton production including grazing, restricted grazing time plus supplementary feeding and house-feeding. The different feeding methods led to the meat quality change, such as intramuscular fat deposits increasing in lamb meat, specifically over-rich in ω -6 polyunsaturated fatty acids but low in ω -3 polyunsaturated fatty acids. Generally, the ratio of ω -6 to ω -3 fatty acids in meat increases from 1 to 20 when lambs are switched from a grazing pasture to house-feeding with concentrate. It is impressed that the ω -6/ ω -3 ratio with restricted grazing time of 0 hr, 2 hr, 4 hr, 8 hr and 12 hr was decreasing gradually with 20.23, 9.74, 6.18, 4.99 and 4.28 for the weaned male Tan lambs, and with 5.75, 3.8, 3.67, 3.94, 3.45 and 1.26 in the weaned male Ujumuin lambs, since the different kinds of grass were intake in different pasture between them. However, the ω -6/ ω -3 ratio in the muscle of Hu sheep was significantly lower than that of Tan sheep and Duper sheep by feeding the same diet. The fatty acid composition of lamb can be improved by feed additives. The addition of vitamin E to the diet reduce the drip loss of meat and the content of stearic acid and branched-chain fatty acids related to the 'mutton odour', but improve the content of CLA and unsaturated fatty acids in muscle. Feeding different types of oil in diet had a significant effect on the fatty acids composition in lamb meat. The soybean oil and canola oil increased the ω -6/ ω -3 ratio from 9.59 to 14.23, but fish oil decreased the ratio to 1.70 significantly. The addition of alfalfa saponins, a compound that regulates lipid metabolism, reduced the ω -6/ ω -3 ratio from 6.45 to 5.60. In summary, there has been an adverse effect on the composition change of fatty acids in lamb meat by changing grazing system to housing feeding. However, this adverse effect can be improved by either grazing regime plus concentrate feeding or house feeding by different additives, or special sheep breed with the high preferred fatty acid composition.

Comparison of sheep meat eating quality thresholds for Chinese, American and Australian consumersR.A. O'Reilly^{1,2}, D.W. Pethick^{1,2}, G.E. Gardner^{1,2}, A.B. Pleasants³ and L. Pannier^{1,2}¹College of Science, Health, Engineering and Education, Murdoch University, WA, 6150, Australia, ²Australian Cooperative Centre for Sheep Industry Innovation, NSW, 2351, Australia, ³Massey University, Al-Rae Centre for Animal Breeding and Genetics, Hamilton, 3214, New Zealand; r.oreilly@murdoch.edu.au

A new cuts-based Meat Standards Australia (MSA) model has been developed within Australia to predict eating quality grades of sheep products. It is based on untrained Australian consumers therefore it is important to examine whether the expectations of consumer groups in other countries align with Australian perceptions. The objective of this study was to examine American, Australian, and Chinese consumer allocation of Australian lamb and yearling products into MSA quality grades and determine whether differences exist in the eating quality grade thresholds between these consumer groups. Untrained consumers were recruited across Australia, China and the USA (720 per country). Each consumer tasted and scored 6 grilled sheep meat samples (3 loin and 3 topside muscles) collected from 164 lambs and 168 yearlings. Samples were scored on tenderness, juiciness, liking of flavour and overall liking on a scale line of 0-100, in addition to assignment of a quality grade: 2 star (fail), 3 star, 4 star, or 5 star. Linear discriminate analyses were used to weigh the importance of the four sensory traits and determine quality thresholds for each consumer group. Chinese consumers had lower quality grade thresholds than American and Australian consumers, ranging from 6 to 11 points lower. Within each consumer group, there was minimal difference between the thresholds for lamb or yearling products. The combined lamb and yearling thresholds for 2-3 star, 3-4 star and 4-5 star were: 37, 56, 74 for China, 43, 65, 81 for Australia, and 46, 67, 82 for the USA. Thresholds reflected the pattern observed in allocation of samples to quality grades, with Chinese consumers assigning a larger proportion of samples to higher quality grades, while American and Australian consumer allocations were more critical. These findings suggest that quality perceptions can vary for consumer groups, thus assignment of sheep meat products to quality grades may need adjustment to ensure quality expectations are met within export markets.

Session 30

Theatre 5

Differences in liver nutrient metabolism contribute to residual feed intake of beef cattle

Z.M. Zhou

China Agricultural University, No. 2 Yuanmingyuan West Road, Haidian District, Beijing, 100193, China, P.R.; zhouzm@cau.edu.cn

Residual feed intake (RFI) is a good measure of feed efficiency, which is defined as the difference between the actual dry matter intake (DMI) and the predicted DMI based on body size and growth. RFI is a trait independent of growth performance. Compared with the high RFI (HRFI), the low RFI (LRFI) animals can reduce feed consumption without affecting growth performance. As an important metabolic and immune organ, liver plays important roles in physiological processes. The changes of metabolism and gene expression may lead to the variation of feed efficiency. Ninety Angus heifers (410±25 kg, 15 months) were fed with the same diet for 144 days, and all conditions were consistent. All heifers had *ad libitum* access to water and feed. Daily feed intake of individual animals was obtained from an automatic feed intake recording system, and body weight was obtained at the beginning and end of the experiment and at 14-day intervals. Individual RFI value was calculated through dry matter intake, average daily gain, and middle metabolic weight. The liver samples of heifers were collected with the highest (n=6) and the lowest (n=6) RFI values, and stored at -80 °C until subsequent analysis. The results showed that a total of 47 differential metabolites were identified in the liver with different RFI groups ($P<0.05$), which enriched in the following KEGG pathways: protein digestion and absorption, D-Glutamine and D-glutamate metabolism, and aminoacyl-tRNA biosynthesis ($q<0.05$). And a total of 495 differentially expressed genes were enriched in the following KEGG pathways: glutathione metabolism, PPAR signalling pathway, protein processing in the endoplasmic reticulum, B cell receptor signalling pathway ($q<0.05$). For proteomic analysis, a total of 411 differentially expressed proteins ($P<0.05$) only significantly enriched in the glycerophospholipid metabolism pathway ($q<0.05$). After further analysis, we found that PNPLA6, PTSS1, DGK, CDS2, PNPLA8, LYPLA2 and GPAT4 were up-regulated in the LRFI group. Compared with the HRFI group, the LRFI group had stronger glycerophospholipid synthesis, cell proliferation, cell membrane transport, cell signal transduction, and immune function, but fat transport was accelerated.

Marbling in French cattle: average level and factors of variations*A. Nicolazo De Barmon, I. Legrand and J. Normand**Institut de l'Élevage, Service qualité des carcasses et des viandes, 149, rue de Bercy, 75012 PARIS, France; aubert.nicolazodebarmon@idele.fr*

The importance of fat infiltration or 'marbling' in meat for organoleptic quality has been proved. Thus, this is a research axis of the French bovine meat interbranch organization (Interbev) to improve beef quality for consumers. In this respect, the French Livestock Institute (IDELE) developed a grid with 6 levels of marbling (from 1 (no marbling), to 6 (very high marbling)) for the French meat industry to be used in slaughterhouses. The objective of this study is to make a clear picture of marbling levels from French breeds and to see if professional opinions regarding possible factors affecting meat marbling would merit to be further studied. Marbling of 3,218 carcasses from various breeds, categories and slaughterhouses have been evaluated by different graders. Most carcasses were from cows, they can be divided in three classes: 1/3 poorly marbled (1 or 2), 1/3 with a medium level (3) and the last third marbled or extremely marbled (4, 5 or 6). Different carcass traits seem to affect marbling levels. Once again, breed impact has been confirmed: early maturing breeds are more marbled (around 50% of dairy cows graded equal or more than 4) than late maturing ones (only 25% of beef cows). The category also affects marbling level: as previously seen in different studies, young beef bulls are poorly marbled (70 to 80% graded 1 or 2) whereas females have higher marbling score (only 25 to 30% graded 1 or 2). Moreover, carcasses with high marbling level are the more fatty, heavier and with the best conformation. This observation is linked to fattening which affects these characteristics and marbling deposition. However, a large variability exists at the same level of weight, conformation and fatness. Therefore, a given conformation, weight or fatness score doesn't guarantee a marbling level. Age effect on marbling is not really clear and has to be more studied. Thus, these results give references to the French meat industry to better answer to consumers' demands, especially from an organoleptic aspect.

Session 30

Theatre 7

Effect of high sulphur diet on rumen fermentation and epithelial barrier function in beef cattle*H. Wu, Y. Li, Q.X. Meng and Z.M. Zhou**China Agricultural University, College of Animal Science and Technology, 2 Yuanmingyuan West Road, Haidian District, Beijing, 100193, China, P.R.; wu2213@cau.edu.cn*

The aim of the study was to investigate the mechanism of high-sulphur diet inducing rumen epithelial injury and inflammation. Eight 24-month-old Angus steers (350±43 kg) fitted with permanent rumen fistulas were used in a repeated 4×4 Latin square design: Cattles in the control group were fed a basal diet (sulphur content was 0.4%, CON), and those in the experimental groups were fed a diet with sulphur content of 0.6% (LSD), 0.8% (MSD) and 1.0% (HSD) with sodium sulphate, respectively. Total gas production and methane gas concentrations were linearly decreased with dietary sulphur content increasing ($P<0.01$), while hydrogen sulphide gas concentration was significantly increased ($P<0.05$). Compared with CON, the concentration of TVFA and the proportion of butyric acid of HSD were significantly increased ($P<0.01$), but the proportion of propionic acid was significantly decreased ($P<0.01$). The concentration of $\text{NH}_3\text{-N}$ was not significantly different between LSD and MSD, but was significantly lower than that of CON and HSD ($P<0.01$). Total thickness of rumen epithelium in HSD was significantly higher than that in CON and LSD ($P=0.01$), but not significantly different with MSD. Specifically, the thickness of spinous layer and basal layer increased ($P=0.02$), while there was no significant difference between corneum and granular layer. The degree of peeling and keratinization on the rumen papilla surface was more obvious in the HSD. At the same time, the high-sulphur diet led to the formation of large cracks and sprouting of rumen epithelium. The bacteria attached to the rumen epithelium surface were mainly coccus and bacillus in CON, while the high-sulphur diet showed more fusarium and actinomycetes. qPCR results showed that the mRNA expression levels of TJPI and CLDN-1 genes in rumen epithelial cells in HSD were significantly lower than those in CON ($P<0.05$). According to the above results, it can be inferred that dietary excess sulphur can affect rumen fermentation, change the type of rumen fermentation, and damage the integrity of rumen epithelium morphological structure, thereby increasing the permeability of rumen epithelium and destroying barrier function of beef cattle.

Research progress on quality characteristics and regulation of yak meat in ChinaL.Z. Hao¹, B.Q. Bai¹, Y. Xiang¹, Q.X. Meng², J.Z. Niu¹, Y.Y. Huang³ and S.J. Liu¹¹Qinghai University, Qinghai Academy of Animal Science and Veterinary Medicine, Key Laboratory of Plateau Grazing Animal Nutrition and Feed Science of Qinghai Province, Xi'ning, 810016, China, P.R., ²China Agricultural University, Beef Cattle Research Center, Beijing, 100193, China, P.R., ³INRAE, UMR PEGASE, 16 le Clos, 35590 Saint Gilles, France, France; qxmeng@cau.edu.cn

The yak (*Poephagus grunniens*), an indigenous herbivore raised at 3,000 to 5,000 meters above sea level across the Asian highlands, is one of the main livestock grazing on the Qinghai-Tibetan Plateau (QTP). At present, there are approximately 17.6 million yaks in the world, of which more than 95% are raised in China. Yaks play a vital role in ecosystem stability, livelihood security, socio-economic development, and ethnic cultural traditions on the QTP. Yak meat is the main product of yak industry, and its quality characteristics have always been unclear. This research systematically reviewed the eating quality, processing quality, nutrition quality, health safety quality and cultural quality of yak meat by collecting yak meat samples from different species, ages, genders, feeding methods and regions in the QTP. The quality characteristics, advantages and disadvantages of yak beef were demonstrated. On this basis, the research progress of yak meat quality through nutrition regulation was systematically introduced, which provided the basis for the construction of the world's largest green organic yak meat export land and the development of yak industry.

Session 30

Theatre 9

Comparison of beef eating quality terminology databasesA. Barro^{1,2}, K. Insausti^{3,4}, M. Kombolo², M.P. Ellies-Oury^{2,4} and J.F. Hocquette²¹Londrina State University, Highway Celso Garcia Cid, 86057-970 Londrina, Brazil, ²INRAE, Vetagro Sup, UMR1213, 63122 Theix, France, ³Public University of Navarre, ETSIAB-ISFOOD, Arrosadía Campus, 31006 Pamplona, Spain, ⁴Bordeaux Sciences Agro, CS 40201, 33175 Gradignan, France; amandagbarro@gmail.com

The standardisation of the evaluation of beef eating quality is a prerequisite to set up a global meat research database and to drive continuous improvement in meat quality prediction. This is the case of the Meat Standards Australia (MSA) methodology, which is based on common definitions of carcass characteristics for carcass graders to maintain skills and accreditation to ensure data consistency. In this line, the objective of this project was to extract and compare relevant terms related to beef eating quality present in pre-existing ontologies and terminology databases. The technical terms used in the MSA methodology were considered as the reference. Their equivalence in different languages (French, Portuguese and Spanish) including minor languages (e.g. Basque) was recorded. A semi-automatic search was carried out in existing databases. This was followed by a manual part to search for the available definitions and establish the equivalence of the terms in the different databases. A total of 19 databases freely accessible online were consulted, including specific ontologies for animal production, (ATOL, NAL USDA, and GACS), the Meat thesaurus available in the AGROPORTAL ontology, online dictionaries, and materials from world-renowned institutions (MLA, ICAR, USDA, IBEEF, AMSA). In total, we identified 56 terms used in the meat industry, in animal production, carcass quality and sensory characteristics. No database could find all the terms used in this research. Besides, some terms (marbling, subcutaneous fat thickness, carcass weight, ribeye area, etc.) are easy to find but are described differently in each database. For example, marbling is measured differently in some countries, which is important to point out in the database. In conclusion, among the consulted sources and ontologies for animal production already established, some of the more specific terms used in the MSA methodology are still missing. Conversely, carcass classification databases lack information on pre-slaughter factors that influence beef quality, mainly for the MSA methodology.

Comparison of slaughter performance and meat quality of Tan sheep under different feeding regimes

X.G. Zhao, C. Zhang, M. Liu and H.L. Luo

China agriculture University, college of animal science and technology, animal nutrition and feed science, 2 West Yuanmingyuan Road, 100193, China, P.R.; 1404010216@cau.edu.cn

Grazing with time limited is a burgeoning production technology which improves production efficiency and maintains the balance between forage and animal. The change of feeding regime, however, had additional effects on the quality of the meat. The aim of this study is to accurately compare the slaughter performance and meat quality of the Tan Sheep under different feeding regimes. In this study, three groups of three-month-old Tan Sheep were raised in three regimes, grazing(G), grazing with time limited + supplementary feeding (GT) and indoor feeding (F). The sheep of three groups were slaughtered after three months. The results showed the final body weight of the GT was significantly higher than the G and F group. The proportion of subcutaneous fat to carcass of the F group was significantly higher than GT and G groups. The proportion of tail fat to carcass of the F group was significantly higher than GT group, which was significantly higher than G groups. The Longissimus thoracis et lumborum (LTL) muscle pH45min of the G group was significantly higher than the F group, but pH24h was lower than F group. The initial and 24 hours after slaughter lightness of LTL muscle of the F group were significantly higher than the GT group and G group. The lightness of 48 hours after slaughter of LTL muscle of the F group was significantly higher than the GT group. The yellowness of 24 hours after slaughter of LTL muscle of the F group was significantly higher than the G group. The drip loss of the G group was significantly lower than the F group and the GT group. The cooking loss of the F group was significantly lower than the GT groups, which was lower than the G group. In summary, Tan Sheep under grazing with time limited + supplement feeding regime had higher meat production than grazing regime, and the meat quality was more similar to grazing sheep.

Session 30

Theatre 11

Effect of *Piper sarmentosum* extract on the growth and nutrient digestion of Hainan Black goatG.D. Ren^{1,2}, Z.Y. Sheng^{1,2}, Y.X. Chen^{1,2}, X.G. Zhao², H. Zhang², H.L. Zhou³, W.L. Lv³ and H.L. Luo^{1,2}

¹China Agricultural University, Yazhouwan Science and Technology City, 57200, China, P.R., ²China Agricultural University, 2 Yuan Mingyuan Xilu, Haidian District, Beijing, 100193, China, P.R., ³Chinese Academy of Tropical Agricultural Sciences, 4 Xueyuan Road, Longhua District, Haikou, 571101, China, P.R.; guodongren630@cau.edu.cn

Piper sarmentosum as a naturally occurring medicinal plant in the tropics, whose extracts have a wide range of bioactive substances due to their anti-inflammatory, antioxidant and insecticidal activities. This study was conducted to investigate the effects of *P. sarmentosum* extract (PSE) addition on the growth performance and meat quality of Hainan black goat. Thirty-six goats (body weight=9.48±0.25 kg, age=90±10 day; mean ± SD) were fed a 50:50 concentrate: roughage basal diet and randomly divided into four groups: 0 (control), 200 (200 PSE), 400 (400 PSE), or 600 mg/kg DM (600PSE) PSE, respectively. The experimental period was 105 days, with 15 days for adaptation and 90 days for data collection. The results showed that feed efficiency responded linearly ($P<0.05$) with the highest values for the 400PSE group. Average daily gain and dry matter gain were not affected by dietary supplementation with PSE ($P>0.05$). Dietary supplementation with PSE linearly increased the pH24h of longissimus dorsi (LD) muscle ($P<0.05$) but decreased the value of L^* 24 h ($P<0.05$). As supplementation with the PSE increased, the value of b^* in LD muscle responded linearly ($P<0.05$), and 600PSE group had lower values of b^* 45 min and b^* 24h than other treatment groups ($P<0.05$). The carcass weight, net meat weight and internal organ development indexes were not influenced by dietary supplementation with PSE ($P>0.05$). Goats receiving 400 mg/kg DM PSE addition had higher digestibility of DM, NDF and ADF ($P<0.05$). In addition, the serum content of glucose, IL-2, IL-4 and IL-6 responded linearly ($P<0.05$) with addition of PSE. The blood activity of glutathione peroxidase and level of total antioxidant capacity were linearly ($P<0.05$) increased in the PSE addition groups whereas decreased in malondialdehyde ($P<0.05$). Therefore, the results indicated that dietary addition of 400 mg/kg DM PSE improved feed efficiency, nutrient digestion and antioxidant capacity in Hainan black goats.

Effects of grazing intensities and supplementary levels on the nutritional composition of lamb meat*H. Yang, J. Ji and H.L. Luo**China Agricultural University, State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, 100193, Beijing, China, P.R.; yanghuan2021@cau.edu.cn*

Our research objective is to determine the effects of different grazing intensities and supplementary levels on the nutritional composition of lamb meat. Six treatments were compared, with 2 grazing intensities and 3 supplementary levels investigated at both grazing intensities. The 2 grazing intensities were moderate grazing (MG, the utilization rate of grassland is 80%, the plot area is 0.2 ha) and heavy grazing (HG, the utilization rate of grassland is 40%, the plot area is 0.4 ha); The 3 supplementary levels were as follows: 0% supplement (NS), 1% supplement (LS) and 2% supplement (HS) of lamb weight. 72 healthy three-month-old male Hulanbeier lambs were used in a randomized complete block design and divided in 6 groups for the entire experiment, which had 12 lambs (3 plots for each treatment, and 4 lambs in each plot) in each treatment group. After 90 days of grazing, the slaughter experiment was conducted. The results showed that the GR value of lambs decreased with the increase of grazing intensity as well as the decrease of supplementary level ($P<0.05$). The net meat percentage increased with the increase of supplementary level ($P<0.05$). The water content of lumborum muscle in of NS group was higher than that of LS and HS groups ($P<0.05$) and crude protein content was increased in LS group compared to NS group ($P<0.05$). Decreasing the intensity of grazing and increasing the level of supplementary led to a linear increase the proportion of intramuscular fat ($P<0.05$). The n-3 PUFA, including C18:3n3 and C20:5n3 increased in muscle of NS group, and the ratio of n-6/n-3 decreased from 4.76 to 3.03 with decreased supplement level, while the ratio of MUFA to SFA increased in HS group ($P<0.05$). The HG group and NS group increased the contents of EAA (e.g. threonine, valine, isoleucine, leucine, phenylalanine and lysine) and sweet amino acids (e.g. asparagine, glutamic acid, alanine and arginine) ($P<0.05$), compared to MG group and supplementary groups. In conclusion, moderate grazing and supplementary concentrate improved the yield and quality of lamb meat, while the meat content of fatty acids and amino acids under NS or HG was more beneficial to human health.

Session 30

Poster 13

Perspectives on consumer attitudes to meat consumption*P. Purslow¹, W. Zhang² and J.F. Hocquette³**¹The University of Melbourne, 3010, Victoria, Australia, ²Nanjing Agricultural University, College of Food Science and Technology, Nanjing, China, P.R., ³INRAE, UMR Herbivores, 63122, France; jean-francois.hocquette@inrae.fr*

The production and consumption of meat are regularly discussed in the public sphere. As the first widely recognized journal in its field, the scientific journal Meat Science must provide objective data concerning evolution in perception of meat production and consumption. This is the purpose of a special issue focusing on the range, consensus and diversity of consumer attitudes to meat in the world. Several of the 24 papers on this issue highlight different consumer attitudes between countries. For instance, whereas debates around health, environment and welfare issues are quite strong in the USA, there is a sustained demand for meat in this country, despite success of meat alternatives for mostly young, highly-educated and rich consumers. In China, increasing income is the main factor explaining meat consumption, while the biggest concern is safety. Other countries also express their own specific drivers and concerns. An affordable price and safety but also health, animal welfare and environmental issues are among the factors which explain the decrease in meat consumption. Conversely, the pleasure of eating meat, culinary culture, cultural aspects and national traditions are among the main drivers of meat consumption in relationship to the reported customs and social attitudes. Based on this complexity, a compromise has sometimes to be found, for instance between sensory traits and ethical issues related to pig castration and other practices rejected by consumers in many countries. Whereas plant-based products are already commercialized, there are significant technical, ethical and regulatory issues to fix before getting 'cultured meat' available in the market. Indeed, information on production processes and product composition are not publicly available, making it impossible to check product characteristics and sustainability. However, consumer reactions are dominated by affective, rather than by cognitive factors. To sum up, the current market is disrupted. Meat producers and also the promoters of meat substitutes must adapt their strategies according to these general trends, nuanced by local specificities, while being more transparent.

Effects of different grazing intensities and supplementary feeding levels on meat quality of Hulunbu

X.H. Ma, Z. Li, X.G. Zhao, H. Yang and H.L. Luo

China Agricultural University, No.2 Yuanmingyuan West Road, Haidian District, Beijing, 100193, China, P.R.; 2095602677@qq.com

Many studies have shown that meat quality is better in sheep under grazing conditions. However, the changes in meat quality under different grazing levels and supplementary feeding levels are not clear. In this study, 72 Hulunbeier sheep were selected for testing under different grazing and supplementary feeding levels. The results showed that moderate grazing and high supplementary feeding significantly increased the pre-slaughter live weight and carcass weight of the sheep ($P<0.05$), but had no effect on their slaughter rate. Low levels of supplementation significantly ($P<0.05$) increased the greater retinal lipid index in sheep. There was no significant effect on other fat indices. The pH of Hulunbeier lamb ranged from 6.53 to 6.91 at 45 min after slaughter and from 5.70 to 6.23 at 24 h. The pH at 24 h decreased overall compared to the pH at 45 min. This is in line with the pattern of decreasing pH after slaughter. The pH decreased the slowest at the low re-feeding level compared to 45 min. The pH range of 5.8 to 6.2 measured after 24 h of slaughter at low temperatures. L values at 0 h were significantly higher in the no and low supplementation meat colours than in the high supplementation level, while L values at 24 h were higher in the high supplementation level than in the other two groups. The fact that the yellowness values at 0 h were higher in the no- and low-feeding levels than in the high-feeding level, but not in the 24 h level, also indicates that the no- and low-feeding levels were favourable to the development of flesh colour. Moderate grazing significantly reduced the yellowness values at 24 h. The a-values at 24 h were significantly higher at no and low levels of supplementation than at high levels of supplementation. Drip loss was significantly reduced by no and low levels of supplemental feeding. Overall, no and low levels of supplemental feeding were more favourable to the development of good meat quality under moderate grazing conditions.

Session 30

Poster 15

Progress of yak carcass grading in Qinghai-Tibet Plateau of China

S.S. Zhang

Institute of Animal Science Chinese Academy of Agricultural Sciences, 2# Yuanmingyuan West Road, Haidian District, Beijing, 100193 Beijing, China, P.R.; 474002029@qq.com

Yak, as a precious species resource in the Qinghai-Tibet Plateau of China, has great commercial development potential due to its high protein content, low fat content, high Ca, Fe, Zn, Mg and other minerals, and yak meat is the main resource of animal protein for Tibetans. Traditional yaks are fat in autumn and lean in winter because of their grazing conditions which makes them grows slowly. The yaks are mainly slaughtered at the age 5-7. The growth characteristics and industry periodicity of yak are different from those of ordinary beef cattle, so that its quality evaluation system should be different from that of ordinary beef cattle. The current beef grading standard is not applicable to yak meat grading, and the absence of national or industrial yak carcass grading standard makes the evaluation of yak carcass a confusion. So, carrying out yak carcass grading is conducive to the high-quality development of yak industry in the Qinghai-Tibet Plateau.

Future-proofing the sustainability of pasture based beef production systems

A.K. Kelly and T.M. Boland

University College Dublin, Agriculture and Food Science Centre, Belfield, Dublin 4, Ireland; alan.kelly@ucd.ie

Beef is a high-quality source of protein and demand is increasing globally. However, population growth and environmental constraints will continue to pressure beef producers and wider industry to improve productivity, efficiency and sustainability. Most notably, beef producers and beef industries face significant environmental and sustainability challenges around greenhouse gas emission, water quality, arresting and reversing environmental degradation, land use (food vs feed) and biodiversity loss. Future proofing the sustainability of beef farm production systems will require a combined approach supporting high on-farm efficiency and productivity, paramount to farm profitability and succession, coupled with financial incentives that rewards producers in achieving target-market specifications for higher-value premium quality beef, using suitable genetics and appropriate management principles, that contribute to reduced environmental and animal welfare impacts necessary for provenance and social licence to farm. This review provides an overview of the principles and practices that support efficient, high output, productive pastoral-based beef production systems, including rule of genetics, nutritional strategies and other management practices. Reducing the environmental footprint of pasture-based beef cattle production systems will undoubtedly be a challenge and a secondary objective of this review GHG mitigation solutions, both currently available and under development, for temperate pasture-based beef cattle production systems.

Session 31

Theatre 2

Effect of sward type on growth performance and methane output of lambs in the post-weaning periodS. Woodmartin¹, P. Creighton¹, T.M. Boland², A. Monaghan¹ and F. McGovern¹

¹Teagasc, Animal and Grassland Research and Innovation Centre, Mellows Campus, Athenry, Galway, Ireland, H65R718, Ireland, ²School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, D04FX62, Ireland; sarah.woodmartin@teagasc.ie

In Irish sheep systems, a large proportion of lambs grazing perennial ryegrass swards (*Lolium perenne* L.; PRG) in the post-weaning period have live weight gains below target. Subsequently, forage inclusion is gaining popularity alongside PRG to enhance animal performance. The aim of this study was to assess the effect of sward type on lamb performance and methane (CH₄) output in the post-weaning period. Five sward types were investigated, PRG only, PRG plus white clover (*Trifolium repens* L.; PRG+WC), PRG plus red clover (*Trifolium pratense* L.; PRG+RC), PRG plus chicory (*Chicorium intybus* L.; PRG+Chic) and PRG plus plantain (*Plantago lanceolata* L.; PRG+Plan). A complete randomised block design experiment was used creating five farmlets each representing a dietary treatment. Lambs were weaned at 14 weeks and a leader-follower grazing system was implemented. Methane measurements were obtained using portable accumulation chambers (PAC) on 120 lambs over two production seasons (n=24 per treatment). Lambs were weighed fortnightly and drafted accordingly, targeting a 20 kg carcass. Days to slaughter (DTS) was calculated as the number of days from birth to slaughter. Results show that lambs grazing swards containing a forage had reduced DTS of between 16 days (PRG+Plan) and 47 days (PRG+RC) ($P < 0.0001$) relative to those grazing PRG only swards. The lambs grazing PRG+RC (10.3±0.225) ranked lowest for CH₄ production (g/day) in comparison to all other dietary treatments. Lambs grazing PRG+WC (11.6±0.225) and PRG+Plan (11.8±0.225) ranked intermediately and lambs grazing PRG+Chic and PRG only (12.9±0.225) ranked the highest ($P < 0.0001$). The addition of forages to the grazed sward offered to lambs post-weaning gives the potential to reduce DTS and lower the ranking of CH₄ (g/day) output when compared to lambs grazing PRG monocultures. Lambs finished on the PRG+RC sward had superior growth performance coupled with the lowest CH₄ output. Forage inclusion can benefit the environmental and economic performance of lamb finishing systems.

On farm grass growth prediction in Ireland – 4 year evaluationE. Ruelle¹, L. Bonnard^{1,2}, D. Hennessy¹, L. Delaby³ and M. O'Donovan¹¹Teagasc, Moorepark, Fermoy, Co. Cork, Ireland, ²MTU, Cork, Co. Cork, Ireland, ³INRAe, Institut Agro, PEGASE, 35590 Saint-Gilles, France; elodie.ruelle@teagasc.ie

In pasture-based systems farmers need to make daily management decisions to ensure that their livestock have good quality feed in adequate quantities. 2018 was a challenging year in Ireland due to a late start to grass growth in the spring and a drought in the summer. This situation highlighted the need to be able to predict grass growth weekly to help farmers manage their grass and better anticipate grass shortages in a changing climate. The grass growth modelling program at Moorepark, based on the MoSt Grass Growth Model, increased from 39 farms in 2019 to 78 in 2022 allowing a good representation of grass growth across Ireland. To predict grass growth, data from the farms participating in the project are extracted from PastureBase Ireland (PBI – a grassland decision support tool). Data includes number of paddocks and their area, grazing and cutting dates, number of grazing animals and feed supplementation, and nitrogen fertiliser application date and rate. Other data required by the model include the soil type for each paddock, and historical and forecast weather data (provided by Met Éireann, the Irish Meteorological Service). This paper will present the evaluation of four years of grass growth prediction by the latest version of the MoSt model compared to PBI farmer data using historical weather data. The number of available data points possible for comparison was 191,021 at the paddock level and 9,695 when averaged at farm level. At farm level, the average RMSE was of 13.5 (39 farms), 17.5 (56 farms), 15.7 (78 farms) and 14.3 kg DM/ha (78 farms) for 2019, 2020, 2021, and 2022, respectively. At paddock level (n=121,021), the error was higher and was 24.2 (1,295 paddock), 27.3 (1,880 paddock), 26.0 (2,471 paddock) and 24.8 kg DM/ha (2,478 paddock) for 2019, 2020, 2021, and 2022, respectively. The lower accuracy at paddock level is expected due to the difficulty in accurately replicating inter-paddock variability and the low reliability of the data entered into PBI at paddock level. While the predictions are not perfect, the accuracy at farm level is sufficient to make the MoSt model a useful tool for grassland management on Irish farms.

Session 31

Theatre 4

Incorporating plantain forage into a grazing dairy system: effect on farm productivity

O. Al-Marashdeh and H.M.G.P. Herath

Lincoln University, Faculty of Agriculture and Life Sciences, Lincoln, Canterbury 7647, New Zealand; omar.al-marashdeh@lincoln.ac.nz

Plantain (*Plantago lanceolata* L.) has been exploited as a natural mitigation strategy to reduce nitrate leaching from pastoral dairy systems. However, the productivity of dairy farm system that incorporated plantain into a ryegrass/white clover mixed swards has not been reported yet. Therefore, in a replicated farm system study and over full production season, the objective of this study was to investigate the effect of the increasing proportion of plantain in a ryegrass-white clover (RGWC) mixed sward on farm productivity. The study was conducted at Lincoln University Research Dairy Farm, Lincoln, New Zealand using a total of 108 Jersey × Friesian dairy cows during 2021/2022 production season (start calving date 27th July 2021 and dry-off date 11th May 2022). Cows were blocked into replicated herds of 12 cows (total of nine herds), and randomly allocated into one of three pasture treatments (n=3) sown with an increasing plantain seed rate: (1) RGWC with nil plantain (PL0); (2) RGWC + 3 kg/ha plantain seed rate (PL3); or (3) RGWC + 6 kg/ha plantain seed rate (PL6). A total of 32 ha of 0.3-ha paddocks were allocated to farmlets in this study, with 12 paddocks (total area 3.6 ha) per farmlet. During the period of study, farmlets were maintained on their treatments and managed individually. Individual cow's milk yield was recorded at each milking event and fortnightly herd test was conducted for determining milk composition. Individual paddock herbage mass was estimated weekly by a calibrated rising plate meter, and daily pasture growth rate was calculated. Annual pasture production was similar (13.0±0.61 t DM/ha) across treatments. Total milk yield (average 4,052±111.9 kg) and milk solid production (fat + protein; 406.9±11.93 kg/cow) were not different between treatments. Total milk fat (232±9.2 kg/cow) and protein (175±3.4 kg/cow) yields of cows did not differ between treatments. Integrating plantain in a mixed sward of ryegrass-white clover does not seem to affect productivity of dairy system, and if environmental benefits are confirmed at farm scale, plantain could be used as a mitigation strategy to reduce environmental impact of grazing dairy systems with no impact on farm profitability.

Dry matter production of multispecies swards under dairy grazing in two chemical nitrogen scenariosC. Hearn^{1,2}, M. Egan², M.B. Lynch^{1,3} and M. O'Donovan²¹University College Dublin, School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, D04 V1W8, Ireland, ²Teagasc, Animal and Grassland Research and Innovation Centre, Moorepark, Fermoy, Co. Cork, P61 P302, Ireland, ³Teagasc, Environmental Research Centre, Johnstown Castle, Co. Wexford, Y35 Y521, Ireland; michael.odonovan@teagasc.ie

Irish dairy farmers have become increasingly interested in the use of multispecies (MS) swards for intensive grazing systems. A grazed plot experiment was established to investigate the annual dry matter (DM) yield and botanical composition of MS swards containing three plant functional groups; grass, legumes and herbs under two nitrogen (N) fertiliser scenarios; zero N (N0) and a more conventional 200 kg N/ha/year (N200). Five sward types were established which included a perennial ryegrass (PRG, *Lolium perenne* L.) monoculture and sward mixtures of the following species: PRG, white clover (WC, *Trifolium repens* L.), chicory (CH, *Chicorium intybus* L.) and ribwort plantain (PL, *Plantago lanceolata* L.); with monoculture PRG N200 as the control. Plots were grazed by lactating dairy cows on eight, nine and eight occasions in years one, two and three, respectively. Swards in the N200 treatment produced a higher level of DM with an average of 2,497.4 kg DM/ha/year more than N0 swards ($P < 0.001$). The sward mixture of PRG, WC, CH & PL produced the highest level of DM; 2,184.3 kg DM/ha more than the PRG monoculture sward on average across both N scenarios. Swards including WC produced an average of 1,599.8 kg DM/ha/year more than those sown without WC ($P < 0.001$); the level of WC was influenced by N fertiliser where MS swards in the N200 protocol had a WC content of 15.4% less than that of those in the N0 protocol ($P < 0.001$). These results indicate that the inclusion of WC in grazed MS swards is crucial to increased DM production and the level of WC in grazed MS swards is influenced by the application of chemical N fertiliser.

Session 31

Theatre 6

Nitrogen herbage yield in grass and grass-white clover swards receiving zero nitrogen

Á. Murray, B. McCarthy and D. Hennessy

Teagasc, Animal and Grassland Research and Innovation Centre, Paddy O Keeffe Building, Moorepark Teagasc, P61C996, Ireland; aine.murray@teagasc.ie

Grazed grass is considered the cheapest feed available for dairy cows in temperate regions but is highly reliant on nitrogen (N) inputs. Nitrogen fertilisers are a major contributor to ammonia (NH₃) and greenhouse gas (GHG) emissions through their inputs in grazed herbage systems. Nitrogen use efficiency (NUE) can be increased through reduced N inputs to grazed herbage systems but production needs to be maintained. The objective of this study was to evaluate the nitrogen uptake yield from perennial ryegrass (*Lolium perenne* L.; PRG) and PRG-white clover (*Trifolium repens* L.; WC) herbage receiving zero nitrogen inputs. The study consisted of zero N plots that were set up in 2020 and 2021 within paddocks grazed by dairy cows of either PRG-only or PRG-WC sward types at Clonakilty Agricultural College, Cork, Ireland. The plots received no chemical or organic N and were not grazed by animals for the duration of the grazing season. Plots were relocated within paddock between grazing seasons. Herbage yield was measured within the plots at the same time as herbage yield for the paddock was measured prior to each grazing. The PRG-only sward plots yielded 7,950 kg DM/ha per year and 203 kg N/ha within this herbage. The PRG-WC swards yielded significantly higher herbage (11,499 kg DM/ha per year) and N (306 kg N/ha) than the PRG-only swards ($P > 0.001$). The results provide an indication of background N mineralization and biological N fixation within PRG-only and PRG-WC swards receiving zero nitrogen. This study warrants further measurements to be carried out to gain a better understanding of the N dynamics and responses within grazed swards to allow for better utilization of this valuable resource and in turn reduce N use and increase NUE.

Grassland-based dairy farms of French Massif Central adapt to climate change with diverse strategiesL. Allart¹, V. Oostvogels², F. Joly¹, C. Mosnier¹, N. Gross³ and B. Dumont¹¹Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, 63122 Saint-Genès-Champanelle, France,²Wageningen University & Research, Animal Production Systems group, De Elst 1, 6708 WD Wageningen, the Netherlands,³Université Clermont Auvergne, INRAE, Unité de Recherche sur les Ecosystèmes Prairiaux, 5 Chemin de Beaulieu, 63100 Clermont-Ferrand, France; lucie.allart@inrae.fr

Grassland-based dairy systems from upland areas, which are based on the grazing or mowing of semi-natural grasslands, are threatened by climate change, e.g. more frequent and severe summer droughts. The choices of adaptation of farmers can include the preservation of semi-natural grasslands or their conversion to other land-use as fodder crops. We surveyed 15 dairy farmers from French Massif central and investigated their perceptions of climate change, biodiversity, and grassland function in their adaptive capacity by semi-structured interviews. Using framework analysis and Multiple Component Analysis (MCA), we built four groups based on axes of the MCA explaining 71% of the variance. The first group (7 farms) is made of farmers who have a clear adaptive strategy that largely relies on permanent grassland management (e.g. building stocks by decreasing or optimising fodder consumption, changing harvesting methods to stabilise fodder yields and quality to cope with climate variability) among other levers. A second group of farmers (2 farms) also has clear strategies to adapt, based on building stocks from fodder crops and temporary grasslands, and preservation of hedgerows and trees. Farmers from the third group (3 farms) are still developing their adaptive strategy. So far, they give limited value to permanent grasslands in their adaptation strategy. The fourth group (3 farms) is characterised by a low intention to adapt. Grassland appreciation of the first group was not related to specific systems, as farm area and annual milk yield did not distinguish the first group from the others. Only the share of permanent grasslands in farm area was significantly higher in the first group than in all three others (89 vs 57%, $P < 0.05$). These preliminary results reveal how dairy farmers from the same area have contrasted perceptions on how grassland diversity allows adapting to climate change.

Session 31

Theatre 8

Effect of grazing intensity on nitrogen cycle of alpine summer pasture soilS. Raniolo¹, A. Squartini¹, L. Da Ros², F. Camin^{3,4}, L. Bontempo³, L. Maretto¹, D. Gianelle², M. Ramanzin¹, E. Sturaro¹ and M. Rodeghiero³¹University of Padova, DAFNAE, Viale dell'Università 16, 35020, Italy, ²Free University of Bolzano, Faculty of science and technology, piazza Università 5, 39100, Italy, ³Fondazione Edmund Mach di San Michele all'Adige, Via Edmund Mach 1, 38098, Italy, ⁴Center Agriculture Food Environment, Agriculture Food Environment Centre, Via Edmund Mach 1, 38098, Italy; salvatore.raniolo@phd.unipd.it

Alpine pastures are relevant agro-ecosystems classified as High Nature Value Farmland thanks to their high biodiversity. The aim of this study is to characterize the agroecological relationships among grazing animals, soil conditions, and microorganisms in an alpine summer pasture located in the Dolomites, Eastern Italian Alps, at an elevation around 2,000 m asl, grazed by dairy cows from mid-June to mid-September, with an area of 180 ha and a stocking rate of 0.84 livestock unit/ha. The grazing intensity was characterized at a fine spatial scale by combining GPS tracking of grazing animals and farmer's interviews. To assess the impact of grazing on soil conditions and microbial functions, topsoil cores were sampled at two different depths in three pasture areas at different grazing intensity during September, the end of the grazing period. Topsoil samples were analysed for bulk density, content of ammonium, nitrate, and the N isotopic ratio ($\delta^{15}\text{N}$), as an index of relative rates of N inputs and losses. In addition, the functional potentials of microbial communities were assessed by quantifying with real-time PCR the abundances of target genes *nirK* and *nosZ* for denitrification, *amoA* Archaea and Bacteria for nitrification, and *nifH* for nitrogen fixation. Nitrogen content and bulk density were significantly affected by both grazing intensity and soil depth and their interaction, while microbial functions was significantly affected only by grazing intensity, showing a likely and diversified impact of grazing on nitrogen cycle into topsoil. These results could be used to develop minimally invasive biophysical indicators of regulating ecosystem services in grasslands soils. These tools can inform sustainable management of grazing livestock systems in accordance with agroecology principles.

The visibility of the invisible: analysing heifers reactions while learning the virtual fence system

D. Hamidi¹, N.A. Grinnell¹, M. Kominda¹, L. Wilms¹, F. Riesch^{1,2}, J. Horn¹, M. Hamidi¹, I. Traulsen³ and J. Isselstein^{1,2}

¹University of Goettingen, Crop Sciences, Von-Siebold-Str. 8, 37075 Göttingen, Germany, ²University of Goettingen, Centre for Biodiversity and Sustainable Land Use, Büsingenweg 1, 37077 Göttingen, Germany, ³University of Goettingen, Animal Sciences, Burckhardtweg 2, 37077 Göttingen, Germany; dina.hamidi@uni-goettingen.de

An interesting approach to optimising the role of ruminants in sustainable food systems is the use of virtual fencing (VF) to graze land that cannot be managed with ground-based fencing. VF is an innovative technology with the potential to substitute common fencing systems. However, animal welfare concerns are a general problem for the wider implementation. When the animals approach the VF boundaries an acoustic signal is emitted by the collar followed by a short time electric pulse if the animal continues moving forward. Both signals are coupled, as the electric pulse is emitted by the last note of a melody rising in pitch. The heifers' reaction that led to the stopping of the coupled signal was used to analyse the learning success. We defined a reaction score (RS) to classify the heifers' reactions while turning around causing the signal to stop. RS 1: continue grazing/walking slowly <three steps, RS 2: walking >three steps/jumping with front legs, RS 3: running (trot/canter), RS 4: escaping. Data collection was conducted in a 12-day training trial in northern Germany (2021) with 16 Fleckvieh heifers fitted with VF collars (Nofence®, Norway), equally divided into two groups. Four 'focus' heifers per group were observed by one observer. The heifers were naive with VF prior to the study. Each RS was observed for each of the heifers' except RS 4 (observed twice). On the first day of the trial, 10.13 reactions per hour were observed (RS 1: 18%; RS 2: 60%; RS 3: 22%). On the second day, proportions for the respective RS changed to 61% (RS 1), 29% (RS 2) and 10% (RS 3). On the last day, 100% RS 1 was observed. By observing the heifers, it was possible to analyse the behavioural change in the animals' reactions to the invisible VF signals as a visible sign of learning success.

Session 31

Theatre 10

Sheep integration into cropping systems for agroecological transition of farming systems in France

F. Stark¹, J. Ryschawy², R. Mettauer³, M. Grillo², I. Shaqura¹ and M. Moraine⁴

¹SELMET, Univ Montpellier, INRAE, CIRAD, L'Institut Agro, Montpellier, France, ²AGIR, Univ Toulouse, INPT, INRAE, Toulouse, France, ³SAS, INRAE, L'Institut Agro, Rennes, France, ⁴INNOVATION, Univ Montpellier, INRAE, CIRAD, L'Institut Agro, Montpellier, France; fabien.stark@inrae.fr

Limits of the specialization of agriculture are widely documented in the scientific literature in terms of environmental, social and economic impacts. At the same time, ecological issues and agroecological transition of agri-food systems must be considered both at farm and territorial levels. Crop-livestock integration at both levels seems a promising avenue for building sustainable systems. In this study, we elaborate scenarios of agroecological transitions based on innovative crop-livestock synergies. We studied sheep integration into organic wines and cereals cropping systems in South-western France. We firstly assessed the technical potential for crop-livestock integration at a territorial level with a seasonal supply-demand model. Secondly, we designed acceptable future scenarios from real situation through a participative process and simulated them. These scenarios are related to climate change impact on resources, use of new fodder resources, and adaptation of animal requirements to fodder resources availability. Our results show that in heterogeneous landscape mosaic as it is the case here, sheep herds are fed with a wide range of resources, available in a complementary way throughout the seasons. Under climate change, current situation won't be sustainable due to insufficient fodder resources at certain critical times (in summer specifically). However, additional resources at territorial scale (legume fodder, rangeland, vineyard inter-row) could be used at different seasons to maintain or even increase the number of sheep bred. Moreover, transhumance during summer could decrease animal needs when fodder resources are missing and transhumance during winter could increase the number of sheep bred when the demand for weed control in the vineyard is high. Finally, we discuss brakes and levers resulting from the analysis to assess to what extent and in what terms this innovative initiative draws a model of agroecological transition of farming systems at territorial level.

Nutrient cycling and efficiency: a comparative flow analysis of meat and dairy sheep farming systemsF. Stark¹, N. Amposta², W. Nasri^{1,3}, M. Lamarque², S. Parisot², P. Salgado^{1,3} and E. González-García¹¹SELMET, Univ Montpellier, INRAE, CIRAD, L'Institut Agro, Montpellier, France, ²La Fage, INRAE, Roquefort-sur-Soulzon, France, ³CIRAD, UMR SELMET, Montpellier, France; fabien.stark@inrae.fr

Nutrient cycling and efficient use of resources are issues of concern for the future of sustainable livestock systems. A deep analysis of nutrient flows involved in the functioning of meat and dairy sheep farming systems (FS) was undertaken using the Ecological Network Analysis (ENA) method. Farm autonomy, efficiency and productivity performances were assessed. As part of the TrustFarm project (ERANET), the La Fage INRAE experimental farm (Aveyron, France) was the case studied. It is composed of two sub-systems comprising: (1) a dairy sheep flock (600 Lacaune ewes), under semi-intensive conditions and mostly fed with on-farm fodder; and (2) a meat flock (280 Romane ewes) extensively reared on rangelands and complemented in winter with on-farm fodder. A historical dataset (2015-2019) was used to represent nutrient flows (i.e. nitrogen, N) between FS components (i.e. flocks, feeds, effluents, crops, grasslands and rangeland). Outcomes on annual farm' balance revealed that internal N flows between components (excluding inputs, outputs and losses) are responsible for half of the nutrient cycling, which is mainly concerned by forage distribution, forage autonomy representing around 80%. In a counter-intuitive way, on-farm fodder distributed to meat flock covers almost half of requirements despite grazing on rangelands all year round. In the same line, dairy flock' N outputs are mostly determined by lamb exports, rather than milk production which is supposed to be the objective of dairy production (46 vs 14%). The farm' N use efficiency was 52%, with high variability between system components, meat flock presenting a better efficiency than dairy flock (139 vs 90%), whereas rangeland and effluent components showed the lowest values (23 and 43%). These preliminary results on nutrient balance provide a different, complementary approach to analyse performances at different scales of the FS. It contributes to deeper analyses of nutrient cycling aiming to adjust management practices for designing more sustainable and agroecological systems.

Session 31

Theatre 12

Pasture-based ruminants and biodiversity in contrasting contexts: an account of farmers' narrativesV.J. Oostvogels¹, B. Dumont², H.J. Nijland³, L. Allart², I.J.M. De Boer¹ and R. Ripoll-Bosch¹¹Wageningen University & Research, Animal Production Systems group, De Elst 1, 6708 WD Wageningen, the Netherlands,²Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Theix, 63122 Saint-Genès-Champanelle, France,³Hanneke J. Nijland Research & Consultancy – Antennae, Beeklaan 48, 6869 VH Heveadorp, the Netherlands; vincent.oostvogels@wur.nl

In debates about roles for pasture-based ruminants in sustainable food systems, biodiversity is a central theme. Different narratives occur as to how pasture-based ruminants and biodiversity relate and which courses of action should be taken. To arrive at effective and just solutions, it is essential to include in these debates the narratives of local stakeholders such as farmers. However, there is still little insight in their narratives, and how these may vary within and between individuals and areas, considering differences in socioecological context. Therefore, we conducted a study to unravel farmers' narratives in two contrasting areas with pasture-based dairy farming: an area in Massif Central in France and a fen peat area in the Netherlands. These areas differ, among others, in land use intensity, environmental conditions, and value chains. We followed a qualitative approach, based on interpretative analysis of 30 one-hour in-depth interviews (15 in each area). We encountered diverse and sometimes conflicting narratives, with different problem definitions and proposed ways forward. We found that these differences were grounded in underlying differences in biodiversity conceptualizations and values. The two areas showed similarities in the narratives' basic lines of reasoning. For instance, in both areas we encountered 'productivist' as well as 'post-productivist' narratives. Nevertheless, there were differences in the specific topics that were linked to the narratives. For example, in the Dutch area more links were made with religion, and in the French area with food culture. Our results highlight the pluralism and – on certain points – strong context-specificity in the encountered narratives. We argue that better understanding and inclusion of stakeholder's narratives, with more attention for this pluralism and context-specificity, can benefit the debate around biodiversity in pasture-based production.

Meat quality in Podolian young bulls grazing on wood-pasture in a South Italy marginal areaF. Giannico¹, S. Tarricone², A. Caputi Jambrenghi², L. Tedone², D. Campanile³ and M.A. Colonna²¹ University of Bari Aldo Moro, Department of Veterinary Medicine, Valenzano (BA), 70010, Italy, ²University of Bari Aldo Moro, Department of Soil, Plant and Food Sciences, Bari, 70125, Italy, ³Puglia Region, Department of Agriculture, Rural and Environmental Development, Bari, 70121, Italy; francesco.giannico@uniba.it

In dry marginal areas, pasture plays an important role in land preservation and wildfire prevention. The aim of the study was to evaluate meat production and quality in autochthonous Podolian young bulls grazing on spontaneous grass and wood-pasture vegetation in South Italy marginal areas. Sixteen Podolian male calves grazed with their dams until they were 10 months old (± 15 days). Afterwards, two groups of calves homogeneous for weight (310 ± 10 kg) were made. The control group (C) was kept in a loose barn with a straw-bedded resting area and an open exercise area with a total space allowance of $15 \text{ m}^2/\text{subject}$. They received a commercial feed (B/82 – Bovi mix, Galtieri, Italy; $6.0 \text{ kg/day/subject}$) and wheat straw (2 kg/day/subject). The second group grazed during the day on a spontaneous 10 ha wooded pasture (WP); at housing, in the evening, the calves received 2 kg/subject of the same commercial feed and straw *ad libitum*. Pasture availability and composition were monitored during the experiment and the nutritive value was assessed by *in vitro* gas production (IVGP). All the calves were slaughtered at 18 months of age. In WP bulls, the average daily gain (1.25 vs 0.95) and final weight (520 vs 485) were lower ($P < 0.05$) as compared with control. Grazing worsened meat colour in terms of lightness (32.8 vs 33.9) but it increased ($P < 0.05$) red (21.98 vs 20.87) and yellow (2.04 vs 1.96) indices. Meat from the WP group showed a lower cooking loss as compared to C bulls, while tenderness (WBS) was markedly lower ($P < 0.05$). The concentration of conjugated linoleic acid (CLA) in the Longissimus dorsi muscle was significantly higher in WP bulls (0.28 vs 0.18 ; $P < 0.05$). Results of the consumer test showed that although panellists detected differences in meat tenderness and chewiness, they recognized and tended to prefer ($P < 0.05$) meat from the WP bulls for its taste and flavour.

Poster 14

Good management of the pasture makes it possible to reduce the supplementation of autumn calves

D. Douhay

Institut de l'Elevage, Saône-et-Loire, La Prairie, 71250 Jalogny, France; jeremy.douhay@idele.fr

The production of weanlings born in the fall, a practice not very widespread in the Charolais suckling area, was set up at FERM'INOV, the experimental farm of Jalogny in Saône-et-Loire as part of a system study aimed at producing heavy lean males of 400-420 kg live at destined for the Italian market during low production period (June-July). To meet this commercial objective, experimental work aims to determine the optimal level of supplementation under the mother and to study the impact of good spring grazing management on the growth of calves until weaning. The growth target is $1,400 \text{ g/d}$ between birth and sale. The latest round of work conducted in 2020/2021 shows promising results. On average, over the 'birth-sale' period, the average daily gain levels of the two groups of calves of around $1,550 \text{ g/d}$ are not different and are above the growth target. The group not supplemented on pasture was weaned 15 days later to ensure an identical selling weight between the two groups. The absence of supplementation on pasture allows a saving of 100 kg of concentrates per calf, i.e. around $\text{€}25/\text{calf}$ for a feed price of between $\text{€}250$ and $\text{€}270/\text{T}$ (2021 economic situation). Weaning and sale are deferred for 15 days with no impact on the selling price per kg of weanling ($\text{€}2.7/\text{kg}$ live for the two groups of calves). In 2021 grazing conditions, a difference in the feed cost margin of $\text{€}41/\text{grazing}$ in favour of the group not supplemented with grazing is observed. A winter supplement of 1 kg of concentrates per 100 kg of live weight is sufficient to produce weanlings born in the fall of 400 kg of live weight at weaning at the end of June, when the feeding of suckler cows allows the expression of their full dairy potential. In the spring, optimized rotational grazing management, with control of grass heights at each entry and exit from the plot, has a positive impact on the growth performance of calves that do not need to be supplemented. It allows a gain of autonomy and a saving of work related to the distribution of the concentrates.

Investigating the effects of lactation number, stage, and milking interval on nitrogen use efficiency

Y.M. Hu

Gembloux Agro-Bio Tech (GxABT)/ University of Liège, Precision Livestock and Nutrition, Passage des Déportés, 2, 5030 Gembloux, Belgium; yumei.hu@student.uliege.be

Nitrogen use efficiency (NUE) is considered one of the most important indicators of ruminant feed utilization. The objective of this study was to describe the relationship of NUE with lactation number, stage, and milking interval in Holstein dairy cows using an automatic milking system. Data was collected between May 2021 and June 2022 from a dairy farm equipped with an automated milking system (AMS), with a total of 466 dairy cows (260 primiparous cows and 206 multiparous cows). The AMS management system recorded the date and time of milking during the 24 h, and the milk yield of each cow as measured by the milk meters installed on each AMS unit. AMS concentration intake was recorded at each milking and the partial mixed ration (PMR) was recorded every day. Compared with primiparous cows, the multiparous cows had higher NUE, AMS concentration N intake, PMR N intake, and Milk N ($P<0.001$). In contrast, Manure N was higher in primiparous cows ($P<0.001$). There were significant differences were found in the NUE ($P<0.001$) between different lactation stages, and cows in DIM 0 to 100 days has the highest NUE (31.74%). The milking frequency had a significant influence on NUE ($P<0.001$). Meanwhile the NUE of cows increases with milking frequency and is most frequent between the milking intervals of 7 to 12 hours. We recorded the highest NUE with the multiple parties, in the early lactation stage (DIM 0 to 100 days) at a $3\times$ milking frequency/d. Overall, detailed knowledge of these factors associated with increasing NUE using AMS, such as lactation number, stage, and milking interval, will help guide future recommendations to producers for maximizing NUE in the dairy industry.

Poster 16

Plasma urea and diet crude protein concentration relationship in grazing dairy cows

R. Delagarde and N. Edouard

PEGASE, INRAE, Institut Agro, 16 Le Clos, 35590 Saint-Gilles, France; remy.delagarde@inrae.fr

It is well known that plasma urea (PU, mg/dl) is a good indicator of protein status in dairy cows fed conserved forages, and also that this relationship may differ between conserved forages and fresh herbage. The objective of this study was to relate plasma urea of grazing dairy cows to herbage, supplements, diet, grazing and cows characteristics. A dataset of 8 experiments carried out between 1993 and 2014, in which herbage intake was measured individually, was used. Herbage intake was measured from the faecal output (Cr_2O_3 or Yb_2O_3)/faecal index (N and ADF) method, or by the n-alkanes method. Diet crude protein (CP) concentration (dietCP, g/kg DM) was determined from measured intake and CP concentration of each feed, including grazed herbage. Supplements (conserved forages and/or concentrates) represented 12% of the diet (0 to 34%). Multiple regression analyses including cows, feeds, diet and grazing variables, either with individual cow $\times$ period data ($n=709$), or with data averaged per herd and period ($n=114$), showed that dietCP explained almost all the PU variability. Addition of cows (weight, milk production, daily DM intake), supplements (amount, nature, proportion of diet), or pasture and grazing (fibre concentration, digestibility, sward height, herbage allowance, daily access time to pasture) characteristics did not improve the model. Plasma urea and dietCP averaged 21 mg/dl (6 to 43) and 171 g/kg DM (106 to 246), respectively. At herd level, PU may thus be predicted from dietCP only: $\text{PU} = 0.236 \text{ dietCP} - 20$, $R^2=0.82$, $\text{s.d.}=3.8$. This equation means that any increase of 10 mg/dl of PU originates from an increase of 42 g CP/kg DM of the diet. Plasma urea may also be used as an indicator of dietCP, with $\text{dietCP} = 3.47 \text{ PU} + 99$, $R^2=0.82$, $\text{s.d.}=14.6$. This equation suggests a total urea recycling when dietCP is close to 100 g/kg DM, with no more urea in plasma. When measured simultaneously in the morning before feeding, PU and milk urea were strongly correlated, with a slope of one and an origin of zero. It is concluded that plasma urea or milk urea may be good indicators of diet crude protein concentration in grazing dairy cows, and vice versa.

An assessment of woody forage resources indigenous to southern Africa

M. Trytsman¹, F.L. Müller¹, M.I. Samuels¹, C.F. Cupido¹ and A.E. Van Wyk²

¹Agricultural Research Council, Animal Production: Range and Forage Sciences, Private Bag X2, 0062 Irene, South Africa, ²University of Pretoria, Department of Plant and Soil Sciences, Private Bag X20, 0028 Hatfield, South Africa; mtrytsman@arc.agric.za

The South African National Forage Genebank (SA-NFG) mandated to identify, collect, conserve, and evaluate important indigenous forage genetic resources, initiated a project to identify valuable indigenous South African woody (trees and shrubs) forages. To date, a total of 722 species and infraspecific taxa from 76 families have been recorded, which were statistically grouped into seven distinct phytochoria with clear geographical patterns. The aim of this work was to prioritize woody species within each phytochorion, based on relevant forage attributes documented in, among others, scientific publications and textbooks. These include identifying key families and species, functional traits (degree of deciduousness, seed-bearing structure, and growth form), utilization by game and livestock (plant part and browser type), nutritive values (crude protein, ADF and NDF), and the presence of secondary compounds. Preliminary findings show that Asteraceae and Leguminosae are important families, the former mostly in the Succulent Karoo Biome and the latter in the Savanna Biome. Furthermore, Leguminosae contains the most species with crude protein values higher than 7%, however, contains many species with relatively high condensed tannin levels. This browse forage database, together with the Leguminosae and Poaceae databases, will continuously be updated, and accessed by the SA-NFG for collection, conservation, screening, and characterization strategies of these indigenous forage genetic resources.

Poster 18

The Effect of heterofermentative lactic acid bacteria on quality of King Napier grass

P. Lounglawan

Suranaree University of Technology, School of Animal Technology and Innovation, Suranaree University of Technology, Nakhon Ratchasima, Thailand, 30000, 30000, Thailand; pipat@sut.ac.th

This research aimed to study the chemical change of Napier grass (*Pennisetum purpureum* × *Pennisetum americanum*) silage after using lactic acid producing bacteria in heterofermentative lactic acid bacteria group. The experiment aims to select the type of Heterofermentative lactic acid bacteria suitable for Napier grass silage. The results showed that *L. buchneri* at the level of 1×10^6 cfu/g of fresh forage resulted in the higher acetic acid content of Napier grass silage than other bacteria. However, the use of this bacterium was found to negatively affect the quality of Napier grass silage. In addition, the use of *P. pentosaceus* at 1×10^6 cfu/g of fresh forage gave the fermentation plants a higher lactic acid content than those of other bacteria.

Grass chemical composition to predict methane production from grazing sheep at high latitude

Q. Lardy^{1,2}, M. Hetta¹, M. Ramin¹ and V. Lind²

¹Swedish University of Agricultural Sciences, Department of Animal Nutrition and Management, SLU, Umea, Sweden,

²Norwegian Institute of Bioeconomy Research, Department of Grassland and Livestock, NIBIO, Steinkjer, Norway; marten.hetta@slu.se

Our study aimed to investigate the effects of seasonal changes in the chemical composition of temperate pasture and their impact on the potential enteric methane (CH₄) production in grazing sheep. The cultivated pasture was located 100 km south of the arctic circle. The experimental periods represent contrasting vegetative conditions under a Norwegian conditions. The month of July is used to produce silage while the animals are in the mountain grazing and august is usually dedicated to grazing to finish the lambs. Twelve grass samples were collected with an automatic clipping machine, then dried, grinded and pooled together every two days during 10 days at each period. The five samples per period were analysed by NIRS for chemical composition and incubated for 48 hours using the automated *in vitro* gas production technique for estimating *in vivo* CH₄ production from ruminants. The average pasture height was 13.5±1.4 cm in July and 28.5±3.23 cm in August. The chemical composition (g/kg DM) of the pasture for July and August, respectively, was CP 104±4.1 and 150±5.7; NDF 572±20.5 and 501±5.5; sugar 209±20.1 and 183±10.9; OM 930±1.3 and 918±1.1. The estimated potential *in vivo* CH₄ production of the grass were significantly higher in July (34.6±2.19 ml CH₄/g DM) than in August (31.0±1.02 ml CH₄/g DM). Organic matter (3.19; 0.77), NDF (0.60; 0.59) and sugar content of the grass (0.48; 0.61) have a positive impact on the potential CH₄ production (coefficient; r²). On the other hand, CP (-0.77; 0.59) had a negative correlation with the potential CH₄ production. We observed a difference in chemical composition and nutritive values of the grasses between the two periods. Our findings suggest that the chemical composition of the herbage in combination with recordings with the automated *in vitro* gas production technique may be useful tools to predict enteric CH₄ production from grazing sheep. However, estimates of herbage intake is needed to quantify the CH₄ emission from the grazing animals.

Session 31

Poster 20

Forage height of native grasslands as an indicator of spatial and temporal grazing management

P. Aparicio, I. Paparamborda and P. Soca

Universidad de la República, Faculty of Agronomy, Animal Production and Pastures, Av. E Garzón 780, 12900, Sayago, Montevideo, Uruguay; patriciaam@live.com

In the Pampa Biome, cow-calf systems on native grasslands are pivotal in giving competitiveness to the meat chain, providing ecosystem services and biodiversity conservation. Campos grasslands are composed of C4 species; therefore, there is a period of forage production and another utilization. We postulate that forage height in autumn, winter and spring, together with its intrafarm variability, is an indicator of spatial and temporal grazing management. Our study aimed to quantify the forage height of the native grasslands, forage allowance and the Body Condition Score (BCS) of cows in production systems of the Sierras del Este region in Uruguay. In 8 cow-calf systems during the period March 2021- March 2022, forage height (cm), forage mass (kg DM/ha), and forage allowance (kg DM/kg BW) was measured every 30 days, and BCS was quantified four times during the year. The study cases were selected in a paired manner considering grazing intensity, available resources, soil types and location. In this way, 2 groups were formed (G1 and G2), one of moderate and the other of low grazing intensity. With a matrix of dimensions 92×6 made up of monthly records of height (cm), stocking rate (kg PV/ha) and forage supply (kg DM/kg PV) for each of the 7 systems, an analysis of variance was carried out considering the categorical variable. Explanatory to the grazing intensity group to which it corresponded and to the other variables as a response. For body condition, a database with 570 records was used at 3 important moments and the same procedure was applied as for the other variables. In this analysis, G1 presents an average forage height of 5 +1.4 cm of deviation, a stocking rate of 327±45.0 kg PV/ha and 5+0.8 points of BCS. Instead, G2 had an average height of 6+1.4 cm, a load of 354±45.5 kg PV/ha and 5.2±0.7 BCS points. The forage height has a significant effect on the formation of groups with a *P*-value of 0.01, the same as the BCS. The stocking rate affects significantly with a *P*-value of 0.01. These differences between G1 and G2 would be indicating that the spatio-temporal management of the grazing intensity would improve the forage stock and the body condition of the herd.

Improve the efficiency of fattening grazing sheep on rangeland by supplementary feeding

Y. Zhang and M. Xu

China Agricultural University, 2 Yuan Ming Yuan Xilu, Beijing, 100193, China, P.R.; zhangyj@cau.edu.cn

We performed an experiment to investigate the efficiency improvement of fattening sheep grazing on open rangeland. This experiment was set as a factorial design with two factors (grazing intensity and supplement feeding level). Grazing intensity has two levels: 80% (heavy) and 40% (moderate) of grassland utilization. Supplementary feeding included no supplementation low supplementation (1% of body weight), and high supplementation (2% of body weight). This experiment was conducted at the Tenihe Ranch in Inner Mongolia, China (49°26'47"N, 120°9'30"E). Our results showed that low levels of supplementary feeding increased intake of *Leymus chinensis* and *Artemisia tanacetifolia*, but decreased selectivity by high levels of supplementary feeding. Grazing intensity decreased the sheep intake of organic matter, crude protein, NDF and ADF. Dry matter intake was increased by supplementary feeding. For example, compared with no supplementation low and high supplementary feeding increased dry matter intake by 214.53 and 325.82 g/d, respectively. There was a significant positive correlation between the levels of concentrate supplementation and dry matter intake of sheep, with regression equations of $DMI = 0.743 \times Sup + 895.38$, $R^2=0.547$. Grazing intensity decreased dry matter intake by 135.23 g/d. Grassland livestock productivity increased with increasing grazing intensity and supplementary feeding levels. For instance, livestock productivity was increased by 46.89 and 107.57 kg/ha, respectively with low and high levels of supplementary feeding. Grazing intensity increased livestock productivity by 110.28 kg/ha. Feeding conversion rate reached 8.45 ± 1.49 , 10.73 ± 2.18 and $13.97 \pm 3.28\%$, respectively, for the no, low and high feeding supplementary levels. Organic matter digestibility and crude protein digestibility was significantly increased with increasing levels of supplementary feeding, while NDF and ADF digestibility was decreased. Low and high supplementary feeding decreased methane emissions per unit of sheep weight gain by 26 and 48%, and methane emissions per unit of digestible organic matter intake by 24 and 34%, respectively. In conclusion, supplementary feeding can improve sheep fattening efficiency and decrease greenhouse gases emission.

Session 31

Poster 22

The use of sheep of native breeds in the control of invasive plants

M. Pasternak, M. Puchala, J. Sikora and A. Kawęcka

National Research Institute of Animal Production, Department of Sheep and Goat Breeding, 2 Sarego Street, 31-047 Kraków, Poland; michal.puchala@iz.edu.pl

Sheep grazing can be used to care for valuable natural landscapes and help maintain the specific nature of ecosystems and biodiversity of wild species. In addition to the protective function, it can also be used to combat and limit the expansion of invasive plants. An invasive species is an alien species whose introduction causes a threat to local biodiversity and human management. There are many species of invasive plants in Poland, including *Heracleum sosnowskyi* and *Solidago canadensis* L. These plants have a negative impact on the environment by transforming natural habitats and displacing native species as a result of competition or limiting the food base. They also cause economic damage and may be dangerous for human and animal health. None of the chemical and mechanical methods of control is fully effective, therefore an attempt was made to use native sheep grazing for these purposes. The Department of Sheep and Goat Breeding of the National Research Institute of Animal Production in Balice participates in the implementation of the Norwegian project entitled 'The use of sheep grazing to reduce the occurrence of invasive plants'. The project is financed from the European Economic Area Financial Mechanism under the 'Environment, Energy and Climate Change' Program. The activities include sheep grazing in two locations: Ojców National Park (30 ewes of Olkuska sheep, reducing Canadian goldenrod) and Cieszyńskie Źródła Tufowe (30 ewes of Polish Pogórza sheep, reducing *Heracleum sosnowskyi*), both are the area of Natura 2000. Two rounds of grazing, approximately one month long, were carried out in May and July, separated by the period needed for the regrowth of the pasture sward. Sheep were on the pasture 24 hours a day. After the first year of the experiment, better results were found in the case of fighting goldenrod, which was very eagerly eaten by sheep. In the case of hogweed, the intended effect was not achieved, which was probably due to the late start of grazing. The stems were too hard and reluctantly eaten by the sheep. In the next year of the experiment, it is planned to modify the date of the first grazing and repeat the botanical inventory, which will allow to assess the effects obtained.

Post-rumen health and its implications on health and performance*M.V. Sanz-Fernandez**Trouw Nutrition R&D, P.O. Box 299, 3800 AG Amersfoort, the Netherlands; victoria.sanz-fernandez@trouwnutrition.com*

The gastrointestinal (GI) tract is a highly sensitive organ that can be negatively impacted by multiple factors during the productive cycle of cows. Diet management and characteristics, feed deprivation, local and systemic inflammation, and psychological and environmental stress, can all disrupt the barrier function. Further, several of these factors occur simultaneously at specific times, like around dry-off and calving. In healthy conditions, the GI barrier function maintains a regulated separation between the luminal content and the host. However, when disrupted, material from the lumen infiltrates through the enterocyte lining resulting in hyperpermeability or leaky gut. In this context, luminal content of the GI tract becomes a source of inflammatory stimuli and contributes to systemic immune activation. Inflammation constitutes an animal welfare issue, as well as an economic burden for producers, as it diverts nutrient and energy resources away from production toward the immune cells. Further, immune activation might play a role in metabolic maladaptation during the transition period, as an enhanced inflammatory status has been associated with an increased incidence of metabolic diseases. In cattle, rumen health has received the most attention in the context of subacute ruminal acidosis, however, it is increasingly evident that other sections of the GI tract can be negatively affected by similar factors. For instance, the lactation ration is associated with a large fraction of bypass starch that can induce hindgut acidosis. Despite acidosis developing similarly in both the rumen and the hindgut, the latter might be more vulnerable based on its structure, buffer capacity and immunity. It has been demonstrated that inducing hindgut acidosis independently of the rumen results in leaky gut with systemic consequences. Further, nutritional strategies intended to improve hindgut health improve performance, demonstrating that the energetic cost of poor hindgut health is diverting resources away from productivity.

Session 32

Theatre 2

Impacts of inflammation and inflammatory diseases on reproduction in dairy cows*J.E.P. Santos**University of Florida, Animal Sciences, 2250 Shealy Drive, Gainesville, FL 32611, USA; jepsantos@ufl.edu*

Calving and the onset of lactation are associated with increased risk of diseases, many of which are linked with inflammatory responses. Approximately 30 to 35% of the dairy cows develop at least one clinical disease in the first month of lactation, and postpartum diseases often result in local as well as systemic signs of inflammation. A conserved mechanism during disease is suppression of appetite, presumably to attenuate the inflammatory response; however, acute inflammatory diseases also alter the partition of nutrients with increased used by immune cells and the hepatic tissue for immune activation and the acute phase response. Collectively, inflammatory processes further exacerbate the negative nutrient balance dairy cows experience in early lactation, and the degree of negative nutrient balance is linked with the ability of the cow to resume oestrous cyclicity and become pregnant. Nevertheless, inflammation and inflammatory mediators have direct effects on oocyte competence, granulosa cell function, follicle development, the uterine environment, and on embryo and conceptus development that ultimately compromise the establishment and maintenance of pregnancy in dairy cattle. Pathogens that colonize the reproductive tract damage the superficial and glandular epithelia and increase the expression of inflammatory genes, and endometrial inflammation alters the composition of the uterine histotroph and disrupt conceptus development. Cows that develop uterine diseases have reduced fertilization, compromised early embryo development, impaired conceptus elongation, and increased risk of pregnancy loss. Inducing endometritis in cows promoted an acute phase response with increased concentrations of haptoglobin, suppressed appetite, and transiently reduced milk yield. Conceptuses from cows subjected to induced endometritis synthesized less interferon tau and had molecular signatures compatible with inflammation and reduced anabolic pathways needed for cell proliferation. Induced endometritis resulted in endometrial changes with reduced presence of immune cells required for tolerance to conceptus alloantigens. Diseases and the resulting inflammatory responses compromise nutrient balance and result in systemic and localized responses that compromise reproduction in dairy cows.

The role of mycotoxins in the rumen and intestinal health of dairy cows

A. Gallo

Università Cattolica del Sacro Cuore, Department of Animal Science, Food and Nutrition – DIANA, Via E. Parmense 84, 29122, Italy; antonio.gallo@unicatt.it

With an increased knowledge of the mechanism of action of mycotoxins, the concept that these substances are deleterious only for monogastric species is obsolete. Indeed, most mycotoxins can be converted into less toxic compounds by the rumen microflora of healthy animals. However, mycotoxin absorption and its conversion to more toxic metabolites, as well as their impact on rumen and intestinal functionality, immune response and subsequently animal welfare, reproductive function, and milk quality, during chronic exposure should not be neglected. Among the Fusarium-produced mycotoxins, the most studied are deoxynivalenol (DON), zearalenone (ZEN), and fumonisins from the B class (FB). Further, a lot of emerging mycotoxin can be detected in feed used in ruminant diets, including stored forage, and they are starting to be studied by scientific community. Anyway, it is remarkable that there is a paucity of *in vivo* researches, with a low number of studies on nutrient digestibility and impact of these substances on rumen and intestinal function. Moreover, most of the *in vitro* studies are related to the reproductive function or are restricted to rumen incubation. When evaluating the production performance, milk yield is used as an evaluated parameter, but its quality for cheese production is often overlooked. Here, the most recent findings regarding the adverse effects of these mycotoxins on dairy cattle are presented, with special attention to their performance and the effects of mycotoxin on rumen and intestinal functionality.

Session 32

Theatre 4

Absorption, metabolism and secretion of tocopherol (vitamin E) stereoisomers in dairy cows

S.K. Jensen and S. Lashkari

Aarhus University, Department of Animal and Veterinary Sciences, Blichers Alle 20, 8830 Tjele, Denmark; skj@anivet.au.dk

Tocopherols (Toc) in cattle feed are often a combination of synthetic Toc (all-rac- α -Toc) from vitamin supplements and natural tocopherols (RRR- α -Toc) and tocotrienols (T-3) from the feed. Among different stereoisomers of all-rac- α -Toc, RRR- α -Toc has the highest biological activity. Pre-absorption metabolism of Toc and T-3 in ruminants differs from monogastrics due to the extensive microbial fermentation in the anaerobic rumen. Two experiments were conducted. The first study examined ruminal metabolism and intestinal digestibility of Toc and T-3 in four ruminal and intestinal cannulated Danish Holstein cows. Cows were fed a TMR consisting of oat, fava beans, grass silage and a mineral/vitamin mixture with all-rac- α -Toc acetate. This gave a daily intake of 1,862 mg total α -Toc (819 mg natural α -Toc and 1,043 mg all-rac- α -Toc), 63 mg α -T-3 and 224 mg γ -Toc. Total α -Toc (102, mg/day) and synthetic α -Toc (279 mg/day) was degraded in the rumen, in contrast RRR- α -Toc was formed in the rumen (221 mg/day). The small intestinal and feed-ileum digestibility ranked in the following order: RRR > synthetic 2R > 2S- α -Toc. Results showed the first evidence for RRR- α -Toc formation under anaerobic condition in rumen. In addition, synthetic α -Toc stereoisomers, γ -Toc and α -T-3 were degraded in the rumen, and small intestinal absorption seems to favour of RRR- α -Toc absorption. The second experiment studied the pharmacokinetics of stereoisomers of all-rac- α -Toc and investigated the discrimination and distribution of α -Toc stereoisomers in plasma and milk as well as quantitative secretion into milk with lactating Holstein cows after a single intramuscular injection of 2.50 g of all-rac- α -Toc acetate. The highest half-life (2.92/h) and lowest elimination rate (0.36/h) were found for RRR- α -Toc. Highest maximal daily increase (8.36 mg/day) and accumulated secretion (50.8 mg) were observed for milk RRR- α -Toc. The majority of the 2S stereoisomers was found in the liver 36 h post injection, while the 2R stereoisomers were more equally distributed between liver and plasma. The present findings showed a clear discrimination between RRR- α -Toc, synthetic 2R stereoisomers and 2S stereoisomers in milk and plasma of dairy cows.

The role of rumen health (acetate) on milk fat synthesis and dietary strategies to increase milk fat*K.J. Harvatine and C. Matamoros**Penn State University, Department of Animal Science, University Park, PA 16802, USA; kjh182@psu.edu*

Major advances have been made over the past 25 years in our understanding of milk fat synthesis. Nutritionally, milk fat depression (MFD) can decrease milk fat by up to 50% and garnered most of the research interest for years. Bioactive intermediates of ruminal fatty acid biohydrogenation were identified as the causative factor and provided insight into the regulation of mammary lipogenesis and led to targeted approaches to manage milk fat. Large changes in milk fat are undoubtedly due to these bioactives, but recent work has shown that other nutritional factors can have smaller impacts on milk fat and are economically important. Milk fat synthesis requires acetate as a source of carbon and reducing equivalents. We initially ruminally infused acetate to investigate the effect of acetate spared during MFD on adipose tissue metabolism and observed an unexpected increase in milk fat yield. We then conducted a dose titration experiment and observed a maximal response of 220 g of milk fat with a ruminal infusion of 600 g of acetate. The increase in milk fat has also been observed when feeding sodium acetate in a total mixed ration. The response has been consistent, and further experiments have found no interaction with dietary starch, fibre digestibility, or unsaturated fatty acids despite the potential for these factors to change rumen fermentation. Acetate also did not interact with *trans*-10, *cis*-12 CLA, indicating that the mechanism is likely independent of bioactive FA that cause MFD. It is still unclear if acetate increases milk fat simply by increasing substrate to the mammary gland or if it increases metabolic capacity by changing cellular physiology. Although sodium acetate supplementation is not practical, this work highlights the importance of fibre digestibility and maintaining optimal rumen function. Genetic selection is increasing the potential for milk fat synthesis and acetate supply will likely be increasingly important to meet genetic potential. Thus, maximizing milk fat yield requires not just minimizing MFD, but also optimizing acetate supply and other dietary and management factors.

Theatre 1

EUNetHorse-European network to improve the resilience and the performance of equine farms*M. Addes**French Horse and Riding Institute, La Jumenterie du Pin, 61310 Exmes, France; marlene.addes@ifce.fr*

The overall objective of EUNetHorse is to establish an active multi-stakeholder network in France, Portugal, Spain, Belgium, Germany, Romania, Poland, and Finland, in order to increase the resilience and performance of their equine farms to face environmental, social, health, economic or political crises by widely disseminating practices, tools and solutions that improve (1) their resilience and socio-economic performance, (2) animal welfare and health on farms, and (3) the environmental sustainability of the sector. To achieve this, EUNetHorse will: (1) increase the flow of practical information between farmers in these 8 countries in a geographically balanced way and taking into account the differences between territories by structuring National- Horse AKISSs in each country; (2) collect and assess grassroots solutions and practices, disseminate best practices and solutions on the three thematic areas mentioned above replying to specific needs; (3) achieve a greater user acceptance of the collected solutions and best practices, through cross-fertilisation between all actors of the sector (horse breeders, advisors, trainers, technical experts, scientists, policy makers, sector representatives, etc.) and all levels (local, regional, national and European), during exchange activities allowing peer-to-peer learning, such as workshops, demonstration days, training and cross visits; (4) maintain the practical knowledge in the long term – beyond the project period – by sharing the full set of project results on the EUFarmbook platform accessible to all, by training advisors and trainers during the project on these topics, by setting up a sustainable network of trainers and advisors who can continue to train equine farmers and disseminate these solutions using the training kit made available through their activities with equine farmers.

Robustness of equine business structures and global coherence*S. Boyer**IDELE, Route de troche, 19230 Arnac Pompadour, France; sophie.boyer-lafaurie@idele.fr*

Whatever the hazards encountered by farm operators, whether external to the farm (health crisis) or internal to the operation (health problems), some always manage to bounce back and maintain good economic results. We advance the idea that beyond the techno-economic results and the skills of the farm operator, the robustness of the operation lies in the human dimension. It is the interpersonal skills, the ability to listen and to challenge oneself, to have the courage to make those changes which will enable a farm operator to develop his/her operation in such a way as it remains consistent with his/her values and resources. Our study combined an analysis of the technical and economic data of 87 equine business structures, which had been monitored within the Equine Network, and ten surveys, referred to as 'trajectory analysis', exploring the way farm operators had implemented the sociological dimension in the running of their operations. The ten qualitative surveys were conducted in France: four in riding schools, five in livery stables and one in a horse farm. The aim of these semi-structured interviews was to identify the levers used to overcome any difficulties which may have been encountered. Six main types of levers were identified: knowledge, know-how, interpersonal skills, strategic elements, available resources, and finally professional and personal objectives and values. We will present these results in the form of an allegory. The levers are represented as a living and ever-growing plant: the flowers symbolizing knowledge; the leaves, the means; the roots, the resources; the stem, the strategy and the objectives of the operator, all of which is nourished by the soil which represents the values. We will present a synthetic analysis of the trajectories analysed, highlighting the importance of the ability to react to hazards, to grow one's business in such a way as it is always in line with one's aspirations. These initial results provide us with a wealth of information and would appear to be particularly useful, for future equine project leaders and for established farm operators undergoing a transitional period and who need to give new-found meaning to their project. Before presenting these results, a short overview will be given of the French equine systems covered in this study.

Session 33

Theatre 3

The equine network, a tool for horse professionals, advisors and teachers*G. Mathieu**Institut de l'élevage, 149 rue de Bercy, 75012 PARIS, France; guillaume.mathieu@idele.fr*

The Equine Network is a French partnership between the livestock Institute, the Chambers of Agriculture, the French Institute for Horse and Riding and the Federation of Horse Councils. It is based on the INOSYS livestock network method. The Equine Network provides technical and economics guides and tools for advice and planning. All of these tools are intended for experts, advisors, horse professionals, institutional decision-makers, teachers and students. In total, 130 organizations are monitored, representing the different equine sectors: riding schools, equestrian tourism centers, boarding stables, trotter equine stables, draught horse breeders, horse drafting providers. To that, additional organizations on specific and least well-known activities such as mare's milk, shared stables or innovative stables are monitored. In the 130 organizations, technical, economic, environmental and social data are collected. The collected data is analysed and used to produce various supports with dashboards, technical and economic summaries, typical cases, and books. The network aim is to understand the operating logic of each of the farming systems that are monitored. These results can be used in the field to help installing a new horse professional, to have references to compare economic results, to improve horse professional practices and to obtain economic data that decision makers can rely on.

Does the diversity of the French territories impact farms keeping equines?*J. Veslot and G. Bigot**INRAE, UMR Territoires, 9 avenue Blaise Pascal, 63170 Aubière, France; jacques.veslot@inrae.fr*

In spite of professional and institutional databases on French horse activities, it remains difficult to have a national panorama of this industry, and its specificities according to the diversity of territories. To answer this question, we analysed the French Farm Structural Survey (FSS), where more than 54,000 farms with equines in 2010 kept almost half of the national herd. This study resulted in a typology of equine herds in farms, using herd size, type of breeds (warmblood, coldblood and donkeys) and the presence of mares, and resulting in 18 groups (8 'specialized' structures, and 10 groups with very small herds). A clustering of the 90 French departments (areas equivalent to European NUTS3) was carried out using numbers of farms in these 18 groups, leading to 9 types of areas with different local characteristics of horse keeping. The density of farms and predominant equine types raised, differed largely between regions according to altitude, the importance of grassland in agricultural area and the presence of large cities (more than 150,000 inhabitants). For example, 'Manche' (in Normandy) and 'Pyrénées Atlantiques' presented both high densities of farms with equines, but differed in their predominant type of breed: warmblood in Manche and coldblood in Pyrénées Atlantiques. The analysis also highlighted noticeable patterns: most areas in uplands (Pyrénées, Massif Central, Vosges) with a medium density of farms and mainly coldblood horses; and clusters of areas in lowlands, mainly located in the centre and in the South-East of France, with low densities of farms with equines. This classification of territories based on the diversity of farms keeping equines could be interesting for future studies on the territorial impacts of changes in the horse industry.

Session 33

Theatre 5

Equestrian practitioners: essential services to support self-organization*C. Eslan^{1,2,3}, C. Vial^{2,3} and S. Costa³**¹FFE, Parc fédéral, 41600 Lamotte-Beuvron, France, ²IFCE, Pôle Développement Innovation et Recherche, La jumenterie, 61310 Exmes, France, ³INRAE, MoISA, Place Viala, 34000, France; celine.vial@ifce.fr*

Sporting practices are increasingly breaking away from the federal model, leading to a shift from clubs to more independent organizations. Consequently, since the 1990s, self-organized people have been steadily turning towards private service providers for support. A wide range of services is on offer: initiation, teaching, rental, training or even advice. The French equestrian sector is mainly organized around professional structures such as riding schools or livery stables. Nevertheless, it is facing a decrease in the number of federal memberships and an increase in independent practices. Consequently, the French equine industry is interested in people who organize themselves to take care of their equines outside professional structures. They are often located on the outskirts of cities or in rural areas even though the service offer is a fortiori closer to densely populated areas. Based on these observations, our research analyses the service needs of self-organized equestrian users for the practice of their sport and the daily management of their horses. A quantitative online survey conducted in 2021 among self-organized equestrian users shows that needs for services differ according to the type of organization. Nevertheless, more than a quarter of the respondents have difficulties finding service providers adapted to their needs (19%), and advice (9%). Advice or training on agricultural issues, access to large machinery such as a rotary slasher or to products for the maintenance of land seem essential for 17% of the self-organized people. Still, they do not have these services available. 41% of them find arrangements with neighbouring farmers. For the practice of their sport, self-organized equestrian users do not find coaches who meet their expectations. Respondents who value more than everything else the luxury of having their horses close to home cannot entertain the idea of renewing membership in a club-like structure. These results show the importance of adapting the offer of services to the needs of self-organized equestrian users. Moreover, the development of this market can be instrumental in the sustainable development of rural and suburban areas.

Agricultural animal traction in France: characterization of the practice and its usersM.M. Miara¹, M.G. Gafsi² and P.B. Boudes³¹INET, 17, cours Xavier Arnoz, 33000 Bordeaux, France, ²LISST, 5 All. Antonio Machado, 31100 Toulouse, France,³ESO, 65 Rue de Saint-Brieux, 35000 Rennes, France; maurice.miara@gmail.com

Faced with the challenges that emerge in our modern societies, many injunctions to achieve the agro-ecological transition and the energy transition are being raised. Animal traction seems to meet these two objectives and is benefiting from an emerging dynamic in France with an increase in the use of working equids, whether in communities, in the forest, or in agriculture. However, despite its growth, this practice remains little studied and its characterization remains unclear. From this perspective, our study aims to understand what is animal traction in agriculture in France, who are its users, what are its networks and how it is mobilized in practice. To answer our questions, we used an interview methodology to question the practice in the field. Thus, 32 semi-directive surveys were conducted with users of animal traction in France during the year 2022. 16 market gardeners, 10 wine growers, 4 nurserymen and 2 cereal growers were interviewed. Our paper will detail the profile of these users and their farms through a sociological analysis. Thus, our analysis enabled us to understand the life paths of animal traction users, as well as the motivations that led them to this practice. Our study enabled us to characterize the practice and the farms that use it by identifying farmer typologies and associated farm management strategies. Thus, the farms are oriented towards autonomy and short circuits, on relatively small surfaces and a high added value per hectare. Motivations for using animal traction vary according to the respondents. We find passion for the horse, political choice, or technical interest as the main modality. There is a high proportion of neo-rural users, but a significant proportion have a family link to agriculture and horses. Although heterogeneous, animal traction is part of a redesign of agriculture, a societal paradigm shift, where the animal has a central place in the peasant project carried out by these farmers.

Theatre 7

Effects of milking interval and frequency on milk yield in the mare

J. Auclair-Ronzaud, M. Bouchet, L. Laschon, E. Lambolez and L. Wimmel

IFCE – Plateau Technique de Chamberet, 1 Impasse des Haras, 19370 Chamberet, France; juliette.auclair-ronzaud@ifce.fr

Mare milk production is expending in France but practices vary widely from one farm to another, especially due to the lack of technical information provided to the producers. This study aims to explore the effect of milking interval and frequency on milk yield. Twenty-three mares were studied with a mean age of 9.6 ± 4.2 years old. Mares and foals were kept in group in pasture and were weighed every two weeks. Two groups were studied, a group of 13 mares milked once (1M) with 5 primiparous and 8 multiparous, and a group of 10 mares milked twice (2M) with 3 primiparous and 7 multiparous. Milking protocol was performed at week 5, 9 and 13 of lactation. These weeks, mares were milked during 5 consecutive days according to the following procedure. At 8:30, foals were equipped with muzzle to prevent them from suckling. After one hour, 2M mares were milked for the first time. Then, two hours from the muzzling of the foals, 2M mares were milked a second time, and 1M mares were milked. Milkings were performed using a manual milker, starting by the right udder. For each udder, collected milked was weighed. The effect of mare parity, age and weight, foal gender and weight, day of milking (from 1 to 5), week of milking and group on milk yield was studied using a linear mixed model with individual as random effect. No effect of mare weight nor parity, foal gender and day of milking was shown. Lack of significance regarding parity, however, has to be taken with caution as few primiparous mares were studied. Milk yield was significantly influenced by the week of milking, mares producing more milk at the 5th week (326.70 ± 140.63 g) compared to the 9th (309.76 ± 141.36 g) and 13th week (290.59 ± 156.77 g) and more during the 9th week than during the 13th. In addition, foal weight is positively correlated with milk yield, mares caring for larger foals producing more milk. Regarding group, 2M mares produced significantly more milk than 1M mares (377.59 ± 148.25 g and 255.52 ± 122.11 g, respectively). Thus, one hour interval between two milking is sufficient to increase daily milk production. This result highlight the importance of milking interval on milk yield and more research on this theme would benefit the equid milk industry.

Mineral profile of pasture-based mare milk from Basque Mountain horse breed: effect of lactation

A. Blanco-Doval, L.J.R. Barron and N. Aldai

University of the Basque Country (UPV/EHU), Pharmacy and Food Science, Paseo de la Universidad 7, 01006 Vitoria-Gasteiz, Spain; ana.blancod@ehu.eus

Minerals are essential elements that play a key role in human physiology and need to be acquired through diet. Milk and dairy products are a good source of some minerals, e.g. calcium and phosphorous, although the mineral composition of milk differs among mammal species. In this respect, mare milk is very similar to human milk, both with lower overall mineral contents than ruminant milk. However, studies on mare milk minerals are particularly scarce. In this study, the content of 7 macrominerals (Ca, K, P, S, Na, Mg and Cl) and 4 trace elements (Zn, Fe, Cu and Mn) in mare milk from Basque Mountain Horse breed was analysed. This is an autochthonous equine breed from northern Spain and its milk has never been studied before. Furthermore, the effect of lactation and farm management on the milk mineral composition was studied. Milk samples (n=310) were collected all along the lactation period (six months) from 18 mares belonging to three different commercial farms with different management system. Inductively coupled plasma mass spectrometry (ICP-MS) was used for mineral analysis, and the ANOVA Linear Mixed Model was used for the statistical analysis. Major macrominerals and trace elements in mare milk were Ca, K and P, and Zn and Fe, respectively. Mn was only quantifiable in 11% of the samples. In comparison to milk from other horse breeds, milk from Basque Mountain Horse breed presented similar Ca, K, P, Na, Mg, Zn and Cu contents, but lower Cl and S and higher Fe contents. Lactation stage significantly affected the content of all minerals: Ca, K, P, S and Mg decreased along lactation, whereas Na, Zn and Cu contents increased and Cl and Fe contents fluctuated. Significant differences were also found in Ca, P, S and Na contents between milk from mares with long and short grazing period, probably due to grazing activity in agreement with previous findings in cow milk. These results substantiate the quality of mare milk from Basque Mountain Horse breed from a human consumption perspective, contributing to the valorisation of the food produced (milk), the breed and extensive equine grazing systems.

Session 33

Theatre 9

Sustainable utilisation of horse manure

M. Meyer¹, C. Eiberger², T. Schilling¹, D. Winter³ and L.E. Hoelzle¹

¹University of Hohenheim, Institute of Animal Science, Department Livestock Infectiology and Environmental Hygiene, Garbenstraße 30, 70593 Stuttgart, Germany, ²Marbach State Stud, Gestütshof 1, 72532 Gomadingen, Germany, ³University of Applied Science Nuertingen-Geislingen, Neckarsteige 6-10, 72622 Nürtingen, Germany; madeline.meyer@uni-hohenheim.de

Horse manure is a challenge for everyone who has responsibility for at least one horse and is therefore in charge of proper storage and utilisation of produced manure. Increasingly, horse farms, especially in urban areas and farms with no or only small agricultural land, have serious problems with the utilisation of horse manure. Experts assume that the possibilities for manure utilisation decrease and the associated costs will even increase in the future. In summary, approaches associated with storage and especially sustainable utilisation of horse manure are currently of enormous importance and highly demanded. In this research project, light is shed on different utilisation options of horse manure with special regard to storage capacity, nutrient availability, labour management as well as hygiene parameters. Advantages and disadvantages of the respective possibilities are determined to deliver practical solutions for a sustainable utilisation of horse manure. The project has four different research goals. The first focus involves the analysis of the composting process of horse manure. Within the scope, four differently treated experimental muck heaps remain on the manure plate for six weeks, two heaps are turned over after three weeks. The muck heaps are spiked with temperature loggers as well as parasite and *Salmonella* samples. Furthermore, nutrients samples are taken at the beginning and at the end of the research trail. In the second subproject, the impact of the usage of a combi-mulcher and rotting accelerator is tested in a field and an exact trail. Furthermore, the third focus deals with the influence of the biogas process on the hygienic status of the digestate. Various hygiene samples are examined in the laboratory for this purpose. The last research field analyses the use of a rotting accelerator in loose housing and its effect on the composting process of horse manure in the stable.

Use of green waste compost as an alternative bedding to straw in horse husbandry*H. Unseld¹, D. Winter¹ and M. Meyer²**¹University of Applied Sciences Nürtingen-Geislingen, Applied agricultural research, Neckarsteige 6-10, 72622 Nürtingen, Germany, ²Principal and State Stud Marbach, Gestüthshof 1, 72532 Gomadingen, Germany; harald.unseld@hfwu.de*

Horse care is associated with high demands for owners and boarding stables. A demand-oriented and high-quality supply of feed and bedding materials also represents a high cost item for horse-keeping operations. Animal welfare means that high-quality feed must not be skimmed on. Cost savings and working time represent important challenges. With regard to animal welfare, the bedding used must fulfil multiple functions. For example, the materials must be hygienic, dry and low in dust, and have good binding of urine and noxious gases. In addition, they should be easy to muck out to save labour time, produce a small volume of manure to limit manure storage space, and be inexpensive to purchase. In addition, they should provide good lying comfort for the horses. This paper addresses the question if composted green manure meets these requirements. Green compost and wheat straw were investigated for their water absorption capacities in laboratory tests. In addition, practical tests were conducted to determine the working times for manure removal and the necessary material requirements, for re-spreading various bedding materials. The cost rates were shown and compared in each case. The stable air factors ammonia and particulate matter, were measured for the different bedding variants. In addition, the lying behaviour of horses was investigated. The results showed, that about 50% of the bedding costs could be saved by using green waste compost, compared to straw bedding. In particular, the material costs of green waste compost are, on an annual average, 80% lower than those of wheat straw. The manure quantity of green compost litter is reduced by 50% compared to straw. The ammonia load in the trial is lower than with straw, but the dust load is higher than with straw. In summary, it can be said that green waste compost has an enormous savings potential in terms of material and labour costs compared to straw. Green waste compost at a bedding height of 20 cm provides a good indoor climate with non-perceivable ammonia values that are far below the official limits.

Session 33

Theatre 11

Grazing management on practical horse farms*C. Siede¹, M. Komaind¹, B. Tonn², S.C.M. Wolter¹, A. Schmitz¹ and J. Isselstein^{1,3}**¹University of Goettingen, Department of Crop Science, Von-Siebold-Str. 8, 37075 Göttingen, Germany, ²FiBL Switzerland, Department of Livestock Science, Ackerstr. 113, 5070 Frick, Switzerland, ³University of Goettingen, Centre for Biodiversity and Sustainable Land Use, Büsingenweg 1, 37077 Göttingen, Germany; caroline.siede@uni-goettingen.de*

Grassland offers horses the opportunity to act on their natural foraging and grazing behaviour and allows them movement and social contacts which all enhances their wellbeing. However, little is known about pasture management and pasture-based nutrition of horses on farms. Therefore, we investigated the actual grazing management and to what extent aboveground herbage (AGH, kg/ha) changes throughout the grazing season on six practical horse farms around Göttingen, Germany, from May till October 2019. Compressed sward height (CSH) was measured monthly on all pastures that were used for horse grazing. On four focus pastures per farm in two short-grazed (CSH<7.2) and two tall-rejected (CSH≥7.2) grass sward areas AGH was cut close to ground level of known CSH to develop a linear model for prediction of standing AGH from CSH values. The proportions of each area were calculated per pasture and month. The farmers had to fill out a grazing diary on a daily basis to obtain a measure of stocking intensity, as expressed in terms of livestock unit grazing days (LUGD) per month and pasture. There was a significant interaction between farm×month×area on the AGH ($P=0.002$). As the proportion of tall grass sward areas declined progressively over the season, short grass sward areas increased correspondingly. This coincided with an increase of AGH in short grass sward areas per ha of horse pasture. In addition, we found no correlation between AGH per pasture and the LUGD. LUGD were relatively constant on almost all farms throughout the grazing season, whereas only one farm showed a pattern of LUGD adapted to the grass growth. On most practical horse farms, grassland is rather used for movement and social contacts than nutrition. With adjusting the stocking, grassland could provide sufficient herbage and thus reduce inputs of supplemental feeding. There is a need to inform horse farmers about improved grassland management.

Use of digital technologies in horse husbandry to increase animal welfare and health

M. Pfeiffer¹, D. Winter¹, U. Dickhoefer² and L.T. Speidel¹

¹Nuertingen-Geislingen University, Institute of Applied Agricultural Research (IAAR), Neckarsteige 6-10, 72622 Nuertingen, Germany, ²Kiel University, Institute of Animal Nutrition and Physiology, Hermann-Rodewald-Strasse 9, 24118 Kiel, Germany; linda.speidel@hfwu.de

Even if horses have been domesticated, their needs concerning their living conditions have hardly changed. However, under today's husbandry conditions, the daily routine of horses partly deviates from the horses' natural time budget, which can have negative psychological and physical effects on the horses. The recording of long-term activities serves to control the horses' time budget. Furthermore, it can also serve as a basis for the evaluation of management, feeding and husbandry decisions. The collection of animal-related indicators by humans is very time-consuming, subjective and reflects a snapshot. Digital technologies can continuously and objectively collect indicators and ensure their documentation. The aim of the present work was to show different ways in which horse farms can use digital technologies to ensure animal welfare and health and to record activities in the long term. The studied indicators include feeding, resting and exercise behaviour. These were recorded using a video-based system supported by artificial intelligence. In addition, horses' reactions to the use of digital technologies were recorded when the feeding process was changed from manual to automated for a total of six horses in two farms. During manual concentrate feeding, statistically significant higher heart rates of horses were found compared to automated feeding. For roughage feeding, horse heart rates were slightly higher with automated feeding than with manual roughage feeding. Digital technologies can support farm management in the continuous and objective recording and documentation of indicators. In addition, animal welfare can be improved, especially in the area of feeding, through the possibility of automated feed presentation. Possible challenges related to the digitalisation in horse husbandry must be assessed together with the farm managers in the future.

Session 33

Poster 13

Working time requirements of work processes in the individual keeping of horses

L.T. Speidel¹, D. Winter¹ and U. Dickhoefer²

¹Nuertingen-Geislingen University, Institute of Applied Agricultural Research (IAAR), Neckarsteige 6-10, 72622 Nuertingen, Germany, ²Kiel University, Institute of Animal Nutrition and Physiology, Hermann-Rodewald-Strasse 9, 24118 Kiel, Germany; linda.speidel@hfwu.de

Working time requirements in horse husbandry depend on the type of husbandry and stabling, the associated mechanisation as well as the arrangement of the buildings and the services offered. Current data from the literature can be used for personnel planning and the calculation of labour costs on horse farms. However, these data are more than ten years old. Therefore, current data on essential areas of activity in horse husbandry were collected in the present work. In general, the working time per horse and day varies between 1-10 minutes per horse for the individual activities. Most of the time is spent on manure and pasture care, the least time is needed for the manual feeding of concentrated feed. The use of technology saves time, especially for manure removal, and should be considered in operational planning. The required working times vary considerably for the different activities and depend on many factors, such as the experience and motivation of the employees, the distances travelled, and the technology used. This should always be considered when calculating labour costs and the associated pension prices. A possible addition to this study is the comparison with group husbandry of horses and automated work processes.

Equine traction in viticulture: what about the workload of the horse-driver pair?B. Pasquier¹, N. Delepouve¹ and C. Bénézet²¹Institut français du cheval et de l'équitation, Plateau technique de Saumur, Avenue du Cadre Noir, BP207, 49411 Saumur, France, ²Institut français du cheval et de l'équitation, Plateau technique d'Uzès, Mas des tailles, 30700 Uzès, France; benoit.pasquier@ifce.fr

Animal welfare is a growing social concern. In this context, the mobilization of equids for the realization of various urban, agricultural or even natural sensitive works can raise questions not only concerning their daily management (feeding, housing, care) but also concerning their working conditions. A return to the use of equine traction in vineyards is currently observed, mainly for soil maintenance. In this context, we are interested in the workload of the horse-driver pair, with the Caract-Equivigne project. Our goal is to provide first references on the effort represented by this work according to the operation carried out, the type of worked plot and the tool used. For this study, 14 equine-driver pairs, working for vineyards spread over different regions, have been selected. Each pair will be followed for two years. For each vineyard, we observe two contrasting plots in terms of effort (variation in slope, soil type, etc.). Two cultivation operations are measured each year (ridging and plowing the ridges). We analyse the locomotion of the horse with an accelerometer. We monitored both horse and driver heart rate. The traction effort is determined by a dynamometer placed between the hitch lines and the collar. In addition, the horse is filmed throughout the measurement session: the videos are then used to analyse its behaviour. For the traction and cardiac data, different effort thresholds have been considered and allow to estimate the time spent above and below each threshold. These data will allow to characterize the effort levels provided by the equids in different soil maintenance situations and will be compared to references in other work situations. The references built at the end of the project could be used to create educational resources for driver training.

Physiological and behavioural responses of donkeys to effort and discomfortN. Seguin¹, C. Bonnin¹, A. Ruet² and S. Biau²¹INET, 17 Cours Arnozan, 33000 Bordeaux, France, ²IFCE, Avenue de l'ENE BP207, 49411 Saumur, France; nosequin@hotmail.fr

In a preliminary study, the physiological solicitation and behaviours expressed by donkeys were described in different work situations. The objective of this new study was to analyse the effects of two loads being pulled, with or without physical discomfort, on cardiac physiology and behaviour of donkeys in a standardised context. Twelve donkeys (6±4 years) were tested with no load (F0), with a load being pulled of 10±2% (F10) and 20±2% (F20) of weight, with and without discomfort (C). This last consisted of a piece of rope placed unilaterally between the collar and the neck at the point of traction. Modalities order was randomised. Mean heart rates (HR) and occurrences of 10 behaviours were recorded for each modality. For behavioural analyses, four Z-scores were calculated: Z-score 'locomotion' (spontaneous stops, gait changes, trampling, lowering of hips), Z-score 'mobility' (head and ear movements, chewing, snorting), Z-score 'tail movement', Z-score 'defecation'. Non-parametric Friedman's tests and post-hoc tests with Bonferroni correction were performed, with a significance level ≤0.05. HRs were significantly different ($X^2=13.4$, $P<0.01$) between F0 (101.6±10.8 bpm) and F20+C (131.7±29.0 bpm; $P<0.01$). The Z-score 'locomotion' was significantly different ($X^2=21.4$, $P<0.001$) between F0 (-0.36±0.33) and F20 (0.51±0.40; $P<0.01$), and F10 (-0.25±0.33) and F20 ($P<0.01$). The Z-score 'mobility' was significantly different ($X^2=13.9$, $P<0.01$) between F0 (0.60±0.74) and F20 (-0.22±0.41; $P<0.05$), and F0 and F20+C (-0.40±0.40; $P<0.05$). The other two Z-scores did not show significant differences between modalities. The presence of discomfort did not have a significant effect on HR and Z-scores. These results show an increase in HR, indicating increased physiological effort, with the presence of loads being pulled. The donkeys also appeared to express more difficulty in moving and showed an overall decrease in forehead movements with increasing loads. Physical discomfort was not expressed in this study, either because the rope did not induced discomfort or the effort masked the discomfort. This standardised test with a sample of donkeys allowed to identify physiological and behavioural indicators enabling the working effort to be monitored.

Offering horse meat in restaurants to develop the demandC. Vial^{1,2}, M. Sebbane^{1,3} and A. Lamy^{1,3}¹MoISA, Univ Montpellier, CIHEAM-IAMM, CIRAD, INRAE, Institut Agro, IRD, Montpellier, France, ²IFCE, pôle développement innovation et recherche, 61310 Exmes, France, ³Centre de recherche, Institut Paul Bocuse, 69131 Ecully, France; celine.vial@inrae.fr

Although historically the consumption of horse meat in France has never been very high, it is currently declining significantly. Out of all French people who do not eat horse meat, 15% would be ready to do so if they had the opportunity, mainly with friends and relatives, or in restaurants. In this context, our research focuses on the obstacles and levers regarding the development of the horse meat offer in commercial catering. Qualitative interviews were conducted with 12 chefs, questioning their relationship to meat in general and their representations and knowledge about horse meat. According to the chefs, horse meat is rarely on the menu in restaurants because it would not appeal to many consumers, its consumption poses a problem of acceptability, its price is high, there is a lack of recipes and no teaching is given on this subject to chefs-in-training. Chefs also lack knowledge about the horse meat sector. Nevertheless, they present characteristics suggesting that they could be interested in this product: meat occupies an important place in general for them, they are open to innovation and new produce, they are interested in healthy menus, animal welfare, the environment, and local produce. Concerning the produce itself, they mention its advantages: colour, taste, adaptation to certain types of restaurants, and they are curious about the French breeding sector of draft horses for butchery. Finally, three profiles stand out among the chefs interviewed: the connoisseurs, those who are pragmatic, and those who are reluctant. Thus, first thoughts are emerging to develop the horse meat market in France. On the one hand, they rely on enhancing the nutritional, organoleptic and environmental qualities of this produce, which can meet the current challenges of food sustainability. On the other hand, it is necessary to increase the visibility and availability of the offer, for consumption at home, but also in commercial catering that appears to be relevant to familiarize new potential consumers with this produce. This involves overcoming the lack of knowledge of chefs regarding horse meat and the lack of a recipe index.

Relationship between average daily gain and an estimation of consumed grass

L. Wimmel, C. Lesoudard and J. Auclair-Ronzaud

IFCE – Plateau Technique de Chamberet, 1 Impasse des Haras, 19370 Chamberet, France; laurence.wimmel@ifce.fr

Grassland, as base of equine alimentation, is not used consistently by owners as the resource management is difficult. Thus, to broaden the use of grassland it is important to give owners information regarding horse performances when they are fed exclusively with grass. Relationship between average daily gain (ADG) and disappeared grass quantity (DGQ; expressed as kilograms of dry matter of grass consumed by horse per day) was studied on 3 grazing seasons (2018; 2019 and 2020). Horses were kept in herds and grassland was managed with rotational grazing. Grazing seasons started between the begging of April and mid April and ended between begging of October and begging of November. In total 188 horses were studied (80 in 2018; 111 in 2019 and 104 in 2020) some being studied for several years. DGQ was estimated using grass height measured before and after grazing (from 75 to 150 points depending on the plot size). Dry matter was estimated by sampling grass on 0.5m² surface. Grass height was measured before and after cutting with a mini-mower. Cut grass was then weight after and before drying at 60 °C for 72 hours. Relationship between ADG and DGQ was studied using a generalized mixed model with ADG as the variable to explain, DGQ, age of the horses, year, month of grazing and interactions (DGQ:age, DGQ:year and DGQ:month) as fixed variables, and individual as random variable. Surprisingly, a significant negative correlation appeared between ADG and DGQ, which might reflect the impossibility for horses already reaching a high weight to gain more. Moreover, needs increasing with weight, heavier horses will have to ingest more grass to cover the needs and not inducing weight gain. A significant effect of month of grazing on ADG was also demonstrated, being a reflect of grass growth which depends on environmental factors. Moreover, ADG was lowered by age of the horses which might be explained by ingestion capacity. The latter is influenced by body weight and growing horses are lighter than adults. As a relationship was established between ADG and DGQ, the later might be a good indicator of the former, even though more studies are need as several factors seem to influence the correlation.

Comparison of flying and soil invertebrates' biodiversity on meadows with or without horse grazingG. Goudet¹, F. Reigner² and M. Beltramo¹¹INRAE, PRC, 37380 Nouzilly, France, ²INRAE, PAO, 37380 Nouzilly, France; ghylene.goudet@inrae.fr

By grazing preferentially some spots, horses create patches of short grass and tall vegetation in which they concentrate their dungs. This leads to habitat heterogeneity that could increase grassland animal biodiversity. This pilot study aimed to test a method to compare, using non-lethal protocols, invertebrates' biodiversity on meadows undergoing or not horse grazing. This 2-years study was performed in our experimental farm facilities using one-hectare paddocks with meadows 5-years-old and similar bordering environment. Two paddocks were grazed from April to November by 6 pony mares each and 2 paddocks were not grazed. For bees monitoring, 2 trap nests of 32 tubes each were placed at paddocks' edge. Nest occupancy was monitored by counting sealed tubes from March to October. Butterflies were monitored once per month from May to September by recording all butterflies in a 5×5×5 m cube around the observer during a 10-min long transect. To monitor soil invertebrates, 3 wooden boards of 30×50 cm were laid on the ground, 2 at the edge and 1 at the centre of the paddock. Once per month from March to November all invertebrates present under the board were identified and assigned to 3 categories: predators (carabid beetle and spiders), herbivores (mollusks), and detritivores (earthworms, millipedes, woodlouse, ants). The nests were occupied by solitary bees in the genus *Osmia* and *Megachile*, and the number of sealed tubes was different between grazed and non-grazed meadows. Butterflies from Hesperidae, Pieridae, Lycaenidae and Nymphalidae families were observed. Their abundance and diversity tend to be higher in grazed meadows. The abundance of predators was similar between grazed and non-grazed meadows, but the abundance of mollusks and detritivores tend to be different. These tendencies should be considered with caution because of the short period of observation and the limited number of meadows included in the study. Collection of additional data is in progress to consolidate the data and confirm the impact of horse grazing. In spite of this limitation, this pilot study shows that wild biodiversity can be studied using non-lethal protocols on horse-grazed meadows and that horse grazing may influence some invertebrates groups.

Session 33

Poster 19

Alterations of faecal microbiota in Jeju crossbred weanling horses

J.A. Lee, M.C. Shin, J.Y. Choi and S.M. Shin

National Institute of Animal Science, Subtropical Livestock Research Institute, 593-50, Sanrokbukro, 63242, Korea, South; amasss@korea.kr

This study was conducted to discover changes in taxonomic composition and diversity of faecal microbiota in Jeju crossbred weanling horses, by 16S rRNA gene amplicon sequencing. Faecal balls were collected from 27 Jeju crossbred (Jeju × Thoroughbred) horses, from 4 months and 8 months of age. Genomic DNA was extracted from each faecal ball using QIAamp PowerFecal DNA kit according to manufacturer's instructions. The faecal microbiota was characterized on the basis of the V3-V4 hypervariable region of the 16S rRNA gene. At 4 months, *Firmicutes* (45%), *Bacteroidetes* (27%), *Spirochaetes* (7%) and *Fibrobacteres* (6%) were identified as the major phyla. On the other hand, the major phyla were changed at 8 months in the order of *Firmicutes* (40%), *Fibrobacteres* (18%), *Bacteroidetes* (18%) and *Spirochaetes* (14%). Interestingly, *Fibrobacter* was observed as the most dominant genus at 4 and 8 months, relative abundances of *Fibrobacter* were higher at 8 months. The results of α -diversity analysis showed that the richness (Chao1, ACE, Jackknife) in microbial communities were statistically significant ($P < 0.001$), and the evenness (Shannon) was similar ($P = 0.21$) between 4 and 8 months. The PCoA (principal coordinates analysis) results indicated that 4 and 8 months were divided into two groups with PC1(48%) and PC2(24%) at the species level. The PERMANOVA (permutational multivariate analysis of variance) showed that the microbiota composition differences between 4 and 8 months were statistically significant ($q < 0.001$) with Unifrac distance matrix. LEfSe (Linear discriminant analysis effect) was performed to select taxonomic makers between 4 and 8 months. At the genus level, EF436358_g ($q < 0.001$) and AB494828_g ($q < 0.001$) were identified as markers in 4 months, whereas *Treponema* ($q < 0.01$), *Streptococcus* ($q < 0.01$) were selected in 8 months. We also performed PICRUSt (phylogenetic investigation of communities by reconstruction of unobserved states) analysis to predict metagenome functional content between 4 and 8 months. Purine metabolism, starch and sucrose metabolism were predicted in 4 months, Steroid hormone biosynthesis was predicted at 8 months, respectively.

Colic incidence among horses in different husbandry systems*E. Schlotterbeck, L.T. Speidel and D. Winter**Nuertingen-Gesilingen University, Institute of Applied Agricultural Research (IAAR), Neckarsteige 6-10, 72622 Nürtingen, Germany; linda.speidel@hfwu.de*

Colic is considered one of the most common diseases of domestic horses and is influenced and caused by many different factors. Due to the small stomach volume compared to the body size, the digestive system of horses is particularly prone to disorders. The present study was initiated to find out whether there is a correlation between the frequency of colic and the type of husbandry. To answer the research question, a quantitative survey was conducted. For this purpose, an online survey was created and published via Google Forms. The questionnaire consisted of 35 questions and was distributed over a period of eight weeks via social media and horse magazines. 2,039 horse owners and farm managers participated in the survey. The survey asked about the demographics of the participants, the keeping of the horses, the frequency of feeding, the quality of feed and bedding and the colic of the horses. The 'Numbers' and 'R' programmes were used for the analysis. The study shows that there is a significant correlation between the type of housing and the frequency of colic. Horses kept individually (56%) suffer more frequently from colic than those kept in groups (44%), whereby the frequency of colic decreases with increasing access to pasture, regardless of the type of housing. In the present study, no significant correlation between feeding management and colic frequency could be found. As an explanation for this result, it is assumed that the feeding management of the participating horses can be assessed as optimal. The most common form of colic in this study was constipation. Further studies on colic symptoms could examine the individual types of husbandries in more detail and include the type of use and training of the horses.

Session 34

Theatre 1

The effect of feeding a soy-free diet on performance and carbon footprint of the feed intake by pigs*S. Millet¹, M. Lourenço¹, S. Palmans² and C. De Cuyper¹**¹ILVO, Scheldeweg 68, 9090 Melle, Belgium, ²PVL, Kaulillerweg 3, 3950 Bocholt, Belgium; sam.millet@ilvo.vlaanderen.be*

Because of its balanced digestible amino acids content, soybean meal is a common ingredient in pig feed. However, its production is associated with high greenhouse gas emissions, especially related to deforestation. Therefore, interest in alternative protein sources for pig diets is growing. We describe a trial where pigs were fed either a control diet with soy or a soy-free test diet with alternative protein sources. Three-phase feeding was used and diets were formulated in consultation with Flemish stakeholders. Diets were isocaloric (9.6, 9.4, and 9.25 MJ NE/kg diet, for phase 1, 2 and 3, respectively) and were low in crude protein (155, 140 and 125 g/kg). Soy-free diets were more expensive (15.8, 8.4 and 0.9 euro/ton for phase 1, 2 and 3, respectively) than the control diets. Performance, nitrogen efficiency and carbon footprint of the feed intake were calculated. The daily gain (773±30 vs 773±30 g/day), daily feed intake (1,826±99 vs 1,818±64 g/day), feed conversion ratio (2.36±0.1 vs 2.35±1 g/g), carcass gain per kg feed (351±15 vs 354±12 g/kg) or nitrogen efficiency (56.5±2.7 vs 56.0±2.1) did not differ significantly between control and test diet ($P>0.05$). Carcass yield was significantly higher in the control than the treatment group (79.4±0.2 vs 78.6±0.2, $P<0.01$), while meat percentage did not differ significantly (64.3±0.2 vs 63.9±0.2, $P>0.05$). The carbon footprint of the feed intake, expressed as CO₂eq per kg of carcass gain was significantly higher in the control group (2,448±100 CO₂eq) compared to the soy-free group (1,752±56 CO₂eq). The experiment showed that it is possible to obtain similar technical results when feeding a growing-finishing diet without soy. This may lead to a lower climate impact of pig production but it comes with an increased cost. This research was funded by the Flemish Government and the European Agricultural Fund for Rural Development.

Exploring variation in feed efficiency of grower-finisher pigsM. Van Der Heide¹, J.V. Nørgaard¹ and J.G. Madsen²¹Aarhus University, Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, ²University of Copenhagen, Veterinary and Animal Sciences, Grønnegårdsvej 2, 1870 Frederiksberg C, Denmark; johannes.g.madsen@sund.ku.dk

Improving feed efficiency (FE) of grower-finisher pigs is of great importance considering its impact on production economy, nutrient excretions to the environment as well as carbon-footprint. Feed efficiency estimated on pen level, does take individual feed intake per day (FID), time spent feeding (TSF) and meal frequency (MF) into account, and thus variation between pen mates is impossible to establish. Thus, by using advanced feeding stations enabling individual measurements of these parameters, this study aimed to explore the variation in FE between pen mates fed one of three levels of crude protein (CP). The study included 60 gilts divided in two series, housed as 10 pigs/pen. From 30-115 kg BW, pigs were fed either a low (L; 113 CP g/kg), standard (S; 121 CP g/kg) or high (H; 124 CP g/kg) CP diet, and traits BW, AWG, FCR (weekly based), and FID, TSF and MF (daily based) were estimated on individual basis. The data were analysed in R as a linear mixed model with dietary treatment (DT; L, S or H), week (W; 7-14 from 30 kg BW) or day (D; 50-100 from 30 kg BW) and DT × W or DT × D as fixed, and series, station within series and animal (repeated measurement) as random effects. Crude protein level had no effect on any traits, whereas W had a significant effect on all traits measured. There was a DT × W interaction where BW was greater ($P < 0.05$) in H-compared with S- and L-CP during W12-14 (W14; 82.5, 76.9 and 76.0 kg BW), slope for AWG varied significantly ($P < 0.05$) as from W12 on slope decreased for H-CP and increased for L-CP, whereas slope FCR between W12-W14 increased steeper ($P < 0.05$) than S-CP and L-CP (decreasing slope). With respect to FID, TSF and MF there were also several DT × W interaction effects, notably, H-CP had on D70, D90 and D100 steeper increasing ($P < 0.05$) slope FID than L-CP, H-CP had on D70 and D100 lower ($P < 0.05$) slope TSF than L-CP, and L-CP had higher ($P < 0.05$) absolute MF than H-CP on D60-70. Together the results suggest that there is a change in efficiency of nutrient utilization over time, indicating that the response to dietary CP level is of dynamic nature during the grower-finisher phase.

Session 34

Theatre 3

Former food slightly affect pig faecal microbiota without impairing jejunal integrity and physiologyM. Tretola^{1,2}, S. Mazzoleni¹, P. Silacci², L. Pinotti¹ and G. Bee²¹University of Milan, Department of Veterinary Medicine and Animal Science, Via dell'Università 6, 26900 Lodi, Italy,²Agroscope, Institute for Livestock Sciences, La Tioleyre 4, 1725 Posieux, Switzerland; marco.tretola@agroscope.admin.ch

Food industry leftovers, also called former foodstuffs products (FFPs) are promising alternative ingredients to improve the circular economy in food production. This study investigated the effects of salty and sugary FFPs on gut microbiota and intestinal integrity of grower-finisher pigs. Thirty-six Swiss Large White barrows were assigned to three grower and finisher diets: (1) standard diet (ST); (2) 30% conventional ingredients replaced by sugary FFPs (SU); and (3) 30% conventional ingredients replaced by salty FFPs (SA). At the beginning of the trial (T1), at the end of the growing period (T2) and 1 day before the slaughter (T3), faeces were collected from the rectal ampulla, snap-frozen, and used for next-generation sequencing to analyse the composition and the alpha and beta diversity indexes of the microbial population. At slaughter, a minimum of 7 pigs per group were randomly selected for electrophysiology measurements. For each pig, two jejunal samples were collected and mounted in Ussing chambers to evaluate the trans-epithelial resistance (TEER) and the active uptake of D-glucose, L-Arginine, L-Methionine and L-Glutamate. For each time point, no difference in the faecal microbiota alpha and beta diversity indexes were found between the dietary treatments. At T3, the core microbiota of the SU pigs was composed by 12 ASVs, while in the ST and SU groups it was characterized by 9 and 8 ASVs, respectively. The Linear Discriminant analysis of effect size (LefSe) showed that at T1, no differential taxa between groups were found. However, differences ($P < 0.05$) at the genus level between ST, SU and SA groups were found at T2 and T3. The dietary treatments did not affect ($P > 0.05$) the TEER nor the D-Glucose uptake. Among the selected AAs, only the L-Glutamate uptake differed ($P < 0.05$), with a higher uptake in SU compared to SA (+366%). When used to partially replace traditional ingredients in growing-finishing pig's diet, both SU and SA FFPs can slightly modulate specific bacterial taxa in faecal microbiota but without impairing the intestinal integrity and physiology.

Bakery products and legume seeds in the diet of growing-finishing pigsM. Van Helvoort¹ and P. Bikker²¹De Heus Animal Nutrition, Rubensstraat 175, 6171 VE, the Netherlands, ²Wageningen University & Research, Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; mhelvoort@deheus.com

It is fundamental for future pig production to raise the animals as part of a circular food system. The aim of this study was to determine the effect of total or partial replacement of soybean meal, palm kernel expeller and cereal grains by bakery products and legume seeds in the diet of growing-finishing pigs to improve the circularity of food production. In total 736 pigs (26.0±4.5 kg) were randomly allocated to 8 dietary treatments by mixing 3 diets on pen level with the computerised feeding system. Three grower diets for week 1-3 and three finisher diets for week 4 onwards were produced: (1) a control diet: high in cereal grains, with soybean meal and palm kernel meal; (2) a diet high in bakery products with approximately 50% bread meal; and (3) a diet high in legume seeds with 22.5% peas and 25% faba beans. The dietary treatments were fed to slaughter at 125 kg of live weight. Efficiency of nitrogen (N) and phosphorus (P) utilisation was calculated using reference values for N and P content in pigs. Carbon footprint of the feeds was based on list version 5 of Nevedi (2022). Data were analysed with analysis of variance using Genstat with pen as the experimental unit. Dietary treatments had limited effects on growth performance and feed efficiency of the pigs. The efficiency of N and P utilisation was reduced by approximately 4-5 and 8-9% units, respectively ($P<0.001$) due to the higher N and P content of the diets with bakery products and legume seeds. The carbon footprint of the feeds expressed in g CO₂ eq. per kg of carcass gain was reduced by inclusion of bakery products with 64% including and 38% excluding land use change (LUC) ($P<0.001$). In contrast, inclusion of legume seeds reduced the carbon footprint including LUC with 23% but increased the carbon footprint excluding LUC with 23% ($P<0.001$). Overall, these results indicate that cereal grains and soybean meal can be replaced by bakery products and legume seeds with minor effects on growth performance of the pigs, but efficiency of N and P utilisation is reduced. Replacement by bakery products and legume seeds reduced the carbon footprint including LUC, however legume seeds increased the carbon footprint excluding LUC.

Recycling agricultural by-products: using purple carrots as an ingredient in layer quails feedingA.S.-G. Sarmiento-García^{1,2}, A.B.-D. Benito-Díaz¹, C.V.-A. Vieira-Aller¹ and O.O. Olgun³¹Instituto Tecnológico Agrario de Castilla y León, Estación Tecnológica de la Carne, Avenida de Filiberto Villalobos, 5, 37770 Guijuelo, Salamanca, Spain, ²Universidad de Salamanca, Área de Producción Animal, Departamento de Construcción y Agronomía, C/Filiberto Fillalobos 119, 37007, Salamanca, Spain, ³University of Selçuk, Department of Animal Science, Faculty of Agriculture, Ardiçlı, Selçuk Ünv. Alaaddin Keykubat Kampüsü No:371, 42250, Selçuk, Konya, Turkey; asarmg00@usal.es

The carrot (*Daucus carota* L.) is an interesting ingredient due to its chemical composition. In the last years, there has been an increase in the intake of coloured carrots due to apparent health benefits. Nevertheless, it has resulted in increasing amounts of agricultural waste by-products. The goal of the current experiment was to establish the effect of dietary concentrations of purple carrot powder (PCP) waste by-products on performance, egg production, eggshell quality, and yolk colour of layer quails (*Coturnix coturnix Japonica*). A total of one hundred and fifty 22-week-old Japanese laying quails were allotted to 5 dietary treatments each with 6 replicates of 5 quails. Purple carrots were provided by local markets (Konya, Turkey), which had been discarded for human sale. The carrots were dried in an oven (100 °C until reaching 20% humidity) and subsequently ground. The PCP was incorporated into the basal diet (0%) by replacing the proportional part of corn as follows: 0.1, 0.2, 0.3, and 0.4% PCP which were supplied *ad libitum* for 10 weeks. No differences were detected between dietary treatments for any of the performance parameters or egg production. Eggshell weight ($P<0.01$) and eggshell thickness ($P<0.01$) were linearly affected by dietary PCP supplementation, reaching maximum levels at 0.4% of PCP supplementation, while the percentage of damaged egg and egg-breaking strength remained similar for all experimental groups ($P>0.05$). Above the aforementioned results, using PCP, an agricultural by-product that is both safe and easily available, as an ingredient for laying quail diets was found to be effective without negatively affecting quail production or egg quality.

Effect of camelina cake doses as soybean meal substitutions on growth and gut health of piglets

D. Luise¹, F. Correa¹, S. Virdis¹, C. Negrini¹, G. Cestonaro², L. Nataloni², G. Tittori², E. Sattin³, E. Costanzo² and P. Trevisi¹

¹University of Bologna, Viale G Fanin, Bologna, 4127, Italy, ²Ceral Docks S.p.A, Camisano Vincentino, 36043, Italy, ³BMR genomics, Via della repubblica, Padova, 35131, Italy; diana.luise2@unibo.it

The camelina cake (CAM) is a co-product proposed as an alternative protein source; however, data on piglets are still limited. This study aimed to evaluate the effect of different doses of CAM in substitution of soybean meal on growth and gut health of weaned pigs. At 14 days post-weaning (d0), 64 piglets balanced for body weight and litter, were assigned to one of the four following isoenergetic and isoproteic diets: standard diet (CO) or a diet with the inclusion of 4% (C4), of 8% (C8) or 12% (C12) of CAM. Pigs were weighed weekly. Faeces and blood were collected at d7 and d28 for microbiota (v3-v4 of 16s rRNA gene) and ROMs analysis. At d28, pigs were slaughtered; pH was recorded on gut contents, organs were weighed and jejunum was used for morphological and gene expression analysis. A mixed-model including diet as a fixed factor and pen and litter as random factors was applied. From d0-d7, the CAM linearly reduced the average daily gain (ADG) ($P \leq 0.01$). No effect was observed in the subsequent weeks, but, from d0-d28, the CAM linearly reduced the ADG ($P = 0.01$). From d0-d7, the feed intake linearly decreased ($P = 0.04$), and the feed to gain linearly increased ($P = 0.004$) with the increase of CAM. The liver weight linearly increased with the rise in CAM ($P < 0.0001$). The diet did not affect ROMs, intestinal pH and morphology, and jejunal gene expression except for the expression of zonulin-1 ($P = 0.07$, quadratic effect). The CAM, at all doses, increased the alpha diversity indices at d28 ($P < 0.05$). The C4 diet promoted the abundance of *Butyricicoccaceae_UCG-008* and *Erysipelatoclostridiaceae_UCG-004*, which are usually correlated with resilient piglets' gut microbiome. In conclusion, despite reducing the ADG of piglets, the CAM did not affect gut health and enhanced resilient gut microbiome. CAM could be evaluated as a potential alternative protein source in weaned pigs. Theatre 7

The dietary fibre solubility in the maternal diet does not affect the muscle development of piglets

M. Girard¹, F. Correa², P. Palumbo², P. Silacci¹ and G. Bee¹

¹Agroscope, Tioleyre 4, 1725 Posieux, Switzerland, ²University of Bologna, Department of Agricultural and Food Sciences, viale G Fanin 44, 40127 Bologna, Italy; marion.girard@agroscope.admin.ch

Within litter, piglets born with the same birthweight may have very contrasting growth in the suckling period. Investigating the underlying mechanism behind this is important to harmonize weaning weights. Piglet weaning weight is affected by the insoluble (IDF)-to-soluble (SDF) dietary fibres ratio in sow diet. The present study investigated whether the IDF/SDF ratio in the maternal diet can affect the myofibre development and the lifetime growth of slow (S)- and fast (F)-growing piglets. From 85 days of gestation to weaning, 32 sows were fed a gestation and a lactation diets containing either 4% of IDF or 4% of SDF. The birth order as well as the birth weight and the weight at one day were recorded to calculate colostrum intake. On day 17, one or two pairs of S and F piglets per litter with similar birth weights were selected. On day 25, the semitendinosus muscle was collected on 32 piglets. The 48 remaining piglets were fattened until 110 kg. There was a maternal diet $\times$ growth interaction ($P < 0.05$) for colostrum intake with IDF-F piglets having a greater ($P < 0.05$) colostrum intake than IDF-S and SDF-S with intermediate values for SDF-F. The maternal diet had no effect on the birth weight, ponderal index or myofibre development but IDF piglets had a greater ($P < 0.05$) growth from birth to 17 days. However, the growth until slaughter and the age at slaughter were similar between IDF and SDF pigs. Regardless of the maternal diet, F and S piglets had similar birth characteristics. Nevertheless, besides a similar number and proportion of type I and II myofibres, S piglets had smaller ($P < 0.01$) myofibres than F piglets. In addition, S pigs were on average 13 days older ($P < 0.001$) at slaughter due to a slower ($P < 0.001$) growth compared to F pigs. This study shows that S piglets have a reduced myofibre hypertrophy at 25 days and do not have compensatory growth until slaughter. In addition, the positive effect of the maternal diet on piglet growth fades during the fattening period and is not related to muscle development on day 25.

Improving the sustainability of the Australian pork industry

G.L. Wyburn

Australian Pork Limited, 2 Brisbane Avenue, Barton 2600 Australian Capital Territory, Australia; gemma.wyburn@australianpork.com.au

In recent years, the Australian pork industry has embraced the sustainability challenge and implemented a program of research, development and extension to help industry understand, measure and improve their performance. Australian Pork Limited (APL), the national industry body has developed a Sustainability Framework that has goals across the categories of people, pigs, planet and prosperity. The framework goals with respect to 'Planet' cover carbon and nutrient accounting, natural resource stewardship and reducing waste. Two industry roadmaps have been developed – one on activities to help reduce a farms' carbon footprint and the other to reduce waste on farm. In addition, a full lifecycle assessment (LCA) of the Australian pork industry's key environmental impacts based on the 2020 financial year was conducted. The study looked at the footprints of 32 farrow to finish operations representing 44% of the total Australian pork industry based on sow numbers. This study included all major Australian pork processors. Outcomes of the LCA showed that manure, feed production, land use and direct land use change and farm services were the biggest carbon emissions contributors. The average emission was calculated at 3.7 kg of CO₂-e per kg of liveweight with a range from 1.4 to 6.4 kg CO₂-e for scope 1,2 and 3 emissions at farm gate. This represents a reduction of 13% since the last measurement taken in 2010. When post- farm processing is included, total emissions had an average of 5.9 kg CO₂-e per kg of wholesale pork. Water and energy usage have reduced more than expected and the report also quantifies for the first time the eutrophication impact for phosphorus (P) and nitrogen (N) across the industry for both direct and indirect impacts. Apart from outdoor producers, P results were low and N results varied depending on which grain growing region they sourced feed from. High industry participation and the nation-wide scope of the life-cycle assessment project, together with the industry roadmaps has provided the Australian pork industry with a clear position on the progress made to date and the sustainability challenges and opportunities that lie ahead. The author wishes to acknowledge the work of Integrity Ag and Environment in undertaking these studies.

Session 34

Theatre 9

Are tailor-made health plans effective in triggering changes in pig farm management?P. Levallois¹, M. Leblanc-Maridor¹, A. Scollo², P. Ferrari³, C. Belloc¹ and C. Fourichon¹¹Oniris, INRAE, BIOEPAR, 44300 Nantes, France, ²University Torino, Grugliasco, 10095 Torino, Italy, ³CRPA, 42121 Reggio Emilia, Italy; christine.fourichon@oniris-nantes.fr

A tailor-made health plan is a set of recommendations for a farmer to achieve and maintain a high health and welfare status. Tailored to each farm, it is intended to be an effective way of triggering change and meeting new expectations. This study aimed to evaluate the effectiveness of tailor-made health plans in pig farms, designed in various situations after a systematic biosecurity and herd health audit. An intervention study was carried out on 20 farrow-to-finish pig farms. An initial standardised audit and discussion between the farm veterinarian and the farmer resulted in a specific plan. Compliance with recommendations was monitored 8 months. Changes in health, performance and antimicrobial use were monitored. We defined two categories of plans: (1) 14 plans targeting a given health disorder present in a farm; (2) 17 plans to improve prevention, not targeting a specific disorder (one farm could have both types of plans). A small number of priority recommendations were made per farm. In 18 farms, farmers implemented 1 to 4 recommendations (none in 2 farms). Of the 17 non-disorder-specific plans, 11 were considered effective (>50% recommendations implemented), 3 intermediate (at least one but less than half of the recommendations implemented) and 3 ineffective (no implementation). Of the 14 disorder-specific plans, 9 were followed with full or good compliance (>50% recommendations implemented), 2 with intermediate compliance (1 recommendation implemented out of 2) and 3 with no compliance (no recommendation implemented). When at least one recommendation was implemented, change in clinical, performance and antimicrobial use indicators was assessed if a biological association with the disorder was deemed plausible and if their initial value showed room for improvement. Improvement was evidenced 4/9, 1/6 and 1/6 times for these indicators, respectively. Independently, veterinarians concluded in effectiveness for 8/14 plans. Overall, tailor-made health plans were effective in triggering changes in farm management. Several approaches were combined to investigate their effects, in the perspective of multicriteria assessment.

Pork production can contribute positively to human protein supply

R.J.E. Hewitt, D.N. D'Souza and R.J. Van Barneveld

SunPork Group, 6 Eagleview Place, Eagle Farm, 4009, Australia; robert.hewitt@sunporkfarms.com.au

The respective sustainability of our foods systems is increasingly under focus as we are challenged to produce more food from diminishing resources to feed a growing global population. Historically, livestock produced nutrient-rich food from lower value inputs that were not consumed by humans. Ruminants consumed inedible fodder from generally non-arable land, whilst monogastrics were fed undesired human food by-products such as excess grain, dairy co-products and waste streams from milling or other food processing. Livestock production today has become reliant on feed crops grown on arable land to improve efficiency, reduce the cost of production or meet premium market requirements. Livestock feed consumption now competes directly with human food, with one-third of global grain production being fed to livestock. The simple solution would be to divert human-edible feedstuffs directly to humans, but all proteins are not the same, they vary in nutritional profile, digestibility, environmental implications, and consumer acceptance. Livestock can bank poorer quality proteins and make them available for humans. Net Protein Contribution (NPC) describes the contribution of a production system to meeting human nutritional requirements, with values greater than one indicating a system is contributing more human edible protein than it consumes. In determining a systems NPC, we must understand the attributes of the protein and its quality, the efficiency of its conversion and the contribution it makes to meeting the needs of the consumer. The Australian pork production system is characterised by the utilisation of co- and by-products of other agricultural systems, including the utilisation of non-human edible processed animal proteins that are notable omissions from most pig diets in Europe and to some extent North America. An intensive Australian pork supply chain is estimated to contribute over three times the human edible protein that it consumes (NPC=3.26), which compares favourable to current European NPC estimates of pork, and other livestock, production systems. Focussing livestock systems on the utilisation of waste streams, co-products and human-inedible feedstuffs ensures they can make a sustainable contribution to human food supply.

Session 34

Theatre 11

Environmental and economic assessment of a French free-range chicken production systemB. Méda¹, E. Barlier¹, E. Péchernart², J.-Y. Limier³ and S. Mignon-Grasteau¹¹INRAE, Université de Tours, BOA, 37380 Nouzilly, France, ²ITAVI, 7 Rue du Faubourg Poissonnière, 75009 Paris, France,³CAFO, 41 B Av. Chanzy, 41240 Beauce-la-Romaine, France; bertrand.meda@inrae.fr

French 'Label Rouge' (LR) chicken production is particularly appreciated by consumers for its animal-friendly production conditions (outdoor access, lower animal density and growth rate) and the organoleptic qualities of its meat. Yet, it is also facing various challenges, such as a poorer feed efficiency and a larger exposure to climate change than in conventional production. Analysing LR value chains is a prerequisite to identify progress margins for poultry operators. The aim of this study was thus to assess the environmental/economic performances of one representative chicken LR value chain in the centre of France, the 'Poulet de l'Orléanais'. Environmental and economic performances were assessed using Life Cycle Analysis and by calculating production costs (PC), respectively. For 1 kg of live weight at farm gate, PC was estimated to be 2.07 € and environmental impacts were: 2.58 kg CO₂-eq for climate change (CC), 26.7 MJ for cumulated energy demand (CED), 0.048 kg SO₂-eq for acidification (AC), 0.019 kg PO₄³⁻-eq for eutrophication (EU), and 4.38 m².y for land occupation (LO). Using an economic allocation approach, the same indicators were calculated at slaughter house gate for 1 kg of ready-to-cook chicken and 1 kg of breast meat. For these two products, results were respectively: 3.40 and 12.46 € for PC, 3.79 and 8.93 kg CO₂-eq for CC, 42.8 and 100.8 MJ for CED, 0.068 and 0.161 kg SO₂-eq for AC, 0.027 and 0.064 kg PO₄³⁻-eq for EU, and 6.33 and 14.92 m².y for LO. Regardless of the functional unit, environmental impacts differed between the two genetics strains used in this production (S757N and G657N), with higher values for S757N (CC: +8.8%; CED: +4.5%; AC: +5.3%; EU: +0.9%), except for LO (-5.0%). Despite a better feed efficiency, the S757N strain had greater feed impacts, because of higher corn and soybean dietary contents. These results suggest that improvements should be made regarding genetic selection and nutrition in order to decrease the environmental impacts of LR chicken products. In particular, much attention should be paid to cut parts such as breast meat, since consumer demand is rapidly increasing.

Effects of values and calculation changes in three IPCC guidelines on greenhouse gas inventories

E. Nugrahaeningtyas, J.S. Lee and K.H. Park

Kangwon National University, Department of Animal Industry Convergence, 1 Gangwondaehakgil, Chuncheon-si, 24341, Korea, South; eskanugrahaeningtyas@kangwon.ac.kr

The increase in anthropogenic activities since the industrial era has increased GHG emissions (CH_4 , N_2O , etc), resulting in climate change and global warming. Based on the Life Cycle Assessment (LCA), livestock represents 14.5% of total anthropogenic emissions. Despite emphasizing how livestock production affects the environment, it ignores how livestock contributes to food security (i.e. nutrient-dense food and the transformation of non-edible food into edible food) as well as other industries (i.e. pharmaceuticals). LCA identifies the impacts on the environment from the whole process but does not display Transparency, Accuracy, Completeness, Comparability, Consistency (TACCC), as does GHG inventory (GHGI). GHGI as the main tool for GHG reporting targets the main sources of livestock emissions, enteric fermentation (CH_4) and manure management (CH_4 , N_2O). It accounts for 4.96% of total carbon dioxide equivalent ($\text{CO}_2\text{-eq}$) emissions and 51.04% of total agricultural emissions. Calculation of GHGI is based on Intergovernmental Panel on Climate Change Guidelines (IPCC GL), which are available in 1996 GL, 2006 GL, and 2019 Refinement. There is a difference in the emissions among guidelines due to different default values in the guidelines. Consequently, guidelines should be used carefully to prevent overestimating or underestimating the calculation which may be used to gain an advantage. GHG emissions from Korea's livestock were calculated to explain guidelines differences. The result showed that the estimated emission was different with each guideline. The emissions using 1996 GL and 2019 Refinement were nearly similar and the emission using 2006 GL was higher than that in others. Although the emissions were similar in 1996 GL and 2019 Refinement, the contribution of emission's sources differed. This difference may result in uncertainty when changing a GL and can be used to gain some benefits. Hence, changing to the most recent guidelines is the best practice regardless of the results of estimated emissions. Since an improved method is used to calculate emissions, the 2019 Refinement may better represent livestock conditions in the country.

Session 34

Poster 13

Bioavailability and repellent activity of phytocompounds against red mites

C. Carlu, T. Chabrilat, C. Girard and S. Kerros

Phytosynthese, 57 avenue Jean Jaurès, 63200 Mozac, France; claire.carlu@phytosynthese.fr

Dermanyssus gallinae, known as the 'red mite,' is a blood feeding ectoparasite, commonly found in laying hens and is one of the most important epidemiological and economic problem. An uncontrolled red mite population affects animal performance and welfare. Adding plant bioactives to diets may be an efficient and natural alternative to chemical repellents. *D.gallinae* repellent activity appears to come from neurotoxic effects, blocking γ -aminobutyric acid and reducing the ability of neurons in the nervous system. This *ex vivo* experiment measures the repellent activity of PhytoDerm against red mites. PhytoDerm is a natural solution composed of monoterpenes from essential oils and plants known for their activity against arthropods. Broilers from Phytosynthese experimental farm were separated in 2 groups of 2,200 birds JA657; one group received PhytoDerm from 64 to 70 days-old through drinking water at 1 ml/l. At 70 days of age, blood samples were collected from 6 broilers from the control group and 6 broilers from the supplemented group. In a partner lab, 3 groups of blood were realized: (1) C made with the blood from the 6 control birds; (2) A made with the blood from the control birds with an artificial supplementation of PhytoDerm at 1 ml/l at the lab; (3) B made with the blood from the 6 birds supplemented at the farm. Each blood sample was put into contact with 200 unfed mites via an artificial feeding model using skin of broilers and maintained at 38 °C. After one hour in the dark, red mites and dark mites were visually counted; mites were considered fed according the red colour. Trial was performed with 6 repetitions. The number of red-fed-mites were significantly reduced in A and B groups, respectively -34 and -28% ($P<0.001$). No statistical difference was observed between blood samples from groups A and B ($P=0.3$). This *ex-vivo* trial was able to evaluate, the effect of PhytoDerm based on plant bioactives to reduce *D. gallinae* feeding behaviour and the positive effect of oral supplementation of PhytoDerm implying a good bioavailability of its bioactives in poultry blood. Further trials in farming conditions are carried out to evaluate how this preliminary repellent activity is influencing the mites' population dynamic.

Riboflavin yield of common raw ingredients for organic poultry dietsV. Decruyenaere¹, N. Everaert², P. Rondia¹ and J. Wavreille¹¹Walloon agricultural Research Centre, Animal production Unit, 8 rue de Liroux, 5030 Gembloux, Belgium, ²KU Leuven, Department of Biosystems, 30 Kasteelpark Arenberg, 3001 Leuven, Belgium; v.decruyenaere@cra.wallonie.be

The supply in vitamin B2 or riboflavin is strictly necessary for poultry. Prolonged deficiency leads to serious health problems and reduced performances. The riboflavin previously used in organic poultry feed was derived from a process using GMOs, although this is strictly prohibited. The research for alternative sources is therefore becoming a necessity for the organic poultry industry. The riboflavin recommended level is 3.6 mg/kg feed from 0-6 weeks and 3 mg/kg of feed from 6-8 weeks for broilers. For laying hens, at the pullet stage, 3.4 to 3.6 mg/kg feed is needed. From 8 to 12 weeks of age, requirements are covered by 1.7 to 1.8 mg/kg of feed and from 18 weeks to the first egg, 1.7 to 2.2 mg/kg of feed. During laying, the recommended riboflavin content is 3.1 mg/kg of feed. To determine the riboflavin content of feedstuffs included in poultry diets, a bibliography research was conducted. It appeared that milk powder (20 mg/kg), algae (20-40 mg/kg), insect flours (>15 mg/kg), beer yeasts (12 mg/kg) and forages (12-17 mg/kg) had riboflavin contents higher than cereal (1-2 mg/kg) and oilseed cakes (2-4 mg/kg), or protein grains (2 mg/kg). Feed samples were collected on Walloon farms and from manufacturers and their riboflavin content was determined (n≈170 feedstuffs, Eurofins method EN 14152 2006 mod. [CN Food]). Within product category, the variability in vitamin B2 levels was high. For cereals, the dosed values were lower than those announced in feed tables. Among cereals, maize had the lowest values (0.67 mg/kg) followed by wheat (0.82 mg/kg). Milk powder, oilseed cakes and protein grains had values comparable to those of feed tables. Many feedstuffs included in poultry diets did not meet the riboflavin recommended level. Only few ingredients rich in riboflavin can be used in poultry formulations (yeast, milk powder, dehydrated forage feeds, insect flours). Their rate of incorporation in formulas is limited and their cost sometimes high (milk powder for example). The search for alternative forms of vitamin B2 for organic poultry diets must continue.

Session 34

Poster 15

Sustainable poultry production: biocontrol measures, dietary approaches and packaging strategies

G. Maiorano and S. Tavaniello

University of Molise, Department of Agricultural, Environmental and Food Sciences, Via F. De Sanctis snc, 86100 Campobasso, Italy; siria.tavaniello@unimol.it

The aim of the project is to develop, implement and transfer concrete innovations into practice based on a farm-to-fork approach to reduce the use of antibiotics in poultry production. It is an integrated approach along the entire food chain, acting: (1) at embryonic stage by *in ovo* synbiotic injection; (2) during the rearing period by nano-encapsulated polyphenol extracts (PE) (from olive leaves and olive mill wastewater) administered in feed; (3) at packaging using antioxidant-releasing film. The *in ovo* delivery of synbiotics, as the earliest method to stimulate intestinal environment, combined with dietary supplementation of nano-encapsulated PE, could be a promising strategy to eliminate all non-prudent use of antibiotics, while optimizing productivity. Moreover, the incorporation of PE into film packaging could be an effective method to extend shelf-life of meat, reducing food waste. The project includes pilot and field trials for the characterisation of the modes of action and for evaluating the robustness and effectiveness of the results in practice. The first part of the project includes: the set-up of the synbiotic formulation and the extraction of different polyphenolic compounds from olive by-products. Thereafter, *in vitro* studies will be carried out to evaluate the antimicrobial activity of PE against the major poultry pathogens. Based on the combined information coming from *in vitro* results and computer modelling by computational chemistry, the best PE and the relative dose will be chosen for the encapsulation process. A field trial will be carried out to characterize the overall response of chickens to synbiotic and PE administration on: gut microbiota; gene expression pattern; growth performance; carcass and meat quality traits. The last step will be the development, by experimental and theoretical methods, of packaging with the incorporation of PE, as a method to extend meat shelf-life. The integrated approach proposed in this project will give the scientific support to develop an innovative and sustainable poultry production chain. Acknowledgments PRIN 2020 project (Prot. 2020ENLMHA), Ministry of University and Research (MUR), Italy.

Genetic correlations between feeding behaviour, meat quality, carcass and production traits in pigsA.T. Kavlak¹, T. Serenius² and P. Uimari¹¹University of Helsinki, Koetilantie 5, 00790 Helsinki, Finland, ²Figen Oy, Kuusisaarentie 1, 68600 Pietarsaari, Finland; alper.kavlak@helsinki.fi

The Finnish pig breeding programmes have been very successful in the genetic improvement of economically important traits such as average daily gain (ADG), feed conversion rate (FCR) as well as carcass traits during the last decades. Even though the main goal for selection would be to improve feed efficiency, the genetic association within feeding behaviour and other traits among pigs could also be used in a selection program for modifying the improvement in efficiency for specific environments which could have a direct effect on pork production. Therefore, the objective of this study is to estimate the heritability of these traits and the genetic correlations between feeding behaviour, production, meat quality, and carcass traits. In this study, the data consists of purebred Finnish Yorkshire and Finnish Landrace pigs and their F1-crosses raised in a controlled test station environment located in Längelmäki (Figen Oy). The data were collected from 7,405 pigs that had entered the test station between 2011 and 2016. Pigs arrived at the test station at an average age of 89 ± 10 days (mean $\pm$ standard deviation) and an average weight of 34.7 ± 6.4 kg. The slaughter age is 186 ± 10 days, and the slaughter weight is 121.2 ± 12.9 kg. In this study, the most important feeding behaviour traits (FBT) are considered as number of visits per day (NVD, counts), time spent in feeding per day (TPD, min), daily feed intake (DFI, g), time spent in feeding per visit (TPV, min), feed intake per visit (FPV, g) and feed intake rate (FR, g/min). The production traits (PT) are considered in pig breeding programmes are average daily gain (ADG, g) and feed conversion rate (FCR, g/g) while the meat quality traits (MQT) are considered as pH of loin and ham (Loin_{ph} and Ham_{ph}) and the lightness (L), redness (a) and yellowness (b) of loin and ham (Loin_L, Loin_a, Loin_b). Lastly, the carcass quality traits (CQT) include meat percentage (M%, kg) as well as backfat thickness (BF, mm) and muscle depth (MD, mm). The restricted maximum likelihood method (REML) and the DMU software are going to be used for the variance component estimations. The results will be presented and discussed during the conference.

Session 34

Poster 17

The effect of plant-derived terpenes additive in *Ascaris suum* management in organic fattening pigs

H. Bui, E. Belz, J. Ligonniere and M.E.L.A. Benarbia

Nor-Feed, R&D, 3 rue Amedeo Avogadro, 49070, France; hoa.bui@norfeed.net

Ascaris suum is the most prevalent intestinal parasite in pig production. The infection causes significant economic losses due to health and production issues. Today, within the high risk of resistance development and the residual concern, sustainable alternatives to conventional anthelmintics are under demand. The objective of this study was to assess the effect of the plant-based feed additive (PB-A) on *A. suum* and compare it to flubendazole in fattening pigs. PB-A is standardized in terpenes, composed mainly of natural essential oils (EOs) including *Cymbopogon nardus* and *Citrus scinensis* 160 pigs, at 10- weeks age, were randomly divided into 2 groups. PB-A group: 80 pigs received a standard diet supplemented PB-A at 10g/ 100 kg of body weight (bw), during 5 consecutive days, at 16 and 21 weeks of age. Control group (CT): 80 pigs had standard diet supplemented flubendazole at 10 g/100 kg bw during 5 consecutive days, at 16 week of age. *A. suum* infection was evaluate before and after trials using ELISA method to quantify the specific serum antibody derived from *A. suum* infective larvae 3 (L3). 8 random blood samples were taken per group for every evaluation. Statistical analysis was performed by using ANOVA. Obtained results showed that both tested groups were negative to L3 at the beginning of trial. There was no significant difference in the antibody titer between the two group before supplementation. However, at the end, pigs in the control group were tested positive to L3 while pigs from PB-A group remained negative. The average antibody titer in CT pigs (0.3) were significantly higher ($P=0.0004$) compared to the one of STPA pigs (0.18). In conclusion, PB-A supplementation in feed during fattening period resulted in significantly restricting the proliferation of *A. suum* pressure compared to flubendazole in such experimental condition. It was also observed that the single flubendazole treatment during fattening in accordance with French organic farming regulation may be not effective enough. This protocol was adapted to be close to farm practical condition so that the negative control group was not possible to install. Further study with controlled conditions should be carried out to reinforce the results.

Effect of fattening and slaughter value of gilts on their lifetime piglet production*M. Szyndler-Nędza, M. Tyra and A. Mucha**National Research Institute of Animal Production, Department of Pig Breeding, ul. Krakowska 1, 32-083 Balice, Poland; magdalena.szyndler@iz.edu.pl*

The purpose of this study was to examine how the performance traits of young female pigs (gilts) influence the number of piglets born and raised during their reproductive life. The data for the study was gathered from the entire population of Puławska sows in breeding herds that were part of a genetic resources conservation program. The study included 2,722 Puławska gilts with complete information on their fattening and slaughter evaluation and reproductive performance. The data collected from the fattening and slaughter evaluation included body weight, daily gain, backfat thickness, average backfat thickness, loin eye height, and carcass meat percentage. This data was paired with information on how many purebred piglets the sows had given birth to and reared in successive litters. The collection contained information on 12,665 purebred litters from 71 breeding herds and parities 1 to 15. In order to determine the impact of certain factors on sow production performance, four groups of factors were created based on parity, body weight, daily gain, and meatiness. The study found that young gilts evaluated at a body weight of up to 55.9 kg and with daily gains of up to 519 g/day had the poorest production parameters in both the first and subsequent parities. Females with excessive carcass meat content ($\geq 60\%$, class S) had fewer piglets born and reared mainly in the first parities, while a high meatiness value in the second and third parities contributed to a reduction in the number of piglets reared. The work financed from the National Research Institute of Animal Production (Task no. 01-11-05-11).

Session 34

Poster 19

Are the ethics of pig breeding addressed in literature?*M. Van Der Sluis, R.S.C. Rikkers and K.H. De Greef**Wageningen Livestock Research, P.O. Box 338, 6700 AH Wageningen, the Netherlands; malou.vandersluis@wur.nl*

Animal breeding activities may raise ethical concerns, especially because of the technologies used and the (potential) effects on the animals. This study examined to what extent ethics of genetic selection in pigs are discussed in the scientific literature, and which themes are focused on. A literature search was performed in Scopus, based on titles, key words and abstracts, using a combination of three search term groups: (1) an animal part; (2) a breeding part; and (3) an ethics part. The search was limited to publications from 1990 to 2022, resulting in 130 publications retrieved on December 15th 2022. Subsequent manual selection resulted in 31 publications that met the criterium of mentioning ethics of pig genetic selection. Of these, 14 only used the term ethics without elaborating on it, whereas 17 addressed ethics explicitly. The majority of these publications were not pig-specific, but addressed multiple species or farm animals in general. Ethical analysis of explicit pig-related themes that raise concerns (such as for example litter size) was scarce. Overall, three main ways of addressing ethics were identified: (1) the term 'ethics' being used as a synonym for societal acceptance, for example regarding genome editing, where ethics sometimes appear to be considered as a hurdle to overcome before implementation; (2) identification of ethical aspects of (consequences of) breeding, largely focusing on animal welfare; or (3) an ethical analysis of choices or dilemmas in breeding was posed, for example the balance between production economics (e.g. efficiency traits) and non-market value traits (e.g. animal welfare) in breeding programs. Overall, ethical analysis of specific pig breeding issues appears to be scarce in literature. An inventory of issues surrounding animal breeding across species (and in general) will likely be more informative for insight in ethical considerations. However, this will probably lack attention for specific pig issues.

Benzoic acid reduces environmental impact in fattener pig diets using life cycle assessmentE. Perez-Calvo¹, S. Lagadec², C. Drique², D. Planchenault³, S. Potot¹ and C. Valliere¹¹DSM Nutritional Products, 576 Wurmisweg, 4303, Kaiseraugst, Switzerland, ²Chambre d'Agriculture de Bretagne, 56 Rue de la Fontaine, 56300 Pontivy, France, ³DSM Nutritional Products, 71 Boulevard National, 92250 La Garebde-Colombes, France; estefania.perez-calvo@dsm.com

The objective of this study was to calculate the environmental impact of raising pigs from 30 to 115 kg fed a commercial diet supplemented with benzoic acid (BA) vs unsupplemented (C) using life cycle assessments (LCA). One hundred and forty-four pigs were randomly placed into 24 pens and assigned to treatments. Basal diets included corn, barley, wheat and sunflower meal as main ingredients and feed enzymes (phytase and xylanase). BA was included at 0.5%. A Two-phase feeding was used including 14% CP (grower) and 12.2% CP (finisher) and animals' weight and feed intake were monitored. Data were analysed by one way ANOVA in JMP. Overall performance showed that BA pigs increased ADG compared to C pigs (905 vs 939 g/d, $P=0.04$) and FCR was also improved in BA pigs compared to C pigs (2.56 vs 2.45, $P=0.04$). LCA were performed including the impact of feed production, housing and slurry management using an attributional approach. The results were given according to the 19 impact categories of the EU PEF methodology using Sustell™ LCA software (ISO: 14040/44). Over the 19 environmental impact categories and after normalization, 4 categories, including Global Warming Potential (GWP100 – fossil, biogenic, land use and land transformation), respiratory inorganics (RI), marine eutrophication (MA), and freshwater eutrophication (FE), were found to be the most relevant impact categories for this study. Feed production was identified as the main contributor for climate change (GWP 100), (up to 44%), as well as MA (up to 67%) and FE (up to 73%) in both groups. Inclusion of BA in the diet helped to reduce by 6, 7, 9 and 11% in GWP100, EF, EM and RI, respectively, mainly through improved performance. Additionally, BA intervention reduced emissions on ammonia by 13% and methane from the manure management process by 3%. In conclusion, 0.5% BA supplementation to GF pig diets resulted in improved performance and consequently in a reduced environmental impact especially in climate change and ammonia emissions.

Session 35

Theatre 1

Is there a future for experimental animal research in Europe?J. Van Milgen¹ and T. Chalvon-Demersey²¹INRAE, Institut Agro, Pegase, Le Clos, 35590 Saint-Gilles, France, ²METEX Animal Nutrition, 32, rue Guersant, 75017 Paris, France; jaap.vanmilgen@inrae.fr

Research involving experiments with animals is increasingly questioned by society. In 2021, the European Parliament asked the European Commission to 'Develop plans and actions to accelerate the transition to innovation without the use of animals in research, regulatory testing and education'. The resolution was adopted with 664 votes in favour, 4 against, and 16 abstentions. In February 2022, The European Commission responded that 'The legal obligation to replace the use of animals when new non-animal methods become available is firmly embedded in EU legislation, providing a step-wise approach as science advances'. The Commission also indicated that it is impossible to predict when these new methods become available and that non-animal alternatives are most efficiently developed in clearly defined contexts of use. Later that year, a European Citizens' Initiative was launched asking the European Commission to 'Modernize science in the EU' and to 'Commit to a legislative proposal plotting a roadmap to phase-out all animal testing in the EU before the end of the current legislative term'. The initiative collected more than one million signatories (from at least seven EU countries with a threshold for each country), which means that the European Commission has to consider it and a formal reply from the Commission is expected by July 2023. The 'legal obligation to replace the use of animals when new non-animal methods become available' and the 'clearly defined contexts of use' means that we, as an animal science community are not only concerned by, but also have a responsibility on how research on livestock production will be done in the future. This includes the development and training of future generations of animal scientists on using alternative methods (such as *in vitro* methods and computer modelling), and in engaging in an open and constructive debate with legislators and society. It also means that the data that we have generated in the past and that we generate now from animal experiments will have a great scientific value in the future. Open Data will allow us to bring new life in old data.

Testing minimally invasive blood collection techniques in pigs used for researchF.A. Eugenio¹, F. Gondret², M. Oster³ and C. Ollagnier¹¹Swine Research Unit, Agroscope, Posieux, 1725 Fribourg, Switzerland, ²PEGASE, INRAE, Le Clos, 35590 Saint-Gilles, France, ³Research Institute for Farm Animal Biology (FBN), German, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany; florence.gondret@inrae.fr

The collection of blood to monitor circulating concentrations of metabolites is an important tool for research to better describe the nutritional and health status of animals. In pigs, venepuncture requires the animal to be restrained, which can be stressful and painful, and large veins are also not very visible which complicates the procedure. An alternative is catheterization, but this involves a surgical procedure which induces an inflammatory response that can mask certain metabolic responses, and needs the housing of pigs in isolated pens. This study aimed to test alternative blood collection procedures and associated scaled down methods to assess circulating metabolites in growing pigs. In Exp 1, four blood collection methods were tested in pigs (n=6 females, 61 kg body weight): (1) catheterization; (2) venepuncture with the aid of a handheld infra-red imaging tool; (3) ear pricking with a lancet to collect drops of blood in filter papers; and (4) blood sucking *Dipetalogaster maxima* parasites. Blood collection was done at four time points using each method in a randomised order after feeding the pigs a liquid glucose meal. Methods were compared for the relative ease of collection, animal stress indicators, and obtained concentrations of cortisol and glucose. In Exp 2, glucose sensors with an intradermal needle were secured on the neck of pigs (n=8 females, 50 kg body weight); pigs were also equipped with a jugular catheter to serve as a control. Circulating glucose concentrations analysed by the sensor were obtained during five days with two diets (high starch then a high fat). Both basal concentrations and postprandial glucose curves during four hours after two meal test procedures were also compared with those obtained by blood sampling through the catheter. Ongoing laboratory and data analysis will reveal the best suitable approach in minimising the negative impact of blood collection in pigs used in experimental research. The PIGWEB project has received funding from European Union's Horizon 2020 under Grant Agreement No 101004770.

Theatre 3

Development of protocols for standard management and recording in pig research facilitiesA. Wallenbeck¹, M. Girard², M. Johansen³, S. Döpjan⁴, M. Aluwe⁵, C. De Cuyper⁵, E. Labussière⁶, M. Font-I-Furnols⁷, M. Heetkamp⁸ and R. Westin¹¹SLU, Box 234, 523 32 Skara, Sweden, ²Agroscope, Rte de la Tioleyre 4, 1725 Posieux, Switzerland, ³AU, S20, 3310, 8830 Tjele, Denmark, ⁴FBN, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany, ⁵ILVO, Scheldeweg, 68, 9090 Melle, Belgium, ⁶INRAE, Saint, Gilles, France, ⁷IRTA, Finca Camps i Armet, 17121 Monells, Spain, ⁸WUR, P.O. Box 338, 6700 AH Wageningen, the Netherlands; anna.wallenbeck@slu.se

European pig research infrastructures have different focus areas, but share common challenges. All perform basic pig management and often the same standard traits are recorded, providing possibilities for (improvement of) standard operating procedures (SOPs) within and across facilities. Researchers are not always aware of SOPs and their impact on the quality of their studies and data, while facility staff might not be fully aware of the potential impact of deviation from standard procedures. To safeguard good research and data quality, this awareness needs to be improved in all involved parties. In the PigWeb project, one of the aims is to improve and harmonise protocols for standard management and recording in pig experimental facilities of eight partners in the network. The process to reach this aim included three main steps: (1) Identification of key areas of standard management and recording; (2) Development of improved protocols based on compilation of current practises, and (3) SWOT analyses on implementation of improved protocols. We conclude that procedures varied between facilities but key areas with potential for improvements and harmonisation could be identified. Many facilities had no written SOPs in place, even though adequate routines were applied. The primary suggestion for improvement is that if SOPs are not in place, the first important step is to develop SOPs on current procedures, leading to harmonisation within the facility. The suggested improved protocols developed in the process described above are not to be used strictly, but as templates to facilitate and promote development of SOPs that suit the specific facility and initiate communication between facility staff and researchers. Important activities in further harmonisation over facilities are knowledge exchange on SOP development.

Development of a protocol for administering a capsule to sample small intestine content

I. Garcia Viñado, M. Tretola, G. Bee and C. Ollagnier

Agroscope, Rte de la Tioleyre 4, 1725, Switzerland; catherine.ollagnier@agroscope.admin.ch

Pig's microbiome has recently been the focus of research, as modulating microbiota has profound effects on health. So far, stool samples have been the only non-invasive method to study gut microbiota, but the microbiome composition and diversity are different along the entire gastrointestinal tract (GIT) and faeces. The Capsule for Sampling (CapSa) is a swallowable device that transits through the natural digestive pathway, collects small intestine content, and is excreted with the faeces. First administration of capsules to pigs revealed that the capsules were chewed, got stuck in the stomach, or were lost to the environment after excretion in the faeces. A total of eight pilot studies have been conducted to test and optimize the procedure to administer the capsule and to improve capsules' recovery rate in the faeces. To validate the procedure, 93 Swiss Large White pigs (ranging from 6.45 to 67.1 kg) were administered 2 capsules each and monitored the following 3 days to search for the CapSas in the faeces. Subsequently, the pigs were euthanized to locate the missing capsules. In all trials, the pH of the capsules' content was assessed and a pH level of 6 or higher was considered to rule out a stomach sampling. The capsules could be administered to 97% of the pigs, and 44% were found in the faeces within 72 hours of administration, 31% were retrieved in the stomach after euthanasia, while 25% could not be located. There was a correlation between the pigs' BW and the ability of the capsule to pass the stomach ($P < 0.05$) and to be retrieved in the faeces ($P = 0.03$). Capsules were not able to pass the stomach in pigs with a body weight lower than 12 kg. Overall, 72% of capsules retrieved from faeces had a $\text{pH} > 5.5$, indicating they had sampled gut content. It is necessary to conduct additional studies to validate the administration protocol and to study the microbiome in order to verify that Capsa samples the content of the small intestine.

A modelling approach to investigate metabolic fluxes of amino acids in the small intestine of pigsC.J.J. Garçon^{1,2}, J. Van Milgen², N. Le Floc'h² and Y. Mercier¹¹Adisseo SAS, 2 rue marcel Lingot, 03082 Commentry, France, ²INRAE, UMR PEGASE, 16 Le clos, 35590 St-Gilles, France; clement.garcon@inrae.fr

Studies on animal metabolism often require invasive interventions and may be limited in the coming years because of ethical concerns. This is the case to study *in vivo* metabolic processes linked to digestion, which is done with catheterized animals. Several *in silico* models of digestion or post-absorptive nutrient utilization have been developed, however little attention has been given to the intestinal tract itself. Therefore, our aim was to aggregate current knowledge to better understand the dynamics of metabolic fluxes of amino acids (AA) in the small intestine of pigs. A mechanistic model was built as a series of differential equations representing the metabolism of an unspecific AA in the intestine of pigs. The model was built with a series of functional intestinal segments, with an identical structure. Each segment included four state variables representing dietary proteins, luminal free AA, free AA in intestinal cells, and protein-bound AA. These state variables were linked by fluxes representing the main metabolic pathways of AA metabolism, namely hydrolysis of dietary protein, absorption of resulting AA, synthesis and degradation of cellular protein, endogenous secretions, and exchanges with blood. To parametrize the model, data were obtained from the literature and, if not available, values assumed as reasonable were used. A simulation was done with 1000 intestinal segments during a period of 24 h in which the animal received five meals followed by an overnight fast. During periods of feed intake, the model simulated the export of AA to the blood, while during fasting it simulated the importation of AA from the blood to maintain cellular homeostasis. About 30% of the absorbed AA did not appear in the blood due to their usage for synthesis of intestinal proteins. Part of these proteins were redirected to the intestinal lumen as endogenous secretions driven by the presence on intestinal content. In this version of the model, recycling of endogenous proteins was not yet considered, which led to an increase in intestinal sequestration of AA. This first model constitutes a basis for the further development as well as a tool to test hypotheses about metabolic fluxes of AA in the intestine.

***In vitro* gas production of pre-treated or untreated feedstuffs using cecum inoculum from horses**R.H. Jensen¹, R.B. Jensen², M.O. Nielsen¹ and A.L.F. Hellwing¹¹Aarhus University, Department of Animal and Veterinary Sciences, Blichers Allé 20, 8830 Tjele, Denmark, ²Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Universitetstunet 3, 1433 Ås, Norway; annelouise.hellwing@anivet.dk

Horses are hindgut fermenters, and the composition and digestibility of feedstuffs reaching the hindgut might have an impact on the gas/methane production. Sugar, starch, protein and fat are degraded and absorbed in the small intestine so the nutrient content in digesta entering the hindgut differs from the original feedstuff. The aim of the study was to compare *in vitro* gas production from feedstuffs pre-treated to remove sugar, starch, protein and fat or untreated, using cecum fluid from horses as inoculum. Twelve feedstuffs (early or late cut grass hay, alfalfa haylage, maize silage, seed grass straw, barley straw, dried carrots, oat, maize, dried sugar beet pulp, dried apple pulp and peas) were investigated. Pre-treated feedstuffs were exposed to α -amylase and pepsin at 38 °C and washed in acetone. Both untreated and pre-treated feedstuffs were incubated for 48 hours (h) in buffered cecum fluid in the ANKOM RF gas production system. Data were fitted to a monophasic model and maximum gas production (MGP) ml/g dry matter (DM), time point of half of the MGP ($T_{1/2}$) in h and the rate constant (C) were calculated. The data were analysed in PROC GLM with the effect of pretreatment and feedstuff. Pre-treatment removed from 17% (seed grass straw) to 78% (carrots) of the DM. Pre-treatment affected the MGB and $T_{1/2}$, and the average MGP was 167 and 180 ml/g DM for pre-treated and untreated feedstuffs, respectively. $T_{1/2}$ was 13.7 and 16.0 h for the pre-treated and untreated feedstuffs. There was a significant effect of feedstuffs on MGB, $T_{1/2}$ and C. The highest MGB was found on peas (311 ml/g DM) and the lowest barley straw (69 ml/g DM). $T_{1/2}$ was highest on grass seed straw (28 h) and lowest for dried sugar beet pulp (7 h). The rate constant was highest for maize silage and lowest for late cut grass hay. The pre-treatment decreased the gas production due to removal of dietary components with high degradability. This highlights the importance of pre-treating feedstuffs when evaluating the gas/methane production in *in vitro* systems to reflect the horse.

Session 35

Round table discussionJ. Van Milgen¹ and T. Chalvon-Demersey²¹INRAE, Institut Agro, Pegase, Le Clos, 35590 Saint-Gilles, France, ²METEX Animal Nutrition, 32, rue Guersant, 75017 Paris, France; jaap.vanmilgen@inrae.fr

A round table discussion with early-career scientists will be organized.

UpDown – an R Package to characterize unknown disturbances from longitudinal observationsI. David¹, V. Le^{1,2} and T. Rohmer¹¹INRAE, GenPhySE, Castanet Tolosan, 31320, France, ²Alliance R&D, Le Rheu, 35650, France; ingrid.david@inrae.fr

The response of an animal to a disturbance depends on its resilience and the characteristics of the disturbance experienced (intensity and duration). As the latter are generally not registered on the farm, the R package UpDown was developed in order to detect and characterize unknown disturbances from the analysis of longitudinal individual observations that are now available in many species thanks to the development of electronic devices. Depending on their nature, disturbances are likely to affect one or more animals organised in hierarchical groups. For instance, in pig farming, the animals are grouped in pens which are themselves grouped in batches leading to a 3-levels hierarchical organization (individual, pen, batch). The UpDown method consists in analysing the summarised longitudinal observations at these different group levels in order to gain power to detect disturbances and facilitate their characterisation. The Up step identifies elements undergoing a disturbance at the different hierarchical levels that is validated and characterised in the down step. The UpDown package can consider as many hierarchical levels as desired and different validation options in the down step, which allow it to be adapted to different farming systems and environmental conditions. Applied to simulated data mimicking 100 days of observations in a pig farming system, the UpDown package showed a sensibility to detect elements undergoing a disturbance that increased with the hierarchical level (from 43% at the individual level to 93% at the batch level) and was associated with a good specificity for all levels (>95%). The quality of the characterization of the disturbances increased with their duration. The correlations between the estimated and the true intensities were large (>0.72 for the group scales). The median gap between the estimated and true starting (ending) date was lower than 3 days. Different information on individual trajectories can be obtained from the output of the UpDown package and used to analyse the resilience of animals after correction by the disturbances identified and characterized by the UpDown package.

Session 36

Theatre 1

Effect of sex ratio and density mating on reproductive performances in *Tenebrio molitor*

E. Soucat, K. Paul, Q. Li, A. Masseron, F. Gagnepain-Germain, A. Chauveau, E. Sellem and T. Lefebvre

Ynsect, R&D Biotech, 1 rue Pierre Fontaine, 91000 Evry, France; katy.paul@ynsect.com

Ynsect is leading an ambitious R&D program called YnFABRE, aiming to develop a genetic and genomic selection for *Tenebrio molitor*. In this way, reproduction skills belong to a trait of interest, which may be improved through genetics and environmental ways. This work aims to study the effect of sex ratio deviation and breeders' density on each female's egg quality and production. We set up an experimental design, with equivalent-aged individuals from the Ynsect population, containing 15 conditions with 2 replicates for 5. We examined the influence of sex ratio on reproductive traits with 7 different sex ratios tested (polyandry: 0.25, 0.33, 0.5; ex-aequo: 1; polygamy: 2, 3, 4); and also the effect of 8 different densities (2 to 10 animals per cup of 16 cm²). We followed the egg production per cup twice weekly during the two first weeks. Five weeks after the start of the experimentation, egg quality was assessed by measuring the hatching rate. The sex ratio does not affect significantly the females' performance (number of eggs). Indeed, during the 2 first weeks, each female produced on average 223, 219 and, 194 eggs in the various sex ratio groups (i.e. polyandry, ex-aequo, and polygamy, respectively). It is, therefore, possible to increase the number of females to males (polygamy) in a tray to improve egg production per tray with the same breeders' number. However, on average hatching rate was significantly lower under polygamy (68%; $P < 0.005$) than under polyandry or with equal breeders' sex ratio (79 and 77%). Furthermore, limiting the spawner density (~less than 0.056 g/cm²) should be necessary, as this parameter seems negatively correlated to individual female egg production. These preliminary results provide guidelines for modifying density and sex ratio in mealworm breeding to improve egg production. Further analysis is needed to confirm these first results on a larger number of density and sex ratio with more replicates. In addition, to better understand the variation in performance due to sexual behaviour under various sex ratios and density environments, breeder tracking will be also developed.

Behavioural responses of black soldier fly to olfactory stimuli: evaluation of a Y-tube olfactometer

A. Spindola and M. Pulkoski

Enviroflight, Animal Biology, 2100 Production Drive, 27539, USA; aline.malawey@enviroflight.net

Secondary colonizers are sensitive to microbial volatile organic compounds (MVOs) that relay information about resources, potential mates, oviposition site, and habitat suitability. These colonizers' responses are partially governed by the sex and physiological state (e.g. gravid and non-gravid) of the fly and concentration of the MVOs. Two days-old black soldier flies (BSF) virgin and mated males and females and gravid females were examined, by group, in a Y-tube olfactometer. The results showed a relationship between sex and physiological state related to dose-dependent attraction to MVOs, suggesting that specific MVOs provide distinct types of information to the flies with differing foraging interests. Specific MVOs at a given concentration could prevent oviposition outside of egg collectors and the nuisance presence of conspecific males and non-gravid females within the oviposition site.

Session 36

Theatre 3

Cold storage: a tool for delayed and stable black soldier fly (*Hermetia illucens*) pupae eclosionD. Deruytter¹, S. Bellezza Oddon², L. Gasco² and C.L. Coudron¹¹Inagro, Insect Research Centre, Ieperseweg 87, 8800, Belgium, ²University of Turin, Department of agricultural, Forest and Food Sciences, Via Verdi 8, 10124 Turin, Italy; david.deruytter@inagro.be

The black soldier fly (BSF) is known and revered for its rapid development. Although this comes with its drawbacks. The fast and single egg clutch deposit by BSF females may be quite a challenge especially for small scale productions and or research colonies. One of the ways to delay and stabilize the production is to ensure control of when the eclosion of the pupae occurs. In this study, BSF (pre)pupae of different ages (from prepupae to 5 day old pupae) were stored at different cold temperatures (15 and 18 °C) for a range of exposure times (2-35 days). After cold storage, the pupae were transferred back to control conditions (28-30 °C). Finally, the 18 °C exposure experiment was done for 2 populations (Belgium and Italy) to assess any differences. During the experiments the eclosion time was assessed on a daily basis and the mortality was recorded. Based on this, the 50% eclosion time was then calculated. The results indicate that lower temperatures slowed the development of the pupae and, surprisingly, this decrease was irrespective of the pupae age or the exposure time. At 15 °C the development slowed down to 15% of the control rate and at 18 °C this increased to 31-33%. This means that it is easy to predict the eclosion of the flies when only 3 parameters are known: the age of the pupae, the storage-time in the cooler and the normal development time. The latter may differ between populations as the normal development rate at Inagro (Belgium) was 8 days, this was only 5.4 days at Unito (Italy). Finally, although storing them in a cold environment is good for delaying pupation it may significantly increase the mortality. At Inagro this was observed when storing at 15 °C for more than 14 days and near complete mortality after 35 days, but no mortality occurred at 18 °C. At Unito up to 60% mortality was observed at 18 °C. The apparent combined faster development with a lower cold tolerance does mean that cold storage is less effective for Unito compared to Inagro. Further research is needed to elucidate what causes the different observations.

Influence of temperature on coloration in honey bees

J. Bubnič and J. Prešern

Agricultural Institute Of Slovenia, Animal production department, Hacquetova 17, 1000, Slovenia; jernej.bubnic@kis.si

Abdominal coloration of honeybees was one of the first traits used to describe subspecies. The main disadvantage in using abdominal coloration as an indicator of the honeybee subspecies is the lack of knowledge of the genetic background of the trait and the subjectivity of coloration grading. Coloration seems to be strongly subjected to the environmental impact: previous studies showed that a change in abdominal coloration in workers of *A. cerana* can be induced by manipulating the environmental temperature to which workers are exposed as pupae. Similar results were obtained in *A. mellifera* queens. We incubated honey bee (*Apis mellifera carnica*) brood obtained from two colonies, one exhibiting yellow marks on the abdomen of workers and the other not (workers had only gray abdomens; labels gray or yell) at two different temperatures (30 and 34 °C; labels 30 or 34). We collected hatched workers and photographed abdomens under the stereo microscope. Images were analysed using custom written R script to obtain single value that represents the coloration of abdomen and vectors of average pixel values. We tested influence of brood origin and temperature on coloration using ANOVA. We used vectors for UMAP analysis and to train and test the support vector machine model. The mean value for coloration in 34gray group was 446.7 ± 19.3 and 458.1 ± 19.2 in 34yell group. In 30gray group the mean value was 441.9 ± 23.9 and 454.0 ± 21.1 in 30yell group. ANOVA did not reveal differences between 30gray and 34gray ($P=0.477$) nor between 30yell and 34yell ($P=0.742$). Differences were confirmed between groups 34yell and 34gray ($P=0.031$) and between 30yell and 30gray ($P=0.009$). UMAP analysis did not position individual abdomens according to experimental group. The performance of trained model was: area under ROC was 0.776 classification accuracy was 0.543 F1 is 0.0541 precision was 0.547, and recall was 0.543. We observed differences in abdominal colour between different temperature regimen, however those differences were not significant. We developed a useful tool for quantifying abdominal coloration. The outputs of the tool could be used in various statistical analysis for scientific purposes as well as on field when assessing subspecies purity.

Session 36

Theatre 5

The juvenile hormone analogue, pyriproxifen, alters the body composition of *Tenebrio molitor* larvae

V. Hill, T. Parr, J. Brameld and A. Salter

University of Nottingham, School of Biosciences, Sutton Bonington, LE12 5RD, United Kingdom; victoria.hill1@nottingham.ac.uk

Tenebrio molitor larvae (yellow mealworms, MW) are a potential alternative protein source, but they contain relatively high concentrations of fat (25-36%). The aim of the study was to determine if the juvenile hormone analogue, pyriproxifen, could alter MW body composition. MW were fed wheat bran (WB) containing 3 ml acetone vehicle control (Vcont) or 2 mg pyriproxifen/kg WB (JH-L) or 15 mg pyriproxifen/kg WB (JH-H) with 4 replicate groups per treatment, each with 300 MW per group. MW were housed in an incubator in the dark at 25 °C and 60% humidity, and fed *ad libitum* feed and water. Dead and pupated MW were removed throughout. After 28 days, MW were culled and proximate nutrient and amino acid analysis conducted, along with protein analysis using SDS-PAGE. Data were analysed by one or two-way ANOVA using Genstat (20th Edition). There was a significant time $\times$ treatment interaction for average individual MW body weight ($P<0.05$), which was not different until day 28 when JH-L treated MW were significantly heavier than JH-H ($P<0.05$), but not heavier than the Vcont treatment group. After 28 days of treatment, both JH-L and JH-H treated MW had significantly ($P<0.001$) decreased fat contents, with JH-H decreasing by 68% compared to Vcont. Crude protein (CP) was significantly increased ($P<0.001$) in both JH-L and JH-H, the latter being increased by 46% compared to Vcont. SDS-PAGE indicated JH-H induced changes in the types of protein present, with the apparent induction of a distinct 150 kDa protein in JH-H, which proteomics identified as the egg-yolk protein, vitellogenin. This was accompanied by a significant ($P<0.001$) 17.5% increase in lysine content in JH-H compared to Vcont. The shift in protein to fat ratio demonstrates the potential to manipulate MW body composition, with the CP (70.26% of dry matter (DM)) and fat (8.88% of DM) contents of JH-H treated MW being similar to fishmeal (CP, 70.7% of DM; fat, 10% of DM). The change in CP is accompanied by changes in protein composition, which may be responsible for the increase in lysine content. However, it remains to be established to what extent the overall change in body composition is due to increased protein or reduced lipid deposition.

Fate of food pathogens during black soldier fly rearing and processing

J. De Smet, D. Van De Weyer, E. Gorrens, N. Van Looveren and M. Van Der Borgh

KU Leuven Campus Geel, Department of Microbial and Molecular Systems, Kleinhoefstraat 4, 2440 Geel, Belgium; jeroen.desmet@kuleuven.be

The black soldier fly (*Hermetia illucens* L.) is a commonly used insect for the bioconversion of organic waste on an industrial scale. One of the reasons explaining its success is the ability of the larvae of *H. illucens* to thrive on a wide range of organic materials, ranging from rotting fruit to manure. While these niches can be a rich source of nutrients, they are also known to contain a high microbial load. It is thus important to evaluate the prevalence and risks associated with the presence of food pathogens during both the rearing cycle and downstream processing of the larvae. Our group has worked on this topic in the frame of three projects: Entobiota, Upwaste and SUSINCHAIN. Here, we provide an overarching view of the main findings in these projects, some of which have been published. By focusing on the fate of *Salmonella* spp. and *Staphylococcus aureus* during rearing, we observed a more nuanced pathogen reduction by the larvae, than sometimes reported in literature. Based on these findings, we advise to be careful with claims on the ability of the black soldier fly larvae to reduce pathogens. Therefore downstream processing steps are crucial to ensure sufficient reduction of food pathogens that may persist in the larvae. We have investigated the effectiveness of three innovative strategies for processing: extrusion, microwave, and radio-frequency drying. Another observation is that some food pathogens are only rarely associated with insects (e.g. *Clostridium perfringens*), making it difficult to assess the effectivity of the current processing steps against these food pathogens. In the future, we will therefore also use pathogen supplementation during processing to fully understand the final microbiological risk for the end-consumer of insects.

Session 36

Theatre 7

Insect as animal feed: Fourier-transformed spectroscopy to reveal their protein molecular structure

J. Ortuño and K. Theodoridou

Institute of Global Food Security, Queen's University Belfast, 19 Chlorine Gardens, Belfast, BT9 5DL, United Kingdom; k.theodoridou@qub.ac.uk

The aim was to characterize for first time the protein molecular structure of four insect species (black soldier fly larvae-BSF, Mealworms-MW, Field Crickets-FC and Banded Crickets-BC) in correlation with their nutritive value, for monogastric animals. Three batches of those species were purchased in three consecutive weeks from a commercial supplier. Insects were sieved to remove frass and litter, fasted for 12 h at room temperature, washed, freeze-dried until constant weight, milled and sieved (<1 mm). In total 12 samples were analysed using 3 different techniques: FTIR, wet chemistry and *in vitro* nutrient digestibility (DMd). No significant difference for CP or EE content between the two types of crickets, while BSF showed the lowest ($P<0.001$) CP compared with the rest of the species. Both crickets had higher ($P<0.05$) chitin content than BSF and MW. NDF was similar between BSD and MW but lower ($P<0.001$) than FC and BC. MW showed the highest DMd (81.2%) ($P<0.05$) than the other species. This is the first study exploring *in vitro* the kinetics of the different DMd phases in insects. The pancreatic DMd in both cricket species was higher (>30%) ($P<0.05$) than for MW (<20%) and BSF (<10%). The protein molecular structure was identified and the AmideII height was greater ($P<0.05$) in BSF, followed by the two crickets and MW. AmI band used to predict protein secondary structure, was lower ($P<0.001$) for BSF (0.311) compared to MW, FC and BC (0.644, 0.810, 0.712, respectively). BSF contained lower ($P<0.001$) percentage of α -helix (0.307) and β -sheet (0.303), compared to MW, FC, and BC (0.609, 0.778, 0.679 and 0.599, 0.756, 0.653, respectively). Positive correlation ($r>0.95$; $P<0.001$) between the AmI height, α -helix and β -sheet with the CP was found. Chitin showed only a modest correlation ($r=0.58$; $P<0.05$) with the α -helix/ β -sheet ratio. Digestibility during the pancreatic phase was correlated ($P<0.01$) with CP ($r=0.91$) and NDF ($r=0.80$). Insect powders showed differences in their nutritive value which was reflected in their protein molecular structure. In conclusion, FTIR has the potential to become a rapid technique to predict nutritive value of insect powders included in animal diet and prevent fraud and adulteration.

Proteomics evaluation of the barrier role of insects for the indirect recycling of fast food in feed

M.C. Lecrenier¹, M. Aerts², A. Cordonnier¹, L. Plasman¹, O. Fumière¹ and V. Baeten^{1,2}

¹Walloon Agricultural Research Centre (CRA-W), Chaussée de Namur, 24, 5030 Gembloux, Belgium, ²University of Louvain-la-Neuve (UCLouvain), Croix du Sud, 2, 1348 Louvain-la-Neuve, Belgium; m.lecrenier@cra.wallonie.be

Since 2021, insect meal is authorised in feed intended for pig and poultry, in addition to that for fish. Insect meal is considered as one of the most promising alternative ingredient totally in line with the EU goal aiming to reduce its dependency on critical feed materials like soya. Even these regulatory changes seem to increase the insect market, its use in feed remains limited and still more expensive than other protein sources. One of the reasons for this high price is linked to the limitation of authorised substrates for breeding. Indeed, from a legislation point of view, edible insects are considered as farmed animals and therefore they must follow EU animal by-products regulation. Following the same sustainability strategy, EU has also adapted legislation to promote the use of another feed source, the former foodstuffs (FFS). FFS retain a significant nutritional value and their use is completely in line with the current trend of circular economy. However, FFS containing meat or fish remain prohibited. Their use as a substrate for insect breeding could in the future be a contributing way to tackle food waste and an indirect use of these products for non-ruminants by having a role as health barrier. But is it really a sufficiently strong barrier? At the end of the insect rearing, insects are separated from feed media and incorrect procedure may lead to the presence of residual feed materials. The objective of this study was to develop a UHPLC mass spectrometry-based proteomics method to detect the presence of animal proteins in insect meal. Non-ruminant meat, raw or cooked or under its fast food form, were used to identify specific peptides markers. In order to evaluate the sensitivity of the protocol, insect substrate adulterated or not with meat as well as insect reared on this substrate were analysed. Analyses were performed by liquid chromatography (Acquity UHPLC system, Waters) coupled with a triple quadrupole mass spectrometer (Xevo TQ-XS, Waters). Results will be presented and discussed during the meeting.

Session 36

Theatre 9

Scaling up fly mating chambers: lessons learned from operating 4 and 24 m³ fly mating chambers

S.P. Salari and M.L. De Goede

InsectoCycle, Bronland 10, 6708 WH, the Netherlands; sepp.salari@insectocycle.nl

InsectoCycle has been dedicated to developing large-scale black soldier fly reproduction units. These units feature a fly mating chamber (light cages) that is either 4 or 24 m³ and have been in operation for the past two years. Compared to typical laboratory scale experiments, these units are notably larger, resulting in new interactions and diverse microclimates within the cage. In-depth research has been conducted to comprehend the key factors that impact fly mating and egg deposition, as well as how to measure and influence these factors. Some of the factors that have been examined include air temperature, surface temperature differences between the floor and walls, humidity at the floor vs the ceiling, airflow through the cage, and the necessary refreshment rate to regulate CO₂ and ammonia levels for optimal performance. However, controlling these elements simultaneously can be challenging and determines the success and stability of the reproduction process.

ALL-Yn: An automated solution for phenotyping *Tenebrio molitor* larvaeQ. Li¹, T. Mangin², J. Richard¹, E. Sellem¹, A. Masseron¹, F. Gagnepain-Germain¹, T. Lefebvre¹ and R. Baude²¹Ynsect, R&D Biotech and Innovations, 1 rue Pierre Fontaine, 91000 Evry, France, ²Apres-Solutions, 2 allée André Guinier, 54000 Nancy, France; qi.li@ynsect.com

Tenebrio molitor is a promising alternative to produce high quality protein products with low environmental impact. The industrial scale production handles an important number of insects, putting forward the emphasis on genetic diversity and performances. The high number of individuals leads to the development of automated solutions for insect phenotyping. To that end, All-Yn has been developed to automatically count the number of larvae and assess the biomass of both larvae and feed leftover by associating artificial intelligence state of the art and parametric computer vision algorithm. 50 samples, containing in total 969 larvae, have been simultaneously counted and weighted manually and with All-Yn. According to the sample, different larval weights were assessed (min=23.8 mg, max=247.5 mg). The feed leftover were also quantified. Anova analysis has been used to validate these comparisons. Out of 969 larvae, 939 are detected and segmented for the first batch of samples, with no false positives counted. A subset of 224 larvae was assessed with the laboratory set up to phenotype the weight. The first results show no significant ($P>0.05$) differences between the predicted biomass and the reference (respectively $1,958.5\pm999.2$ mg and $1,951.2\pm975.6$ mg on average). The feed leftover biomass evaluation is still ongoing. These first outcomes are promising and will empower the AI learning. The dataset has to be completed with more samples aiming to reach higher detection rate. Through the cooperation of neural network and segmentation, we will be able to propose a highly robust and flexible set up for daily laboratory work by reducing the bench lab duration (minutes per sample) and by increasing the data accuracy and objectivity. These technological approaches, applied to other phenotypes will improve and facilitate the traits assessments in large population for the development of a genetic or genomic selection scheme.

Theatre 11

Does sex matter? The impact of sex on the buffalo pupation phase

N. Gianotten, N. Heijmans and N. Steeghs

Ynsect Netherlands, R&D Biotech, Harderwijkerweg 141B, 3852 AB, the Netherlands; natasja.gianotten@ynsect.com

In insect rearing, the number of individuals per tray or container can be very large. Depending on the type of rearing system, tens of thousands or even hundreds of thousands of individual insects per tray are not uncommon. In lesser mealworms (*Alphitobius diaperinus* or buffalo) the sex of an individual is not easy to distinguish. Currently, in the large-scale lesser mealworm rearing at Ynsect Netherlands, the sex is not considered, both in the larval and the adult stage. Previous publications have shown an impact of sex on the individual weights of pupae and beetles, with females being bigger than males. These experiments were executed more than 25 years ago, which is very long in this field of work. It was therefore decided to repeat this experiment with our current line of *A. diaperinus*, which is already artificially reared for feed and food purposes for more than 40 years. Additional to individual weights of female and male pupae and beetles, also the impact of sex on moment of pupation, and on length of pupal period is investigated. The possible impact of biological parameters like individual weight, length of pupation period and male/female ratio in ovipositing beetles on the large-scale rearing of the *A. diaperinus* will be discussed.

Assessment of chemical hazards in insect meal production for aquaculture feeds

I. Amaral¹, S.M. Ahmad¹, M. Ângelo¹, P. Correia Da Silva¹, A. Quintas¹, J.A.A. Brito¹, D. Murta^{1,2}, M.V. Santos³, I. Vieira³, T. Ribeiro² and L.L. Gonçalves¹

¹CiiEM (Centro de Investigação Interdisciplinar Egas Moniz, Egas Moniz School of Health and Science, Monte de Caparica, 2829-511 Caparica, Portugal, ²Entogreen – Ingredient Odyssey, S.A., R. Eng. Albertino Filipe Pisca Eugénio no.140, 2005-079 Santarém, Portugal, ³Thunder Foods, Rua Santo António Lt 9, Zona Industrial Santarém, 2005-002 Santarém, Portugal; lgoncalves@egasmoniz.edu.pt

Insect meals are sustainable alternatives to the ingredients currently used in formulation of aquaculture feeds. However, the use of insects as feed raises safety concerns, stemming from a combination of factors: the nature of the substrate used to feed the insects, the specific production methods, the harvest stage, the insect species as well as the methods used for further processing. In fact, the presence of a wide variety of chemical contaminants, including heavy metals (Hg, Cd, Pb), metalloids (As), and POPs (persistent organic pollutants) such as Dioxins, PCBs, pesticides, can be found in these products. However, published data on hazardous chemicals in captive bred insects and their possible transfer from different substrates to insects and from insects to other animal species are scarce. Thus, the present study aims to assess the abovementioned chemical risks in insect meals and in fish feed, throughout the food chain. For that purpose, 6 agricultural by-products selected for the growth of *Tenebrio molitor* (TM) and *Hermetia illucens* (BSF) and fish feed formulations obtained from the mentioned insects were screened for elements of toxicological concern by wavelength dispersive X-ray fluorescence spectrometry (WDXRF), using a 4 kW commercial system (Bruker S4 Pioneer), according to published methods. Pesticide residues, such as organochlorides, were monitored in the same samples, by GC-MS (Agilent 6890N with a 5973 Network GC/MS system at SIM mode), using a QuEChERS method from the literature. Preliminary results revealed that the agri-food by-products, as well as the insect meals tested, did not present chemical risks that could compromise their future use in feed formulations for aquaculture. Acknowledgments: The InFishMix project (PT-INNOVATION-0094) is funded by Iceland, Liechtenstein and Norway through the EEA and Norway grants.

Session 36

Poster 13

Microbiological risk analysis in insect meal production

D. Guerreiro¹, D. Murta^{1,2}, M.V. Santos³, I. Vieira³, T. Ribeiro² and H. Barroso¹

¹CiiEM, IUEM, Egas Moniz School of Health and Science, Campus Universitario, Qta da Granja, Monte de Caparica, 2829-511 Caparica, Portugal, ²Entogreen, Zona Industrial de Santarém, 2005-079 Santarém, Portugal, ³Thunder Foods, Zona Industrial de Santarém, 2005-332 Santarém, Portugal; mhbarroso@egasmoniz.edu.pt

Currently, the ingredients used in the manufacture of aquaculture feeds are expensive and their use pose a risk to sustainability, which leads aquaculture food producers to look for other, friendlier alternatives. The circular economy is a key to tackle climate change and redefine the economy. With the world population increase, it becomes necessary to look for alternative sources of protein. Insects are a viable alternative with their production having a positive environmental impact. This study is part of the InFishMix project where the main goal is the development of a new ingredient for aquaculture feed, mixing different species of insects produced from agroindustry by-products. Throughout the production process, the quality and safety of by-product substrates, insects, feed and fish will be monitored, with the objective of guaranteeing safe fish for human consumption. So far, microbiological analyses were performed for: (1) the substrates used for the insects feed, namely, vegetable by-products mixture, olive pomace, soy pomace and wheat bran; (2) insects (black soldier fly and *Tenebrio molitor* larvae) fed with these substrates, and (3) processed black soldier fly and *Tenebrio molitor* larvae. The presence of different potentially pathogenic microorganisms of importance to human health were assessed (by conventional methods), as well as mycotoxins (by ELISA assays). The results showed that the processed insect larvae obtained are microbiologically safe. Of the different substrates studied, it was found that olive pomace was the one with the lowest microbial contamination. The use of olive pomace as feed for the larvae may contribute to the resolution of a serious environmental problem. We conclude that the use of the studied agroindustry by-products to feed insects is safe, resulting in a safe ingredient for aquaculture feed in terms of microbiological evaluation. Acknowledgments: The InFishMix project (PT-INNOVATION-0094) is funded by Iceland, Liechtenstein and Norway through the EEA and Norway grants.

Multi directional approach in fly emergence evaluation and forecasting for *Hermetia illucens*

B. Grodzki, M.G. Zhelezarova, T. Bruder and M. Tejeda

Nasekomo AD, Saedinenie 299, 1151, Bulgaria; bartosz.grodzki@nasekomo.life

Various studies have been conducted on intrapuparial BSF development aiming at establishing the concrete development phases from a pupa into fly. Having a clear knowledge about the stages sequence and length can enable prediction of insects emergence time. Furthermore, as synchronicity in development is crucial in black soldier fly farming, this basic knowledge of the fly biology can bring benefit in large scale production operations, by reducing loss due to delayed emergence and facilitate the animals maintenance. The late larva-prepupa-pupa-adult transition were studied simultaneously with three different approaches. A thermal model of development, physiological stage tracking by pupa dissections and an object detection algorithm approach. Production batches were grown into two temperature controlled rearing rooms and monitored from late pupa till emergence, dissections were performed at different stages of pupa development, photographed under the stereomicroscope, and analysed with a computer algorithm. The different approaches combined information allows Nasekomo future production to forecast the batches time of emergence from environmental or dissection data. Furthermore, the algorithm was able to detect specific structures like legs and compound eye of the pharate insect and thus could also be used to determine stage of development and probably, quality of production. Described models and tools can be used for precise management of fly emergence in reproduction sector of BSF colony. Proper evaluation and forecasting of adults emergence allow to deliver constant (in time and numbers) outputs of flies to the system and plan production according to the population's dynamic.

Session 36

Poster 15

Application of NIRS on *Tenebrio molitor* protein mealJ. Richard^{1,2}, L. Darai¹, L. Sanchez¹ and B. Lorrette¹¹Ynsect, R&D Animal Nutrition & Health, 1 rue Pierre Fontaine, 91000 Evry, France, ²Ynsect, R&D Biotech, 1 rue Pierre Fontaine, 91000 Evry, France; lorena.sanchez@ynsect.com

The potential of near infrared spectroscopy (NIRS) was studied to evaluate the ŸnMeal composition of total fat and protein, moisture and minerals. ŸnMeal, a highly digestible protein concentrate from *Tenebrio molitor* larvae, is perfectly suitable for the nutrition of farmed fish and pets. This study presents the development of calibration models of ŸnMeal content with NIRS technology and it's daily use potential during routine applications for quality control. Analyses were done with the NIRS XDS (400 to 2,500 nm; Metrohm) in a moving cell by reflectance with a spot size of 17,25 mm and an average of 32 scans. All the spectra and calibrations have been analysed with Vision®, the dedicated software developed by Metrohm. Each sample involved in calibration, have been analysed by NIRS and sent for external analysis (sub-contractor using COFRAC methods) to obtain reference values. Calibrations are made with PLS method and different mathematic treatments have been used to determine the best parameters for each calibration. Calibrations have been created for moisture, protein, lipid, and ash content from 290 samples, and varying from 0.1 to 12.0%, 62.1 to 77.0%, 8.6 to 15.2% and from 3.1 to 5.5% respectively. Low uncertainty of measurement have been observed (1.0, 1.6, 1.0 and 0.3% for moisture, protein, lipid and ash calibration respectively). Every uncertainty obtained are significantly lower than the standard deviation of the data set. These NIRS calibrations are used in routine quality control since 2018. They are monthly controlled with 5 samples analysed in parallel with an external control and they are fed with new data every year making them more accurate. The accumulated results obtained in our lab conditions, highlight the suitability of NIRS for ŸnMeal content control and pave the road for the development of other product quality controls.

State of the art in understanding interorgan crosstalk and physiology in farm animalsI. Cassar-Malek¹, I. Louveau², C. Boby¹, J. Tournayre¹, F. Gondret² and M. Bonnet¹¹Clermont Auvergne University, INRAE, VetAgro Sup, UMR Herbivores, 63122 Saint-Genès-Champanelle, France,²PEGASE, INRAE, Institut Agro, 35590 Saint-Gilles, France; isabelle.cassar-malek@inrae.fr

One of the challenges for livestock production is to manage phenotypic traits associated with health and production performance across diverse production systems in a wide range of climatic conditions and agro-ecological practices. Such a management requires a better understanding of the physiology of key tissues and organs involved in these traits. Therefore, it is important to determine the mechanisms behind the traits (feed efficiency, body composition, meat quality) and their regulation along physiological states (lactation, reproduction, growth) and in changing environments (robustness), and to get an integrated view at the level of the animal. Inter-organ communication, so called organ crosstalk, is required to regulate the different physiological functions, and to orchestrate multiple signalling molecules to maintain body homeostasis. In this review, we will show that tremendous opportunities are now offered for ruminants and pigs with the recent advances in: (1) omics (transcriptomics, proteomics, lipidomics) technologies for the profiling of organs and biofluids, and the knowledge of mediators in extracellular communication (e.g. microvesicles/exosomes); (2) *in silico* analysis with bio-informatics prediction tools (secretome/surfaceome, interaction networks); (3) integration of heterogeneous data (including multivariate analyses, clustering, network inference, graphs); (4) biosensing technologies; and (5) organ- on- chip systems. This will be helpful to get a holistic view for production and adaptation traits (incl. symbiotic interactions with resident microbiota), and to discover biomarkers to develop minimally invasive phenotyping tools to qualify these traits and assess the impact of rearing practices.

Pig embryonic development differs from that of humans and mice from the blastocyst stage and is characterised by a much later implantation. This particular period is associated with a lengthening and significant growth of the extra-embryonic tissues and is still poorly understood. To better understand the biology of the pig blastocyst, we generated a large dataset of single-cell transcriptomics (scRNAseq) and multi-omics (paired RNAseq and scATAC-seq) at different embryonic stages (early, late, ovoid and elongated blastocysts) and the associated proteomic dataset from the corresponding uterine fluids. These data were cleaned, filtered and represent a total of 35,000 cells. Using these data, we first characterised embryonic and extra-embryonic cell populations and their evolution, and identified specific markers of these populations. We then used a pig-adapted version of the SCENIC package to infer gene regulatory networks (regulons) and selected those that were specifically active in each embryonic population. Meta-analysis of other scRNAseq publications on the preimplantation embryo in pigs and humans increased confidence in the regulons we identified. We then linked these regulons to signalling pathways and biological processes. To do this, we used the CellCom software to build signalling networks from ligands (expressed by cells or present in the uterine fluids), receptors, intermediary players, to transcription factors. Thanks to this integrative study, we have identified key new players controlling the biology of the three main cell lineages and identified novel stage-specific subpopulations. Taken together, our work provides new insights into the functional interactions of the first cell lineages within the conceptus prior to implantation.

¹H-NMR metabolomic study of Large White and Meishan pigs in late gestation: part 1 – foetal placenta

J. Guibert¹, A. Imbert¹, N. Marty-Gasset¹, L. Gress¹, C. Canlet², L. Canario¹, Y. Billon³, A. Bonnet¹, L. Liaubet¹ and C.M.D. Bonnefont¹

¹GenPhySE, Université de Toulouse, INRAE, INPT, ENVT, 31326 Castanet Tolosan, France, ²Axiom Platform, MetaToul-MetaboHUB, National Infrastructure for Metabolomics and Fluxomics, 31027 Toulouse, France, ³GenESI, INRAE, Le Magneraud, 17700 Surgères, France; cecile.bonnefont@inrae.fr

The most critical period for piglet survival is the first three days after birth. The risk of piglet mortality is increased if the piglets have a lower degree of maturity at birth, resulting from intra-uterine growth retardation. Foetal development is highly dependent on the functioning of the placenta, and is accelerated in the later stages of gestation. Therefore we decided to study the placental metabolism at the end of gestation. To better understand the relationship between foetal development and piglet maturity at birth, we chose to compare 14 Large White (LW) sows, representing the European commercial breed that is highly affected by piglet mortality before weaning, with 14 Meishan (MS) sows, representing the Asian breed with lower piglet mortality. All sows were inseminated with mixed semen from both breeds and develop purebred and crossbred foetuses. Placental samples were collected from 224 foetuses at 90 or 110 days of gestation (dg). Hydrophilic metabolites were extracted and ¹H-NMR spectra were acquired. Raw spectra were processed using the ASICS R package to identify and quantify 48 metabolites. PLS-DAs were performed at 90 dg and 110 dg. Both separated the LW and MS purebred foetuses on the 1st latent variable (LV), explaining 22 and 16% of the variability, respectively. The crossbred foetus were intermediate. There were 19 and 21 metabolites important (VIP>1) for the 1st LV at 90 and 110 dg, respectively. The metabolites were mainly involved in amino acid metabolism and in energy metabolism. Metabolites were then correlated with morphological parameters. In particular, placental myo-inositol concentration was negatively correlated with foetal body mass index (BMI, $r=-0.4$) and positively correlated with foetal brain weight/body weight ratio ($r=0.4$), indicating stunted growth. In conclusion, differences in metabolism between the foetal genotypes may be involved in their differences in survival at birth.

Theatre 4

Metabolic pathways leading to different intramuscular fat content in rabbit divergent lines

P. Hernández, A. Blasco and A. Zubiri-Gaitán

Institute for Animal Science and Technology. Universitat Politècnica de València, Camino de Vera S/N, 46022 Valencia, Spain; phernan@dca.upv.es

A divergent selection experiment for intramuscular fat content (IMF) was developed in rabbits at the Universitat Politècnica de València. These divergent lines were used to perform an untargeted metabolomic analysis with the aim of identifying the metabolic pathways involved in their differentiation. Plasma samples were obtained from 24 animals of the high IMF (H) and 24 of the low IMF line (L) at 9 weeks of age, after fasting for 4 h. The metabolomic profile was obtained by UPLC-MS/MS, detecting 997 metabolites. Metabolites with more than 10% of zeros in at least one line were removed, and the remaining zeros were imputed using random forest. ALR transformation was applied to account for the compositional nature; then the data was standardized and analysed using two multivariate approaches: PLS-DA to find the differences between the lines, and PLS to find the metabolites that adjusted linearly to IMF. Double cross-validation was performed to select the relevant metabolites without overfitting. Metabolites with VIP ≥ 0.8 and Jack Knife confidence interval that did not include the 0 were selected. A total of 322 metabolites were relevant in the discrimination between the lines and adjusted linearly to the IMF, being mostly involved in the metabolism of lipids and amino acids. The L line had greater abundance of lipids including, among others, several free fatty acids and acylcarnitines, and greater abundance of metabolites from the arginine metabolism. The H line showed greater abundance of free carnitine, branched-chain amino acids (BCAA) and BCAA-associated species like butyrylcarnitine and propionylcarnitine, and metabolites from the aromatic amino acids and the histidine metabolisms. The changes in lipids metabolism evidenced a reduced uptake in the muscle and adipose tissues and an impaired β oxidation of fatty acids of the L line, indicating a limited capacity to obtain energy from lipids. The H line showed greater BCAA catabolism, which could partially explain its greater IMF content. Additionally, the changes in the metabolisms of BCAA, aromatic amino acids, arginine, and histidine suggest the relevant role of microbiome activity in the development of the trait.

Proteomics profiles of longissimus thoracis muscle of Arouquesa cattle from different systems

L. Sacarrão-Birrento¹, A. Dittmann², S.P. Alves³, L. Kunz², D.M. Ribeiro¹, S. Silva^{4,5}, C.A. Venâncio^{5,6} and A.M. De Almeida¹

¹LEAF, ISA, Tapada da Ajuda, Lisboa, Portugal, ²Functional Genomics Center Zürich, University of Zurich, Zurich, Switzerland, ³CIISA and AI4Animals, FMV, Lisboa, Portugal, ⁴CECAV, UTAD, Vila Real, Portugal, ⁵ECAV, UTAD, Vila Real, Portugal, ⁶CITAB, UTAD, Vila Real, Portugal; laurasvbirrento@isa.ulisboa.pt

Beef is one of the most important protein sources in human nutrition, so it is essential to guarantee its quality. Local breeds, such as the Arouquesa from Northern Portugal, produced under extensive systems lead to high quality and healthier products. The aim of this work was to compare the protein abundance profiles of beef from the Arouquesa traditional production system with improved systems, using label-free proteomics. Sixty animals were allocated to five systems: TF (n=11), the traditional where the animals were weaned and slaughtered at 9 months; TFS1 (n=13), the addition of an initiation supplement (S1); S1S2 (n=15), animals eating S1 until the weaning at 5 months and then a growing supplement (S2) until 9 months; TFS3 (n=10) and S3 (n=11), produced like TFS1 and S1S2, with the addition of a rearing period until 12 months and a finishing supplement (S3). We used label-free quantification to determine protein profile in the Longissimus thoracis muscle (10 samples per group). The meat quality had only differences on the exudative and cooking losses being higher in TF and TFS1 groups. We identified 3,774 proteins in all comparisons. The proteins were considered differentially abundant with $P < 0.05$: 18 in the TFxTFS1 comparison, with TF beef showing higher accumulation of proteins involved in actin (fascin and GC) and calcium binding (hyaluronoglucosaminidase) pathways; 28 in the TFxS1S2 comparison, with actin, ATP and calcium binding metabolic pathways being affected; 65 in the TFxTFS3 comparison that were involved in proteolysis (Tripeptidyl-peptidase 2), muscle contraction (Myosin heavy chain 4) and proteasomal protein processes; and finally, 36 in the TFxS3 comparison involved in glucose metabolic process (Phosphoglucosmutase-1 and fibrillin-1) and in protein transport (exportin-2). Some potential biomarkers of meat quality when comparing the traditional group with the new systems could be established.

Session 37

Serum metabolomics of newborn lambs before and after colostrum feeding

L. Lachemot¹, J. Sepulveda^{1,2}, X. Such¹, J. Piedrafit¹, G. Caja¹ and A.A.K. Salama¹

¹Universitat Autònoma de Barcelona, Ruminant Research Group (G2R), Campus UAB, 08193 Bellaterra, Spain,

²Universidad Nacional de Colombia, Facultad de Medicina Veterinaria y Zootecnia, Edificio Uriel Gutiérrez, Bogotá D.C., Colombia; ahmed.salama@uab.cat

Colostrum feeding to the neonatal lamb is essential for health and survival. Nevertheless, little is known about the changes in blood metabolomics in neonatal lambs during the first hours of life. Ten lambs were separated from their mothers just after birth, and blood samples were collected. Thereafter, lambs received 2 colostrum meals (200 ml each) at 1 and 5 h after birth. A second blood sampling was done at 6 h after birth. Serum was obtained and frozen at -80 °C until the metabolomic analyses. Blood serum was ultra-filtrated (3 KDa cutoff), mixed with DSS (0.5 mM), and analysed using ¹H nuclear magnetic resonance spectroscopy at 600 MHz. Metabolites were quantified using Bayesil (bayesil.ca). Enriched pathways were identified by KEGG using MetaboAnalyst (v. 5.0). Feeding colostrum resulted in an increment ($P < 0.05$) in the blood concentrations of D-glucose (+71%), acetone (+28%), 3- hydroxybutyrate (+61%), isobutyric acid (+111%), formate (+15%), and 8 amino acids (Glu, Ile, Leu, Lys, Met, Phe, Tyr, and Val) that increased by 47 to 189%. On the other hand, colostrum consumption caused decreased ($P < 0.05$) levels of lactate (-42%), acetate (-27%), glycerol (-54%), succinate (-67%), betaine (-31%), carnitine (-34%), choline (-38%), creatinine (-25%), and 5 amino acids (Ala, Arg, Asp, Gly, Thr) that were reduced by 51 to 74%. Additionally, there were 8 altered pathways (FDR < 0.05) after colostrum feeding. These pathways included aminoacyl-tRNA biosynthesis, Phe-Tyr-Trp biosynthesis, Phe metabolism, Gly-Ser-Thr metabolism, Ala-Asp-Glu metabolism, and glyoxylate and dicarboxylate metabolism. In conclusion, the metabolomic blood profiling of neonate lambs revealed several changes in the intermediates of TCA and lipid metabolism to satisfy their energy needs during the first hours of life. Amino acid metabolism pathways were the most affected pathways by colostrum ingestion. Acknowledgments: Funded by the Spanish Ministry of Science and Innovation (Project RTA #PID2020-113913RR).

Characterization of milk small extracellular vesicles to study adaptation to lactation in ruminants

C. Boby¹, A. Delavaud¹, J. Pires¹, L.E. Monfoulet², S. Bes¹, S. Emery¹, L. Bernard¹, C. Leroux¹, A. Imbert¹, M. Turret¹, F. Fournier³, D. Roux³, H. Sauerwein⁴ and M. Bonnet¹

¹Université Clermont Auvergne, INRAE, VetAgro Sup, UMR Herbivores, Centre INRAE CARA, 63122 Saint-Genès-Champanelle, France, ²Université Clermont Auvergne, INRAE, Human Nutrition Unit, Centre INRAE CARA, 63122 Saint-Genès-Champanelle, France, ³INRAE, Herbipôle, Centre INRAE CARA, 63122 Saint-Genès-Champanelle, France, ⁴University of Bonn, Institute of Animal Science, Physiology Unit, Katzenburgweg 7, 53115 Bonn, Germany; celine.boby@inrae.fr

Small extracellular vesicles (EV) are secreted into the extracellular space by all cells. Due to the diversity of their cellular origin and the molecules they contain, small EVs have the ability to ensure extracellular communication and carry molecular signatures of their tissue of origin and its physiological state. In ruminants, early lactation is characterized by profound changes in energy balance and metabolic status. To explore physiological adaptations during early lactation, this study investigated the use of non-invasive milk EVs to identify specific indicators of inter-organ signalling. Milk samples were collected from 8 cows on weeks 2 and 7 postpartum, corresponding to negative and neutral energy balance, respectively. Small EVs were isolated by ultracentrifugation coupled with size exclusion chromatography and characterized by morphological, biophysical and biochemical criteria. Labelled-free shotgun quantitative proteomics was performed by nanoLC-MS/MS. Electron microscopy revealed cup-shaped vesicles with a diameter of about 100 nm, characteristic of small EVs. The diameter was confirmed by Tunable Resistive Pulse Sensing and the specificity of small EVs isolation by the presence of cytoplasmic (TSG101) and membrane (CD63) markers. A total of 508 proteins were identified in milk EVs at weeks 2 and 7 of lactation. Multilevel PCA analysis showed a clear separation between the 2 time points, indicating a strong effect of lactation stage on the protein composition of milk EVs. This proteomic dataset will be analysed to identify small EV molecular signatures of tissue interactions that coordinate nutrient partitioning and adaptation during early lactation.

Theatre 8

Multi-tissue transcriptome analysis of bovine herpesvirus-1 (BoHV-1) challenged dairy calves

S. O'Donoghue^{1,2}, B. Earley², M.S. McCabe², S.L. Cosby³, K. Lemon³, J.W. Kim⁴, J.F. Taylor⁴, D.W. Morris¹ and S.M. Waters²

¹University of Galway, Discipline of Biochemistry, Galway city, Galway, Ireland, ²Teagasc, Animal and Bioscience Research Dept, Grange, Co. Meath, Ireland, ³Agri-food and Biosciences Institute, Veterinary Sciences Division, Stormont, Belfast, United Kingdom, ⁴University of Missouri, Division of Animal Sciences, Columbia, MO, USA; stephanie.odonoghue@teagasc.ie

BoHV-1, a key virus associated with the onset of bovine respiratory disease (BRD), is a leading cause of morbidity and mortality in cattle. Previously, changes in gene expression were identified in the whole blood of BoHV-1 infected dairy calves, but no study has examined responses of key respiratory or immune associated tissues. Our study objective was to examine the gene expression profiles of multiple respiratory and immune associated tissues in BoHV-1 infected dairy calves. Holstein-Friesian bull calves (mean age(SD) 149.2 days(23.8); mean weight(SD) 174.6 kg(21.3)) were challenged with either BoHV-1 inoculate (6.3×10^7 /ml $\times$ 1.35 ml)(n=12) or sterile phosphate buffered saline (n=6). Animals were euthanised on day 6 post-challenge and tissue samples (lesioned (LL) and healthy right cranial lobe (HL), mediastinal (MLN) and bronchial lymph nodes (BLN) and pharyngeal tonsil (PGT)) were collected. Total RNA was extracted, RNA quality determined, libraries prepared using the TruSeq stranded mRNA kit and then sequenced on an Illumina NovaSeq 6000 (paired-end, 100 bp (MLN, PGT) and 150 bp (HL, LL and BLN). Sequence reads were quality assessed, trimmed, and aligned to the ARS-UCD1.2 bovine reference genome. Differential expression analysis was conducted using EdgeR. Differentially expressed genes (DEGs) were input to DAVID for pathway and gene ontology (GO) analysis and DEGs identified between control and infected animals in all tissues ($P < 0.05$, FDR < 0.1 , FC > 2). The PGT had the greatest number of DEGs with 1,833 while 67 were identified in the LL. Across all tissues, KEGG pathways for Influenza A and Hepatitis C and the GO terms defence response to virus, innate immune response and negative regulation of viral genome replication were enriched ($P < 0.05$, FDR < 0.05). The herpes simplex infection pathway was enriched in the MLN, LL and LH. These findings provide further insight into the host immune response to BoHV-1 infection.

Transcriptome analysis reveals a different immune response depending on a SOCS2 gene point mutation

C. Oget-Ebrad¹, C. Cabau¹, S. Walachowski², N. Cebon², J. Sarry¹, C. Allain³, R. Rupp¹, G. Focuras² and G. Tosser-Klopp¹

¹GenPhySE, Université de Toulouse, INRAE, 24 chemin de Borde Rouge, 31326 Castanet-Tolosan, France, ²IHAP, Université de Toulouse, ENVT, INRAE, 23 Chemin des Capelles, 31076 Toulouse, France, ³UE Domaine de La Fage, INRAE, La Fage, 12250 Saint-Jean et Saint-Paul, France; gwenola.tosser@inrae.fr

The suppressor of cytokine signalling 2 (SOCS2) gene encodes a protein involved in the immune response. In sheep, a point mutation in SOCS2 has been associated with higher susceptibility to mastitis in commercial conditions. The objective of this study was to investigate the underlying role of the SOCS-2 protein in response to bacterial infection in a dairy sheep model under controlled experimental settings. We performed an intramammary inoculation of 14 ewes belonging to contrasted genotypes at the SOCS2 R96C point mutation (7 T/T and 7 C/C) with the *Staphylococcus aureus* SA9A strain. We monitored these ewes during 152 hours post inoculation (hpi) with extensive sample collection and measures including clinical observation, milk and blood metabolites and blood transcriptome. The clinical mammary response was more pronounced in susceptible T/T ewes when compared to wild type C/C ewes, as indicated by higher ruminal temperature and detrimental mammary clinical scores. Blood transcriptional analysis revealed large numbers of differentially expressed genes (DEG) from 16 hpi until the end of the challenge with *S. aureus*. DEG between genotypes were detected almost only at 56 hpi (n=177). The most represented pathways according to the Ingenuity Analysis were the interferon signalling and STAT-3 pathways. All genes involved in the latter pathways were overactivated in T/T genotype. At 56 hpi, the modular analysis allows a near perfect clustering according to the genotype groups, showing Inflammation-related modules are more activated in the T/T group. Altogether these data support that the higher susceptibility to mastitis in SOCS2 mutated T/T ewes is not a higher predisposition to infection, but rather a lower capacity of these ewes to master the mammary inflammation leading to the development of a chronic inflammatory state, involving the interferon JAK/STAT3 pathway. This study was funded by the Agence Nationale de la Recherche (REIDSOCs project: ANR-16-CE20-0010).

Theatre 10

Expression quantitative trait loci in whole blood influence putative immune genes in sheep

K. Dubarry¹, M. Coffey² and E. Clark¹

¹The Roslin Institute and Royal (Dick) School of Veterinary Studies, Easter Bush, Edinburgh, United Kingdom, ²SRUC, Easter Bush, Edinburgh, United Kingdom; katie.dubarry@ed.ac.uk

Sheep are livestock animals of global importance for the production of meat, milk, and fibre. Sheep breeding, health, and welfare can be improved through a better understanding of immune function and resilience to disease. Molecular techniques, such as RNA-Sequencing, allow us to interrogate the regulation of the immune system at the gene level, and it has been proposed that integrating molecular phenotypes into breeding algorithms could improve genetic gain and performance. Gene expression (GE) is one such molecular phenotype, and we can investigate the genomic regions driving variation in GE through Expression Quantitative Loci (eQTL) discovery. eQTL are genomic markers that explain a proportion of variance in the transcriptome. Analysing eQTL can identify candidate genes of interest for immunity or other production relevant traits. However, to date only a few eQTL studies have been published in sheep. We performed an eQTL analysis using RNA sequence data generated from whole blood and matched single nucleotide polymorphism (SNP) genotypes produced on the Ovine 50k chip, for a population of 57 Texel × Scottish Blackface lambs. This allowed us to identify 611 genomic variants associated with gene expression patterns ($FDR < 0.05$). Significant eQTL were found across the genome with most related to 'housekeeping' pathways. Two of the top eQTL were associated with STING1 and ENO1, which are known to play a role in immune function in humans. According to the sheep gene expression atlas, STING1 is ubiquitously expressed across tissues but ENO1 is highly expressed in macrophages, indicating it is involved in the innate immune response. In total, STING1 had 15 variants with a significant association, while ENO1 had 2. Our approach demonstrates that eQTL in whole blood have the potential to reveal novel genomic regions of interest underpinning complex immune molecular phenotypes. In particular, these findings indicate that the genomic variants associated with ENO1 and STING1 are possible targets for further investigation, validation, and potentially inclusion in genomic selection algorithms for sheep.

Thigh muscle proteomics revealed key pathways related to feed efficiency in slow-growing chickenP. Kaewsatun¹, C. Poompramun¹, S. Kubota¹, W. Molee¹, P. Uimari² and A. Molee¹¹Suranaree University of Technology, Institute of Agricultural Technology, Nakhon Ratchasima, 30000, Thailand,²University of Helsinki, Department of Agricultural Sciences, Helsinki, 00790, Finland; d5930029@g.sut.ac.th

Korat chicken (KR) is a slow-growing chicken developed in Thailand. It has recently become a popular alternative for meat-type chicken providing tasty meat with a high nutritional value. However, its feed efficiency (FE) is low causing high production costs and low competitiveness compared to commercial breeds. Understanding the metabolic pathways related to FE will allow the identification of potential biomarkers that can be used in the selection for improving feed utilization efficiency chicken. Therefore, this study aimed to investigate the proteome differences of the thigh muscle between male KR with either high FE (HFE) or low FE (LFE) using a label-free liquid chromatography-mass spectrometry (LC-MS) proteomic approach. At ten weeks of age, thigh muscle samples from six animals (three HFE and three LFE chickens) were collected for differential abundant proteins (DAPs) analysis. A total of 75 proteins were different between the two groups ($P < 0.05$), of which 26 proteins had high abundance and 49 proteins had low abundance in the LFE group compared to the HFE group. Furthermore, a functional enrichment and pathway analysis of DAPs revealed that the glycolysis/gluconeogenesis, biosynthesis of amino acid, pyruvate metabolism, pentose phosphate pathway, and fructose and mannose metabolism were significantly enriched within DAPs. These findings provide new insights into understanding the molecular mechanism in the thigh muscle that contributed to FE in slow-growing chickens.

Session 37

Poster 12

Multi-breed, multi-tissue systems biology analysis of beef cattle divergent for feed efficiencyK. Keogh^{1,2}, D.A. Kenny², P.A. Alexandre¹, M. McGee³ and A. Reverter¹¹CSIRO, Agriculture & Food, Queensland Bioscience Precinct, 306 Carmody Rd., St. Lucia, Brisbane, QLD 4067, Australia,²Teagasc, Animal and Bioscience Research Department, Grange, Dunsany, Co. Meath, C15PW93, Ireland, ³Teagasc, Livestock Systems Research Department, Grange, Dunsany, Co. Meath, C15PW93, Ireland; david.kenny@teagasc.ie

Provision of feed in beef production systems is a major determinant of profitability. Thus, the identification of genes implicated in regulating feed efficiency may allow for the selection and subsequent breeding of more feed efficient cattle, with obvious benefits for sustainability. It is also crucial that gene markers identified as contributing to feed efficiency are robust across various factors including breed type as well as environmental influence such as diet. In this study, gene co-expression network analysis was undertaken on RNAseq data generated from *Longissimus dorsi* and liver tissue samples collected from steers of two contrasting breed types (Charolais and Holstein-Friesian) divergent, within breed, for residual feed intake (RFI), across contrasting dietary phases: ((1) high-concentrate; (2) zero-grazed grass; (3) high-concentrate). Differentially expressed genes (DEG) based on the contrasts of breed, diet and RFI phenotype were utilised as nodes of the gene co-expression networks. Significant network connections were identified using an algorithm that exploits the dual concepts of partial correlation and information theory (PCIT). PCIT network analysis resulted in the formation of three RFI specific clusters of co-expressed genes which were separated by tissue type. Pathway analysis revealed enrichment ($P < 0.05$) of biological processes related to fatty acid biosynthesis in both liver and muscle clusters as well as immune-related pathways in a separate muscle specific cluster. Genes contained within the immune-related cluster were also breed specific DEGs highlighting a potential role for these genes as robust biomarkers for RFI across varying breed type. Acknowledgement: This research was funded by the Irish Department of Agriculture, Food and the Marine (RSF13/S/519). Kate Keogh received funding from the Research Leaders 2025 programme (co-funded by Teagasc and the European Union's Horizon 2020, Marie Skłodowska-Curie grant agreement number 754380).

Contribution of plasma proteins to the phenotypic signature of feed efficiency in Charolais bullsI. Cassar-Malek¹, A. Imbert¹, A. Delavaud¹, H. Sauerwein², R. Bruckmaier³, G. Cantalapiedra-Hijar¹ and M. Bonnet¹¹Clermont Auvergne University, INRAE, VetAgro Sup, UMR Herbivores, 63122 Saint-Genès-Champanelle, France, ²University of Bonn, Institute of Animal Science, Physiology Unit, 53115 Bonn, Germany, ³University of Bern, Vetsuisse Faculty, Veterinary Physiology, 3012 Bern, Switzerland; isabelle.cassar-malek@inrae.fr

Improving the efficiency of feed utilization by reducing the amount of feed intake while maintaining the same level of production has significant economic and environmental impacts in beef cattle. One major challenge is to easily phenotype this multifactorial animal trait for the purpose of genetic selection and precision feeding. Biomarkers and proxies of feed efficiency (FE) may contribute to this challenge. In order to identify phenotypic signatures that discriminate FE groups, we characterized 17 Charolais young bulls fed grass silage diets on their FE parameters (Residual Feed Intake: RFI, and feed conversion efficiency: FCE), carcass composition, some targeted blood parameters (hormones: GH, IGF, insulin, adiponectin, leptin, FT4; metabolites: glucose, NEFA, alpha amino nitrogen, BOH butyrate, urea), and plasma proteome. Labelled-free shotgun proteomics enabled identifying 229 plasma proteins (with 2 peptides, 1% FDR). Univariate, multivariate, and a multiblock sPLSDA analyses were applied to obtain a signature combining omics and carcass traits that discriminates the groups of FE animals. For that, we integrated our multiple datasets while explaining their relationship with FE variables (DIABLO method, mixOmics package). For RFI, the first latent variable of plasma protein abundances was strongly correlated with the one of carcass traits ($|r|=0.63$) and with the one of blood parameters ($|r|=0.68$) and enabled a clear discrimination of the groups. The key variables that drove such discrimination were identified as 25 proteins together with 3 carcass parameters and 8 hormones and metabolites. Inefficient bulls (with positive RFI) were characterized by: (1) bigger bladder and heart; (2) higher GH levels, as well as lower insulin and IGF1 levels, higher alpha amino nitrogen and NEFA levels; (3) higher abundance in 20 plasma proteins (incl. ITIH3, IPSP, ASPN and PSA6) and lower abundance in 5 plasma proteins (incl. MBL2, ANGPTL3, CO3).

Serum metabolomics of fattening bulls fed dry-total mixed ration (TMR) or corn silage-based TMRC. Stöcker-Gamigliano^{1,2}, M.H. Ghaffari², C. Koch¹, M. Schönleben³, J. Mentschel³, N. Göres³, P. Fissore³, I. Cohrs⁴, S. Schuchardt⁵ and H. Sauerwein²¹Hofgut Neumühle, Alsenz, 67728, Germany, ²University of Bonn, Bonn, 53111, Germany, ³Sano, Loiching, 84180, Germany, ⁴University of Gießen, Gießen, 35392, Germany, ⁵Fraunhofer ITEM, Hannover, 30625, Germany; morteza1@uni-bonn.de

In Europe and developed countries, fattening bulls are fed corn silage and starch-rich feeds and climate change could affect yields and drive the use of straw and other by-products. The objective of this study was to compare serum metabolites of Simmental bulls fed two diets: a conventional total mixed ration based on corn silage (CONVL) and a dry TMR based on straw and concentrates (DRY) (n=12/group). The main difference between the two rations was the absence or presence of corn silage. Blood samples collected at an average age of 420±11 days underwent targeted metabolomics analysis with the MxP® Quant 500 kit. MetaboAnalyst was used for statistical analysis. After performing multivariate analyses on 282 serum metabolites, it was found that the data differed significantly by treatment. Volcano plot analysis identified 29 significantly different serum metabolites (FDR=0.05 and fold change ≥1.5) from the 282 detected in all samples. The DRY group had lower serum levels of several metabolites compared to the CONVL group, including 3-indolepropionic acid, and hippuric acid. Gut microbiota-derived metabolites with health benefits include 3-indolepropionic acid, a potent neuroprotective antioxidant derived from tryptophan, and hippuric acid, a phenylalanine metabolite that increases with gut development and rumen function and decreases with digestive disorders like displaced abomasum. The DRY diet impacted lipid metabolism and cellular functions, as evidenced by lower levels of three cholesterol esters and five phosphatidylcholine species and higher levels of 17 triacylglycerols. Higher levels of trimethylamine N-oxide (TMAO) were observed in the DRY group compared to the CONVL group. Increased levels of TMAO have been associated with adverse health conditions in human studies. The results of this study suggest that feeding Simmental bulls CONVL or DRY TMR during the fattening period results in changes in serum metabolites related to gut microbiota-derived metabolites, lipid metabolism, and cellular functions.

Physiological importance of blood vitamin E in production characteristics of Japanese Black steersM. Kim¹, T. Masaki², K. Ikuta², E. Iwamoto², Y. Uemoto¹, F. Terada¹, S. Haga¹ and S. Roh¹¹Tohoku University, Lab of Animal Physiology, Graduate School of Agricultural Science, Aramaki-za-Aoba 4681, Aobaku, Sendai, 980-8572, Japan, ²Hyogo Prefectural Technology Center of Agriculture, Forestry and Fisheries, Hyogo, 679-0198, Japan; sanggun.roh@tohoku.ac.jp

Vitamin E plays a critical role in liver function, which is essential for maintaining the health and productivity of beef cattle. The objective of this study was to investigate the physiological features between blood vitamin E and the production characteristics in Japanese Black steers bred and raised in Japan. Twenty-one Japanese Black steers aged 12 months were reared until 30 months of age. The experimental period was divided into early fattening (12-14 mo of age; T1), middle fattening (15-22 mo of age; T2), and late fattening phases (23-30 mo of age; T3). Vitamin E concentrations increased from T1 to T2, decreased to T3, and notably increased from 16 months, reaching their peak at 20 months of age. To demonstrate the physiological importance of vitamin E, cattle were divided into two groups (High vs Low) according to the difference from 16 months to 20 months of age, and the relationship with carcass traits was analysed. Five Japanese Black cattle with high vs low vitamin E were identified. The levels of blood metabolites and hormones were investigated in High and Low cattle groups. Feed intake in T2 was significantly higher ($P < 0.01$) in the High group. This High group in T2 showed high growth performance and carcass traits. The concentrations of blood total cholesterol increased ($P < 0.1$) in the High group, whereas those of blood total protein decreased ($P < 0.01$). Blood AST (asparagine amino transferase) and γ -GTP (gamma-glutamyl transpeptidase) levels were significantly higher ($P < 0.01$) in the Low group. Additionally, this study determined differentially expressed genes (DEGs) in the liver tissues of both High and Low groups in T2 phase. A total of five DEGs were identified and were mainly involved in physiological functions of liver. These results suggest that elevated vitamin E levels in the middle fattening phases depending on high-energy intake may contribute to the mitigation of oxidative stress and inflammation, thereby promoting the enhanced liver health and function of Japanese Black steers.

Poster 16

Age-related changes in ruminal and blood parameters and intramuscular adiposity in Hanwoo steers

S.Y. Kim and M. Baik

Seoul National University, Department of Agricultural Biotechnology and Research Institute of Agriculture and Life Sciences, 1, Gwanak-ro, Gwanak-gu, Seoul, 08826, Korea, South; ksy3773@snu.ac.kr

Understanding age-associated changes in growth, metabolism, and intramuscular adiposity are important for determining beef yield and quality characteristics. We investigated age-related changes in growth rate, ruminal and blood metabolic parameters, and adiposity of longissimus thoracis (LT) of Hanwoo (Korean cattle) steers. Nineteen Hanwoo steers (initial body weight, 352 ± 5.37 kg; age, 12 ± 0.25 months) were used. The blood and rumen fluid were collected at 12, 15, 18, 21, 24, 27, and 30 months of age, and the LT samples were biopsied between the 11th and 12th rib at 12, 18, and 24 months of age. Steers were slaughtered at 31 months of age (772 ± 5.37 kg), and the LT samples were collected. The LT samples were used for histological observation of adipocyte size. Average daily gain and feed efficiency decreased ($P < 0.001$) with age. The ruminal ammonia concentrations increased ($P < 0.001$) with age from 12 to 21 months, thereafter those were unchanged until 30 months of age. Ruminal volatile fatty acid concentrations were unchanged from 12 to 24 months of age, and increased ($P < 0.001$) at 27 months of age. Ruminal acetate proportion decreased with age, whereas propionate proportion increased with age, resulting in decreased acetate: propionate ratio with age (all $P < 0.001$). Serum glucose concentrations decreased with age, whereas serum triglyceride concentrations increased with age (all $P < 0.001$). Serum free fatty acid concentrations increased ($P < 0.001$) with age from 12 to 24 months, thereafter those were unchanged until 30 months of age. Insulin concentrations increased ($P < 0.001$) with age. The adipocyte size, which was measured by image analysis of histological section of the LT, increased ($P < 0.001$) with age. In conclusion, the increased lipogenic parameters including ruminal propionate proportion and serum free fatty acid concentrations and insulin levels may in part contribute to the increased beef adiposity with age.

Post-ruminal urea release impact liver proteomics of beef cows at late gestation

M.M. Santos¹, T.C. Costa¹, R.D. Araújo¹, J. Martín-Tereso², I.P. Carvalho², M.P. Gionbelli³ and M.S. Duarte⁴

¹Federal University of Viçosa, Av. PH Rolfs, S/N, 36570-900, Brazil, ²Trouw Nutrition Research & Development, Stationsstraat 77, 3800, the Netherlands, ³Universidade Federal de Lavras, Av. Sul UFLA – Aqueanta Sol, 37200-000, Brazil, ⁴University of Guelph, Animal Biosciences, 50 Stone Road East, N1G-2W1, Canada; mduarte@uoguelph.ca

We evaluated the effects of post-rumen released urea (PRU) on liver metabolism of pregnant beef cows at late gestation. Twenty-four pregnant cows weighing 545 kg±23 kg were assigned into one of two dietary treatments from 174±23 of gestation up to 270 d of gestation: Control (CON, n=12), consisting of a basal diet supplemented with conventional urea; and PRU (PRU, n=12), consisting of a basal diet supplemented with a urea coated to extensively prevent ruminal degradation. Liver samples were collected and analysed through a NanoAquity high-performance liquid chromatographer (HPLC) coupled with a maXis 3G high-resolution Q-TOF mass spectrometer. The data was then screened for quality control where samples with less than 1% of the proteins identified and proteins represented in less than 10% of samples were removed from the dataset, which resulted in a final dataset with a total of 382 proteins. The data were normalized to library size using the Trimmed Mean of M-values method, via the TMM package using R software. Enriched analyses revealed proteins involved in pathway related to carbohydrate digestion and absorption, glycolysis, pyruvate metabolism, oxidative phosphorylation, pentose phosphate pathway, glutathione synthesis and biosynthesis of amino acids of the exclusively expressed proteins in PRU cows. Enriched pathways were differentiated related to carbohydrate digestion and absorption, glycolysis, pyruvate metabolism, oxidative phosphorylation, pentose phosphate pathway, and biosynthesis of amino acids of the exclusively expressed proteins in PRU cows. The proteomic data and the protein-protein interaction analysis revealed an increase in protein and energy metabolism in the liver of PRU cows. The data also suggest an enhancement in glutathione synthesis due to PRU supplementation, which likely to counteract the oxidative stress from the higher metabolic rates of the liver, since the treatment increased oxidative phosphorylation and glycolysis pathways.

Session 37

Poster 18

Liver transcriptome profiles of dairy cows with different serum metabolotypes

M. Hosseini Ghaffari¹, H. Sadri², N. Trakooljul³, C. Koch⁴ and H. Sauerwein¹

¹University of Bonn, Bonn, 53115, Germany, ²University of Tabriz, Tabriz, 516616471, Iran, ³Research Institute for Farm Animal Biology (FBN), Dummerstorf, 18196, Germany, ⁴Hofgut Neumühle, Münchweiler an der Alsenz, 67728, Germany; morteza1@uni-bonn.de

The objective of this study was to examine the changes in the hepatic transcriptome of cows with different serum metabolotype in early lactation. We performed hepatic transcriptome analysis by RNA sequencing (RNA-seq) for cows in 3 different metabolic clusters: high body condition score (BCS) predicted high BCS (HBCS-PH, n=8), HBCS predicted normal BCS (HBCS-PN, n=6), and normal BCS predicted normal BCS (NBCS-PN, n=8) on day 21 postpartum. A total of 13,118 genes were detected aligned with the bovine genome. Using PCA and heat map analyses, we found that the liver transcriptomes of cows with different metabolotypes were largely overlapped. A total of 48 differentially expressed genes (DEG; ~0.4%; FDR≤0.1 and fold-change >1.5) were found between NBCS-PN and HBCS-PH cows, whereas a total of 24 DEG (~0.18%) were found between HBCS-PN and HBCS-PH cows using DESeq2. Reverse transcription-quantitative real-time PCR (RT-qPCR) was performed for seven DEG and showed consistent results with the sequencing results in terms of relative expression across the comparisons. The study identified 31 down-regulated and 17 up-regulated genes between NBCS-PN and HBCS-PH cows. The downregulated DEG in NBCS-PN cows were involved in biosynthesis, cellular organization, localization, catabolism, and response to external stimuli compared to HBCS-PH cows. The upregulated DEG in NBCS-PN compared to HBCS-PH cows were involved in signal transduction, biological quality, cell motility, and molecular function, indicating altered metabolic adaptations to lactation. Furthermore, in the liver tissue of HBCS-PN vs HBCS-PH cows, DESeq2 analysis detected 14 down-regulated and 10 up-regulated genes involved in various processes, including cellular organization, cell adhesion, and motility. Overall, the slight alterations observed in the liver transcriptome may suggest a reduced role in the development of distinct metabolotypes but post-transcriptional processes may have hidden their contribution.

Comparison of metabolomic profile of the offspring of nulliparous and primiparous Holstein cows

M. Terré and M. Tortadès

IRTA, Ruminant Department, Torre Marimon, 08140, Spain; marta.terre@irta.cat

Foetal imprinting can influence further metabolism of the progeny. Several studies have examined the foetal development among nulliparous, primiparous and multiparous cows and its relationship with reproductive or performance traits of their offspring. The objective of this study was to evaluate metabolic imprinting at the beginning of the first lactation of the offspring from nulliparous or primiparous cows. Sixteen coetaneous primiparous Holstein cows, eight of which were born from nulliparous cows (heifers), and eight from primiparous cows, were raised under the same conditions in a commercial dairy farm. Plasma samples were collected at the beginning of lactation (DIM=32±8.9 days) for a non-targeted metabolomics analysis using a quadrupole time-of-flight mass spectrometry. Data were analysed by principal component analysis, hierarchical clustering heatmaps, random Forest analysis and comparisons of the observed metabolite abundances between treatments by t-test. Neither principal component nor random Forest were able to classify samples by experimental groups. However, t-test found differences ($P<0.01$) in fifteen plasma metabolites. From those 2 were identified: 4- α -carboxy-4- β -methyl-5- α -cholesta-8-en-3 β taol was down-regulated, and spermine was up-regulated in the offspring from primiparous compared to nulliparous cows, suggesting modulatory effects of cow parity on offspring's cholesterol biosynthesis (4- α -carboxy-4- β -methyl-5- α -cholesta-8-en-3 β taol) and cellular oxidative stress (spermine).

In pigs, selective breeding has led to a rise in neonatal mortality, in relation to a reduced maturity of newborn piglets. Piglet maturity and growth accelerate at the end of gestation and this requires considerable nutritional support. The process of maturation varies with foetal genome and uterine environment and depends upon placenta, the tissue that regulates feto-maternal allocation of resources. To better understand the foetal maturation process, purebred and crossbred foetal genotypes were produced from 14 Large White (LW) and 14 Meishan (MS) sows differing for piglet maturity at birth and piglet survival. All the sows were inseminated with mixed semen from the two breeds. We compared the transcriptome in 224 placentas collected according to this four foetal genotypes (FG) and two days of gestation (D90-D110, term at 114 days). The transcriptome was obtained by RNAseq technology and processed by nf-core/maseq pipeline. Statistical analysis was performed using mixed linear models with sow as random effect followed by a correction for multiple testing (FDR<0.001). We documented the expression profile of 8,407 differential transcripts (DEGs) for gestational age, FG and their interaction. These DEGs reflect an important transcriptomic change that occurs between D90 and D110 in the endometrium (2,901 DEGs) and underline genes involved in pathways essential for normal placental development such as the insulin-signalling pathway. In addition, 1,543 DEGs were identified according to FG. Gene Ontology enrichment analysis of the DEGs between FG highlighted the placental fatty acid β -oxidation pathway, which is proposed to be related to maternal nutrition and body composition. Other transcripts (561 DEGs) showed interactions between foetal genotype and gestational age. In conclusion, our study identified pathways that may be associated with differences in maturity at birth. This research is part of the ANR-20-CE20-0020-01 project CO-LOcATION.

Transcriptome of the feto-maternal interface in pigs in late gestation: part 2 – sow endometrium

A. Bonnet¹, S. Maman¹, L. Gress¹, A. Suin², S. Legoueix¹, C. Bravo¹, Y. Billon³, N. Vialaneix⁴, C.M.D. Bonnefont¹ and L. Liaubet¹

¹GenPhySE, Université de Toulouse, INRAE, ENVT, Auzeville, 31326 Castanet, France, ²GeT-PlaGe, INRAE, Genotoul, Auzeville, 31326 Castanet, France, ³GenESI, INRAE, Le Magneraud, 17700 Surgères, France, ⁴Université de Toulouse, INRAE, UR MIAT, Auzeville, 31326 Castanet, France; agnes.bonnet@inrae.fr

In pigs, genetic progress has led to a rise in perinatal mortality, mostly due to a reduced piglet maturity. Piglet maturity acquisition and greater foetal growth occur at the end of gestation and require considerable nutritional support. These processes are closely related to the physiology and nutrition of the dam, as nutrients are transmitted from the endometrium to the foetus via the placenta. The endometrium is critical for implantation, placenta, embryonic and foetal development; many critical morphological and secretory changes occur throughout gestation. In order to understand the role of endometrium during the foetal maturation process, we compared two breeds at two days of gestation (D90-D110, term at 114 days): Large White (LW) and Meishan (MS) with high and low neonatal mortality, respectively. The transcriptome of 224 endometrial samples from the two breeds at two gestational stages was obtained by RNAseq technology and processed by Nextflow nf-core/maseq pipeline. Statistical analysis was performed using mixed linear models with sow as random effect (limma package) followed by a correction for multiple testing (FDR<0.001). We documented the expression profile of 10,080 differential transcripts (DEGs) for gestational age, mother breed and their interactions. These DEGs reflect an important transcriptomic difference between LW and MS breeds (2,721 transcripts) and underlined genes involved in catalytic activity and metabolic process. A smaller transcriptomic change was observed between D90/D110 in the endometrium (607 transcripts), mainly reflecting a change in cell communication. Moreover, 3,210 DEGs showed interactions between gestational age and breed which are grouped into eight clusters of expression profiles. Results from this study suggest endometrial remodelling at D90/D110 and breed differences in catabolism status and strategy to mobilize reserves for foetal growth. This research is part of the ANR-20-CE20-0020-01 COLOcATION project.

1H-NMR metabolomic study of Large White and Meishan pigs in late gestation: part 2 – sow endometrium

A. Imbert¹, N. Duprat¹, N. Marty-Gasset¹, L. Gress¹, C. Canlet², Y. Billon³, N. Vialaneix⁴, C.M.D. Bonnefont¹, A. Bonnet¹ and L. Liaubet¹

¹GenPhySE, Université de Toulouse, INRAE, INPT, ENVT, Auzeville, 31326 Castanet, France, ²Axiom Platform, MetaToul-MetaboHUB, Toxalim, INRAE/INP/UPS, route de Tournefeuille, 31027 Toulouse, France, ³GenESI, INRAE, Le Magneraud, 17700 Surgères, France, ⁴Université de Toulouse, INRAE, UR MIAT, Auzeville, 31326 Castanet, France; laurence.liaubet@inrae.fr

The risk of piglet mortality is highest in the first few days after birth. Therefore, late gestation development is of high importance for piglet survival. The endometrium is the maternal tissue that is in direct contact with the placenta of each foetus and thus is the matrix for feto-maternal interactions. To better understand the relationship between foetal development and piglet maturity, endometrial tissues from Large White (LW) sows, with high piglet mortality, were compared to that from Meishan (MS) sows, a breed with less neonatal mortality. Endometrial samples (n=224) were collected from 28 sows (14 LW and 14 MS) at 90 or 110 days of gestation (dg, birth at 114 days), each sample being in direct contact with each of the 224 placentas. Hydrophilic metabolites were extracted and 1H-NMR spectra were acquired. Raw spectra were processed using the ASICS R package to identify and quantify 46 metabolites. A multivariate analysis revealed a main effect of gestational age (13.1% on 1st axis). Mixed models were used to identify 21 metabolites with differential concentrations between the two following conditions, day of gestation and genotype, their interaction, and with the sow as a random effect (one model fitted to each metabolite independently followed by a correction for multiple testing, FDR<0.05). As expected, fructose was more abundant at 90 dg than at 110 dg. Conversely, L-glutathione-reduced was more concentrated at 110 dg than at 90 dg and more concentrated in MS than in LW sows. Citrate and L-glycine were more concentrated in MS sows than in LW sows at both stages of gestation. These results suggest important metabolic differences between the endometrium of the two breeds. This research is part of the ANR-20-CE20-0020-01 project COLOcATION.

The effect of dietary *Laminaria digitata* on urinary and kidney proteomes of pigletsD.M. Ribeiro¹, A. Dittmann², D.F.P. Carvalho¹, L. Kunz², J.P.B. Freire¹, J.A.M. Prates^{3,4} and A.M. Almeida¹¹Instituto Superior de Agronomia – Universidade de Lisboa, LEAF – Linking Landscape, Environment, Agriculture and Food, Tapada da Ajuda, 1349-017 Lisboa, Portugal, ²ETH Zürich/University of Zurich, Functional Genomics Centre Zürich, Winterthurerstrasse 190, 8057 Zürich, Switzerland, ³Laboratório Associado para Ciência Animal e Veterinária (AL4AnimalS), Avenida da Universidade Técnica, 1300-477 Lisboa, Portugal, ⁴Faculdade de Medicina Veterinária – Universidade de Lisboa, CIISA – Centro de Investigação Interdisciplinar em Sanidade Animal, Avenida da Universidade Técnica, 1300-477 Lisboa, Portugal; davidribeiro@isa.ulisboa.pt

Laminaria digitata is a brown seaweed with prebiotic properties, despite having high levels of ash and a recalcitrant cell wall that prevents an efficient digestion. We hypothesized that enzymatic supplementation in monogastric diets can increase nutrient availability of this feedstuff. The objective of this study was to evaluate if the seaweed affects the kidney and urinary proteomes due to disruption of mineral metabolism homeostasis. Weaned piglets (male, aged 35 days) were randomly assigned to one of three diets (n=10): control (wheat-maize-soybean meal based), LA (10% *L. digitata* replacing control) and LAL (LA+0.01% alginate lyase). Each piglet was housed individually in a metabolic cage with free access to water. The trial lasted for two weeks, after which they were slaughtered, and kidney and urine samples were harvested. Samples were then analysed using a label-free LC-MS/MS approach. The dietary treatments had less effects in the urine proteome, where 52 proteins had differences ($P < 0.05$, $\log_2(FC) > 1$) compared to 253 in the kidney. LAL piglets increased the urinary excretion of complement factor proteins, which have been suggested as a marker for kidney inflammation. LAL vs control yielded the highest number of differences in the kidney, with LAL increasing the abundance of HMOX1 (involved in inflammatory response) and lowering that of ASH1L (negative regulation of inflammatory response). These findings suggest that dietary *L. digitata* may disrupt kidney homeostasis, which is worsened by enzymatic supplementation. This could stem from dietary availability of the mineral fraction, requiring an adaptative response by the piglet.

Vitamin D3 supplementation has little effect on gut microbiome in pigsM. OcZkowicz¹, A. Wierzbicka¹, A. Steg¹ and M. Świątkiewicz²¹National Research Institute of Animal Production, Department of Animal Molecular Biology, ul Krakowska 1, 32-083, Poland, ²National Research Institute of Animal Production, Department of Animal Nutrition and Feed Science, ul Krakowska 1, 32-083, Poland; maria.oczkowicz@iz.edu.pl

Dietary supplementation with vitamin D3 (VD3) is widely used in humans, but there are still disputes about the recommended doses. In farm animals, the effects of supplementation are still at the stage of research and the exact cost-benefit balance has not yet been determined. According to the recommendations of the European Union, the dose of VD3 in the feed should not exceed 2,000 U/kg of feed for domestic pigs. However, higher doses seem to be needed to achieve a health-promoting effect. Our study aimed to evaluate the effect of supplementation with high doses of VD3 (5,000 and 10,000 U/kg) in the pig diet on the gut microbiome. The research covered 30 castrated boars, which were divided into three equally numerous groups: Group I: no VD3, Group II: 5,000 U/kg VD3, and Group III: 10,000 U/kg VD3. VD3 supplementation turned out to be effective, the groups differed significantly in the content of 25OH vitamin D in the blood. Caecal digesta samples were collected at slaughter and bacterial DNA was isolated. DNA was sent to weSeq.it company, where V3 and V4 16sRNA libraries were created and next-generation sequencing and bioinformatics processing were performed. After sequencing, an average of 80,013 raw reads were gained per sample, and consequently an average of 55,499 operational taxonomic units 'OTU' at the 'genus' level. Alpha Diversity analysis showed no statistically significant differences between the groups in any of the parameters studied (Chao1, Ace, Shannon, Simpson, Coverage, PD_whole_tree). Similarly, beta diversity analysis revealed no differences among the analysed groups. Moreover, differential analysis between groups, using ANOVA did not show any differences at all taxonomic levels. The only difference ($P < 0.05$) was observed after Metastats analysis at some rare microorganisms belonging to *Gemmatimonadota*, *Methylomirabilota*, and *Myxococcota* phylum. In conclusion, our results suggest that VD3 supplementation has little effect on the gut microbiome in pigs, however, we can not exclude its influence on certain rare microorganisms.

Equal opportunities in scienceI. Adriaens¹, M. Pszczola² and T. Wallgren³

¹Livestock Technology, Department of Biosystems, Kleinhoefstraat 4, 2440 Geel Belgium, Belgium, ²Poznan University of Life Sciences, Genetics and Animal Breeding, Wolynska 33, 60-637 Poznan, Poland, ³Swedish University of Agricultural Sciences (SLU), Department of Animal Environment and Health, Box 7068, 750 07 Uppsala, Sweden; marcin.pszczola@puls.edu.pl

Early career scientists often doubt what the best (academic) path is to partake, and which decisions along the way can help them reach their goals. One hugely uncertain factor in this context is whether a decision can negatively impact this road, for example, because one chooses to start a family or focus on a path more directed toward teaching rather than research. Additionally, many people experience having to work more or harder than colleagues because they do not come from a similar background, religion, or ethnicity or did not have a similarly high-level yet expensive education. Both in business and in academics, this has been discussed in the past as complying with the 'seven ticks': if you have wealthy or educated parents, are born in a western country, are male, heterosexual, white, and are highly educated, in high school and in university, you have all of them. These people are considered the most favoured people in society that are seldom discriminated against and often reach the top functions rather easily with not that many setbacks. In this Young EAAP session, we invited several people with different backgrounds to talk about 'equal opportunities' and their experience with things like starting a family (and being female), coming from different backgrounds, are not white, etc. The session will include a round of introductions, a panel discussion, and room for questions from the audience.

The responsibilities of authors, readers and learned-societies in animal science publishingJ. Van Milgen¹, I. Ortigues-Marty², G. Bee³, M. Wulster-Radcliffe⁴, J. Sartin⁴, T.A. Davis⁵ and P.J. Kononoff⁶

¹INRAE, Institut Agro, Pegase, Le Clos, 35590 Saint-Gilles, France, ²INRAE, Université Clermont Auvergne, VetAgro Sup, UMRH, 63122, Saint-Genès-Champagnelle, France, ³Agroscope, Rte de la Tioleyre 4, 1725 Posieux, Switzerland, ⁴American Society of Animal Science, P.O. Box 7410, Champaign, IL 61826-741, USA, ⁵USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, 1100 Bates Street, Houston, TX 77030-2600, USA, ⁶University of Nebraska-Lincoln, Department of Animal Science, Lincoln, NE 68583-0908, USA; jaap.vanmilgen@inrae.fr

Scientific publishing was relatively straightforward in the past. Scientific journals, often owned and managed by learned-societies and research organizations, used the expertise in their community to peer-review articles, which was perceived as the gold standard of quality. Peer-review served to weed out low-quality research, but sometimes stringent peer-review standards resulted in work not being published, simply because authors could not find a journal that would accept their sound, but perhaps little-less-novel research. This has changed considerably in the last decade with Open Access publishing. The number of publications in peer-reviewed animal science journals has doubled in just five years (Journal Citation Report, Clarivate). Open Access, combined with the increase in the number of publications, has also resulted in a shift in responsibility from the journals to the reader. Virtually any author with funding can now find a journal willing to publish their research results. But how serious do journals take the peer-review process if they can promise a very rapid time-to-first decision? Of course, we all like to see that our papers are published rapidly and without hassle, but is this really what we want from the journals that we own and manage? The future of animal science publishing has many uncertainties but, as an animal science community, we can certainly shape it. Should peer-review remain the standard to assess 'quality and novelty' or should we, as journals of learned societies, explore new publishing models? How do you see your future as an author and reader in the rapidly changing publishing landscape and what should the role of the journals of learned-societies be in this?

Animal – open space the new member of the animal consortium

G. Bee

Agroscope, Swine Research Group, Route de la Tioleyre 4, 1725 Posieux, Switzerland; giuseppe.bee@agroscope.admin.ch

animal – open space is a new publishing initiative of the animal Consortium, a collaboration between the British Society of Animal Science, INRAe and the EAAP. The journal animal – open space is part of a family of journals including the flagship journal animal and animal – science proceedings. The journal has a wider scope than the flagship animal. The journal fully embraces Open Science and its philosophy is that all carefully conducted reproducible research, the data linked to that research and the associated points of views of the authors contribute to knowledge gain. This knowledge deserves to be rapidly published and open for further discussion from readers and the authors once published. The journal publishes articles that relate to farmed or other managed animals, leisure and companion animals and the use of insects for animal feed and human food. Articles will be accepted from all species if they are in, or contribute knowledge to the aforementioned categories (e.g. cattle, sheep, pigs, poultry, horses, rabbits, fish, cats, dogs). Lack of novelty, negative results or lack of significant treatment differences are not a barrier for publication. The journal publishes three types of articles: data papers, method articles and research articles. The target audiences of animal – open space are animal scientists, stakeholders and policy makers interested in agricultural, biomedical, veterinary and environmental sciences with expected impacts on animal performance and productivity, animal welfare, animal health, food security, environment, climate change, product quality, human health and nutrition, sustainability of animal agriculture, livestock systems and methodology. The impacts can be either of local or international relevance. In conclusion, the final objective of animal – open space is to reinforce the idea of Open Science and by that becoming a source of knowledge of reproducible data obtained from research with farmed or other managed animals, leisure and companion animals and on the use of insects for animal feed and human food.

Artificial intelligence language models in the scientific careerM. Pszczola¹, I. Adriaens² and T. Wallgren³

¹Poznan University of Life Sciences, Genetics and Animal Breeding, Wolynska 33, 60-637 Poznan, Poland, ²Livestock Technology, Department of Biosystems, Kleinhofstraat 4, 2440 Geel Belgium, Belgium, ³Swedish University of Agricultural Sciences (SLU), Department of Animal Environment and Health, Box 7068, 750 07 Uppsala, Sweden; marcin.pszczola@puls.edu.pl

Recent developments in artificial intelligence (AI) language models, such as chatGTP, are revolutionizing many different fields of life. These tools can change how some tasks are performed by enabling quick, effortless, and prompt generation of human-like written text; they can assist in coding tasks or data analysis or produce many other types of content. The generated outcome is difficult to distinguish from the work of human-generated work. Next, to the outstanding capabilities of the developed tools, using these technologies raises many concerns in the scientific community, education, and everyday life. Moreover, blind use of AI language models can produce false information based on imperfections of the currently available tools and low-quality information on the internet. Therefore, AI should be perceived as assistance for humans using them rather than as a replacement for expertise and critical thinking. Another important ethical and legal aspect is the authorship of the outcomes generated by AI language models. Currently, scientific journals do not accept co-authorship of AI language models, and this is an issue that needs more attention shortly. Therefore, using AI language models has to ensure alignment with ethical principles and standards thoughtfully.

TechCare: exploring the use of precision livestock farming for small ruminant welfare managementC. Morgan-Davies¹, G. Tesnière², C. Dwyer¹, G. Jorgensen³, E. Gonzalez-Garcia⁴ and J.M. Gautier²¹SRUC, West Mains Road, EH9 3JG, United Kingdom, ²IDELE, Campus INRAe, 31321 Castanet Tolosan, France, ³NIBIO, Grassland and livestock Division of Food and society, P.O. Box 115, 1431 Ås, Norway, ⁴INRAe, SELMET, Montpellier, France; claire.morgan-davies@sruc.ac.uk

Small ruminant production systems are found in diverse contexts where conditions can be harsh and day to day supervision of animals challenging. Implementing Precision Livestock Farming (PLF) and other new or innovative technologies could help to manage or monitor animal welfare (AWE). The H2020 TechCare project explores such opportunities. Following a series of prioritisation of AWE issues in the 9 partners' countries (France, UK, Ireland, Norway, Israel, Greece, Romania, Italy and Spain), potential PLF and innovative technologies have been identified as promising to help manage, monitor and/or improve AWE. To explore those potentials, a series of pilot studies have been set up in 5 partner countries (France, UK, Norway, Italy and Israel), where the application of near-market technologies is being assessed in different conditions and environments, varying from northern grasslands (UK and Norway) to Mediterranean climates (France, Italy and Israel). Different production purposes are also involved, from dairy sheep to dairy goats and meat sheep, both indoors and outdoors. Alongside those pilots, prototyping and adapting PLF and innovative tools is also performed, where trials under more controlled conditions are being carried out, in order to evaluate the potential of specific tools while adopting adequate approaches for monitoring and/or improving different small ruminant AWE. Those trials are being held in France, UK, Norway, Spain and Italy. Both approaches will inform on the best innovative and PLF technologies, and the most adapted ways to use them, that can most answer AWE priorities in a diversity of small ruminant farming systems. Some of the tools (e.g. Ultra High Frequency tags, proximity loggers) studied are being presented later in this session.
